## **IMPORTANT NOTICE TO THE READER**

Assessment Technologies Institute, LLC, is the publisher of this publication. The content of this publication is for informational and educational purposes only and may be modified or updated by the publisher at any time. This publication is not providing medical advice and is not intended to be a substitute for professional medical advice, diagnosis, or treatment. The publisher has designed this publication to provide accurate information regarding the subject matter covered; however, the publisher is not responsible for errors, omissions, or for any outcomes related to the use of the contents of this book and makes no guarantee and assumes no responsibility or liability for the use of the products and procedures described or the correctness, sufficiency, or completeness of stated information, opinions, or recommendations. The publisher does not recommend or endorse any specific tests, providers, products, procedures, processes, opinions, or other information that may be mentioned in this publication. Treatments and side effects described in this book may not be applicable to all people; likewise, some people may require a dose or experience a side effect that is not described herein. Drugs and medical devices are discussed that may have limited availability controlled by the Food and Drug Administration (FDA) for use only in a research study or clinical trial. Research, clinical practice, and government regulations often change the accepted standard in this field. When consideration is being given to use of any drug in the clinical setting, the health care provider or reader is responsible for determining FDA status of the drug, reading the package insert, and reviewing prescribing information for the most up-to-date recommendations on dose, precautions, and contraindications and determining the appropriate usage for the product. Any references in this book to procedures to be employed when rendering emergency care to the sick and injured are provided solely as a general guide. Other or additional safety measures may be required under particular circumstances. This book is not intended as a statement of the standards of care required in any particular situation, because circumstances and a patient's physical condition can vary widely from one emergency to another. Nor is it intended that this book shall in any way advise personnel concerning legal authority to perform the activities or procedures discussed. Such specific determination should be made only with the aid of legal counsel. Some images in this book feature models. These models do not necessarily endorse, represent, or participate in the activities represented in the images. THE PUBLISHER MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND, WHETHER EXPRESS OR IMPLIED, WITH RESPECT TO THE CONTENT HEREIN. THIS PUBLICATION IS PROVIDED AS-IS, AND THE PUBLISHER AND ITS AFFILIATES SHALL NOT BE LIABLE FOR ANY ACTUAL, INCIDENTAL, SPECIAL, CONSEQUENTIAL, PUNITIVE, OR EXEMPLARY DAMAGES RESULTING, IN WHOLE OR IN PART, FROM THE READER'S USE OF, OR RELIANCE UPON, SUCH CONTENT.

# User's Guide

Welcome to the Assessment Technologies Institute® RN Maternal Newborn Nursing Review Module Edition 11.0. The mission of ATI's Content Mastery Series® Review Modules is to provide user-friendly compendiums of nursing knowledge that will:

- Help you locate important information quickly.
- Assist in your learning efforts.
- Provide exercises for applying your nursing knowledge.
- Facilitate your entry into the nursing profession as a newly licensed nurse.

This newest edition of the Review Modules has been redesigned to optimize your learning experience. We've fit more content into less space and have done so in a way that will make it even easier for you to find and understand the information you need.

## ORGANIZATION

This Review Module is organized into units covering antepartum, intrapartum, postpartum, and newborn nursing care. Chapters within these units conform to one of three organizing principles for presenting the content.

- Nursing concepts
- Procedures
- Complications of pregnancy

Nursing concepts chapters begin with an overview describing the central concept and its relevance to nursing. Subordinate themes are covered in outline form to demonstrate relationships and present the information in a clear, succinct manner.

Procedures chapters include an overview describing the procedure(s) covered in the chapter. These chapters provide nursing knowledge relevant to each procedure, including indications, nursing considerations, and complications.

Complications of pregnancy chapters include an overview describing the complication; assessment, including risk factors and expected findings; and patient-centered care, including nursing care, medications, and client education.

## ACTIVE LEARNING SCENARIOS AND APPLICATION EXERCISES

Each chapter includes opportunities for you to test your knowledge and to practice applying that knowledge. Active Learning Scenario exercises pose a nursing scenario and then direct you to use an ATI Active Learning Template (included at the back of this book) to record the important knowledge a nurse should apply to the scenario. An example is then provided to which you can compare your completed Active Learning Template. The Application Exercises include NCLEX-style questions, such as multiple-choice and multiple-select items, providing you with opportunities to practice answering the kinds of questions you might expect to see on ATI assessments or the NCLEX. After the Application Exercises, an answer key is provided, along with rationales.

## NCLEX® CONNECTIONS

To prepare for the NCLEX-RN, it is important to understand how the content in this Review Module is connected to the NCLEX-RN test plan. You can find information on the detailed test plan at the National Council of State Boards of Nursing's website, [www.ncsbn.org](http://www.ncsbn.org). When reviewing content in this Review Module, regularly ask yourself, "How does this content fit into the test plan, and what types of questions related to this content should I expect?"

To help you in this process, we've included NCLEX Connections at the beginning of each unit and with each question in the Application Exercises Answer Keys. The NCLEX Connections at the beginning of each unit point out areas of the detailed test plan that relate to the content within that unit. The NCLEX Connections attached to the Application Exercises Answer Keys demonstrate how each exercise fits within the detailed content outline.

These NCLEX Connections will help you understand how the detailed content outline is organized, starting with major client needs categories and subcategories and followed by related content areas and tasks. The major client needs categories are:

- Safe and Effective Care Environment
  - Management of Care
  - Safety and Infection Control
- Health Promotion and Maintenance
- Psychosocial Integrity
- Physiological Integrity
  - Basic Care and Comfort
  - Pharmacological and Parenteral Therapies
  - Reduction of Risk Potential
  - Physiological Adaptation

An NCLEX Connection might, for example, alert you that content within a unit is related to:

- Health Promotion and Maintenance
  - Ante/Intra/Postpartum and Newborn Care
    - Assess client psychosocial response to pregnancy.

## **QSEN COMPETENCIES**

---

As you use the Review Modules, you will note the integration of the Quality and Safety Education for Nurses (QSEN) competencies throughout the chapters. These competencies are integral components of the curriculum of many nursing programs in the United States and prepare you to provide safe, high-quality care as a newly licensed nurse. Icons appear to draw your attention to the six QSEN competencies.

**Safety:** The minimization of risk factors that could cause injury or harm while promoting quality care and maintaining a secure environment for clients, self, and others.

**Patient-Centered Care:** The provision of caring and compassionate, culturally sensitive care that addresses clients' physiological, psychological, sociological, spiritual, and cultural needs, preferences, and values.

**Evidence-Based Practice:** The use of current knowledge from research and other credible sources, on which to base clinical judgment and client care.

**Informatics:** The use of information technology as a communication and information-gathering tool that supports clinical decision-making and scientifically based nursing practice.

**Quality Improvement:** Care related and organizational processes that involve the development and implementation of a plan to improve health care services and better meet clients' needs.

**Teamwork and Collaboration:** The delivery of client care in partnership with multidisciplinary members of the health care team to achieve continuity of care and positive client outcomes.

## **ICONS**

---

Icons are used throughout the Review Module to draw your attention to particular areas. Keep an eye out for these icons.

 This icon is used for NCLEX Connections.

 This icon indicates gerontological considerations, or knowledge specific to the care of older adult clients.

 This icon is used for content related to safety and is a QSEN competency. When you see this icon, take note of safety concerns or steps that nurses can take to ensure client safety and a safe environment.

 This icon is a QSEN competency that indicates the importance of a holistic approach to providing care.

 This icon, a QSEN competency, points out the integration of research into clinical practice.

 This icon is a QSEN competency and highlights the use of information technology to support nursing practice.

 This icon is used to focus on the QSEN competency of integrating planning processes to meet clients' needs.

 This icon highlights the QSEN competency of care delivery using an interprofessional approach.

 This icon appears at the top-right of pages and indicates availability of an online media supplement, such as a graphic, animation, or video. If you have an electronic copy of the Review Module, this icon will appear alongside clickable links to media supplements. If you have a hard copy version of the Review Module, visit [www.atitesting.com](http://www.atitesting.com) for details on how to access these features.

## **FEEDBACK**

---

ATI welcomes feedback regarding this Review Module. Please provide comments to [comments@atitesting.com](mailto:comments@atitesting.com).

As needed updates to the Review Modules are identified, changes to the text are made for subsequent printings of the book and for subsequent releases of the electronic version. For the printed books, print runs are based on when existing stock is depleted. For the electronic versions, a number of factors influence the update schedule. As such, ATI encourages faculty and students to refer to the Review Module addendums for information on what updates have been made. These addendums, which are available in the Help/FAQs on the student site and the Resources/eBooks & Active Learning on the faculty site, are updated regularly and always include the most current information on updates to the Review Modules.

# Table of Contents

NCLEX® Connections 1

## UNIT 1 *Antepartum Nursing Care*

	SECTION: <i>Human Reproduction</i>	3
CHAPTER 1	Contraception	3
CHAPTER 2	Infertility	13
	SECTION: <i>Changes During Pregnancy</i>	17
CHAPTER 3	Expected Physiological Changes During Pregnancy	17
CHAPTER 4	Prenatal Care	21
CHAPTER 5	Nutrition During Pregnancy	27
CHAPTER 6	Assessment of Fetal Well-Being	31
	<i>Ultrasound (abdominal, transvaginal, and Doppler)</i>	31
	<i>Biophysical profile</i>	32
	<i>Nonstress test</i>	33
	<i>Contraction stress test</i>	34
	<i>Amniocentesis</i>	35
	<i>High-risk pregnancy: Percutaneous umbilical blood sampling</i>	36
	<i>High-risk pregnancy: Chorionic villus sampling</i>	37
	<i>High-risk pregnancy: Quad marker screening</i>	37
	<i>High-risk pregnancy: Maternal alpha-fetoprotein (MSAFP)</i>	37

SECTION: <i>Complications of Pregnancy</i>		41
<b>CHAPTER 7</b>	<b>Bleeding During Pregnancy</b>	<b>41</b>
	<i>Spontaneous abortion</i>	41
	<i>Ectopic pregnancy</i>	42
	<i>Gestational trophoblastic disease</i>	43
	<i>Placenta previa</i>	44
	<i>Abruption placentae</i>	46
	<i>Vasa previa</i>	46
<b>CHAPTER 8</b>	<b>Infections</b>	<b>49</b>
	<i>HIV/AIDS</i>	49
	<i>TORCH infections</i>	50
	<i>Group B streptococcus</i>	51
	<i>Chlamydia</i>	51
	<i>Gonorrhea</i>	52
	<i>Syphilis</i>	53
	<i>Human papilloma virus</i>	54
	<i>Trichomoniasis</i>	54
	<i>Bacterial vaginosis</i>	55
	<i>Candidiasis</i>	55
<b>CHAPTER 9</b>	<b>Medical Conditions</b>	<b>59</b>
	<i>Cervical insufficiency (premature cervical dilatation)</i>	59
	<i>Hyperemesis gravidarum</i>	60
	<i>Iron-deficiency anemia</i>	60
	<i>Gestational diabetes mellitus</i>	61
	<i>Gestational hypertension</i>	62
<b>CHAPTER 10</b>	<b>Early Onset of Labor</b>	<b>67</b>
	<i>Preterm labor</i>	67
	<i>Premature rupture of membranes and preterm premature rupture of membranes</i>	69

*Intrapartum Nursing Care*

SECTION: <i>Labor and Delivery</i>		75
CHAPTER 11	<b>Labor and Delivery Processes</b>	75
CHAPTER 12	<b>Pain Management</b>	81
CHAPTER 13	<b>Fetal Assessment During Labor</b>	87
	<i>Leopold maneuvers</i>	87
	<i>Intermittent auscultation and uterine contraction palpation</i>	87
	<i>Continuous electronic fetal monitoring</i>	88
	<i>Continuous internal fetal monitoring</i>	92
CHAPTER 14	<b>Nursing Care During Stages of Labor</b>	95
CHAPTER 15	<b>Therapeutic Procedures to Assist with Labor and Delivery</b>	101
	<i>External cephalic version</i>	101
	<i>Bishop score</i>	101
	<i>Cervical ripening</i>	101
	<i>Induction of labor</i>	102
	<i>Augmentation of labor</i>	103
	<i>Amniotomy</i>	103
	<i>Amnioinfusion</i>	104
	<i>Vacuum-assisted delivery</i>	104
	<i>Forceps-assisted birth</i>	104
	<i>Episiotomy</i>	105
	<i>Cesarean birth</i>	105
	<i>Vaginal birth after cesarean (VBAC)</i>	106

**SECTION: Complications of Labor and Delivery****109**

<b>CHAPTER 16</b>	<b>Complications Related to the Labor Process</b>	<b>109</b>
	<i>Prolapsed umbilical cord</i>	109
	<i>Meconium-stained amniotic fluid</i>	110
	<i>Fetal distress</i>	110
	<i>Dystocia (dysfunctional labor)</i>	111
	<i>Precipitous labor</i>	112
	<i>Uterine rupture</i>	112
	<i>Anaphylactoid syndrome of pregnancy (amniotic fluid embolism)</i>	113

NCLEX® Connections 117

UNIT 3

***Postpartum Nursing Care*****119**

<b>CHAPTER 17</b>	<b>Postpartum Physiological Adaptations</b>	<b>119</b>
	<i>Uterus</i>	120
	<i>Lochia</i>	120
	<i>Cervix, vagina, and perineum</i>	121
	<i>Breasts</i>	122
	<i>Cardiovascular system and fluid and hematologic status</i>	123
	<i>Gastrointestinal system and bowel function</i>	124
	<i>Urinary system and bladder function</i>	124
	<i>Musculoskeletal system</i>	125
	<i>Immune system</i>	125
	<i>Comfort level</i>	125
	<i>Psychosocial</i>	126
<b>CHAPTER 18</b>	<b>Baby-Friendly Care</b>	<b>129</b>
<b>CHAPTER 19</b>	<b>Client Education and Discharge Teaching</b>	<b>133</b>

**SECTION: *Complications of the Postpartum Period*** **137**

<b>CHAPTER 20</b>	<b>Postpartum Disorders</b>	<b>137</b>
	<i>Deep-vein thrombosis</i>	137
	<i>Pulmonary embolus</i>	138
	<i>Coagulopathies</i>	139
	<i>Postpartum hemorrhage</i>	139
	<i>Uterine atony</i>	140
	<i>Subinvolution of the uterus</i>	141
	<i>Inversion of the uterus</i>	142
	<i>Retained placenta</i>	142
	<i>Lacerations and hematomas</i>	143
<b>CHAPTER 21</b>	<b>Postpartum Infections</b>	<b>147</b>
	<i>Infections (endometritis, mastitis, and wound infections)</i>	147
	<i>Urinary tract infection</i>	149
<b>CHAPTER 22</b>	<b>Postpartum Depression</b>	<b>153</b>

**NCLEX® Connections 157**

**UNIT 4** **Newborn Nursing Care**

**SECTION: *Low-Risk Newborn*** **159**

<b>CHAPTER 23</b>	<b>Newborn Assessment</b>	<b>159</b>
<b>CHAPTER 24</b>	<b>Nursing Care of Newborns</b>	<b>169</b>
<b>CHAPTER 25</b>	<b>Newborn Nutrition</b>	<b>177</b>
<b>CHAPTER 26</b>	<b>Nursing Care and Discharge Teaching</b>	<b>183</b>

CHAPTER 27	<b>Assessment and Management of Newborn Complications</b>	<b>189</b>
	<i>Neonatal substance withdrawal</i>	189
	<i>Hypoglycemia</i>	190
	<i>Respiratory distress syndrome, asphyxia, and meconium aspiration</i>	191
	<i>Preterm newborn</i>	192
	<i>Small for gestational age newborn</i>	193
	<i>Large for gestational age (macrosomic) newborn</i>	194
	<i>Postmature infant</i>	195
	<i>Tracheoesophageal fistula</i>	196
	<i>Newborn infection, sepsis (sepsis neonatorum)</i>	196
	<i>Birth trauma or injury</i>	197
	<i>Hyperbilirubinemia</i>	198
	<i>Congenital anomalies</i>	199

Basic Concept A1

Diagnostic Procedure A3

Growth and Development A5

Medication A7

Nursing Skill A9

System Disorder A11

Therapeutic Procedure A13

Concept Analysis A15

When reviewing the following chapters, keep in mind the relevant topics and tasks of the NCLEX outline, in particular:

## *Health Promotion and Maintenance*

---

### **ANTE/INTRA/POSTPARTUM AND NEWBORN CARE**

Provide prenatal care and education.

Calculate expected delivery date.

**DEVELOPMENTAL STAGES AND TRANSITIONS:** Identify expected body image changes associated with client developmental age.

### **HEALTH PROMOTION/DISEASE PREVENTION:**

Identify risk factors for disease/illness.

### **LIFESTYLE CHOICES**

Assess client's need/desire for contraception.

Educate client on sexuality issues.

## *Basic Care and Comfort*

---

### **NON-PHARMACOLOGICAL COMFORT INTERVENTIONS:**

Incorporate alternative/complementary therapies into client plan of care.

## *Pharmacological and Parenteral Therapies*

---

### **EXPECTED ACTIONS/OUTCOMES**

Use clinical decision making/critical thinking when addressing expected effects/outcomes of medications.

Evaluate client response to medication.

### **MEDICATION ADMINISTRATION**

Educate client about medications.

Review pertinent data prior to medication administration.

### **ADVERSE EFFECTS/CONTRAINdicATIONS/ SIDE EFFECTS/ INTERACTIONS**

Assess the client for actual or potential side effects and adverse effects of medications.

Identify a contraindication to the administration of a medication to the client.

## *Reduction of Risk Potential*

---

**DIAGNOSTIC TESTS:** Monitor results of maternal and fetal diagnostic tests.

**LABORATORY VALUES:** Compare client laboratory values to normal laboratory values.

**SYSTEM SPECIFIC ASSESSMENTS:** Perform focused assessments.

**THERAPEUTIC PROCEDURES:** Education client about treatments and procedures.

## *Physiological Adaptation*

---

### **ALTERATIONS IN BODY SYSTEMS**

Identify signs of potential prenatal complications

Provide care for client experiencing complications of pregnancy/labor and/or delivery

# CHAPTER 1

UNIT 1

ANTEPARTUM NURSING CARE

SECTION: HUMAN REPRODUCTION

CHAPTER 1

## Contraception

---

Contraception refers to strategies or devices used to reduce the risk of fertilization or implantation in an attempt to prevent pregnancy. The human ovum can be fertilized 24 hr after ovulation. Motile sperm's ability to fertilize the ovum lasts an average of 48 to 72 hr.

A nurse should assess clients' need, desire, and preference for contraception. A thorough discussion of benefits, risks, and alternatives of each method should be discussed. *Q<sub>ecc</sub>*

Sexual partners often make a joint decision regarding a desired preference (vasectomy or tubal ligation). Postpartum discharge instructions should include the discussion of future contraceptive plans.

Expected outcomes for family planning methods consist of preventing pregnancy until a desired time. Nurses should support clients in making the decision that is best for their individual situations.

Methods of contraception include natural family planning; barrier, hormonal, and intrauterine methods; and surgical procedures.

### NATURAL FAMILY PLANNING (FERTILITY AWARENESS-BASED METHODS)

---

#### *Abstinence*

---

Abstaining from having sexual intercourse eliminates the possibility of sperm entering the vagina.

**CLIENT EDUCATION:** Refrain from sexual intercourse. Discuss permissible sexual activities with partners.

#### **ADVANTAGES**

- Most effective method of birth control.
- Abstinence during fertile periods (rhythm method) can be used, but it requires an understanding of the menstrual cycle and fertility awareness.
- Can eliminate the risk of sexually transmitted infections (STIs) if there is no genitalia contact.

#### **DISADVANTAGES:**

- Requires self-control
- High failure rate due to lack of adherence

**RISKS:** If complete abstinence is maintained, there are no risks.

#### *Coitus interruptus (withdrawal)*

---

Withdrawal of penis from vagina prior to ejaculation

**CLIENT EDUCATION:** Be aware that pre-ejaculatory fluid can leak from the penis prior to ejaculation. It can contain sperm, which can fertilize an ovum.

**ADVANTAGES:** Possible choice for monogamous couples who do not have any other contraceptives available

#### **DISADVANTAGES**

- One of the least effective methods of contraception.
- No protection against STIs.

**RISKS:** Possible pregnancy.

#### *Calendar rhythm method*

---

Involves determining fertile days by tracking the menstrual cycle to estimate the time of ovulation, which occurs about 14 days before the onset of the next menstrual cycle. This method can be used to facilitate conception or be used as a natural contraceptive. If trying to conceive, the client would have intercourse during the fertile period. If trying to prevent pregnancy, the client would abstain from intercourse during the fertile period.

#### **CLIENT EDUCATION**

- Maintain a diary. Accurately record the number of days in each menstrual cycle, counting from the first day of menses for a period of at least six menstrual cycles.
- The start of the fertile period is figured by subtracting 18 days from the number of days in the shortest menstrual cycle.
- The end of the fertile period is established by subtracting 11 days from the number of days of the longest cycle.

For example:

Shortest cycle,  $26 - 18 = 8$ th day

Longest cycle,  $30 - 11 = 19$ th day

Fertile period is days 8 through 19.

Refrain from intercourse during these days to avoid conception.

#### **ADVANTAGES**

- Most useful when combined with basal body temperature or cervical mucus method
- Inexpensive

#### **DISADVANTAGES**

- Not a very reliable technique
- Does not protect against STIs
- Requires accurate record-keeping
- Requires adherence regarding abstinence during fertile periods

#### **RISKS**

- Various factors can affect and change the time of ovulation and cause unpredictable menstrual cycles.
- Possible pregnancy due to miscalculating fertile period or not abstaining from intercourse during fertile days.

## ***Standard days method (cycle beads)***

More modern form of the calendar method that uses a standard number of fertile days for each cycle. The cycle beads are color-coded and located on a stringed necklace.

### **CLIENT EDUCATION**

- Start the first day of the menstrual cycle. Use the rubber ring to advance one bead per day.
- Red bead: the first bead and marks the first day of the menstrual cycle.
- Brown beads: nonfertile days.
- White beads: fertile days.

### **ADVANTAGES**

- Increased adherence by using a visual aid
- Mobile app available
- Easy to understand

### **DISADVANTAGES**

- Unreliable for menstrual cycles longer than 32 days or shorter than 26 days
- Can lose track of the days

### **RISKS/POSSIBLE COMPLICATIONS**

- Do not use if menstrual cycles are short or long
- Possible pregnancy
- Less effective with hormonal contraceptives, IUD, breastfeeding

## ***Basal body temperature (BBT)***

BBT is the temperature of the body at rest. Prior to ovulation, the temperature drops slightly and rises during ovulation. Identifying the time of ovulation is a symptom-based method that can be used to facilitate or avoid conception.

### **CLIENT EDUCATION**

- Take temperature immediately after waking up and before getting out of bed. If working at night, take temperature after awakening from the longest sleep cycle. Use a thermometer that records temperature to the tenths. Record the temperatures on a specialized graph.
- The first day the temperature drops or elevates is considered the first fertile day. Fertility extends through 3 consecutive days of temperature elevations.
- Use this method with the calendar method to increase effectiveness.

**ADVANTAGES:** Inexpensive, convenient, and no adverse effects

### **DISADVANTAGES**

- Reliability can be influenced by many variables that can cause inaccurate interpretation of temperature changes (stress, fatigue, illness, alcohol, warmth of sleeping environment).
- Does not protect against STIs.

**RISKS:** Possible pregnancy

## ***Cervical mucus ovulation detection method***

Fertility awareness method (also known as Billings method) is a symptom-based method in which the client analyzes cervical mucus to determine ovulation.

- Following ovulation, the cervical mucus becomes thin and flexible under the influence of estrogen and progesterone to allow for sperm viability and motility.
- The ability for the mucus to stretch between the fingers is greatest during ovulation. This is the spinnbarkeit sign.
- The fertile period begins when the cervical mucus is thin, slippery, and lasts until 4 days after the last day of cervical mucus having this appearance.

### **CLIENT EDUCATION**

- Use this method with the calendar method to increase effectiveness.
- Engage in good hand hygiene prior to and following assessment.
- Begin examining mucus from the last day of the menstrual cycle.
- Mucus is obtained from the vaginal introitus. It is not necessary to reach into the vagina to the cervix.
- Use fingers or tissue paper to examine the cervical mucus.
- The stretchy consistency of egg whites is a good example of how cervical mucus will appear during ovulation.
- Do not a douche prior to assessment.

### **ADVANTAGES**

- A client can become knowledgeable in recognizing their own mucus characteristics at ovulation, and self-evaluation can be very accurate.
- Self-evaluation of cervical mucus can be diagnostically helpful in determining the start of ovulation while breastfeeding and planning a desired pregnancy.

### **DISADVANTAGES**

- Some clients are uncomfortable with touching their genitals and mucus, and therefore find this method objectionable.
- Self-analysis of cervical mucus can be difficult.
- Does not protect against STIs.

### **RISKS/POSSIBLE COMPLICATIONS**

- Assessment of cervical mucus characteristics can be inaccurate if mucus is mixed with semen, blood, contraceptive foams, or discharge from infections.
- Sexual arousal or intercourse (thins secretions), or use of deodorants, douches, medication, or lubricants can alter cervical mucus appearance and affect accuracy.
- Possible pregnancy.

## **2-day method**

A symptom-based method that involves checking for vaginal secretions daily, with no analysis of secretions. After 2 days without the presence of secretions, the fertile period has passed.

**CLIENT EDUCATION:** If vaginal secretions are present 2 days in a row, avoid unprotected intercourse to prevent pregnancy.

**ADVANTAGES:** Simple and easy to use

**DISADVANTAGES:** Requires daily assessment for vaginal secretions

**RISK:** Possible pregnancy

## **BARRIER METHODS**

### **Male condom**

A thin sheath used to cover the penis during sexual intercourse as a contraceptive or as protection against infection. Male condoms can be made of latex rubber, polyurethane, or natural membrane.

**CLIENT EDUCATION**

- Place a condom on the erect penis, leaving an empty space at the tip for a sperm reservoir.
- Following ejaculation, withdraw the penis from the vagina while holding the rim of the condom to prevent any semen spillage to the vulva or vaginal area.
- Can use in conjunction with spermicidal gel or cream to increase effectiveness.
- Check expiration date prior to use.
- Latex and polyurethane condoms protect against STI, but natural skin (made of lamb cecum) condoms do not because they have small pores. Polyurethane condoms can slip or lose shape more easily than latex, and therefore might not be as effective.
- Only water-soluble lubricants should be used with latex condoms, to avoid condom breakage.

**ADVANTAGES**

- Protects against most STIs
- Involves males in the birth control method
- No adverse effects
- Readily accessible

**DISADVANTAGES**

- High rate of nonadherence.
- Can reduce spontaneity of intercourse.
- Decreased sensation.
- The penis must be erect to apply a condom
- Withdrawing the penis while still erect can interfere with sexual intercourse.
- Does not protect against STIs that are transmitted from lesions on the skin or mucus membranes (HPV, HSV, syphilis).
- Condoms have a one-time usage, which creates a replacement cost.

### **RISKS/POSSIBLE COMPLICATIONS/CONTRAINDICATIONS**

- Condoms can rupture or leak, potentially resulting in pregnancy.
- Condoms made of latex should not be worn by those who are sensitive or allergic to latex.

### **Female condom**

Vaginal sheath made of nitrile, a nonlatex synthetic rubber with flexible rings on both ends that is pre-lubricated with a spermicide

**CLIENT EDUCATION**

- The closed end of the condom pouch is inserted into the vagina by the client prior to intercourse and anchored around the cervix. The open ring of the condom covers the labia. The condom is removed and thrown away after each act of intercourse.
- Do not use in conjunction with a male condom.

**ADVANTAGES**

- Offers protection against pregnancy and STIs
- Offers some protection against STI transmitted by skin-to-skin contact (HPV, HSV, syphilis)

**DISADVANTAGES**

- Complicated to use
- Bulky
- Noisy during intercourse
- More expensive than male condoms

### **Spermicide**

Chemical barrier that is available in a variety of forms, and destroys sperm before they can enter the cervix. It causes the vaginal flora to be more acidic, which is not favorable for sperm survival.

**CLIENT EDUCATION**

- Plan to insert spermicide 15 min before intercourse. Spermicide is only effective for 1 hr after insertion, but should not be removed until 6 hr after intercourse.
- Fold films prior to use and insert in the vagina, where it will dissolve.

**ADVANTAGES**

- No prescription needed
- Increases the effectiveness of other methods of contraception when used together
- Various preparations (suppositories, foams, creams, gel, films)

**DISADVANTAGES**

- Messy
- Must reapply after each act of intercourse
- Does not protect against STIs

### **RISKS/CONTRAINDICATIONS**

- Contraindicated in clients who have cervical infections
- Spermicides that contain nonoxynol-9 (N-9) can cause lesions and increase the risk of HIV if used more than twice daily. Clients at high risk for STI should not use products containing N-9.

## **Diaphragm**

---

A dome-shaped cup with a flexible rim made of silicone that fits snugly over the cervix. The effectiveness is increased with the use of a spermicidal cream or gel placed into the dome and around the rim. Diaphragms are available in different sizes.

### **CLIENT EDUCATION**

- Be properly fitted with a diaphragm by a provider.
- Replace every 2 years and refit for a 20% weight fluctuation, after abdominal or pelvic surgery, and after every pregnancy.
- The diaphragm requires proper insertion and removal. Prior to coitus, the diaphragm is inserted vaginally over the cervix with spermicidal jelly or cream that is applied to the cervical side of the dome and around the rim. The diaphragm can be inserted up to 6 hr before intercourse and must stay in place 6 hr after intercourse but for no more than 24 hr.
- Spermicide must be reapplied with each act of coitus.
- Empty the bladder prior to insertion of the diaphragm, to decrease pressure on the urethra.
- The diaphragm should be washed with mild soap and warm water after each use.

### **ADVANTAGES**

- Gives a client more control over contraception
- Easy to insert

### **DISADVANTAGES**

- Inconvenient, interfere with spontaneity, and require reapplication with spermicidal gel, cream, or foam with each act of coitus to be effective
- Requires a prescription and a visit to a provider
- Must be inserted correctly to be effective.
- Does not protect against STIs

### **RISKS/POSSIBLE COMPLICATIONS/CONTRAINdications**

- Not recommended for clients who have a history of toxic shock syndrome (TSS), cystocele, uterine prolapse, or frequent, recurrent urinary tract infections.
- Increased risk of acquiring TSS, which is caused by a bacterial infection. Clinical findings include high fever, a faint feeling, drop in blood pressure, watery diarrhea, headache, macular rash, and muscle aches.
- Proper hand hygiene aids in prevention of TSS, as well as removing the diaphragm promptly 6 to 8 hr following coitus.
- Risk of allergic reaction and UTIs.

## **Cervical cap**

---

Silicone rubber cap that fits tightly around the base of the cervix. This serves as a physical barrier against sperm entering the cervix. Use with a spermicide increases its effectiveness. Cervical caps come in three sizes.

### **CLIENT EDUCATION**

- Insert up to 6 hr before intercourse, and leave in place at least 6 hr after intercourse but for no more than 48 hr at a time.
- Replace every 2 years and refit after any gynecological surgery, birth, or any major weight fluctuation.

### **ADVANTAGES**

- Extended period of use
- No additional application of spermicide needed

### **DISADVANTAGES**

- Possible risk of acquiring TSS
- Risk of allergic reaction
- Does not protect against STIs

### **RISKS/POSSIBLE COMPLICATIONS/CONTRAINDICATIONS:**

Not for clients who have abnormal Pap test results or those who have a history of TSS

## **Contraceptive sponge**

---

Small, round, concave-shaped, polyurethane sponge containing spermicide. It fits over the cervix and acts as a physical/chemical barrier against sperm from entering the vagina.

### **CLIENT EDUCATION**

- One size fits all.
- Moisten with water prior to insertion in the vagina.
- Should be left in place for 6 hr after the last act of intercourse and provides protection for up to 24 hr.

### **ADVANTAGES**

- Can have repeated acts of intercourse
- Easy to insert

### **DISADVANTAGES:** Does not protect against STIs

**RISKS/COMPLICATIONS:** Risk of TSS if left in the vagina greater than 24 hr.

## **HORMONAL METHODS**

---

### **Combined oral contraceptives (COCs)**

---

Hormonal contraception containing estrogen and progestin, which acts by suppressing ovulation, thickening the cervical mucus to block semen, altering the uterine decidua to prevent implantation

### **CLIENT EDUCATION**

- Medication requires a prescription and follow-up appointments with the provider.
- Routine Pap smears and breast examination might be needed.
- Medication requires consistent and proper use to be effective.
- Regular menstrual cycles should occur during the last 7 days.
- Observe for and report manifestations of complications (chest pain, shortness of breath, leg pain [thromboembolism], headache, vision changes [stroke], hypertension).
- In the event of missing a dose, if one pill is missed, take one as soon as possible; if two or three pills are missed, follow the manufacturer's instructions. Instruct the client on the use of alternative forms of contraception or abstinence to prevent pregnancy until regular dosing is resumed.
- If nausea occurs, take at bedtime.

## **ADVANTAGES**

- Highly effective if taken correctly and consistently, preferably at the same time each day.
- Hormonal contraception containing low-dose estrogen (less than 35 mcg) has other therapeutic effects, including decreased menstrual blood loss, decreased iron deficiency anemia, regulation of menorrhagia and irregular cycles, and reduced incidence of dysmenorrhea and premenstrual findings.
- Offers protection against endometrial, ovarian, and colon cancer, reduces the incidence of benign breast disease, improves acne, and protects against the development of functional ovarian cysts.

## **DISADVANTAGES**

- Does not protect against STIs.
- Can increase the risk of thromboembolism, stroke, heart attack, hypertension, gallbladder disease, and liver tumor.
- Exacerbates conditions affected by fluid retention (migraine, epilepsy, asthma, kidney or heart disease).
- Adverse effects include headache, nausea, breast tenderness, and breakthrough bleeding. (Estrogen can cause nausea, breast tenderness, fluid retention. Progestin can cause increased appetite, fatigue, depression, breast tenderness, oily skin and scalp, and hirsutism.)

## **RISKS/POSSIBLE COMPLICATIONS/CONTRAINdications**

- Clients who have a history of thromboembolic disorders, stroke, heart attack, coronary artery disease, gallbladder disease, cirrhosis or liver tumor, headache with focal neurologic findings, uncontrolled hypertension, diabetes mellitus with vascular involvement, breast or estrogen-related cancers, pregnancy, lactating, less than 6 weeks postpartum, or smoking (if over 35 years of age) are advised not to take oral contraceptive medications.
- Oral contraceptive effectiveness decreases when taking medications that affect liver enzymes (anticonvulsants, antifungals, some antibiotics).

## ***Progestin-only pills (minipill)***

Oral progestins that provide the same action as combined oral contraceptives, which decreases the chance of fertilization and implantation

## **CLIENT EDUCATION**

- Take the pill at the same time daily to ensure effectiveness secondary to a low dose of progestin.
- Do not miss a pill.
- Might need another form of birth control during the first month of use to prevent pregnancy.

## **ADVANTAGES**

- Fewer adverse effects when compared with a combined oral contraceptive
- Considered safe to take while breastfeeding

## **DISADVANTAGES**

- Less effective in suppressing ovulation than combined oral contraceptives.
- No protection against STIs.
- Adverse effects include breakthrough, irregular, vaginal bleeding (frequently reported/most common); headache; nausea; and breast tenderness.

## **RISKS/POSSIBLE COMPLICATIONS/CONTRAINDICATIONS**

- Oral contraceptive effectiveness decreases when taking medications that affect liver enzymes (anticonvulsants, some antibiotics).
- Contraindications include bariatric surgery, lupus, severe cirrhosis, liver tumors, and current or past breast cancer.

## ***Emergency oral contraceptive***

Morning-after pill that prevents fertilization from taking place by inhibiting ovulation and the transport of sperm

## **CLIENT EDUCATION**

- The pill is taken within 72 hr after unprotected coitus.
- A provider will recommend an over-the-counter antiemetic to be taken 1 hr prior to each dose to counteract the adverse effects of nausea that can occur with high doses of estrogen and progestin.
- Be evaluated for pregnancy if menstruation does not begin within 21 days.
- Consider counseling about contraception and modification of sexual behaviors that are risky.
- A copper IUD can be used up to 5 days following unprotected intercourse as an emergency contraceptive, but a prescription is required.

## **ADVANTAGES**

- This method is not taken on a regular basis.
- Anyone, regardless of age, is allowed to purchase emergency oral contraceptive at a pharmacy.
- Directions are easy to understand.

## **DISADVANTAGES**

- Nausea, heavier than normal menstrual bleeding, lower abdominal pain, fatigue, and headache
- Does not provide long-term contraception
- Does not terminate an established pregnancy
- Does not protect against STIs

## **RISKS/POSSIBLE COMPLICATIONS/CONTRAINDICATIONS:**

Method is contraindicated if a client is pregnant or has undiagnosed abnormal vaginal bleeding.

## ***Transdermal contraceptive patch***

- Contains estrogen and progesterone or progestin, which is delivered at continuous levels through the skin into subcutaneous tissue
- Inhibits ovulation by thickening cervical mucus

## **CLIENT EDUCATION**

- Apply the patch to dry skin overlying subcutaneous tissue of the buttock, abdomen, upper arm, or torso, excluding breast area.
- Requires patch replacement once a week.
- Apply the patch the same day of the week for 3 weeks with no application on the fourth week.

## **ADVANTAGES**

- Maintains consistent blood levels of hormone
- Avoids liver metabolism of medication because it is not absorbed in the gastrointestinal tract
- Decreases risk of forgetting a daily pill
- Can be used while in water, such as when swimming

#### DISADVANTAGES

- Method does not protect against STIs.
- Same adverse effects as oral contraceptives. Risk of deep-vein thrombosis and venous thromboembolism can be slightly higher in clients using the patch because the hormones get into the bloodstream and are processed by the body differently than hormones from OCPs.
- Skin reaction can occur from patch application.
- Can cause breast discomfort.

#### RISKS/POSSIBLE COMPLICATIONS/CONTRAINDICATIONS

- Same as those of oral contraceptives
- Avoid applying of patch to skin rashes or lesions
- Less effective in clients greater than 198 lb

### ***Injectable progestins***

Medroxyprogesterone is an intramuscular or subcutaneous injection given to a female client every 11 to 13 weeks. It inhibits ovulation and thickens cervical mucus.

#### CLIENT EDUCATION

- Start of injections should be during the first 5 days of the menstrual cycle and every 11 to 13 weeks thereafter. Injections in postpartum nonbreastfeeding clients should begin within 5 days following delivery. For breastfeeding clients, injections should start in the sixth week postpartum.
- Keep follow-up appointments.
- Maintain an adequate intake of calcium and engage in weight-bearing exercise to decrease the risk of osteoporosis.
- Do not massage after IM injections because it decreases the absorption and effectiveness of the medication.

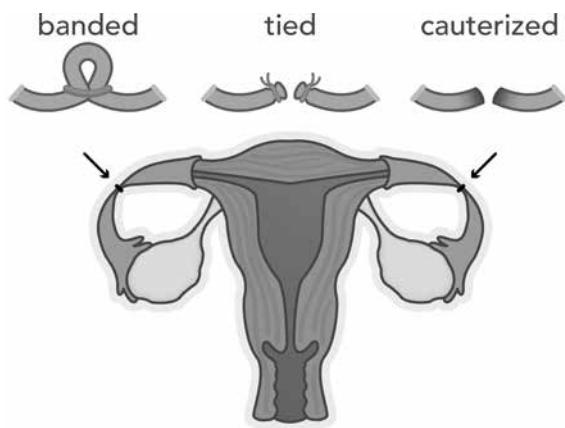

#### ADVANTAGES

- Very effective and requires only four injections per year
- Does not impair lactation
- Possible absence of periods and decrease in bleeding
- Decreased risk of uterine cancer if used long-term

#### DISADVANTAGES

- Adverse effects include decreased bone mineral density, weight gain, increased depression, amenorrhea, headache, and irregular vaginal spotting or bleeding.
- Does not protect against STIs.

#### 1.1 Bilateral tubal ligation

- Return to fertility can be delayed as long as up to 18 months after discontinuation.
- Should only be used as a long-term method of birth control (more than 2 years) if other birth control methods are inadequate.

#### RISKS/POSSIBLE COMPLICATIONS/CONTRAINDICATIONS

- Avoid massaging injection site following administration to avoid accelerating medication absorption, which will shorten the duration of its effectiveness.
- Contraindications include breast cancer, evidence of current cardiovascular disease, abnormal liver function, liver tumors, and unexplained vaginal bleeding.
- This method can impair glucose tolerance for clients who have diabetes mellitus, and increase diabetes risk for clients who do not have diabetes mellitus.

### ***Contraceptive vaginal ring***

A flexible silicone ring that contains etonogestrel and ethynodiol diacetate, which are delivered at continuous levels vaginally

#### CLIENT EDUCATION

- Insert the ring vaginally.
- Perform ring replacement after 3 weeks, and placement of new vaginal ring within 7 days. Insertion should occur on the same day of the week monthly.
- If removed for greater than 4 hr, replace with new ring and use a barrier method of contraception for 7 days.

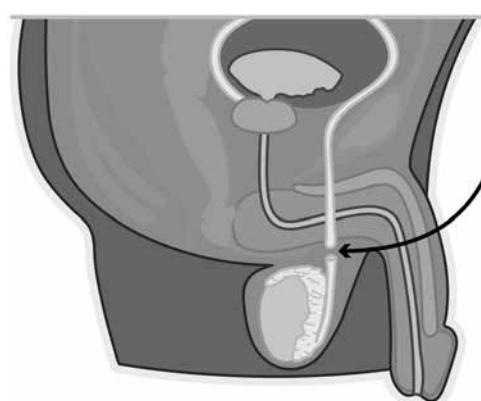

#### ADVANTAGES

- Does not have to be fitted
- Decreases the risk of forgetting to take the pill
- Vaginal route of delivery increases bioavailability of hormones, enabling lower dose and reducing adverse effect

#### DISADVANTAGES

- Method does not protect against STIs.
- Method has the same adverse effects as oral contraceptives.
- Some clients report discomfort during intercourse. The ring can be removed for up to 3 hr without compromising its effectiveness.
- Prescription is required.

#### 1.2 Vasectomy

#### RISKS/POSSIBLE COMPLICATIONS/CONTRAINdications

- Blood clots, hypertension, stroke, heart attack
- Vaginal irritation/discomfort, increased vaginal secretions

#### Implantable progestin

- Small, thin rods consisting of progestin that are implanted by the provider under the skin of the inner upper aspect of the arm
- Prevents pregnancy by suppressing the ovulatory cycle and thickening cervical mucus

#### CLIENT EDUCATION

- Avoid trauma to the area of implantation.
- Wear condoms for protection against STIs.

#### ADVANTAGES

- Effective continuous contraception for 3 years
- Can be inserted immediately after spontaneous or elective abortion, childbirth, while breastfeeding
- Reversible

#### DISADVANTAGES

- Does not protect against STIs.
- Adverse effects include irregular and unpredictable menstruation (most common), mood changes, headache, acne, depression, decreased bone density, and weight gain.
- Scarring at insertion site can warrant the need for removal.

#### RISKS/POSSIBLE COMPLICATIONS/CONTRAINDICATIONS

- Method has increased risk of ectopic pregnancy if pregnancy occurs.
- Contraindications include unexplained vaginal bleeding.
- Infection can occur at site.

#### Intrauterine device (IUD)

A chemically active T-shaped device that is inserted through the cervix and placed in the uterus by the provider. Releases a chemical substance that damages sperm in transit to the uterine tubes and prevents fertilization. The most effective contraceptive methods at preventing pregnancy are the long-acting reversible contraceptive (LARC) methods: implant and IUDs. IUDs can be used by nulliparous and multiparous female clients.

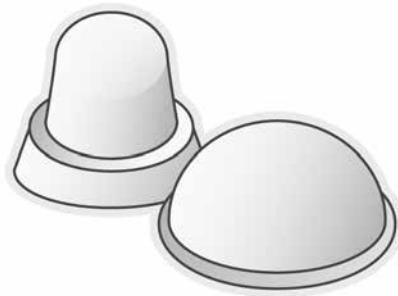

#### CLIENT EDUCATION

- The device must be monitored monthly by clients after menstruation to ensure the presence of the small string that hangs from the device into the upper part of the vagina to rule out migration or expulsion of the device.
- Sign a consent form prior to insertion.
- Pregnancy test, Pap smear, and cervical cultures should be negative prior to insertion.
- If pregnancy is suspected after IUD insertion, a sonogram can be needed to rule out ectopic pregnancy.

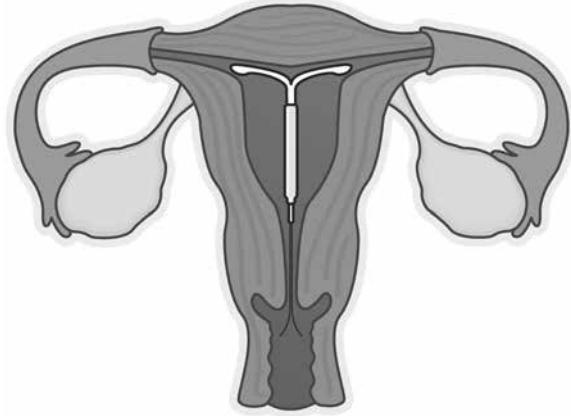

#### ADVANTAGES

- An IUD can maintain effectiveness for 3 to 10 years (hormonal IUD 3 to 5 years; copper IUD 10 years).
- Insertion can be immediately after elective or spontaneous abortion, childbirth, and while breastfeeding.
- Contraception can be reversed with immediate return to fertility.
- Does not interfere with spontaneity.
- Hormonal IUDs decrease menstrual pain and heavy bleeding.
- Copper IUD contains no hormones, so it's safe for clients cautioned against hormonal birth control methods.

#### 1.3 Cervical cap

#### 1.4 Intrauterine device

#### **DISADVANTAGES**

- This method can increase the risk of pelvic inflammatory disease, uterine perforation, or ectopic pregnancy and can be expelled.
- A client should report to the provider late or abnormal spotting or bleeding, abdominal pain or pain with intercourse, abnormal or foul-smelling vaginal discharge, fever, chills, a change in string length, or if IUD cannot be located.
- This method does not protect from STIs.
- Hormonal IUD includes spotting, irregular bleeding, headache, nausea, depression, and breast tenderness.
- Copper IUD includes increase in menstrual pain and bleeding.

#### **RISKS/CONTRAINDICATIONS**

- Best used by clients in a monogamous relationship due to the risks of STIs
- Can cause irregular menstrual bleeding
- Risk of bacterial vaginosis, PID, uterine perforation, or uterine expulsion
- Must be removed in the event of pregnancy

**CONTRAINDICATIONS:** Active pelvic infection, abnormal uterine bleeding, severe uterine distortion

## **TRANSCEVICAL STERILIZATION**

- Insertion of small flexible agents through the vagina and cervix into the fallopian tubes. This results in the development of scar tissue in the tubes, preventing conception.
- Examination must be done after 3 months to ensure fallopian tubes are blocked.

**CLIENT EDUCATION:** Normal activities can be resumed by most clients within 1 day of the procedure.

#### **ADVANTAGES**

- Quick procedure that requires no general anesthesia
- Nonhormonal means of birth control
- 99.8% effective in preventing pregnancy
- Rapid return to normal activities of daily living

#### **DISADVANTAGES**

- Not reversible.
- Not intended for use in the client who is postpartum.
- Delay in effectiveness for 3 months. An alternative means of birth control should be used until confirmation of blocked fallopian tubes occurs.
- Changes in menstrual patterns.
- Does not protect against STIs.

#### **RISKS/POSSIBLE COMPLICATIONS/CONTRAINDICATIONS**

- Perforation can occur.
- Unwanted pregnancy can occur if a client has unprotected sexual intercourse during the first 3 months following the procedure.
- Increased risk of ectopic pregnancy if pregnancy occurs.

## **SURGICAL METHODS**

### ***Female sterilization (bilateral tubal ligation)***

A surgical procedure consisting of severance and/or burning or blocking the fallopian tubes to prevent fertilization

**PROCEDURE:** The cutting, burning, or blocking of the fallopian tubes to prevent the ovum from being fertilized by the sperm.

#### **ADVANTAGES**

- Permanent, immediate contraception.
- This method can be done within 24 to 48 hr after childbirth.
- Sexual function is unaffected.
- This method decreases the incidence of ovarian cancer.

#### **DISADVANTAGES**

- A surgical procedure carrying risks related to anesthesia, complications, infection, hemorrhage, trauma
- Considered irreversible in the event that a client desires conception
- Does not protect against STIs

**RISKS:** Risk of ectopic pregnancy if pregnancy occurs

### ***Male sterilization (vasectomy)***

A surgical procedure consisting of ligation and severance of the vas deferens, which prevents sperm from traveling

**PROCEDURE:** The cutting of the vas deferens in the male as a form of permanent sterilization.

#### **CLIENT EDUCATION**

- Following the procedure, scrotal support and moderate activity for a couple of days is recommended to reduce discomfort.
- Sterility is delayed until the proximal portion of the vas deferens is cleared of all remaining sperm (approximately 20 ejaculations).
- Alternate forms of birth control must be used until the vas deferens is cleared of sperm.
- Follow up with the provider for sperm count testing. Sperm count must be zero on two consecutive tests to confirm sterility.
- Reversal can be done by complicated and expensive procedure.
- Prior to procedure, sperm can be banked for future use.

#### **ADVANTAGES**

- Method is permanent.
- Procedure is short, safe, and simple.
- Sexual function is not impaired.

#### **DISADVANTAGES**

- Surgery is required.
- Reversal is possible but not always successful.
- This method does not protect against STIs.
- Accumulation of sperm can cause granulomas.

**COMPLICATIONS:** Rare, but can include bleeding, infection, anesthesia reaction, hematomas at site, kidney stones, chronic pain (might need reversal)

## Application Exercises

1. A nurse in a health clinic is reviewing contraceptive use with a group of clients. Which of the following client statements demonstrates understanding?

  - A. "A water-soluble lubricant should be used with condoms."
  - B. "A diaphragm should be removed 2 hours after intercourse."
  - C. "Oral contraceptives can worsen a case of acne."
  - D. "A contraceptive patch is replaced once a month."
2. A nurse is instructing a client who is taking an oral contraceptive about manifestations to report to the provider. Which of the following manifestations should the nurse include?

  - A. Reduced menstrual flow
  - B. Breast tenderness
  - C. Shortness of breath
  - D. Increased appetite
3. A nurse in an obstetrical clinic is teaching a client about using an IUD for contraception. Which of the following statements by the client indicates an understanding of the teaching?

  - A. "An IUD should be replaced annually during a pelvic exam."
  - B. "I cannot get an IUD until after I've had a child."
  - C. "I should plan on regaining fertility 5 months after the IUD is removed."
  - D. "I will check to be sure the strings of the IUD are still present after my periods."
4. A nurse is teaching a client about potential adverse effects of implantable progestins. Which of the following adverse effects should the nurse include? (Select all that apply.)

  - A. Tinnitus
  - B. Irregular vaginal bleeding
  - C. Weight gain
  - D. Nausea
  - E. Gingival hyperplasia
5. A nurse in a clinic is teaching a client about a new prescription for medroxyprogesterone. Which of the following information should the nurse include in the teaching? (Select all that apply.)

  - A. "Weight fluctuations can occur."
  - B. "You are protected against STIs."
  - C. "You should increase your intake of calcium."
  - D. "You should avoid taking antibiotics."
  - E. "Irregular vaginal spotting can occur."

## Active Learning Scenario

A nurse is reviewing teaching with a client who is considering a vasectomy. Which of the following should be included in the teaching? Use the ATI Active Learning Template: Therapeutic Procedure to complete this item.

**DESCRIPTION OF PROCEDURE:** Define the procedure.

**INDICATIONS:** Describe one advantage and one disadvantage of this form of contraception.

**CLIENT EDUCATION:** Describe two teaching points for this client.

## Application Exercises Key

1. A. **CORRECT:** Condoms are used with water-soluble lubricants.  
B. A diaphragm should be removed no sooner than 6 hr and no later than 24 hr after intercourse.  
C. Acne is reduced when taking oral contraceptives.  
D. Contraceptive patches are replaced once a week.
2. A. Reduced menstrual flow is a common adverse effect of oral contraceptives and usually subsides after a few months of use.  
B. Breast tenderness is a common adverse effect of oral contraceptives and usually subsides after a few months of use.  
C. **CORRECT:** Shortness of breath can indicate a pulmonary embolus or myocardial infarction and should be reported to the provider immediately.  
D. Increased appetite is a common adverse effect of oral contraceptive and does not have to be reported to the provider.
3. A. An IUD will be replaced every 3 to 5 years, dependent upon the type of IUD used.  
B. Clients do not have to have given birth prior to the insertion of an IUD. It will be necessary for the client to have a negative pregnancy test prior to insertion of the IUD.  
C. Fertility will resume immediately following removal of the IUD.  
D. **CORRECT:** The client should check for presence of IUD strings following each menstruation to ensure the device is still present. A change in the length of the strings should be reported to the provider.
4. A. Tinnitus is not an adverse effect of implantable progestins.  
B. **CORRECT:** Irregular vaginal bleeding is a potential adverse effect of implantable progestins.  
C. **CORRECT:** Weight gain is a potential adverse effect of implantable progestins.  
D. **CORRECT:** Nausea is a potential adverse effect of implantable progestins.  
E. Gingival hyperplasia is not a potential adverse effect of implantable progestins.
5. A. **CORRECT:** Weight fluctuations can occur when taking medroxyprogesterone.  
B. Medroxyprogesterone does not provide protection against STIs.  
C. **CORRECT:** Clients should take calcium and vitamin D to prevent loss of bone density, which can occur when taking medroxyprogesterone.  
D. Antibiotics are not contraindicated when taking medroxyprogesterone.  
E. **CORRECT:** Medroxyprogesterone can cause irregular vaginal bleeding.

NCLEX® Connection: Pharmacological and Parenteral Therapies, Medication Administration

## Active Learning Scenario Key

Using the ATI Active Learning Template: Therapeutic Procedure

**DESCRIPTION OF PROCEDURE:** Surgical procedure involving ligation and severance of the vas deferens.

### INDICATIONS

#### Advantages

- Method is permanent.
- Procedure is short, safe, and simple.
- Sexual function is not impaired.

**Disadvantages:** A surgical procedure; considered irreversible.

### CLIENT EDUCATION

- Scrotal support and moderate activity are recommended for several days after the procedure to improve comfort.
- An alternate form of contraception should be used for approximately 20 ejaculations to ensure that the vas deferens is cleared of remaining sperm.
- A follow-up sperm count should be done.

NCLEX® Connection: Health Promotion and Maintenance, Lifestyle Choices

# CHAPTER 2

UNIT 1

ANTEPARTUM NURSING CARE

SECTION: HUMAN REPRODUCTION

CHAPTER 2

## Infertility

---

Infertility is defined as an inability to conceive despite engaging in unprotected sexual intercourse for a prolonged period of time or at least 12 months. Common factors associated with infertility can include decreased sperm production, endometriosis, ovulation disorders, and tubal occlusions.

Partners who experience infertility can experience stress related to physical inability to conceive, expense, the effect on the couple's relationship, and lack of family support. Infertility assessments, diagnostic procedures, assisted reproductive technologies, and genetic counseling may be undertaken.

### ASSESSMENT

---

#### Female

---

**AGE:** Age greater than 35 years can affect fertility.

**DURATION OF INFERTILITY:** More than 1 year of coitus without contraceptives. For females older than 35 years or who have a known risk factor, the recommendation is for 6 months.

**MEDICAL HISTORY:** Atypical secondary sexual characteristic, such as abnormal body fat distribution or hair growth, is indicative of an endocrine disorder. Assessment should include hormonal and adrenal gland disorders, as these can contribute to infertility.

**SURGICAL HISTORY:** Particularly pelvic and abdominal procedures.

**OBSTETRIC HISTORY:** Past episodes of spontaneous abortions. Other obstetric assessments should include an evaluation of hormone levels throughout the client's cycle. This can provide information about anovulation, amenorrhea, and premature ovarian failure.

**GYNECOLOGIC HISTORY:** Abnormal uterine contours or any history of disorders that can contribute to the formation of scar tissue that can cause blockage of ovum or sperm.

**SEXUAL HISTORY:** Intercourse frequency, number of partners across the lifespan, and any history of STIs.

#### OCCUPATIONAL/ENVIRONMENTAL EXPOSURE RISK

**ASSESSMENT:** Exposure to hazardous teratogenic materials in the home or at a place of employment.

**NUTRITION STATUS:** Overweight or underweight. Nutritional deficiencies, such as anorexia, can contribute to infertility.

**SUBSTANCE USE:** Alcohol, tobacco, heroin, methadone.

#### Male

---

**MEDICAL HISTORY:** Mumps, especially after adolescence; endocrine disorders; genetic disorders; and anomalies in the reproductive system.

**SEXUAL HISTORY:** Intercourse frequency, and history of sexually transmitted infections.

**SUBSTANCE USE:** Alcohol, tobacco, heroin, methadone.

#### OCCUPATIONAL/ENVIRONMENTAL EXPOSURE RISK

**ASSESSMENT:** Exposure to hazardous teratogenic materials in home or work environment, exposure of scrotum to high temperatures.

### DIAGNOSTIC PROCEDURES

---

#### Female

---

**PELVIC EXAMINATION:** Assesses for uterine or vaginal anomalies.

**HORMONE ANALYSIS:** Evaluates hypothalamic-pituitary-ovarian axis to include blood prolactin, FSH, LH, estradiol, progesterone, and thyroid hormone levels.

**POSTCOITAL TEST:** Evaluates coital technique and mucus secretions.

**ULTRASONOGRAPHY:** A transvaginal or abdominal ultrasound procedure performed to visualize reproductive organs.

**HYSTEROSALPINGOGRAPHY:** Outpatient radiological procedure in which dye is used to assess the patency of the fallopian tubes. Assess for history of allergies to iodine and seafood prior to beginning the procedure.

**HYSTEROSCOPY:** A radiographic procedure in which the uterus is examined for defect, distortion, or scar tissue that can impair successful impregnation.

**LAPAROSCOPY:** A procedure in which gas insufflation under general anesthesia is used to observe internal organs.

#### Male

---

**SEmen ANALYSIS:** In 40% of couples who are infertile, inability to conceive is due to male infertility. This test is the first in an infertility workup because it is less expensive and less invasive than female infertility testing. It can need to be repeated.

**ULTRASONOGRAPHY:** An ultrasound procedure is performed to visualize testes and abnormalities in the scrotum. A transrectal ultrasound is performed to assess the ejaculatory ducts, seminal vesicles, and vas deferens.

## PATIENT-CENTERED CARE

---

### THERAPEUTIC PROCEDURES

---

#### NONMEDICAL, LIFESTYLE CHANGES, AND ALTERNATIVE MEASURES

- Nutritional and dietary changes
- Exercise, yoga, and stress management
- Herbal medications, only if prescribed
- Acupuncture
- Avoid high scrotal temperatures

#### MEDICAL THERAPY

- Ovarian stimulation—medications are prescribed to stimulate the ovary to produce follicles:
  - Clomiphene citrate
  - Letrozole
- Other medications used to support ovulation: metformin
- Appropriate antimicrobial medications for preexisting infections

#### ASSISTED REPRODUCTIVE TECHNOLOGIES

- **Intrauterine insemination:** Procedure used to place prepared sperm in the uterus at the time of ovulation.
- **In vitro fertilization—embryo transfer (IVF-ET):** Procedure of collecting the client's eggs from the ovaries, fertilizing the eggs in the laboratory with sperm, and transferring the embryo to the uterus.
- **Gamete intrafallopian transfer:** Oocytes are retrieved and immediately placed with prepared motile sperm. Both are placed together into a thin flexible tube (catheter). The gametes are then injected into the fallopian tubes using a surgical procedure called laparoscopy.
- **Donor oocyte:** Donated eggs are collected from a donor by an IVF procedure. The eggs are inseminated. The embryos are placed in a recipient's uterus. Prior to implantation, the recipient undergoes hormonal therapy to prepare the uterus.
- **Donor embryo (embryo adoption):** Donated embryo is placed in the recipient's uterus, which is hormonally prepared.
- **Gestational carrier (embryo host):** A couple completes the process of IVF with the embryo placed in another person, who will carry the pregnancy. This is a contract agreement with the carrier having no genetic investment with the embryo.
- **Surrogate mother:** A person is inseminated with semen and carries the fetus until birth.
- **Therapeutic donor insemination:** Donor sperm is used to inseminate a person.

### NURSING INTERVENTIONS

---

- Encourage couples to express and discuss their feelings and recognize infertility as a major life stressor. Assist the couple to consider options, and provide education to assist in decision-making. *Qcc*
- Explain role of genetic counselor, reproductive specialist, geneticist, and pharmacist in providing psychosocial and medical care.
- Monitor for adverse effects associated with medications to treat infertility.

- Advise that the use of medications to treat female infertility can increase the risk of multiple births by more than 25%.
- Provide information regarding assisted reproductive therapies (in vitro fertilization, embryo transfer, intrafallopian gamete transfer, surrogate parenting, and reproductive alternatives such as adoption).
- Make referrals to grief and infertility support groups. *Qrc*

### GENETIC COUNSELING

---

- Genetic counseling may be recommended by the provider if there is a family history of birth defects.
- Identify clients who are in need of genetic counseling, such as a client who has a sickle cell trait or sickle cell anemia, or a client older than 35. Make referrals to genetic specialists as necessary.
- Prenatal assessment of genetic disorders (amniocentesis) can pose potential risks to the fetus.
- Provide and clarify information pertaining to the risk of or the occurrence of genetic disorders within a family preceding, during, and following a genetic counseling session.

#### NURSING ACTIONS

- Assist in the construction of family medical histories of several generations.
- Provide emotional support. Client responses vary and include denial, anger, grief, guilt, and self-blame.
- Make referrals to support groups and provide follow-up.

### COMPLICATIONS

---

#### *Ectopic pregnancy*

---

- Ovum implants in the fallopian tubes or abdominal cavity due to the presence of endometrial tissue.
- As ovum increases in size, fallopian tube can rupture, and extensive bleeding occurs, resulting in surgical removal of the damaged tube.
- If ectopic pregnancy is identified prior to rupture of the tube, surgical removal of the products of conception may be performed, or methotrexate is prescribed to dissolve the pregnancy.
- Client faces increased risk of recurrence of an ectopic pregnancy and infertility.

#### *Multiple gestation*

---

Assisted reproductive technology is associated with an increased incidence of multiple gestations. This poses a risk for the mother and babies.

## Application Exercises

- 1.** A nurse in a clinic is caring for a group of female clients who are being evaluated for infertility. Which of the following clients should the nurse anticipate the provider will refer to a genetic counselor?
- A. A client whose sister has alopecia
  - B. A client whose partner has von Willebrand disease
  - C. A client who has an allergy to sulfa
  - D. A client who had rubella 3 months ago
- 2.** A nurse is caring for a couple who is being evaluated for infertility. Which of the following statements by the nurse indicates understanding of the infertility assessment process?
- A. "You will need to see a genetic counselor as part of the assessment."
  - B. "It is usually the female who is having trouble, so the male doesn't have to be involved."
  - C. "The male is the easiest to assess, and the provider will usually begin there."
  - D. "Think about adopting first because there are many babies that need good homes."
- 3.** A nurse in an infertility clinic is providing care to clients who have been unable to conceive for 18 months. Which of the following data should the nurse assess? (Select all that apply.)
- A. Occupation
  - B. Menstrual history
  - C. Childhood infectious diseases
  - D. History of falls
  - E. Recent blood transfusions
- 4.** A nurse in a clinic is caring for a client who is postoperative following a salpingectomy due to an ectopic pregnancy. Which of the following statements by the client requires clarification?
- A. "It is good to know that I won't have a tubal pregnancy in the future."
  - B. "The doctor said that this surgery can affect my ability to get pregnant again."
  - C. "I understand that one of my fallopian tubes had to be removed."
  - D. "Ovulation can still occur because my ovaries were not affected."
- 5.** A nurse is reviewing the medical record of a client who is to undergo hysterosalpingography. Which of the following data alert the nurse that the client is at risk for a complication related to this procedure?

### VITAL SIGNS

Temperature  
36.1° C (97° F)

Heart rate 60/min

### HISTORY AND PHYSICAL

Employed as a radiology technician  
Allergy to shrimp  
Tonsillectomy at age 18

- A. Vital signs
- B. History and physical
- C. Laboratory findings
- D. Medications

### LABORATORY FINDINGS

Glucose 103 mg/dL  
Hgb 13.1 g/dL  
Total cholesterol 265 mg/dL  
  
**MEDICATIONS**  
Rosuvastatin  
Magnesium oxide  
Mafenide acetate

## Active Learning Scenario

A nurse in an infertility clinic is counseling a couple regarding infertility. Use the ATI Active Learning Template: System Disorder to complete this item.

**ALTERATION IN HEALTH (DIAGNOSIS):** Define infertility.

**RISK FACTORS:** List at least three categories to address.

**DIAGNOSTIC PROCEDURES:** Describe at least three.

## Application Exercises Key

1. A. Alopecia is a nonhereditary disorder and does not warrant referral to a genetic counselor.  
B. **CORRECT:** Von Willebrand disease is a genetic bleeding disorder and warrants a client being referred to a genetic counselor.  
C. Allergy to sulfa is a nonhereditary condition and does not warrant referral to a genetic counselor.  
D. A recent episode of rubella in a nonpregnant female does not warrant a referral to a genetic counselor.
  2. A. A referral to a genetic counselor occurs if there is a reason to suspect birth defects or other physiological concerns. It is not included in all infertility assessment processes.  
B. Factors affecting males and females can affect fertility. Both partners should be evaluated.  
C. **CORRECT:** A sperm analysis is one of the first steps in the infertility assessment process and can identify a cause of infertility in a less invasive and costly manner.  
D. Adoption is an option for the infertile couple after identifying a possible cause for the infertility.
  3. A. **CORRECT:** Occupational hazards include exposure to teratogenic substances in the workplace (radiation, chemicals, herbicides, pesticides).  
B. **CORRECT:** Menstrual history can identify hormone-related patterns (anovulation, pituitary disorders, endometriosis).  
C. **CORRECT:** Childhood infectious diseases can identify the male partner having had the mumps.  
D. A history of falls is not a consideration in the assessment.  
E. A recent blood transfusion is not a consideration in the assessment.
  4. A. **CORRECT:** The risk of recurrence of an ectopic pregnancy is increased following an ectopic pregnancy.  
B. Infertility can occur as a result of an ectopic pregnancy.  
C. A salpingectomy involves the removal of a fallopian tube.  
D. A salpingectomy does not involve the removal of the ovaries.
  5. A. An elevated heart rate or temperature could indicate infection, which would be a contraindication to the procedure.  
B. **CORRECT:** An allergy to seafood is a contraindication to the dye used in hysterosalpingography.  
C. The client's total cholesterol is elevated, but this does not place the client at risk for a complication related to the procedure.  
D. There are no contraindications related to the medications the client is taking.
- NCLEX® Connection: Health Promotion and Maintenance, Health Promotion/Disease Prevention
- NCLEX® Connection: Health Promotion and Maintenance, Lifestyle Choices
- NCLEX® Connection: Health Promotion and Maintenance, Health Screening
- NCLEX® Connection: Reduction of Risk Potential, Lifestyle Choices
- NCLEX® Connection: Reduction of Risk Potential, Diagnostic Tests

## Active Learning Scenario Key

Using the ATI Active Learning Template: System Disorder

### DESCRIPTION OF DISORDER/DISEASE PROCESS:

Inability to conceive despite engaging in unprotected sexual intercourse for a prolonged period of time or at least 12 months. For females over the age 35 or with a known risk factor, the recommendation is for 6 months.

### RISK FACTORS

- Age
- Weight
- Duration of infertility
- Medical history
- Surgical history
- Obstetric history
- Gynecologic history
- Occupational/environmental exposure risk

### DIAGNOSTIC PROCEDURES

- Semen analysis
- Pelvic examination
- Hormone analysis
- Postcoital test
- Ultrasonography
- Hysterosalpingography
- Hysteroscopy
- Laparoscopy

NCLEX® Connection: Reduction of Risk Potential, Therapeutic Procedures

# CHAPTER 3

UNIT 1

ANTEPARTUM NURSING CARE  
SECTION: CHANGES DURING PREGNANCY

CHAPTER 3

## Expected Physiological Changes During Pregnancy

Recognizing changes during pregnancy is helpful for both clients and nurses. The nurse and provider assess findings during the client's initial prenatal visit.

Signs of pregnancy are classified into three groups: presumptive, probable, and positive.

Calculating delivery date, number of pregnancies, and evaluating the physiological status of a client who is pregnant are performed.

### SIGNS OF PREGNANCY

#### PRESUMPTIVE SIGNS

Presumptive signs are changes that the client experiences that make them think that they might be pregnant. These changes might be subjective manifestations or objective findings. Signs also might be a result of physiological factors other than pregnancy (peristalsis, infections, stress).

- **Amenorrhea**
- **Fatigue**
- **Nausea and vomiting**
- **Urinary frequency**
- **Breast changes:** darkened areolae, enlarged Montgomery's glands
- **Quickenings:** slight fluttering movements of the fetus felt by the client, usually between 16 to 20 weeks of gestation
- **Uterine enlargement**

#### PROBABLE SIGNS

Probable signs are changes that make the examiner suspect a client is pregnant (primarily related to physical changes of the uterus). Signs can be caused by physiological factors other than pregnancy (pelvic congestion, tumors).

- **Abdominal enlargement** related to changes in uterine size, shape, and position
- **Hegar's sign:** softening and compressibility of lower uterus
- **Chadwick's sign:** deepened violet-bluish color of cervix and vaginal mucosa
- **Goodell's sign:** softening of cervical tip
- **Ballottement:** rebound of unengaged fetus
- **Braxton Hicks contractions:** false contractions that are painless, irregular, and usually relieved by walking
- **Positive pregnancy test**
- **Fetal outline** felt by examiner

#### POSITIVE SIGNS

Positive signs are those that can be explained only by pregnancy.

- **Fetal heart sounds**
- **Visualization of fetus by ultrasound**
- **Fetal movement** palpated by an experienced examiner

#### VERIFYING PREGNANCY

**Blood and urine tests** provide an accurate assessment for the presence of human chorionic gonadotropin (hCG). hCG production can start as early as the day of implantation and can be detected as early as 7 to 8 days before expected menses.

- Production of hCG begins with implantation, peaks at about 60 to 70 days of gestation, declines until around 100 to 130 days of pregnancy, and then plasma levels remain at this lower level for the remainder of the pregnancy.
- Higher levels of hCG can indicate multifetal pregnancy, ectopic pregnancy, hydatidiform mole (gestational trophoblastic disease), or a genetic abnormality such as Down syndrome.
- Lower blood levels of hCG might suggest a miscarriage or ectopic pregnancy.
- Some medications (anticonvulsants, diuretics, tranquilizers) can cause false-positive or false-negative pregnancy results.
- Home pregnancy test: Urine samples should be first-voided morning specimens and follow the directions for accuracy.

#### CALCULATING DELIVERY DATE AND DETERMINING NUMBER OF PREGNANCIES FOR PREGNANT CLIENT

**Nägele's rule:** Take the first day of the client's last menstrual cycle, subtract 3 months, and then add 7 days and 1 year, adjusting for the year as necessary.

**Measurement of fundal height** in centimeters from the symphysis pubis to the top of the uterine fundus (between 18 and 30 weeks of gestation). Approximates the gestational age, plus or minus 2 gestational weeks.

**Gravidity:** number of pregnancies.

- Nulligravida: a client who has never been pregnant
- Primigravida: a client in their first pregnancy
- Multigravida: a client who has had two or more pregnancies

**Parity:** number of pregnancies in which the fetus or fetuses reach 20 weeks of pregnancy, not the number of fetuses. Parity is not affected whether the fetus is born stillborn or alive.

- Nullipara: no pregnancy beyond the stage of viability
- Primipara: has completed one pregnancy to stage of viability
- Multipara: has completed two or more pregnancies to stage of viability

**Viability:** the point in time when an infant has the capacity to survive outside the uterus. There is not a specific weeks of gestation; however, infants born between 22 to 25 weeks are considered on the threshold of viability.

#### GTPAL acronym

- Gravidity
- Term births (37 weeks or more)
- Preterm births (from viability up to 37 weeks)
- Abortions/m miscarriages (prior to viability)
- Living children

## PHYSIOLOGICAL STATUS OF PREGNANT CLIENT

### BODY SYSTEMS

#### *Reproductive*

Uterus increases in size and changes shape and position. Ovulation and menses cease during pregnancy.

#### *Cardiovascular*

Cardiac output increases (30% to 50%) and blood volume increases (30% to 45% at term) to meet the greater metabolic needs. Heart rate increases during pregnancy beginning around week 5 and reaches a peak (10 to 15/min above prepregnancy rate) around 32 weeks of pregnancy.

#### *Respiratory*

Maternal oxygen needs increase. During the last trimester, the size of the chest might enlarge, allowing for lung expansion, as the uterus pushes upward. Respiratory rate increases and total lung capacity decreases.

#### *Musculoskeletal*

Body alterations and weight increase necessitate an adjustment in posture. Pelvic joints relax.

#### *Gastrointestinal*

Nausea and vomiting might occur due to hormonal changes and/or an increase of pressure within the abdominal cavity as the pregnant client's stomach and intestines are displaced within the abdomen. Constipation might occur due to increased transit time of food through the gastrointestinal tract and, thus, increased water absorption.

#### *Renal*

Filtration rate increases secondary to the influence of pregnancy hormones and an increase in blood volume and metabolic demands. The amount of urine produced remains the same. Urinary frequency is common during pregnancy.

#### *Endocrine*

The placenta becomes an endocrine organ that produces large amounts of hCG, progesterone, estrogen, human placental lactogen, and prostaglandins. Hormones are very active during pregnancy and function to maintain pregnancy and prepare the body for delivery.

## BODY IMAGE CHANGES

- Due to physical and psychological changes that occur, the pregnant client requires support from their provider and family members.
- In the first trimester of pregnancy, physiological changes are not obvious. Many clients look forward to the changes so that the pregnancy will be more noticeable.
- During the second trimester, there are rapid physical changes due to the enlargement of the abdomen and breasts. These changes can affect a client's mobility. Skin changes also occur (stretch marks, hyperpigmentation). They might find themselves losing their balance and feeling back or leg discomfort and fatigue. These factors might lead to a negative body image. The client might make statements of resentment toward the pregnancy and express anxiousness for the pregnancy to be over soon.

## EXPECTED VITAL SIGNS

#### *Blood pressure*

- Blood pressure measurements are within the prepregnancy range during the first trimester.
- **Systolic:** slight or no increase from prepregnancy levels
- **Diastolic:** slight decreases around 24 to 32 weeks; will gradually return to prepregnancy level by the end of the pregnancy.
- The position of the pregnant client also might affect blood pressure. In the supine position, blood pressure might appear to be lower due to the weight and pressure of the gravid uterus on the vena cava, which decreases venous blood flow to the heart. Maternal hypotension and fetal hypoxia might occur, which is referred to as supine hypotensive syndrome or supine vena cava syndrome. Manifestations include dizziness, lightheadedness, pallor, and clammy skin. Encourage the client to engage in maternal positioning on the left-lateral side, semi-Fowler's position, or, if supine, with a wedge placed under one hip to alleviate pressure to the vena cava.

#### *Pulse*

Pulse increases 10 to 15/min around 32 weeks of gestation and remains elevated throughout the remainder of the pregnancy.

#### *Respirations*

Respirations are unchanged or slightly increased. Respiratory changes in pregnancy are attributed to the elevation of the diaphragm by as much as 4 cm, as well as changes to the chest wall to facilitate increased maternal oxygen demands. Some shortness of breath might be noted.

## EXPECTED FINDINGS Q<sub>EBP</sub>

- Fetal heart tones are heard at a normal baseline rate of 110 to 160/min with reassuring FHR accelerations noted, which indicates an intact fetal CNS.
- The client's heart changes in size and shape with resulting cardiac hypertrophy to accommodate increased blood volume and increased cardiac output. Heart sounds also change to accommodate the increase in blood volume with a more distinguishable splitting of S<sub>1</sub> and S<sub>2</sub>, with S<sub>3</sub> more easily heard following 20 weeks of gestation. Murmurs also might be auscultated. Heart size and shape should return to normal shortly after delivery.
- Uterine size changes from a uterine weight of 50 to 1,000 g (0.1 to 2.2 lb). By 36 weeks of gestation, the top of the uterus and the fundus will reach the xiphoid process. This might cause the pregnant client to experience shortness of breath as the uterus pushes against the diaphragm.
- Cervical changes are obvious as a purplish-blue color extends into the vagina and labia, and the cervix becomes markedly soft.
- Breast changes occur due to hormones of pregnancy, with the breasts increasing in size and the areolas darkening.

### SKIN CHANGES

- Chloasma: an increase of pigmentation on the face
- Linea nigra: dark line of pigmentation from the umbilicus extending to the pubic area
- Striae gravidarum: stretch marks most notably found on the abdomen and thighs

## NURSING INTERVENTIONS

- Acknowledge the client's concerns about pregnancy and encourage sharing of these feelings while providing an atmosphere free of judgment.
- Discuss with the client the expected physiological changes and a possible timeline for a return to the prepregnant state.
- Assist the client in setting goals for the postpartum period in regard to self-care and newborn care.
- Refer the client to counseling if body image concerns appear to have a negative impact on the pregnancy. Q<sub>rc</sub>
- Provide education about the expected physiological and psychosocial changes. Common discomforts of pregnancy and ways to resolve those discomforts are reviewed during prenatal visits.
- The client is encouraged to keep all follow-up appointments and to contact the provider immediately if there is any bleeding, leakage of fluid, or contractions at any time during the pregnancy. Q<sub>s</sub>

## Application Exercises

1. A nurse is caring for a client who is pregnant and states that their last menstrual period was April 1st. Which of the following is the client's estimated date of delivery?
  - A. January 8
  - B. January 15
  - C. February 8
  - D. February 15
2. A nurse in a prenatal clinic is caring for a client who is in the first trimester of pregnancy. The client's health record includes this data: G3 T1 P0 A1 L1. How should the nurse interpret this information? (Select all that apply.)
  - A. Client has delivered one newborn at term.
  - B. Client has experienced no preterm labor.
  - C. Client has been through active labor.
  - D. Client has had two prior pregnancies.
  - E. Client has one living child.
3. A nurse is reviewing the health record of a client who is pregnant. The provider indicated the client exhibits probable signs of pregnancy. Which of the following findings should the nurse expect? (Select all that apply.)
  - A. Montgomery's glands
  - B. Goodell's sign
  - C. Ballottement
  - D. Chadwick's sign
  - E. Quickenings
4. A nurse in a prenatal clinic is caring for a client who is pregnant and experiencing episodes of maternal hypotension. The client asks the nurse what causes these episodes. Which of the following responses should the nurse make?
  - A. "This is due to an increase in blood volume."
  - B. "This is due to pressure from the uterus on the diaphragm."
  - C. "This is due to the weight of the uterus on the vena cava."
  - D. "This is due to increased cardiac output."
5. A nurse in a clinic receives a phone call from a client who would like to be tested in the clinic to confirm a pregnancy. Which of the following information should the nurse provide to the client?
  - A. "You should wait until 4 weeks after conception to be tested."
  - B. "You should be off any medications for 24 hours prior to the test."
  - C. "You should be NPO for at least 8 hours prior to the test."
  - D. "You should collect urine from the first morning void."

## Application Exercises Key

1. A. **CORRECT:** April 1st minus 3 months plus 7 days and 1 year equals an estimated date of delivery of January 8.  
B. This is incorrect using Nägele's rule.  
C. This is incorrect using Nägele's rule.  
D. This is incorrect using Nägele's rule.

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

2. A. **CORRECT:** T1 indicates the client has delivered one newborn at term.  
B. P0 indicates the client has had no preterm deliveries.  
C. A1 indicates the client has had one miscarriage.  
D. **CORRECT:** G3 indicates the client has had two prior pregnancies and the client is currently pregnant.  
E. **CORRECT:** L1 indicates the client has one living child.

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

3. A. Montgomery's glands are a presumptive sign of pregnancy.  
B. **CORRECT:** Goodell's sign is a probable sign of pregnancy.  
C. **CORRECT:** Ballottement is a probable sign of pregnancy.  
D. **CORRECT:** Chadwick's sign is a probable sign of pregnancy.  
E. Quickening is a presumptive sign of pregnancy.

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

4. A. An increase in blood volume during pregnancy results in cardiac hypertrophy.  
B. Pressure from the gravid uterus on the diaphragm might cause the client to experience shortness of breath.  
C. **CORRECT:** Maternal hypotension occurs when the client is lying in the supine position and the weight of the gravid uterus places pressure on the vena cava, decreasing venous blood flow to the heart.  
D. An increase in cardiac output during pregnancy results in cardiac hypertrophy.

NCLEX® Connection: *Physiological Adaptation, Alterations in Body Systems*

5. A. The production of hCG can be detected as early as 7 to 8 days before expected menses.  
B. Do not advise the client to stop taking medications in preparation for pregnancy tests. Review the client's medications to determine whether they can affect the results.  
C. Do not advise the client to remain NPO prior to pregnancy testing. Blood tests are not affected by food or fluid intake.  
D. **CORRECT:** Urine pregnancy tests should be done on a first-voided morning specimen to provide the most accurate results.

NCLEX® Connection: *Reduction of Risk Potential, Laboratory Values*

## Active Learning Scenario

A nurse is caring for a client who is in the fourth week of gestation. The client asks about skin and breast changes that can occur during pregnancy. What information should the nurse include in the teaching? Use the ATI Active Learning Template: Basic Concept to complete this item.

**RELATED CONTENT:** Describe at least three changes that occur to the skin and breasts during pregnancy.

**UNDERLYING PRINCIPLES:** Describe the basis for these changes.

## Active Learning Scenario Key

*Using the ATI Active Learning Template: Basic Concept*

**RELATED CONTENT**

- Skin changes: hyperpigmentation; linea nigra; chloasma (mask of pregnancy) on the face; striae gravidarum (stretch marks), most pronounced on abdomen and thighs
- Breast changes: darkening of the areola, enlarged Montgomery's glands, increase in size and heaviness, increased sensitivity

**UNDERLYING PRINCIPLES:** Increase in estrogen and progesterone occurring during pregnancy

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

CHAPTER 4 

## Prenatal Care

Prenatal care involves nursing assessments and client education for pregnant clients. When providing prenatal care, nurses must take into account cultural considerations.

Prenatal education encompasses information provided to a client who is pregnant. Major areas of focus include assisting the client in self-care of the discomforts of pregnancy, promoting a safe outcome to pregnancy, and fostering positive feelings by the pregnant client and their family regarding the childbearing experience.

Prenatal care dramatically reduces infant and maternal morbidity and mortality rates by early detection and treatment of potential problems. A majority of birth defects occur between 2 and 8 weeks of gestation. 

### NURSING ASSESSMENTS

Nurses play an integral role in assessing a client's current knowledge, previous pregnancies, and birthing experiences.

### CLIENT HISTORY

Nursing assessment in prenatal care includes obtaining information regarding:

- **Reproductive and obstetrical history** (contraception use, gynecological diagnoses, history of STIs, previous pregnancies, obstetrical difficulties).
- **Medical history**, including physical preexisting conditions, surgical procedures, any handicapping conditions, and the client's immune status (rubella and hepatitis B).
- **Nutritional history**, a complete dietary assessment can alert the practitioner to deficient practices and food allergies. Good nutrition is important and has a direct effect on the growth and development of the fetus.
- **Family history**, such as genetic disorders or conditions that could affect the mother or fetus.
- Any recent or current illnesses or infections.
- **Current medications**, including substance use and alcohol consumption. The nurse should display a nonjudgmental, matter-of-fact demeanor when interviewing a client regarding substance use and observe for clinical findings such as lack of grooming.

- **Psychosocial history** (a client's emotional response to pregnancy, adolescent pregnancy, spouse, support system, history of depression, domestic violence issues).
- Any hazardous environmental exposures; current work conditions. 
- Current exercise and lifestyle.
- **Abuse history or risk**; assess all clients for all forms, including physical, sexual, or psychological abuse, because the risk increases during pregnancy.

### BIRTH PLAN

A nurse ascertains what a client's goals are for the birthing process. The nurse should discuss birthing methods, such as Lamaze, and pain control options (epidural, natural childbirth). 

### PRENATAL ASSESSMENTS

Prenatal care begins with an initial assessment (within the first 12 weeks) and continues throughout pregnancy. In an uneventful pregnancy, prenatal visits are scheduled monthly for weeks 16 through 28, every 2 weeks from 29 through 36 weeks, and every week from 36 weeks until birth.

#### *Initial prenatal visit*

- Determine the estimated date of birth based on the last menstrual period.
- Obtain medical and nursing history to include social supports and review of systems (to determine risk factors).
- Perform a physical assessment to include a client's baseline weight, vital signs, and pelvic examination.
- Obtain initial laboratory tests, including hemoglobin, hematocrit, WBC, blood type and Rh, rubella titer, urinalysis, renal function test, Pap test, cervical cultures, HIV antibody, hepatitis B surface antigen, toxoplasmosis, and RPR or VDRL.

#### *Ongoing prenatal visits*

- Monitor weight, blood pressure, and urine for glucose, protein, and leukocytes.
- Monitor for the presence of edema.
- Monitor fetal development.
  - FHR can be detected at early appointments by ultrasound. The heartbeat can be heard by Doppler late in the first trimester. Listen at the midline, right above the symphysis pubis, by holding the Doppler firmly on the abdomen.
  - Measure fundal height starting in the second trimester. From weeks 18 to 30, the fundal height in centimeters is approximately the same as the number of weeks gestation.
  - Fetal health assessment: Begin assessing for fetal movement between 16 and 20 weeks of gestation.
- Provide education for self-care to include management of common discomforts and concerns of pregnancy (nausea and vomiting, fatigue, backache, varicosities, heartburn, activity, sexuality).

## Nursing care

- Perform or assist with Leopold maneuvers to palpate presentation and position of the fetus.
- Assist the provider with the gynecological examination. This examination is performed to determine the status of a client's reproductive organs and birth canal. Pelvic measurements determine whether the pelvis will allow for the passage of the fetus at delivery. *Qrc*
  - The nurse has the client empty their bladder and take deep breaths during the examination to decrease discomfort.
- Administer RhO(D) immune globulin IM around 28 weeks of gestation for clients who are Rh-negative.

## Routine laboratory tests

### Blood type, Rh factor, and presence of irregular antibodies:

Determines the risk for maternal-fetal blood incompatibility (erythroblastosis fetalis) or neonatal hyperbilirubinemia. Indirect Coombs' test identifies clients sensitized to Rh-positive blood. For clients who are Rh-negative and not sensitized, the indirect Coombs' test is repeated between 24 and 28 weeks of gestation.

**CBC with differential, Hgb, and Hct:** Detects infection and anemia.

**Hgb electrophoresis:** Identifies hemoglobinopathies (sickle cell anemia and thalassemia).

**Rubella titer:** Determines immunity to rubella.

**Hepatitis B screen:** Identifies carriers of hepatitis B.

**Group B Streptococcus (GBS):** Obtain a vaginal/anal culture at 35 to 37 weeks of gestation to assess for GBS infection.

**Urinalysis with microscopic examination of pH, specific gravity, color, sediment, protein, glucose, albumin, RBCs, WBCs, casts, acetone, and human chorionic gonadotropin:** Identifies pregnancy, diabetes mellitus, gestational hypertension, renal disease, and infection.

**One-hour glucose tolerance (oral ingestion with venous sample taken 1 hr later [fasting not necessary]):** Identifies hyperglycemia; done at initial visit for at-risk clients and at 24 to 28 weeks of gestation for all pregnant clients (greater than 140 mg/dL requires follow up).

**Three-hour glucose tolerance (fasting overnight prior to oral ingestion or IV administration of concentrated glucose with a venous sample taken 1, 2, and 3 hr later):** Used in clients who have elevated 1-hr glucose test as a screening tool for diabetes mellitus. A diagnosis of gestational diabetes requires two elevated blood-glucose readings.

**Papanicolaou (Pap) test:** Used as a screening tool for cervical cancer, herpes simplex type 2, and/or human papillomavirus.

**Vaginal/cervical culture:** Detects streptococcus beta-hemolytic, bacterial vaginosis, or sexually transmitted infections (gonorrhea and chlamydia).

**PPD (tuberculosis screening), chest x-ray after 20 weeks of gestation with PPD test:** Identifies exposure to tuberculosis.

**Venereal disease research laboratory (VDRL):** Syphilis screening mandated by law.

**HIV:** Detects HIV infection (the Centers for Disease Control and Prevention and the American College of Obstetricians and Gynecologists recommend testing all clients who are pregnant unless the client refuses testing).

**Toxoplasmosis, other infections, rubella, cytomegalovirus, and herpes virus (TORCH) screening when indicated:** Screening for a group of infections capable of crossing the placenta and adversely affecting fetal development.

**Maternal serum alpha-fetoprotein (MSAFP):** Screening occurs between 15 to 22 weeks of gestation. Used to rule out Down syndrome (low level) and neural tube defects (high level). The provider might decide to use a more reliable indicator and opt for the Quad screen instead of the MSAFP at 16 to 18 weeks of gestation. This includes AFP, inhibin-A, a combination analysis of human chorionic gonadotropin and estriol.

## CLIENT EDUCATION

Prenatal education includes health promotion, preparation for pregnancy and birth, common discomforts of pregnancy, and warning/danger signs to report.

## HEALTH PROMOTION

Preconception and prenatal education emphasizes healthy behaviors that promote the health of the pregnant client and their fetus. *Qcc*

- Avoid all over-the-counter medications, supplements, and prescription medications unless the provider who is supervising their care has knowledge of this practice.
- Alcohol (birth defects) and tobacco (low birth weight) are contraindicated during pregnancy.
- Substance use of any kind is to be avoided during pregnancy and lactation. Strategies to reduce or eliminate substance use are reviewed.
- Exercise during pregnancy yields positive benefits and should consist of 30 min of moderate exercise (walking or swimming) daily if not medically or obstetrically contraindicated.
- Avoid the use of hot tubs or saunas.
- Consume at least 8 to 10 glasses (2.3 L) of water each day.

The nurse educates a client about the following:

- Need for flu immunization
- Smoking cessation
- Treatment of current infections
- Genetic testing and counseling
- Exposure to hazardous materials

## **PREPARATION FOR PREGNANCY AND BIRTH**

- Nurses provide anticipatory teaching to the pregnant client and their family about the following:
  - Physical and emotional changes during pregnancy and interventions that can be implemented to provide relief.
  - Indications of complications to report to the provider.
  - Birthing options available to enhance the birthing process.
- Maternal adaptation to pregnancy and the attainment of the maternal role—whereby the idea of pregnancy is accepted and assimilated into the client's way of life—includes hormonal and psychological aspects.
  - Emotional lability is experienced by many clients with unpredictable mood changes and increased irritability, tearfulness, and anger alternating with feelings of joy and cheerfulness. This might result from hormonal changes.
  - A feeling of ambivalence about the pregnancy, which is a normal response, might occur early in the pregnancy and resolve before the third trimester. It consists of conflicting feelings (joy, pleasure, sorrow, hostility) about the pregnancy. These feelings can occur simultaneously, whether the pregnancy was planned or not.
- The nurse anticipates reviewing prenatal education topics with a client based on their current knowledge and previous pregnancy and birth experiences. The client's readiness to learn is enhanced when the nurse provides teaching during the appropriate trimester based on learning needs. Using a variety of educational methods (pamphlets, videos) and having the client verbalize and demonstrate learned topics will ensure that learning has taken place. 

### **FIRST TRIMESTER**

- Physical and psychosocial changes
- Common discomforts of pregnancy and measures to provide relief
- Lifestyle: exercise, stress, nutrition, sexual health, dental care, over-the-counter and prescription medications, tobacco, alcohol, substance use, and STIs (encourage safe sexual practices)
- Possible complications and indications to report (preterm labor)
- Fetal growth and development
- Prenatal exercise
- Expected laboratory testing

### **SECOND TRIMESTER**

- Benefits of breastfeeding
- Common discomforts and relief measures
- Lifestyle: sex and pregnancy, rest and relaxation, posture, body mechanics, clothing, seat belt safety and travel 
- Fetal movement
- Complications (preterm labor, gestational hypertension, gestational diabetes mellitus, premature rupture of membranes)

- Preparation for childbirth and childbirth education classes
- Review of birthing methods
- Development of a birth plan (verbal or written agreement about what the client wishes during labor and delivery)

### **THIRD TRIMESTER**

- Childbirth preparation 
  - Childbirth classes or birth plan
  - Coping methods
  - Breathing and relaxation techniques
  - Use of effleurage and counter pressure
  - Application of heat/cold, touch and massage, and water therapy
  - Use of transcutaneous electrical nerve stimulation (TENS)
  - Acupressure and acupuncture
  - Music and aromatherapy
  - Discussion regarding pain management during labor and birth (natural childbirth, epidural)
  - Use of a doula during labor
  - Indications of preterm labor and labor
  - Labor process
  - Infant care
  - Postpartum care
- Fetal movement/kick counts to ascertain fetal well-being: A client should be instructed to count and record fetal movements or kicks daily. There are several different methods to complete kick counts.
  - One method: Clients should count fetal activity two or three times a day for 2 hr after meals or bedtime. Fetal movements of less than 3 per hr or movements that cease entirely for 12 hr indicate a need for further evaluation.
- Diagnostic testing for fetal well-being (nonstress test, biophysical profile, ultrasound, and contraction stress test)

## **COMMON DISCOMFORTS OF PREGNANCY**

**Nausea and vomiting** might occur during the first trimester. The client should eat crackers or dry toast before rising in the morning to relieve discomfort. Instruct the client to avoid having an empty stomach and ingesting spicy, greasy, or gas-forming foods. Encourage the client to drink fluids between meals.

**Breast tenderness** might occur during the first trimester. The client should wear a bra that provides adequate support.

**Urinary frequency** might occur during the first and third trimesters. The client should empty the bladder frequently, decrease fluid intake before bedtime, and use perineal pads. The client is taught how to perform Kegel exercises (alternate tightening and relaxation of pubococcygeal muscles) to reduce stress incontinence (leakage of urine with coughing and sneezing).

**Urinary tract infections** (UTIs) are common during pregnancy because of renal changes and the vaginal flora becoming more alkaline.

- UTI risks can be decreased by encouraging the client to wipe the perineal area from front to back after voiding, avoiding bubble baths, wearing cotton underpants, avoiding tight-fitting pants, and consuming plenty of water (8 glasses per day). 
- The client should urinate before and after intercourse to flush bacteria from the urethra that are present or introduced during intercourse.
- Advise the client to urinate as soon as the urge occurs because retaining urine provides an environment for bacterial growth.
- Advise the client to notify the provider if their urine is foul-smelling, contains blood, or appears cloudy.

**Fatigue** might occur during the first and third trimesters. The client is encouraged to engage in frequent rest periods.

**Heartburn** might occur during the second and third trimesters due to the stomach being displaced by the enlarging uterus and a slowing of gastrointestinal tract motility and digestion brought about by increased progesterone levels. The client should eat small, frequent meals, not allow the stomach to get too empty or too full, and check with the provider prior to using any over-the-counter antacids. The client should not immediately lie down after eating, as this can exacerbate reflux.

**Constipation** might occur during the second and third trimesters. The client is encouraged to drink plenty of fluids, eat a diet high in fiber, and exercise regularly.

**Hemorrhoids** might occur during the second and third trimesters. A warm sitz bath, witch hazel pads, and application of topical ointments will help relieve discomfort.

**Backaches** are common during the second and third trimesters. The client is encouraged to exercise regularly, perform pelvic tilt exercises (alternately arching and straightening the back), use proper body mechanics by using the legs to lift rather than the back, and use the side-lying position.

**Shortness of breath** and dyspnea might occur because of the enlarged uterus, which limits inspiration. The client should maintain good posture, sleep with extra pillows, and contact the provider if manifestations worsen.

**Leg cramps** during the third trimester might occur due to the compression of lower-extremity nerves and blood vessels by the enlarging uterus. This can result in poor peripheral circulation, as well as an imbalance in the calcium/phosphorus ratio. The client should extend the affected leg, keeping the knee straight, and dorsiflex the foot (toes toward head). Application of heat over the affected muscle or a foot massage while the leg is extended can help relieve cramping. The client should notify the provider if frequent cramping occurs.

**Varicose veins and lower-extremity edema** can occur during the second and third trimesters. The client should rest with the legs and hips elevated, avoid constricting clothing, wear support hose, avoid sitting or standing in one position for extended periods of time, and not sit with the legs crossed at the knees. The client should sleep in the left-lateral position and exercise moderately with frequent walking to stimulate venous return.

**Gingivitis, nasal stuffiness, and epistaxis** (nosebleed) can occur as a result of elevated estrogen levels causing increased vascularity and proliferation of connective tissue. The client should gently brush their teeth, observe good dental hygiene, use a humidifier, and use normal saline nose drops or spray.

**Braxton Hicks contractions**, which occur from the first trimester onward, might increase in intensity and frequency during the third trimester. Inform the client that a change of position and walking should cause contractions to subside. If contractions increase in intensity and frequency (true contractions) with regularity, the client should notify the provider.

**Supine hypotension** occurs when a client lies on their back and the weight of the gravid uterus compresses the vena cava. This reduces blood supply to the fetus. The client might experience feelings of lightheadedness and faintness. Teach the client to lie in a side-lying or semi-sitting position with the knees slightly flexed.

## DANGER SIGNS DURING PREGNANCY

The following indicate potential dangerous situations that should be reported to the provider immediately.

### FIRST TRIMESTER

- Burning on urination (infection)
- Severe vomiting (hyperemesis gravidarum)
- Diarrhea (infection)
- Fever or chills (infection)
- Abdominal cramping and/or vaginal bleeding (miscarriage, ectopic pregnancy)

### SECOND AND THIRD TRIMESTER

- Gush of fluid from the vagina (rupture of amniotic fluid) prior to 37 weeks of gestation
- Vaginal bleeding (placental problems such as abruption or previa)
- Abdominal pain (premature labor, abruptio placentae, or ectopic pregnancy)
- Changes in fetal activity (decreased fetal movement might indicate fetal distress)
- Persistent vomiting (hyperemesis gravidarum)
- Severe headaches (gestational hypertension)
- Elevated temperature (infection)
- Dysuria (urinary tract infection)
- Blurred vision (gestational hypertension)
- Edema of face and hands (gestational hypertension)
- Epigastric pain (gestational hypertension)
- Concurrent occurrence of flushed dry skin, fruity breath, rapid breathing, increased thirst and urination, and headache (hyperglycemia)
- Concurrent occurrence of clammy pale skin, weakness, tremors, irritability, and lightheadedness (hypoglycemia)

## Application Exercises

1. A nurse is teaching a group of clients who are pregnant about measures to relieve backache during pregnancy. Which of the following measures should the nurse include? (Select all that apply.)

  - A. Avoid any lifting.
  - B. Perform Kegel exercises twice a day.
  - C. Perform the pelvic rock exercise every day.
  - D. Use proper body mechanics.
  - E. Avoid constrictive clothing.
  
2. A nurse is caring for a client who is pregnant and reviewing manifestations of complications the client should promptly report to the provider. Which of the following complications should the nurse include?

  - A. Vaginal bleeding
  - B. Swelling of the ankles
  - C. Heartburn after eating
  - D. Lightheadedness when lying on back
  
3. A client who is at 7 weeks of gestation is experiencing nausea and vomiting in the morning. Which of the following information should the nurse include?

  - A. Eat crackers or plain toast before getting out of bed.
  - B. Awaken during the night to eat a snack.
  - C. Skip breakfast and eat lunch after nausea has subsided.
  - D. Eat a large evening meal.
  
4. A nurse is teaching a client who is at 6 weeks of gestation about common discomforts of pregnancy. Which of the following findings should the nurse include? (Select all that apply.)

  - A. Breast tenderness
  - B. Urinary frequency
  - C. Epistaxis
  - D. Dysuria
  - E. Epigastric pain
  
5. A client who is at 8 weeks of gestation tells the nurse "I am not sure I am happy about being pregnant." Which of the following responses should the nurse make?

  - A. "I will inform the provider that you are having these feelings."
  - B. "It is normal to have these feelings during the first few months of pregnancy."
  - C. "You should be happy that you are going to bring new life into the world."
  - D. "I am going to make an appointment with the counselor for you to discuss these thoughts."

## Active Learning Scenario

A nurse is caring for a client at 14 weeks of gestation and is reviewing self-care concepts regarding the prevention of urinary tract infections (UTIs). What should the nurse include in the teaching? Use the ATI Active Learning Template: Basic Concept to complete this item.

**UNDERLYING PRINCIPLES:** Describe two.

**NURSING INTERVENTIONS:** Describe two actions that decrease the risk of UTIs as they relate to each of the following types of interventions: When? Why? and How?

## Application Exercises Key

1. A. Lifting can be done by using the legs rather than the back.
- B. Kegel exercises are done to strengthen the perineal muscles and do not relieve backache.
- C. **CORRECT:** The pelvic rock or tilt exercise stretches the muscles of the lower back and helps relieve lower-back pain.
- D. **CORRECT:** The use of proper body mechanics prevents back injury due to the incorrect use of muscles when lifting.
- E. Avoiding constrictive clothing helps prevent urinary tract infections, vaginal infections, varicosities, and edema of the lower extremities.

❷ NCLEX® Connection: Basic Care and Comfort, Non-Pharmacological Comfort Interventions

2. A. **CORRECT:** Vaginal bleeding indicates a potential complication of the placenta such as placenta previa. Instruct the client to notify the provider immediately.
- B. Swelling of the ankles is a common occurrence during pregnancy and can be relieved by sitting with the legs elevated.
- C. Heartburn occurs during pregnancy due to pressure on the stomach by the enlarging uterus. It can be relieved by eating small meals.
- D. Supine hypotension can be experienced by the client who feels lightheaded or faint when lying on their back. Instruct the client about the side-lying position to remove pressure of the uterus on the vena cava.

❷ NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

3. A. **CORRECT:** Nausea and vomiting during the first trimester might be relieved by eating crackers or plain toast prior to rising in the morning.
- B. Eating during the night can cause heartburn and does not relieve nausea and vomiting during the first trimester.
- C. Instruct the client to avoid an empty stomach for prolonged periods to reduce nausea and vomiting.
- D. Eating a large meal in the evening can cause heartburn and does not relieve morning nausea and vomiting.

❷ NCLEX® Connection: Physiological Adaptation, Alterations in Body Systems

4. A. **CORRECT:** Breast tenderness is a common discomfort occurring during the first trimester of pregnancy.
- B. **CORRECT:** Urinary frequency is a common discomfort occurring during the first trimester of pregnancy.
- C. **CORRECT:** Epistaxis is a common discomfort occurring during the first trimester of pregnancy.
- D. Dysuria is a complication that might occur during pregnancy. Instruct the client to report this finding to the provider.
- E. Epigastric pain is a clinical finding of pregnancy-induced hypertension. Instruct the client to report this finding to the provider

❷ NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

5. A. This is a nontherapeutic response by the nurse and does not acknowledge the client's concerns.
- B. **CORRECT:** Feelings of ambivalence about pregnancy are normal during the first trimester.
- C. This is a nontherapeutic response by the nurse and indicates disapproval.
- D. This is a nontherapeutic response by the nurse and does not acknowledge the client's feelings.

❷ NCLEX® Connection: Health Promotion and Maintenance, Developmental Stages and Transitions

## Active Learning Scenario Key

Using the ATI Active Learning Template: Basic Concept

**UNDERLYING PRINCIPLES:** UTIs are common because of renal changes during pregnancy and the vaginal flora becoming more alkaline.

### NURSING INTERVENTIONS

Decrease risk of UTIs by:

- How, When: Encouraging client to wipe the perineal area from front to back after voiding.
- How: Avoiding bubble baths.
- How: Wearing cotton underpants, avoiding tight-fitting pants.
- How: Consuming at least 8 glasses of water per day.
- How, Why: Instructing the client to urinate before and after intercourse to flush bacteria from the urethra that are present or introduced during intercourse.
- How, Why: Advising the client to urinate as soon as the urge occurs because retaining urine provides an environment for bacterial growth.
- When, Why: Advising the client to notify the provider if their urine is foul-smelling, contains blood, or is cloudy, so evaluation and early treatment can be initiated.

❷ NCLEX® Connection: Physiological Adaptation, Illness Management

# CHAPTER 5

UNIT 1

ANTEPARTUM NURSING CARE  
SECTION: CHANGES DURING PREGNANCY

CHAPTER 5

## Nutrition During Pregnancy

Adequate nutritional intake during pregnancy is essential to promoting fetal and maternal health.

Recommended weight gain during pregnancy, based on a single pregnancy, is usually 11.3 to 15.9 kg (25 to 35 lb). The general rule is that clients should gain 1 to 2 kg (2.2 to 4.4 lb) during the first trimester and after that approximately 0.5 kg (1 lb) per week for the last two trimesters. Underweight clients are advised to gain 12.7 to 18.1 kg (28 to 40 lb); overweight clients, 6.8 to 11.3 kg (15 to 25 lb).

Excessive weight gain can lead to macrosomia and labor complications. Inability to gain weight could result in low birth weight of the newborn.

It is important for the nurse to evaluate the pregnant client's nutritional choices, possible risk factors, and diet history. The nurse also should review specific nutritional guidelines for at-risk clients. Assistance is given to clients to develop a postpartum nutritional plan.

### NURSING ASSESSMENT AND INTERVENTIONS

#### ASSESSMENT

##### Obtain subjective and objective dietary information.

- Journal of the client's food habits, eating pattern, and cravings
- Nutrition-related questionnaires
- Health history, including contraceptive history, previous pregnancies, chronic diseases
- The client's weight on first prenatal visit and follow-up visits
- Laboratory findings (Hgb, iron levels)

#### Determine the client's caloric intake. Q<sub>PCC</sub>

Have the client record everything eaten during a 24-hr period. The nurse, dietitian, or client can identify the caloric value of each item. This record can provide better objective data about the client's nutrition status. (5.1)

#### CLIENT EDUCATION

Adhere to and maintain the following during pregnancy.

- **Increase calories:** An increase of 340 calories/day is recommended during the second trimester. An increase of 452 calories/day is recommended during the third trimester. If the client is breastfeeding during the postpartum period, additional caloric intake is advised. The American Academy of Pediatrics (AAP) recommends that breastfeeding clients who are well-nourished should add 450 to 500 calories/day to a balanced diet.
- **Increasing protein intake** is essential to basic growth.
- **Folic acid** is crucial for neurologic development and the prevention of fetal neural tube defects. Folate found naturally in foods is converted to folic acid. Foods high in folate include leafy vegetables, dried peas and beans, seeds, and orange juice. Breads, cereals, and other grains are fortified with folic acid. The March of Dimes recommends that clients who wish to become pregnant and clients of childbearing age take 400 mcg of folic acid and clients who become pregnant take 600 mcg of folic acid. Q<sub>EBP</sub>
- **Iron supplements** are often added to the prenatal plan to facilitate an increase of the maternal RBC mass. Iron is best absorbed between meals and when given with a source of vitamin C. Milk and caffeine interfere with the absorption of iron supplements. Food sources of iron include beef liver, red meats, fish, poultry, dried peas and beans, and fortified cereals and breads. A stool softener might need to be added to decrease constipation experienced with iron supplements.
- **Calcium**, which is important to a developing fetus, is involved in bone and teeth formation. Sources of calcium include milk, calcium-fortified soy milk, fortified orange juice, nuts, legumes, and dark green leafy vegetables. Daily recommendation is 1,000 mg/day for pregnant and nonpregnant clients 19 to 50 years of age, and 1,300 mg/day for those under 19 years of age.
- **Fluid:** 8 to 10 glasses (2.3 L) of fluid are recommended daily. Preferred fluids are water, fruit juice, and milk.

#### 5.1 Plan of care for a pregnant client

##### Expected outcomes

The client will consume the recommended dietary allowances/nutrients during their pregnancy.

##### Evaluation of the plan

Is there adequate weight gain?  
Is the client compliant with the nursing plan of care?

##### Interventions

The nurse assesses the client's dietary journal during prenatal visits.  
The nurse provides educational materials regarding nutritional benefits to the mother and their newborn.  
The nurse provides encouragement and answers questions that the client has regarding their dietary plans.  
The nurse weighs the client and monitors for manifestations of inadequate weight gain.  
The nurse makes a referral if needed.

- **Limit caffeine:** The American College of Obstetricians and Gynecologists (ACOG) and March of Dimes recommend a daily intake of no more than 200 mg of caffeine. Excessive intake of caffeine can contribute to infertility, spontaneous abortion, or intrauterine growth restriction (IUGR). 
- It is recommended that clients abstain from alcohol consumption during pregnancy.

## RISK FACTORS

Age, culture, education, and socioeconomic issues could affect adequate nutrition during pregnancy. Also, certain conditions specific to each client might inhibit adequate caloric intake.

- Adolescents might have poor nutritional habits (a diet low in vitamins and protein, not taking prescribed iron supplements).
- Clients who follow a vegetarian diet might have decreased intake of protein, calcium, iron, zinc, and vitamin B<sub>12</sub>.
- Nausea and vomiting during pregnancy
- Anemia
- Eating disorders (anorexia nervosa, bulimia nervosa)
- Pica (craving to eat nonfood substances such as dirt or red clay); this disorder might diminish the amount of nutritional foods ingested.
- Inability to purchase/access food. 

## DIETARY COMPLICATIONS DURING PREGNANCY

### Nausea and constipation

Nausea and constipation are common during pregnancy.

#### CLIENT EDUCATION

- For nausea, eat small amounts frequently (every 2 to 3 hr) to avoid large meals that distend the stomach, and avoid alcohol, caffeine, and fried, fatty, and spicy foods. Also avoid consuming excessive amounts of fluid, and DO NOT take a medication to control nausea without first checking with the provider. Ginger (ginger ale soda, ginger tea, ginger candies) and herbal tea (peppermint, raspberry) might also be helpful.
- For constipation, increase fluid consumption, perform physical activity, and include extra fiber in the diet. Fruits, vegetables, and whole grains all contain fiber.

### Maternal phenylketonuria

Maternal phenylketonuria (PKU) is a maternal genetic disease in which high levels of phenylalanine pose a danger to the fetus (intellectual disability, behavioral problems).

- It is important for the client to resume the PKU diet for at least 3 months prior to pregnancy and continue the diet throughout pregnancy.
- The diet includes foods that are low in phenylalanine. Foods high in protein (fish, poultry, meat, eggs, nuts, dairy products) must be avoided due to high phenylalanine levels. Aspartame, which contains phenylalanine, should be avoided by pregnant clients who have PKU.
- The client's blood phenylalanine levels are monitored during pregnancy.

### Diabetes mellitus

Both preexisting diabetes mellitus and gestational diabetes mellitus are complications that require nutritional interventions.

- Monitor the amount of carbohydrates in the diet and keep glucose levels within target range.
- Limit the amount of sweets and desserts, which typically have large amounts of carbohydrates.
- Meet with a registered dietitian.

## CREATING A POSTPARTUM NUTRITIONAL PLAN

- A lactating client's nutritional plan includes the following instructions.
  - Increase protein and calorie intake while adhering to a recommended, well-balanced diet.
  - Increase oral fluids, but avoid alcohol and caffeine.
  - Avoid food substances that do not agree with the newborn.
  - Take calcium supplements if unable to consume an adequate amount of dietary calcium.
- A nutritional plan for a client who is not breastfeeding should include resumption of a previously recommended well-balanced diet.
- Refer clients who need financial assistance to Women, Infants, and Children (WIC), which are federally funded state programs for pregnant clients and their children (up to 5 years old). 

## Application Exercises

1. A nurse in a prenatal clinic is providing education to a client who is at 8 weeks of gestation. The client states, "I don't like milk." Which of the following foods should the nurse recommend as a good source of calcium?

  - A. Dark green leafy vegetables
  - B. Deep red or orange vegetables
  - C. White breads and rice
  - D. Meat, poultry, and fish
  
2. A nurse in a prenatal clinic is caring for four clients. Which of the following clients' weight gain should the nurse report to the provider?

  - A. 1.8 kg (4 lb) weight gain and is in the first trimester
  - B. 3.6 kg (8 lb) weight gain and is in the first trimester
  - C. 6.8 kg (15 lb) weight gain and is in the second trimester
  - D. 11.3 kg (25 lb) weight gain and is in the third trimester
  
3. A nurse in a clinic is teaching a client of childbearing age about recommended folic acid supplements. Which of the following defects can occur in the fetus or neonate as a result of folic acid deficiency?

  - A. Iron deficiency anemia
  - B. Poor bone formation
  - C. Macrosomic fetus
  - D. Neural tube defects
  
4. A nurse is reviewing a new prescription for iron supplements with a client who is at 8 weeks of gestation and has iron deficiency anemia. Which of the following beverages should the nurse instruct the client to take the iron supplements with?

  - A. Ice water
  - B. Low-fat or whole milk
  - C. Tea or coffee
  - D. Orange juice
  
5. A nurse is reviewing postpartum nutrition needs with a group of clients who have begun breastfeeding their newborns. Which of the following statements by a member of the group indicates an understanding of the teaching?

  - A. "I am glad I can have my morning coffee."
  - B. "I should take folic acid to increase my milk supply."
  - C. "I will continue adding 330 calories per day to my diet."
  - D. "I will continue my calcium supplements because I don't like milk."

## Active Learning Scenario

A nurse manager in a prenatal clinic is preparing an in-service education program for a group of newly licensed nurses about risk factors preventing adequate nutrition during pregnancy. What information should the nurse include in this presentation? Use the ATI Active Learning Template: Basic Concept to answer this item.

### UNDERLYING PRINCIPLES

- Identify one that is age-related.
- Identify two that are related to culture/lifestyle.
- Identify one that is related to a socioeconomic factor.
- Identify two that are related to dietary complications during pregnancy.

**NURSING INTERVENTIONS:** Describe a federal program that is available to women and children to provide nutrition support.

## Application Exercises Key

1. A. **CORRECT:** Good sources of calcium for bone and teeth formation include low-oxalate, dark green leafy vegetables (kale, artichokes, turnip greens).
- B. Deep red or orange vegetables are good sources of vitamins C and A.
- C. White breads and rice do not contain high levels of calcium.
- D. Meat, poultry, and fish are sources of protein but do not contain high levels of calcium.

NCLEX® Connection: Basic Care and Comfort, Nutrition and Oral Hydration

2. A. This client has gained the appropriate weight of 3 to 4 lb for a client in the first trimester.
- B. **CORRECT:** The nurse should be concerned about this client because they have exceeded the expected 3- to 4-lb weight gain of a client in the first trimester.
- C. This client has gained the appropriate weight of 3 to 4 lb. in the first trimester and approximately 1 lb per week in the second trimester.
- D. This client is within the recommended weight gain of 25 to 35 lb during the third trimester.

NCLEX® Connection: Health Promotion and Maintenance, Health Promotion/Disease Prevention

3. A. Iron deficiency anemia is the result of a lack of iron-rich dietary sources (meat, chicken, fish).
- B. Calcium deficiency can result in poor bone and teeth formation.
- C. Maternal obesity can lead to a macrosomic fetus.
- D. **CORRECT:** Neural tube defects are caused by folic acid deficiency. Food sources of folic acid include fresh green leafy vegetables, liver, peanuts, cereals, and whole-grain breads.

NCLEX® Connection: Health Promotion and Maintenance, Health Promotion/Disease Prevention

4. A. Water does not promote absorption of iron, but drinking plenty of water can prevent constipation, which is an adverse effect of iron supplements.
- B. Milk interferes with iron absorption.
- C. Caffeine, found in tea and coffee, can interfere with iron absorption. The client should consume no more than 200 mg/day because it increases the risk of spontaneous abortion or fetal intrauterine growth restriction.
- D. **CORRECT:** Orange juice contains vitamin C, which aids in the absorption of iron.

NCLEX® Connection: Pharmacological and Parenteral Therapies, Medication Administration

5. A. Clients who are breastfeeding should avoid caffeine intake because it affects iron absorption and infant weight gain.
- B. Folic acid does not increase milk production.
- C. Clients who are breastfeeding require an additional 450 to 500 calories per day to support adequate nutrition.
- D. **CORRECT:** Postpartum clients who are at risk for inadequate dietary calcium should continue taking calcium supplements during lactation.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

## Active Learning Scenario Key

Using the ATI Active Learning Template: Basic Concept

### UNDERLYING PRINCIPLES

- Age-related: Adolescents may have poor nutritional habits during pregnancy.
- Culture/lifestyle: Vegetarians may have diets low in protein, calcium, zinc, and vitamin B<sub>12</sub>. Excessive weight gain can lead to macrosomia and labor complications.
- Socioeconomic factor: Inability to purchase or access foods can limit nutrition during pregnancy.
- Dietary complications: Nausea and vomiting during pregnancy, anemia, eating disorders (anorexia nervosa or bulimia nervosa), inability to gain weight, presence of the appetite disorder pica.

NURSING INTERVENTIONS: Women, Infants, and Children (WIC) is a federally funded state program that provides nutritional support to pregnant women and their children (up to 5 years old).

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

# CHAPTER 6

UNIT 1

ANTEPARTUM NURSING CARE  
SECTION: CHANGES DURING PREGNANCY

CHAPTER 6

## Assessment of Fetal Well-Being

This chapter includes the assessments that determine the well-being of a fetus during pregnancy. Diagnostic procedures include ultrasound (abdominal, transvaginal, Doppler), biophysical profile, nonstress test, contraction stress test (nipple, oxytocin), and amniocentesis. Additional diagnostic procedures for high-risk pregnancy include percutaneous umbilical cord blood sampling, chorionic villus sampling, quad marker screening, and maternal alpha-fetoprotein blood levels.

### Ultrasound (abdominal, transvaginal, and Doppler)

Ultrasound is a procedure lasting approximately 20 min that consists of high-frequency sound waves used to visualize internal organs and tissues by producing a real-time, three-dimensional image of the developing fetus and maternal structures (fetal heart rate [FHR], pelvic anatomy). An ultrasound allows for early diagnosis of complications, permits earlier interventions, and thereby decreases neonatal and maternal morbidity and mortality. There are three types of ultrasound: external abdominal, transvaginal, and Doppler.

#### External abdominal ultrasound

A safe, noninvasive, painless procedure whereby an ultrasound transducer is moved over the client's abdomen to obtain an image. An abdominal ultrasound is more useful after the first trimester when the gravid uterus is larger. The client should have a full bladder for the procedure. 

#### Transvaginal ultrasound

An invasive procedure in which a probe is inserted vaginally to allow for a more accurate evaluation. An advantage of this procedure is that it does not require a full bladder.

- It is especially useful in clients who are obese and those in the first trimester to detect an ectopic pregnancy, identify abnormalities, and to establish gestational age.
- A transvaginal ultrasound also can be used in the third trimester in conjunction with abdominal scanning to evaluate for preterm labor.

### Doppler ultrasound blood flow analysis

A noninvasive external ultrasound method to study the maternal-fetal blood flow by measuring the velocity at which RBCs travel in the uterine and fetal vessels using a handheld ultrasound device that reflects sound waves from a moving target. It is especially useful in fetal intrauterine growth restriction (IUGR) and poor placental perfusion, and as an adjunct in pregnancies at risk because of hypertension, diabetes mellitus, multiple fetuses, or preterm labor.

**Two-dimensional (2D):** standard medical scan; black, white, or shades of gray

**Three-dimensional (3D):** multiple pictures at once; almost as clear as a photograph; images look more lifelike than standard ultrasound images

**Four-dimensional (4D):** like 3D but also shows fetal movements in a video

### **INDICATIONS**

#### **POTENTIAL DIAGNOSES**

- Confirming pregnancy
- Confirming gestational age by biparietal diameter (side-to-side) measurement
- Identifying multifetal pregnancy
- Determining site of fetal implantation (uterine, ectopic)
- Assessing fetal growth and development
- Assessing maternal structures
- Confirming fetal viability or death
- Ruling out or verifying fetal abnormalities
- Locating the site of placental attachment
- Determining amniotic fluid volume
- Observing fetal movement (fetal heartbeat, breathing, and activity)
- Assessing fetal position
- Placental grading (evaluating placental maturation)
- Adjunct for other procedures (amniocentesis, biophysical profile)

#### **CLIENT PRESENTATION**

- Vaginal bleeding evaluation
- Questionable fundal height measurement in relationship to gestational weeks
- Reports of decreased fetal movements
- Preterm labor
- Questionable rupture of membranes

## CONSIDERATIONS

### NURSING ACTIONS

#### *Abdominal ultrasound*

##### CLIENT PREPARATION

- Explain the procedure and that it presents no known risk to self or fetus.
- Advise the client to drink 1 quart of water prior to the ultrasound to fill the bladder, lift and stabilize the uterus, displace the bowel, and act as an echolucent to better reflect sound waves to obtain a better image of the fetus.
- Assist the client into a supine position with a small pillow under their head and knees.

##### ONGOING CARE

- Apply an ultrasonic/transducer gel to the client's abdomen before the transducer is moved over the skin to obtain a better fetal image, ensuring that the gel is at room temperature or warmer.
- Allow the client to empty their bladder at the termination of the procedure.
- Provide the client with a washcloth or tissues to wipe away gel after completion of ultrasound.

#### *Transvaginal ultrasound*

**CLIENT PREPARATION:** Assist the client into a lithotomy position. The vaginal probe is covered with a protective device such as a condom, lubricated with a water-soluble gel, and inserted by the client or examiner.

##### ONGOING CARE

- During the procedure, the position of the probe or tilt of the table can be changed to facilitate the complete view of the pelvis.
- Inform the client that they might feel pressure as the probe is moved.

### CLIENT EDUCATION

Fetal and maternal structures can be pointed out as the ultrasound procedure is performed.

## *Biophysical profile*

Biophysical profile (BPP) uses a real-time ultrasound to visualize physical and physiological characteristics of the fetus and observe for fetal biophysical responses to stimuli. It combines FHR monitoring (nonstress test) and fetal ultrasound. 

## INDICATIONS

### POTENTIAL DIAGNOSES

- Nonreactive nonstress test
- Suspected oligohydramnios or polyhydramnios
- Suspected fetal hypoxemia or hypoxia

## CLIENT PRESENTATION

- Premature rupture of membranes
- Maternal infection
- Decreased fetal movement
- Intrauterine growth restriction

## CONSIDERATIONS

**NURSING ACTIONS:** Prepare the client following the same nursing management principles as those used for an ultrasound.

## INTERPRETATION OF FINDINGS

BPP assesses fetal well-being by measuring five variables with a score of 2 for each normal finding, and 0 for each abnormal finding for each variable.

### VARIABLES

#### FHR

- Reactive (nonstress test) = 2
- Nonreactive = 0

#### Fetal breathing movements

- At least 1 episode of greater than 30 seconds duration in 30 min = 2
- Absent or less than 30 seconds duration = 0

#### Gross body movements

- At least 3 body or limb extensions with return to flexion in 30 min = 2
- Less than 3 episodes = 0

#### Fetal tone

- At least 1 episode of extension with return to flexion = 2
- Slow extension and flexion, lack of flexion, or absent movement = 0

#### Qualitative amniotic fluid volume

- At least 1 pocket of fluid that measures at least 2 cm in 2 perpendicular planes = 2
- Pockets absent or less than 2 cm = 0

## TOTAL SCORE FINDINGS

8 TO 10: **normal**, low risk of chronic fetal asphyxia

4 TO 6: **abnormal**, suspect chronic fetal asphyxia

LESS THAN 4: **abnormal**, strongly suspect chronic fetal asphyxia

## 6.1 Reactive nonstress test

### Nonstress test

Nonstress test (NST) is the most widely used technique for antepartum evaluation of fetal well-being performed during the third trimester. It is a noninvasive procedure that monitors response of the FHR to fetal movement. A Doppler transducer (used to monitor FHR) and a tocotransducer (used to monitor uterine contractions) are attached externally to a client's abdomen to obtain tracing strips. The client pushes a button attached to the monitor whenever they feel a fetal movement, which is then noted on the tracing. This allows a nurse to assess the FHR in relationship to the fetal movement.

Disadvantages of a NST include a high rate of false nonreactive results with the fetal movement response blunted by sleep cycles of the fetus, fetal immaturity, maternal medications, and nicotine use disorder. 

### INDICATIONS

#### POTENTIAL DIAGNOSES

- Assessing for an intact fetal CNS during the third trimester.
- Ruling out the risk for fetal death in clients who have diabetes mellitus. Used twice a week starting at 28 to 32 weeks of gestation.

#### CLIENT PRESENTATION

- Decreased fetal movement
- Intrauterine growth restriction
- Postmaturity
- History of gestational hypertension or diabetes mellitus
- Systemic lupus erythematosus
- Kidney disease
- Intrahepatic cholestasis
- Oligohydramnios
- Multiple gestation

### CONSIDERATIONS

#### NURSING ACTIONS

##### CLIENT PREPARATION

- Seat the client in a reclining chair, or place in a semi-Fowler's or left-lateral position.
- Apply conduction gel to the client's abdomen.
- Apply two belts to the client's abdomen, and attach the FHR and uterine contraction monitors.

##### ONGOING CARE

- Instruct the client to press the button on the handheld event marker each time they feel the fetus move.
- If there are no fetal movements (fetus sleeping), vibroacoustic stimulation (sound source, usually laryngeal stimulator) can be activated for 3 seconds on the maternal abdomen over the fetal head to awaken the sleeping fetus.
- This test is typically completed within 20 to 30 min.

#### INTERPRETATION OF FINDINGS

- The NST is interpreted as reactive if the FHR accelerates at least 15/min (10/min prior to 32 weeks) for at least 15 seconds (10 seconds prior to 32 weeks) and occurs two or more times during a 20-min period. (6.1)
- Nonreactive NST is a test that does not demonstrate at least two qualifying accelerations in a 20-min window. If this is so, a further assessment, such as a contraction stress test (CST) or BPP, is indicated.

# Contraction stress test

## Nipple-stimulated contraction test

Consists of a client lightly brushing their palm across the nipple for 2 min, which causes the pituitary gland to release endogenous oxytocin, and then stopping the nipple stimulation when a contraction begins. The same process is repeated after a 5-min rest period.

- Analysis of the FHR response to contractions (which decrease placental blood flow) determines how the fetus will tolerate the stress of labor. A pattern of at least three contractions within a 10-min time period with duration of 40 to 60 seconds each must be obtained to use for assessment data.
- Tachysystole of the uterus (uterine contraction longer than 90 seconds or five or more contractions in 10 min) should be avoided by stimulating the nipple intermittently with rest periods in between and avoiding bimanual stimulation of both nipples unless stimulation of one nipple is unsuccessful.

## Oxytocin-stimulated contraction test

Also known as an oxytocin challenge test (OCT), it is used if nipple stimulation fails and consists of the IV administration of oxytocin to induce uterine contractions.

- Contractions started with oxytocin can be difficult to stop and can lead to preterm labor.
- Contraindications include placenta previa, vasa previa, preterm labor, multiple gestations, previous classic incision from a cesarean birth, and reduced cervical competence.

## INDICATIONS

### POTENTIAL DIAGNOSES

- High-risk pregnancies (gestational diabetes mellitus, postterm pregnancy)
- Nonreactive stress test

### CLIENT PRESENTATION

- Decreased fetal movement
- Intrauterine growth restriction
- Postmaturity
- Diabetes mellitus
- Hypertension
- History of previous fetal demise
- Systemic lupus erythematosus
- Kidney disease
- Intrahepatic cholestasis
- Oligohydramnios
- Multiple gestation

## CONSIDERATIONS

### NURSING ACTIONS

#### CLIENT PREPARATION

- Obtain and document a baseline of the FHR, fetal movement, and contractions for 10 to 20 min.
- Explain the procedure to the client, and obtain informed consent. Q<sub>PCC</sub>

#### ONGOING CARE

- Initiate nipple stimulation unless the client is having spontaneous contractions. Instruct the client to roll a nipple between their thumb and fingers or brush the palm across a nipple. The client should stop when a uterine contraction begins.
- Monitor and provide adequate rest periods for the client to avoid tachysystole of the uterus.

#### INTERVENTIONS

Initiate IV oxytocin administration if nipple stimulation fails to elicit a sufficient uterine contraction pattern. If hyperstimulation of the uterus or preterm labor occurs, do the following. Q<sub>EBP</sub>

- Monitor for contractions lasting longer than 90 seconds or occurring more frequently than every 2 min.
- Administer tocolytics as prescribed.
- Maintain bed rest during the procedure.
- Observe the client for 30 min afterward to see that contractions have ceased and preterm labor does not begin.

## INTERPRETATION OF FINDINGS

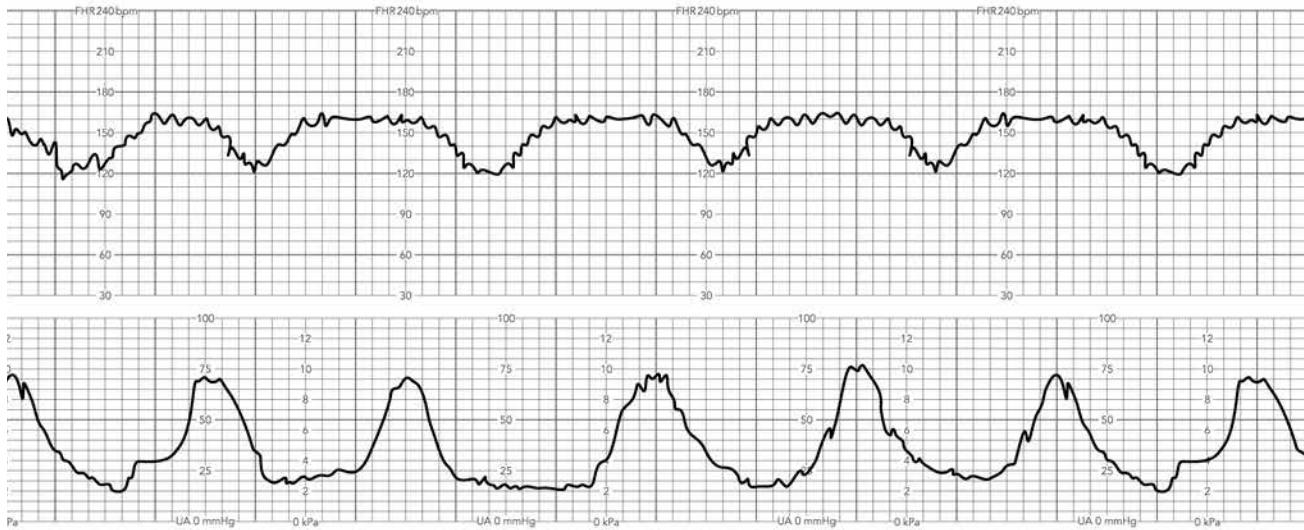

**NEGATIVE CST (NORMAL FINDING):** Indicated if within a 10-min period, with three uterine contractions, there are no late decelerations of the FHR.

**POSITIVE CST (ABNORMAL FINDING):** Indicated with persistent and consistent late decelerations with 50% or more of the contractions. This is suggestive of uteroplacental insufficiency. Variable deceleration can indicate cord compression, and early decelerations can indicate fetal head compression. Based on these findings, the provider may determine to induce labor or perform a cesarean birth. (6.2)

### COMPLICATIONS

Potential for preterm labor

## 6.2 Positive CST

## Amniocentesis

The aspiration of amniotic fluid for analysis by insertion of a needle transabdominally into a client's uterus and amniotic sac under direct ultrasound guidance locating the placenta and determining the position of the fetus. It may be performed after 14 weeks of gestation.

Alpha-fetoprotein (AFP) can be measured from the amniotic fluid between 15 and 20 weeks (16 to 18 weeks of gestation is ideal) and can be used to assess for neural tube defects in the fetus or chromosomal disorders. Can be evaluated to follow up a high level of AFP in maternal blood.

## INDICATIONS

### POTENTIAL DIAGNOSES

- Previous birth with a chromosomal anomaly
- A parent who is a carrier of a chromosomal anomaly
- A family history of neural tube defects
- Prenatal diagnosis of a genetic disorder or congenital anomaly of the fetus
- AFP level for fetal abnormalities
- Lung maturity assessment
- Fetal hemolytic disease

## CONSIDERATIONS

### PREPROCEDURE

**NURSING ACTIONS:** Explain the procedure to the client, and obtain informed consent.

**CLIENT EDUCATION:** Empty the bladder prior to the procedure to reduce its size and reduce the risk of inadvertent puncture. **Qs**

### INTRAPROCEDURE

#### NURSING ACTIONS

- Obtain and document baseline vital signs and FHR prior to the procedure.
- Assist client into a supine position, and place a wedge under their right hip to displace the uterus off the vena cava, and place a drape over the client exposing only the abdomen.
- Prepare client for an ultrasound to locate the placenta.
- Cleanse client's abdomen with an antiseptic solution prior to the administration of a local anesthetic by the provider.

**CLIENT EDUCATION:** Understand there will be a feeling of slight pressure as the needle is inserted. Continue breathing, because holding breath will lower the diaphragm against the uterus and shift the intrauterine contents.

## POSTPROCEDURE

### NURSING ACTIONS

- Monitor fetal heart rate.
- Administer Rho(D) immune globulin to the client if they are Rh-negative (standard practice after an amniocentesis for all clients who are Rh-negative to protect against Rh isoimmunization). 

**CLIENT EDUCATION:** Report to the provider if experiencing fever, chills, leakage of fluid or bleeding from the insertion site, decreased fetal movement, vaginal bleeding, or uterine contractions after the procedure.

## INTERPRETATION OF FINDINGS

### *Alpha-fetoprotein*

**HIGH LEVELS:** Associated with neural tube defects, such as anencephaly (incomplete development of fetal skull and brain), spina bifida (open spine), or omphalocele (abdominal wall defect). High AFP levels also can be present with normal multifetal pregnancies.

**LOW LEVELS:** Associated with chromosomal disorders (Down syndrome) or gestational trophoblastic disease (hydatidiform mole).

### *Fetal lung maturity*

Tests for fetal lung maturity can be performed if gestation is less than 37 weeks, in the event of a rupture of membranes, for preterm labor, or for a complication indicating a cesarean birth. Amniotic fluid is tested to determine whether the fetal lungs are mature enough to adapt to extrauterine life, or if the fetus will likely have respiratory distress. Determination is made whether the fetus should be removed immediately or if the fetus requires more time in utero with the administration of glucocorticoids to promote fetal lung maturity.

**LECITHIN/SPHINGOMYELIN (L/S) RATIO:** A 2:1 ratio indicates fetal lung maturity (2.5:1 or 3:1 for a client who has diabetes mellitus).

**PHOSPHATIDYLGLYCEROL (PG):** Absence of PG is associated with respiratory distress.

## COMPLICATIONS

- Amniotic fluid emboli
- Maternal or fetal hemorrhage
- Fetomaternal hemorrhage with Rh isoimmunization
- Maternal or fetal infection
- Inadvertent fetal damage or anomalies involving limbs
- Fetal death
- Inadvertent maternal intestinal or bladder damage
- Miscarriage or preterm labor
- Premature rupture of membranes
- Leakage of amniotic fluid

## NURSING ACTIONS

- Monitor vital signs, temperature, respiratory status, FHR, uterine contractions, and vaginal discharge for amniotic fluid or bleeding.
- Administer medication as prescribed.
- Offer support and reassurance.

## *High-risk pregnancy: Percutaneous umbilical blood sampling*

Percutaneous umbilical blood sampling, commonly called cordocentesis, is the most common method used for fetal blood sampling and transfusion. This procedure obtains fetal blood from the umbilical cord by passing a fine-gauge, fiber-optic scope (fetoscope) into the amniotic sac using the amniocentesis technique. The needle is advanced into the umbilical cord under ultrasound guidance, and blood is aspirated from the umbilical vein. Blood studies from the cordocentesis can consist of:

- Kleihauer-Betke test that ensures that fetal blood was obtained
- CBC count with differential
- Indirect Coombs' test for Rh antibodies
- Karyotyping (visualization of chromosomes)
- Blood gases

## INDICATIONS

- Determining fetal blood type
- Anemia screening

### POTENTIAL DIAGNOSES

- Fetal chromosomal disorders
- Karyotyping of malformed fetuses
- Fetal infection
- Altered acid-base balance of fetuses with IUGR

## CONSIDERATIONS

### NURSING ACTIONS

- Administer medication as prescribed.
- Offer support.
- Monitor the FHR as prescribed following the procedure.

**CLIENT EDUCATION:** Count fetal movements.

## INTERPRETATION OF FINDINGS

- Evaluates for isoimmune fetal hemolytic anemia
- Assesses the need for a fetal blood transfusion
- Determines specifics regarding genetic mutations

## COMPLICATIONS

- Cord laceration
- Preterm labor
- Hematoma
- Fetomaternal hemorrhage

## *High-risk pregnancy: Chorionic villus sampling*

- Chorionic villus sampling (CVS) is the assessment of a portion of the developing placenta (chorionic villi), which is aspirated through a thin sterile catheter or syringe inserted through the abdominal wall or intravaginally through the cervix under ultrasound guidance.
- CVS is a first-trimester alternative to amniocentesis with one of its advantages being an earlier diagnosis of any abnormalities. CVS is ideally performed at 10 to 13 weeks of gestation.

The advantage of an earlier diagnosis should be weighed against the increased risk of fetal anomalies and death.

### **INDICATIONS**

POTENTIAL DIAGNOSES: Risk for giving birth to a neonate who has a genetic chromosomal abnormality (cannot determine spina bifida or anencephaly)

### **CONSIDERATIONS**

#### NURSING ACTIONS

- Obtain informed consent.
- Provide ongoing education and support.

CLIENT EDUCATION: Drink 1 to 2 glasses of fluid prior to the test and avoid urination for several hours prior to testing. A full bladder is necessary for testing.

### **COMPLICATIONS**

- Spontaneous abortion
- Risk for fetal limb loss (greatest risk prior to 9 weeks of gestation)
- Miscarriage
- Chorioamnionitis and rupture of membranes

## *High-risk pregnancy: Quad marker screening*

A blood test that ascertains information about the likelihood of fetal birth defects. It does not diagnose the actual defect. It can be performed instead of the maternal AFP blood level yielding more reliable findings. Includes testing for:

- **Human chorionic gonadotropin (hCG):** a hormone produced by the placenta
- **Alpha-fetoprotein (AFP):** a protein produced by the fetus
- **Estriol:** a protein produced by the fetus and placenta
- **Inhibin A:** a protein produced by the ovaries and placenta

### **INDICATIONS**

#### CLIENT PRESENTATION

- Preferred at 16 to 18 weeks gestation
- Risk for giving birth to a neonate who has a genetic chromosomal abnormality

### **INTERPRETATION OF FINDINGS**

- Low levels of AFP can indicate a risk for Down syndrome.
- High levels of AFP can indicate a risk for neural tube defects.
- Levels higher than the expected reference range of hCG and inhibin A indicates a risk for Down syndrome.
- Lower levels than the expected reference range of estriol can indicate a risk for Down syndrome.

## *High-risk pregnancy: Maternal alpha-fetoprotein (MSAFP)*

A screening tool used to detect neural tube defects. Clients who have abnormal findings should be referred for a quad marker screening, genetic counseling, ultrasound, and an amniocentesis.

### **INDICATIONS**

POTENTIAL DIAGNOSES: All pregnant clients, preferably between 16 and 18 weeks of gestation

### **CONSIDERATIONS**

#### PREPROCEDURE NURSING ACTIONS

- Discuss testing with the client.
- Draw blood sample.
- Offer support and education as needed.

### **INTERPRETATION OF FINDINGS**

- High levels can indicate a neural tube defect or open abdominal defect.
- Low levels can indicate Down syndrome.
- This is only used as a screening tool. Abnormal results should be confirmed with further testing.

## Application Exercises

1. A nurse is reviewing findings of a client's biophysical profile (BPP). The nurse should expect which of the following variables to be included in this test? (Select all that apply.)

  - A. Fetal weight
  - B. Fetal breathing movement
  - C. Fetal tone
  - D. Fetal position
  - E. Amniotic fluid volume
  
2. A nurse is caring for a client who is in preterm labor and is scheduled to undergo an amniocentesis. The nurse should evaluate which of the following tests to assess fetal lung maturity?

  - A. Alpha-fetoprotein (AFP)
  - B. Lecithin/sphingomyelin (L/S) ratio
  - C. Kleihauer-Betke test
  - D. Indirect Coombs' test
  
3. A nurse is caring for a client who is pregnant and undergoing a nonstress test. The client asks why the nurse is using an acoustic vibration device. Which of the following responses should the nurse make?

  - A. "It is used to stimulate uterine contractions."
  - B. "It will decrease the incidence of uterine contractions."
  - C. "It lulls the fetus to sleep."
  - D. "It awakens a sleeping fetus."
  
4. A nurse is teaching a client who is pregnant about the amniocentesis procedure. Which of the following statements should the nurse include in the teaching?

  - A. "You will lay on your right side during the procedure."
  - B. "You should not eat anything for 24 hours prior to the procedure."
  - C. "You should empty your bladder prior to the procedure."
  - D. "The test is done to determine gestational age."
  
5. A nurse is caring for a client who is pregnant and is to undergo a contraction stress test (CST). Which of the following findings are indications for this procedure? (Select all that apply.)

  - A. Decreased fetal movement
  - B. Intrauterine growth restriction (IUGR)
  - C. Postmaturity
  - D. Placenta previa
  - E. Amniotic fluid emboli

## Active Learning Scenario

A nurse in a prenatal clinic is orienting a newly licensed nurse about how to perform a nonstress test (NST). What should the nurse include in the teaching about the procedure? Use the ATI Active Learning Template: Diagnostic Procedure to complete this item.

**INDICATIONS:** Identify three that relate to the status of the fetus.

**INTERPRETATION OF FINDINGS:**  
Describe a nonreactive NST.

**NURSING INTERVENTIONS:** Two preprocedure, one intraprocedure.

## Application Exercises Key

1. A. Fetal weight is not one of the variables included in the BPP.  
B. **CORRECT:** Fetal breathing movements are included in the BPP.  
C. **CORRECT:** Fetal tone is included in the BPP.  
D. Fetal position is not included in the BPP.  
E. **CORRECT:** Amniotic fluid volume is included in the BPP.
  2. A. AFP is a test to assess for fetal neural tube defects or chromosome disorders.  
B. **CORRECT:** A test of the L/S ratio is done as a part of an amniocentesis to determine fetal lung maturity.  
C. A Kleihauer-Betke test is used to verify that fetal blood is present during a percutaneous umbilical blood sampling procedure.  
D. An indirect Coombs' test detects Rh antibodies in the mother's blood.
  3. A. The acoustic vibration device does not stimulate the uterus.  
B. The acoustic vibration device has no effect on the uterine muscles.  
C. The acoustic vibration device stimulates a sleeping fetus.  
D. **CORRECT:** The acoustic vibration device is activated for 3 seconds on the maternal abdomen over the fetal head to awaken a sleeping fetus.
  4. A. Assist the client into a supine position, place a wedge under the right hip to displace the uterus off the vena cava, and place a drape over the client, exposing only the abdomen.  
B. The client does not need to be NPO for 24 hr prior to the procedure.  
C. **CORRECT:** The client's bladder should be empty to avoid an inadvertent puncture during the procedure.  
D. Amniotic fluid is tested to identify fetal genetic defects. An amniocentesis does not determine gestational age.
  5. A. **CORRECT:** Decreased fetal movement is an indication for a CST.  
B. **CORRECT:** IUGR is an indication for a CST.  
C. **CORRECT:** Postmaturity is an indication for a CST.  
D. Placenta previa is a contraindication of a CST.  
E. Amniotic fluid emboli are a complication of an amniocentesis.
- NCLEX® Connection: Reduction of Risk Potential, Diagnostic Tests
- NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care
- NCLEX® Connection: Reduction of Risk Potential, Diagnostic Tests

## Active Learning Scenario Key

Using the ATI Active Learning Template: Diagnostic Procedure

### INDICATIONS

- Assessment for intact fetal CNS during the third trimester
- Rule out fetal death in a client who has diabetes mellitus
- Decreased fetal movement
- Intrauterine growth restriction
- Postmaturity

**INTERPRETATION OF FINDINGS:** Nonreactive NST is a test that does not demonstrate at least two qualifying accelerations in a 20 minute window. If this is so, a further assessment (contraction stress test, biophysical profile) is indicated.

### NURSING INTERVENTIONS

#### Preprocedure

- Seat the client in a reclining chair in a semi-Fowler's or left-lateral position.
- Apply conduction gel to the client's abdomen.
- Apply the Doppler transducer and the tocotransducer.

Intraprocedure: Instruct the client to depress the event marker button each time they feel fetal movement.

NCLEX® Connection: Reduction of Risk Potential, Diagnostic Tests

# CHAPTER 7

UNIT 1

ANTEPARTUM NURSING CARE

SECTION: COMPLICATIONS OF PREGNANCY

CHAPTER 7

## Bleeding During Pregnancy

Vaginal bleeding during pregnancy is always abnormal and must be investigated to determine the cause. It can impair both the outcome of the pregnancy and the mother's life. (7.1)

### Spontaneous abortion

Spontaneous abortion has occurred when a pregnancy ends as the result of natural causes before 20 weeks of gestation (the point of fetal viability) if a fetus weighs less than 500 g.

Types of abortion are clinically classified according to manifestations and whether the products of conception are partially or completely retained or expelled. Types of abortions include **threatened**, **inevitable**, **incomplete**, **complete**, and **missed**.

### ASSESSMENT

#### RISK FACTORS

- Chromosomal abnormalities (account for 25%)
- Maternal illness, such as type 1 diabetes mellitus
- Advanced maternal age
- Premature cervical dilation
- Chronic maternal infections
- Maternal malnutrition

- Trauma or injury
- Anomalies in the fetus or placenta
- Substance use
- Antiphospholipid syndrome

#### EXPECTED FINDINGS (7.2)

- Abdominal cramping or pain
- Rupture of membranes
- Dilation of the cervix
- Fever
- Manifestations of hemorrhage (hypotension, tachycardia)

#### LABORATORY TESTS

**Hgb and Hct**, if considerable blood loss

**Clotting factors** monitored for disseminated intravascular coagulopathy (DIC): a complication with retained products of conception

**WBC** for suspected infection

**Serum human chorionic gonadotropin (hCG)** levels to confirm pregnancy

#### DIAGNOSTIC AND THERAPEUTIC PROCEDURES

**Ultrasound** to determine the presence of a viable or dead fetus, or partial or complete products of conception within the uterine cavity

**Examination of the cervix** to observe whether it is opened or closed

**Dilation and curettage (D&C)** to dilate and scrape the uterine walls to remove uterine contents for inevitable and incomplete abortions

**Dilation and evacuation (D&E)** to dilate and evacuate uterine contents after 16 weeks of gestation

**Prostaglandins and oxytocin** to augment or induce uterine contractions and expel the products of conception

### 7.1 Causes of bleeding during pregnancy

#### *First trimester*

##### **SPONTANEOUS ABORTION:**

Vaginal bleeding, uterine cramping, and partial or complete expulsion of products of conception

**ECTOPIC PREGNANCY:** Abrupt unilateral lower-quadrant abdominal pain with or without vaginal bleeding

#### *Second trimester*

##### **GESTATIONAL TROPHOBLASTIC DISEASE:**

Uterine size increasing abnormally fast, abnormally high levels of hCG, nausea and increased emesis, no fetus present on ultrasound, and scant or profuse dark brown or red vaginal bleeding

#### *Third trimester*

**PLACENTA PREVIA:** Painless vaginal bleeding

**ABRUPTIO PLACENTAE:** Vaginal bleeding, sharp abdominal pain, and tender rigid uterus

**VASA PREVIA:** Fetal vessels are implanted into the membranes rather than the placenta.

#### *Other causes of bleeding*

**RECURRENT PREMATURE DILATION OF THE CERVIX:** Painless bleeding with cervical dilation leading to fetal expulsion

**PRETERM LABOR:** Bloody discharge, uterine contractions becoming regular, cervical dilation and effacement

**HYDATIDIFORM MOLE:** Benign proliferative growth of the placental trophoblast

## PATIENT-CENTERED CARE

### NURSING CARE

- Perform a pregnancy test.
- Observe color and amount of bleeding (count pads).
- Maintain client on bed rest. Inform client of risk for falls due to sedative medications if prescribed. **Qs**
- Avoid vaginal exams.
- Assist with an ultrasound.
- Administer medications and blood products as prescribed.
- Determine how much tissue has passed and save passed tissue for examination.
- Assist with termination of pregnancy (D&C, D&E, prostaglandin administration) as indicated.
- Use the lay term “miscarriage” with clients because the medical term “abortion” can be misunderstood.
- Provide client education and emotional support.
- Provide referral for client and partner to pregnancy loss support groups.

### MEDICATIONS

- Analgesics and sedatives
- Prostaglandin, as a vaginal suppository
- Oxytocin
- Broad-spectrum antibiotics, in septic abortion
- Rho(D) immune globulin, suppresses immune response of clients who are Rh-negative

### CLIENT EDUCATION

- Notify the provider of heavy, bright red vaginal bleeding; elevated temperature; or foul-smelling vaginal discharge.
- A small amount of discharge is normal for 1 to 2 weeks.
- Take prescribed antibiotics.
- Refrain from tub baths, sexual intercourse, or placing anything into the vagina for 2 weeks.
- Discuss grief and loss with the provider before attempting another pregnancy.

## Ectopic pregnancy

Ectopic pregnancy is the abnormal implantation of a fertilized ovum outside of the uterine cavity usually in the fallopian tube, which can result in a tubal rupture causing a fatal hemorrhage.

Ectopic pregnancy is the second most frequent cause of bleeding in early pregnancy and a leading cause of infertility.

### ASSESSMENT

#### RISK FACTORS

Any factor that compromises tubal patency (STIs, assisted reproductive technologies, tubal surgery, and contraceptive intrauterine device [IUD])

#### EXPECTED FINDINGS

- Unilateral stabbing pain and tenderness in the lower-abdominal quadrant
- Menses that is delayed (1 to 2 weeks), lighter than usual, or irregular
- Scant, dark red, or brown vaginal spotting 6 to 8 weeks after last normal menses; red, vaginal bleeding if rupture has occurred
- Referred shoulder pain due to blood in the peritoneal cavity irritating the diaphragm or phrenic nerve after tubal rupture
- Findings of hemorrhage and shock (hypotension, tachycardia, pallor, dizziness) if a large amount of bleeding has occurred

#### LABORATORY TESTS

Serum levels of progesterone and hCG to help determine whether pregnancy has occurred and whether it is likely to be ectopic

### 7.2 Spontaneous abortion assessment

	CRAMPS	BLEEDING	TISSUE PASSED	CERVICAL OPENING
THREATENED	Possible mild cramps	Slight spotting	None	Closed
INEVITABLE	Mild to moderate	Moderate	None	Usually dilated
INCOMPLETE	Severe	Heavy, profuse	Yes	Dilated with tissue in cervical canal or passage of tissue
COMPLETE	Mild	Minimal	Yes	No (cervix closed after tissue passed)
MISSED	None	None; spotting	None, prolonged retention of tissue	Closed
SEPTIC	Varies	Varies; malodorous discharge	Varies	Usually dilated
RECURRENT	Varies	Varies	Yes	Usually dilated

## DIAGNOSTIC AND THERAPEUTIC PROCEDURES

- Transvaginal ultrasound shows an empty uterus.
- Use caution if vaginal and bimanual examination are used.

### RAPID TREATMENT

- **Medical management** if rupture has not occurred and tube preservation desired.
- **Methotrexate** inhibits cell division and embryo enlargement, dissolving the pregnancy.
- **Salpingostomy** is done to salvage the fallopian tube if not ruptured.
- **Laparoscopic salpingectomy** (removal of the tube) is performed when the tube has ruptured.

## PATIENT-CENTERED CARE

### NURSING CARE

- Replace fluids, and maintain electrolyte balance.
- Provide client education and psychological support.
- Administer medications as prescribed.
- Prepare the client for surgery and postoperative nursing care.
- Provide emotional care and support.
- Provide referral for client and partner to pregnancy loss support group.
- Obtain serum hCG and progesterone levels, liver and renal function studies, CBC, and type and Rh.

### CLIENT EDUCATION

- If taking methotrexate, avoid vitamins containing folic acid to prevent a toxic response to the medication. **Qs**
- Use protection against sun exposure (photosensitivity).

## *Gestational trophoblastic disease*

Gestational trophoblastic disease (GTD) is the proliferation and degeneration of trophoblastic villi in the placenta that becomes swollen, fluid-filled, and takes on the appearance of grape-like clusters. The embryo fails to develop beyond a primitive state and these structures are associated with choriocarcinoma, which is a rapidly metastasizing malignancy. Two types of molar growths are identified by chromosomal analysis.

### *Complete mole*

- All genetic material is paternally derived.
- The ovum has no genetic material, or the material is inactive.
- The complete mole contains no fetus, placenta, amniotic membranes, or fluid.
- There is no placenta to receive maternal blood. Hemorrhage into the uterine cavity occurs, and vaginal bleeding results.
- Approximately 20% of complete moles progress toward a choriocarcinoma.

### *Partial mole*

- Genetic material is derived both maternally and paternally.
- A normal ovum is fertilized by two sperm or one sperm in which meiosis or chromosome reduction and division did not occur.
- A partial mole often contains abnormal embryonic or fetal parts, an amniotic sac, and fetal blood, but congenital anomalies are present.
- Approximately 6% of partial moles progress toward a choriocarcinoma.

## ASSESSMENT

### RISK FACTORS

- Prior molar pregnancy
- Clients in early teenage years or older than age 40

### EXPECTED FINDINGS

Excessive vomiting (hyperemesis gravidarum) due to elevated hCG levels

### PHYSICAL ASSESSMENT FINDINGS

- Rapid uterine growth more than expected for the duration of the pregnancy due to the overproliferation of trophoblastic cells
- Bleeding is often dark brown resembling prune juice, or bright red that is either scant or profuse and continues for a few days or intermittently for a few weeks and can be accompanied by passage of vesicles.
- Anemia from blood loss
- Clinical findings of preeclampsia that occur prior to 24 weeks of gestation

### LABORATORY TESTS

Serum level of hCG is persistently high compared with expected decline after weeks 10 to 12 of pregnancy.

## DIAGNOSTIC AND THERAPEUTIC PROCEDURES

- An ultrasound reveals a dense growth with characteristic vesicles, but no fetus in utero.
- Suction curettage is done to aspirate and evacuate the mole.
- Post-surgery, Rh-negative clients are given Rho(D) immune globulin.
- Following mole evacuation, the client should undergo a baseline pelvic exam and ultrasound scan of the abdomen.
- Serum hCG analysis following molar pregnancy to be done weekly for 3 weeks, then monthly for 6 months up to 1 year to detect GTD.

## PATIENT-CENTERED CARE

---

### NURSING CARE

---

- Measure fundal height.
- Assess vaginal bleeding and discharge.
- Assess gastrointestinal status and appetite.
- Monitor for manifestations of preeclampsia.
- Administer medications as prescribed.
  - Rho(D) immune globulin to the client who is Rh-negative
  - Chemotherapeutic medications for findings of malignant cells indicating choriocarcinoma
- Advise client to save clots or tissue for evaluation.
- Provide client education and emotional support.

### CLIENT EDUCATION

---

- Consider pregnancy loss support groups referred by the nurse.
- Use reliable contraception as a component of follow-up care. Avoid using an intrauterine device (IUD).
- Follow-up is important due to the increased risk of choriocarcinoma.

## *Placenta previa*

---

Placenta previa occurs when the placenta abnormally implants in the lower segment of the uterus near or over the cervical os instead of attaching to the fundus. The abnormal implantation results in bleeding during the third trimester of pregnancy as the cervix begins to dilate and efface. (7.3)

Classified into three types dependent on the degree to which the cervical os is covered by the placenta.

- **Complete or total:** The cervical os is completely covered by the placental attachment.
- **Incomplete or partial:** The cervical os is only partially covered by the placental attachment.
- **Marginal:** The placenta is attached in the lower uterine segment but does not reach the cervical os.
- **Low-lying:** The exact relationship of the placenta to the internal os has not been determined.

## ASSESSMENT

---

### RISK FACTORS

---

- Previous placenta previa
- Uterine scarring (previous cesarean birth, curettage, endometritis)
- Maternal age greater than 35 years
- Multifetal gestation
- Multiple gestations
- Smoking

## EXPECTED FINDINGS

---

- Painless, bright red vaginal bleeding during the second or third trimester
- Uterus soft, relaxed, and nontender with normal tone
- Fundal height greater than usually expected for gestational age
- Fetus in a breech, oblique, or transverse position
- Reassuring FHR
- Vital signs within normal limits
- Decreasing urinary output, which can be a better indicator of blood loss

## LABORATORY TESTS

---

- Hgb and Hct for blood loss assessment
- CBC
- Blood type and Rh
- Coagulation profile
- Kleihauer-Betke test (used to detect fetal blood in maternal circulation)

## DIAGNOSTIC PROCEDURES

---

- Transabdominal or transvaginal ultrasound for placement of the placenta
- Fetal monitoring for fetal well-being assessment

## PATIENT-CENTERED CARE

---

### NURSING CARE

---

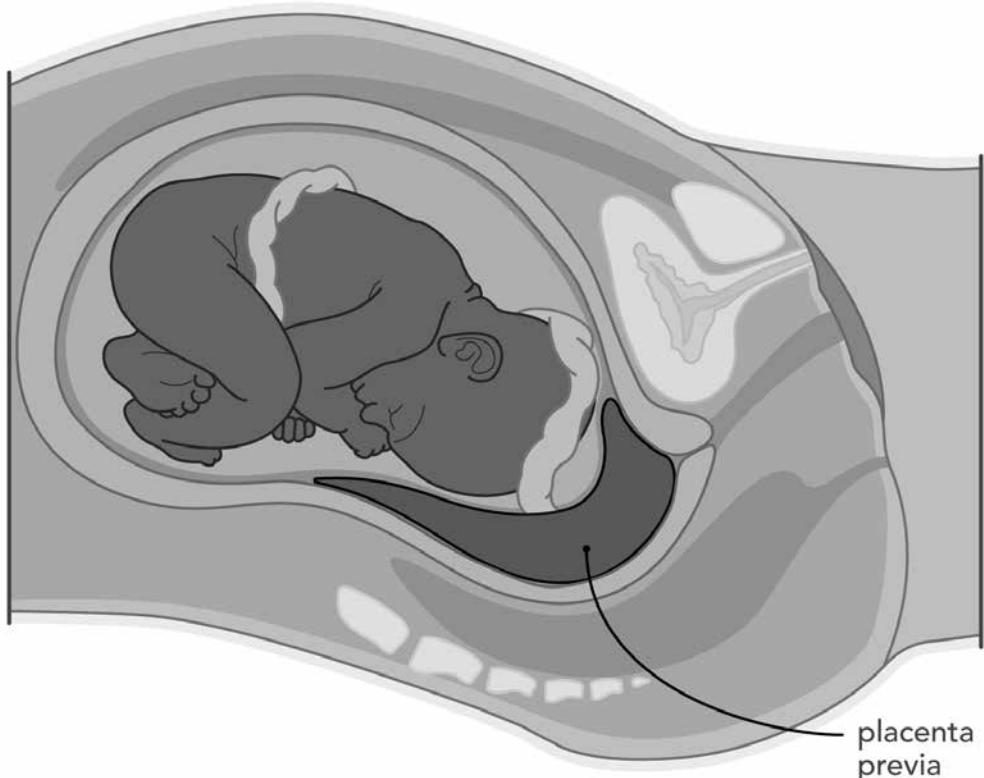

- Assess for bleeding, leakage, or contractions.
- Assess fundal height.
- Refrain from performing vaginal exams (can exacerbate bleeding). **Qs**
- Administer IV fluids, blood products, and medications as prescribed. Corticosteroids, such as betamethasone, promote fetal lung maturation if early delivery is anticipated (cesarean birth).
- Have oxygen equipment available in case of fetal distress.

### CLIENT EDUCATION

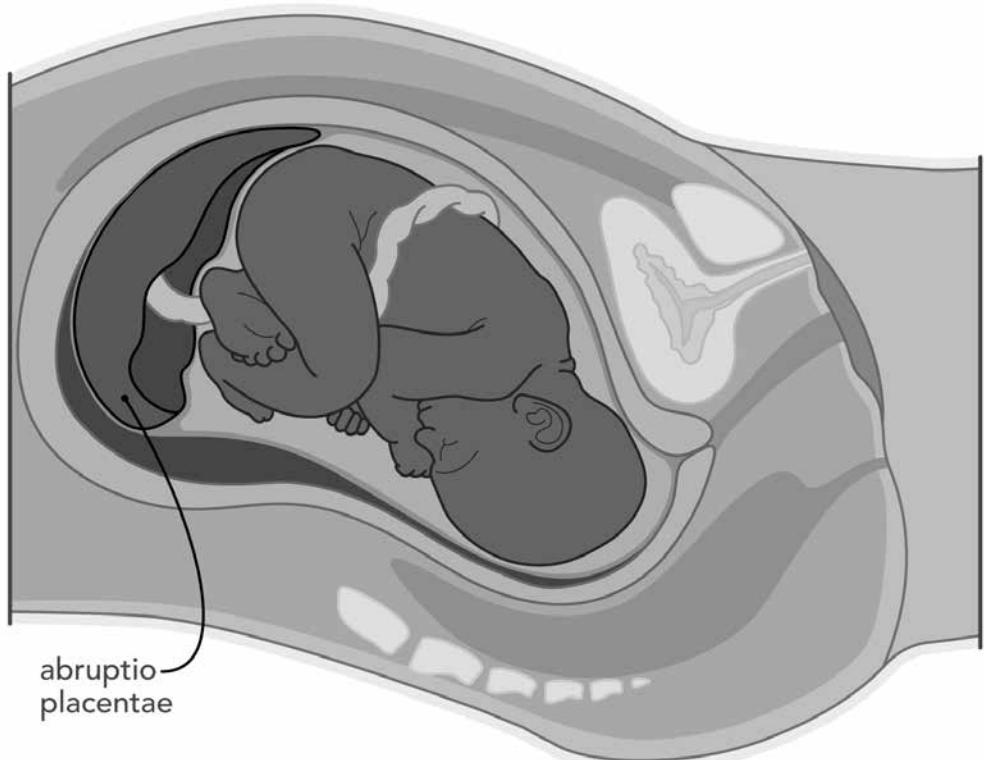

---

- Adhere to bed rest
- Do not insert anything into the vagina because it can worsen bleeding.

### 7.3 Placenta previa

### 7.4 Abruptio placentae

# *Abruptio placentae*

Abruptio placentae is the premature separation of the placenta from the uterus, which can be a partial or complete detachment. This separation occurs after 20 weeks of gestation, which is usually in the third trimester. It has significant maternal and fetal morbidity and mortality and is a leading cause of maternal death. (7.4)

Coagulation defect, such as disseminated intravascular coagulopathy (DIC), is often associated with moderate to severe abruptio.

## ASSESSMENT

### RISK FACTORS

- Maternal hypertension (chronic or gestational)
- Blunt external abdominal trauma (motor-vehicle crash, maternal battering)
- Cocaine use resulting in vasoconstriction
- Previous incidents of abruptio placentae
- Cigarette smoking or other nicotine use
- Premature rupture of membranes
- Multifetal pregnancy

### EXPECTED FINDINGS

- Sudden onset of intense localized uterine pain with dark red vaginal bleeding
- Area of uterine tenderness can be localized or diffuse over uterus and boardlike
- Contractions with hypertonicity
- Fetal distress
- Clinical findings of hypovolemic shock

### LABORATORY TESTS

- Hgb and Hct decreased
- Coagulation factors decreased
- Clotting defects (disseminated intravascular coagulation)
- Cross and type match for possible blood transfusions
- Kleihauer-Betke test (used to detect fetal blood in maternal circulation)

### DIAGNOSTIC PROCEDURES

- Ultrasound for fetal well-being and placental assessment
- Biophysical profile to ascertain fetal well-being

## PATIENT-CENTERED CARE

### NURSING CARE

- Palpate the uterus for tenderness and tone.
- Perform serial monitoring of the fundal height.
- Assess FHR pattern.
- Immediate birth is the management.
  - Administer IV fluids, blood products, and medications as prescribed.
  - Administer oxygen 8 to 10 L/min via face mask.
  - Monitor maternal vital signs, observing for declining hemodynamic status.
  - Perform continuous fetal monitoring
  - Assess urinary output and monitor fluid balance.
- Provide emotional support for the client and family.

## *Vasa previa*

Vasa previa is a condition when the fetal umbilical vessels implant into the fetal membranes rather than the placenta.

There are variations of vasa previa.

- **Velamentous insertion of the cord:** Cord vessels begin in the branch at the membranes and then course to the placenta.
- **Succenturiate insertion of the cord:** The placenta has divided into two or more lobes and not one mass.
- **Battledore insertion of the cord**
  - A marginal insertion
  - Increased risk of fetal hemorrhage

## ASSESSMENT

**DIAGNOSTIC PROCEDURES:** Ultrasound for fetal well-being and vessel assessment

## PATIENT-CENTERED CARE

**NURSING ACTIONS:** Closely monitor the client during labor and delivery for excessive bleeding.

## Application Exercises

1. A nurse in the emergency department is caring for a client who reports abrupt, sharp, right-sided lower quadrant abdominal pain and bright red vaginal bleeding. The client states, "I missed one menstrual cycle and cannot be pregnant because I have an intrauterine device." The nurse should suspect which of the following?

  - A. Missed abortion
  - B. Ectopic pregnancy
  - C. Severe preeclampsia
  - D. Hydatidiform mole
  
2. A nurse is providing care for a client who has a marginal abruptio placentae. Which of the following findings are risk factors for developing the condition? (Select all that apply.)

  - A. Fetal position
  - B. Blunt abdominal trauma
  - C. Cocaine use
  - D. Maternal age
  - E. Cigarette smoking
  
3. A nurse is caring for a client who is at 32 weeks of gestation and has a placenta previa. The nurse notes that the client is actively bleeding. Which of the following medications should the nurse expect the provider will prescribe?

  - A. Betamethasone
  - B. Indomethacin
  - C. Nifedipine
  - D. Methylergonovine
  
4. A nurse at an antepartum clinic is caring for a client who is at 4 months of gestation. The client reports continued nausea; vomiting; and scant, prune-colored discharge. The client has experienced no weight loss and has a fundal height larger than expected. Which of the following complications should the nurse suspect?

  - A. Hyperemesis gravidarum
  - B. Threatened abortion
  - C. Hydatidiform mole
  - D. Preterm labor
  
5. A nurse is caring for a client who is experiencing a ruptured ectopic pregnancy. Which of the following findings is expected with this condition?

  - A. No alteration in menses
  - B. Transvaginal ultrasound indicating a fetus in the uterus
  - C. Blood progesterone greater than the expected reference range
  - D. Report of severe shoulder pain

## Active Learning Scenario

A nurse manager is presenting an educational program on placenta previa for a group of nurses. What should the nurse manager include in this presentation? Use the ATI Active Learning Template: System Disorder to complete this item.

**ALTERATION IN HEALTH (DIAGNOSIS):**

Describe the three types.

**RISK FACTORS:** Identify three.

**DIAGNOSTIC PROCEDURES:** Describe two.

**NURSING CARE:** Describe nursing action that is contraindicated.

## Application Exercises Key

1. A. A client who experienced a missed abortion would report brownish discharge and no pain.
- B. **CORRECT:** Manifestations of an ectopic pregnancy include unilateral lower quadrant pain with or without bleeding. Use of an IUD is a risk factor associated with this condition.
- C. A client who has severe preeclampsia does not have vaginal bleeding and presents with right upper quadrant epigastric pain.
- D. A client who has a hydatidiform mole usually has dark brown vaginal bleeding in the second trimester that is not accompanied by abdominal pain.

❷ NCLEX® Connection: Physiological Adaptation, Alterations in Body Systems

2. A. Fetal position is not a risk factor associated with abruptio placentae.
- B. **CORRECT:** Blunt abdominal trauma is a risk factor associated with abruptio placentae.
- C. **CORRECT:** Cocaine use is a risk factor associated with abruptio placentae.
- D. Maternal age is not a risk factor associated with abruptio placentae.
- E. **CORRECT:** Cigarette smoking is a risk factor associated with abruptio placentae.

❷ NCLEX® Connection: Health Promotion and Maintenance, Health Promotion/Disease Prevention

3. A. **CORRECT:** Betamethasone is given to promote lung maturity if delivery is anticipated.
- B. Indomethacin is prescribed for the client in preterm labor.
- C. Nifedipine is prescribed for the client in preterm labor.
- D. Methylergonovine is prescribed for the client experiencing postpartum hemorrhage.

❷ NCLEX® Connection: Pharmacological and Parenteral Therapies, Expected Actions/Outcomes

4. A. A client who has hyperemesis gravidarum will have weight loss and findings of dehydration.
- B. A client who has a threatened abortion would be in the first trimester and report spotting to moderate bleeding with no enlarged uterus.
- C. **CORRECT:** A client who has a hydatidiform mole exhibits increased fundal height that is inconsistent with the week of gestation, and excessive nausea and vomiting due to elevated hCG levels. Scant, dark discharge occurs in the second trimester.
- D. Preterm labor presents prior to 37 weeks of gestation and is accompanied by pink-stained vaginal discharge and uterine contractions that become more regular.

❷ NCLEX® Connection: Physiological Adaptation, Unexpected Response to Therapies

5. A. A client experiencing a ruptured ectopic pregnancy has delayed, scant, or irregular menses.
- B. A transvaginal ultrasound would indicate an empty uterus in a client who has a ruptured ectopic pregnancy.
- C. A blood progesterone level lower than the expected reference range is an indication of ectopic pregnancy.
- D. **CORRECT:** A client's report of severe shoulder pain is a finding associated with a ruptured ectopic pregnancy due to the presence of blood in the abdominal cavity, which irritates the diaphragm and phrenic nerve.

❷ NCLEX® Connection: Physiological Adaptation, Unexpected Response to Therapies

## Active Learning Scenario Key

Using the ATI Active Learning Template: System Disorder

ALTERATION IN HEALTH (DIAGNOSIS): Types of placenta previa

- Complete or total: Cervical os is covered by the placenta.
- Incomplete or partial: Cervical os is only partially covered by the placenta.
- Marginal: Placenta is attached in the lower uterine segment but does not reach the cervical os.
- Low-lying: The exact relationship of the placenta to the internal os has not been determined.

### RISK FACTORS

- Previous placenta previa
- Uterine scarring due to previous cesarean birth, curettage, or endometritis
- Maternal age 35 to 40 years
- Multifetal gestation
- Multiple gestations
- Smoking

### DIAGNOSTIC PROCEDURES

- Transabdominal or transvaginal ultrasound
- Fetal monitoring

NURSING CARE: Perform a vaginal exam.

❷ NCLEX® Connection: Physiological Adaptation, Unexpected Response to Therapies

# CHAPTER 8

UNIT 1

ANTEPARTUM NURSING CARE

SECTION: COMPLICATIONS OF PREGNANCY

CHAPTER 8

## Infections

Maternal infections during pregnancy require prompt identification and treatment by a provider. These include human immunodeficiency virus (HIV), TORCH infections, group B streptococcus (GBS), chlamydia, gonorrhea, syphilis, human papilloma virus (HPV), trichomoniasis, bacterial vaginosis (BV), and candidiasis.

### HIV/AIDS

HIV is a retrovirus that attacks and causes destruction of T lymphocytes. It causes immunosuppression in a client. Clients who are severely immunosuppressed develop acquired immunodeficiency syndrome (AIDS). HIV is transmitted from the mother to a neonate perinatally through the placenta and postnatally through the breast milk.

- Routine laboratory testing in the early prenatal period includes testing for HIV. Early identification and treatment significantly decreases the incidence of perinatal transmission.
- Testing is recommended in the third trimester for clients who are at an increased risk. Rapid HIV testing should be done if a client is in labor and their HIV status is unknown.
- Procedures such as amniocentesis and episiotomy should be avoided due to the risk of maternal blood exposure.
- Use of internal fetal monitors, vacuum extraction, and forceps during labor should be avoided due to the risk of fetal bleeding. *Qs*
- Newborn administration of injections and blood testing should not take place until after the first bath is given.
- If the client is HIV positive and taking antiviral medications, they should be informed that they can transmit the infection to the neonate.

### ASSESSMENT

#### RISK FACTORS

- IV drug use
- Multiple sexual partners
- Maternal history of multiple STIs

#### EXPECTED FINDINGS

Fatigue and influenza-like findings

#### PHYSICAL ASSESSMENT FINDINGS

- Fever
- Diarrhea and weight loss
- Lymphadenopathy and rash
- Anemia

### LABORATORY TESTS

- Obtain informed maternal consent prior to testing.
- Testing begins with an antibody screening test, such as enzyme immunoassay (EIA). Confirmation of positive results is confirmed by Western blot test or immunofluorescence assay.
- Use rapid HIV antibody test (blood or urine sample) for a client in labor.
- Screen clients for STIs (gonorrhea, chlamydia, syphilis, hepatitis B).
- Obtain frequent viral load levels and CD4 cell counts throughout pregnancy.

### PATIENT-CENTERED CARE

#### NURSING CARE

- Goal is to keep CD4 cell counts greater than 500 cells/mm<sup>3</sup>.
- Provide counseling prior to and after testing.
- Refer the client for mental health consultation, legal assistance, and financial resources.
- Use standard precautions.
- Administer antiretroviral prophylaxis, triple-medication antiretroviral (ART), or highly active antiretroviral therapy (HAART) as prescribed.
- Encourage immunization against hepatitis B, pneumococcal infection, *Haemophilus influenzae* type B, and viral influenza.
- Encourage use of condoms to minimize exposure if partner is the source of infection.
- Review plan for scheduled cesarean birth at 38 weeks for maternal viral load of more than 1,000 copies/mL.
- Vaginal birth can be an option for a client who has a viral load of less than 1,000 copies/mL at 36 weeks of gestation.
- Wear gloves when caring for the newborn after delivery.
- Infant should be bathed after birth before remaining with the mother.

### MEDICATIONS

#### *Antiretroviral therapy (ART)*

- All HIV positive infected clients should be treated with combination therapy. This is given orally and should be taken as soon as possible throughout pregnancy and before the onset of labor or cesarean birth.
- ART can cause bone marrow suppression.

#### *Highly active antiretroviral therapy (HAART)*

Decreases the transmission to child

**INTRAPARTUM:** IV zidovudine 3 hr prior to scheduled cesarean section until birth

**NURSING ACTIONS:** Administer zidovudine to the infant at delivery and for 6 weeks following birth.

## CLIENT EDUCATION

- Discuss HIV and safe sexual relations with the client.
- Continue to use barrier protection during sexual activity to prevent further exposure to the HIV virus, which would increase the viral load.

### DISCHARGE INSTRUCTIONS Q<sub>PCC</sub>

- Do not to breastfeed.
- Consider meeting with providers specializing in care of clients who have HIV.
- All states have a reportable diseases list. HIV/AIDS is a commonly reported condition. It is the responsibility of the provider to report cases of these diseases to their local health department.

## TORCH infections

Toxoplasmosis, other infections (hepatitis), rubella virus, cytomegalovirus, and herpes simplex virus (HSV) are known collectively as TORCH, which is a group of infections that can negatively affect a client who is pregnant. These infections can cross the placenta and have teratogenic effects on the fetus. TORCH does not include all the major infections that present risks to the mother and fetus.

- Rubella can cause fetal consequences (miscarriage, congenital anomalies, death).
- HSV can cause miscarriage, preterm labor, and intrauterine growth restriction.

## ASSESSMENT

### RISK FACTORS

- Toxoplasmosis is caused by consumption of raw or undercooked meat or handling cat feces. Manifestations are similar to influenza or lymphadenopathy.
- Other infections can include hepatitis A and B, syphilis, mumps, parvovirus B19, and varicella-zoster. These are some of the most common and can be associated with congenital anomalies.
- Rubella (German measles) is contracted through children who have rashes or neonates who are born to clients who had rubella during pregnancy.
- Cytomegalovirus (member of herpes virus family) is transmitted by droplet infection from person to person, through semen, cervical and vaginal secretions, breast milk, placental tissue, urine, feces, and blood. Latent virus can be reactivated and cause disease to the fetus in utero or during passage through the birth canal.
- HSV is spread by direct contact with oral or genital lesions. Transmission to the fetus is greatest during vaginal birth if the client has active lesions.

### EXPECTED FINDINGS

- Toxoplasmosis: Often no manifestations, but the client can experience influenza or lymphadenopathy (malaise, muscle aches, and flu-like manifestations).
- Rubella: Joint and muscle pain, rash, and fever

- Cytomegalovirus (CMV): no manifestations or mononucleosis-like manifestations
- Herpes simplex infection: findings consisting of painful blisters and tender lymph nodes

### PHYSICAL ASSESSMENT FINDINGS

- Manifestations of toxoplasmosis include fever and tender lymph nodes.
- Manifestations of rubella include rash, mild lymphedema, and fever.
- HSV initially presents with lesions and tender lymph nodes.

### LABORATORY TESTS

For herpes simplex, obtain cultures from clients who have HSV or are at or near term.

### DIAGNOSTIC PROCEDURES

- TORCH screen: immunologic survey used to identify existence of these infections in the mother (to identify fetal risks) or newborn (detection of antibodies against infections)
- Prenatal screenings

## PATIENT-CENTERED CARE

### NURSING CARE

- Monitor fetal well-being.
- For rubella, immunization of clients who are pregnant is contraindicated because rubella infection can develop. These clients should avoid crowds and young children. Clients who have low titers prior to pregnancy should receive immunizations.
  - Rubella vaccination is received postpartum due to the effects on fetus in utero. Clients should avoid pregnancy for 4 weeks (28 days) after receiving the vaccine.
- Discuss safe sexual relations with client.
- Provide client with emotional support.

### MEDICATIONS

- Administer antibiotics as prescribed.
- Treatment of toxoplasmosis includes sulfonamides or a combination of pyrimethamine and sulfadiazine (potentially harmful to the fetus, but parasitic treatment is essential).

### CLIENT EDUCATION Q<sub>PCC</sub>

- Adhere to prevention practices, including correct hand hygiene and cooking meat properly. Avoid contact with contaminated cat litter.
- Because no treatment for cytomegalovirus exists, prevent exposure by frequent hand hygiene before eating, and after handling infant diapers and toys.
- A cesarean section is recommended for all clients in labor who have active genital herpes lesions or early findings of impending outbreak (vulvar pain, itching.)

## ***Group B streptococcus***

GBS infection is a bacterial infection that can be passed to a fetus during labor and delivery. GBS is often an expected part of the vaginal flora for nonpregnant clients, and present in some who are pregnant. It can cause pneumonia, respiratory distress syndrome, sepsis, and meningitis, if transmitted to the neonate.

### **ASSESSMENT**

#### **RISK FACTORS**

History of positive culture with previous pregnancy

#### **RISK FACTORS FOR EARLY-ONSET NEONATAL GBS**

- Positive GBS culture in current pregnancy
- Prolonged (18 hr or more) rupture of membranes
- Preterm delivery
- Low birth weight
- Use of intrauterine fetal monitoring
- Intrapartum maternal fever ( $38^{\circ}\text{C}$  [ $100.4^{\circ}\text{F}$ ] or greater)

#### **EXPECTED FINDINGS**

**PHYSICAL ASSESSMENT FINDINGS:** Positive GBS can have maternal and fetal effects.

- Preterm labor and delivery
- Chorioamnionitis
- Infections of the urinary tract
- Maternal sepsis
- Endometritis after delivery

#### **LABORATORY TESTS**

Vaginal and rectal cultures are performed at 35 to 38 weeks of gestation.

### **PATIENT-CENTERED CARE**

#### **NURSING CARE**

Administer intrapartum antibiotic prophylaxis to the following clients to decrease transmission to the neonate.

- Client who has a GBS-positive screening during current pregnancy
- Client who has unknown GBS status who is delivering at less than 37 weeks of gestation
- Client who has maternal fever of  $38^{\circ}\text{C}$  ( $100.4^{\circ}\text{F}$ ) or greater
- Client who has rupture of membranes for 18 hr or longer

#### **MEDICATIONS**

Penicillin G or ampicillin are most commonly prescribed for GBS.

- Administer penicillin 5 million units initially IV bolus, followed by 2.5 million units intermittent IV bolus every 4 hr during the intrapartum period. The client can receive ampicillin 2 g IV initially, followed by 1 g every 4 hr.

### **CLIENT EDUCATION**

- Notify the labor and delivery nurse of GBS status.
- Decrease the neonatal risks by being screened for GBS at 35 to 38 weeks of gestation.

## ***Chlamydia***

Chlamydia is a bacterial infection caused by *Chlamydia trachomatis* and is the most commonly reported STI in American women.

- The infection can be difficult to diagnose because the client rarely has manifestations. If chlamydia is left untreated in females, it can lead to pelvic inflammatory disease (PID), which can cause infertility and ectopic pregnancy.
- The Centers for Disease Control and Prevention (CDC) recommends yearly screening of all sexually active females younger than 25 years, as well as older females who have risk factors (new or multiple partners). All pregnant clients should be screened at the first prenatal visit and rescreened in the third trimester if younger than 25 years and/or at high risk.
- If not treated during pregnancy, chlamydia can cause premature rupture of membranes, preterm labor, and postpartum endometritis.
- If transmitted to the neonate, it can cause conjunctivitis and pneumonia after delivery.

### **ASSESSMENT**

#### **RISK FACTORS**

- Multiple sexual partners
- Unprotected sex

#### **EXPECTED FINDINGS**

##### ***Male***

- Penile discharge
- Dysuria
- Testicular edema or pain

##### ***Female***

- Dysuria
- Urinary frequency
- Spotting or postcoital bleeding
- Vulvar itching
- Gray-white discharge

#### **PHYSICAL ASSESSMENT FINDINGS**

- Mucopurulent endocervical discharge
- Easily induced endocervical bleeding

#### **LABORATORY TESTS**

- Endocervical swab culture of cervical discharge
- Urine culture specimen as alternative

## PATIENT-CENTERED CARE

### NURSING CARE

- Instruct the client to take the entire prescription as prescribed.
- Identify and treat all exposed sexual partners.
- Clients who are pregnant should be retested 3 weeks after completing the prescribed regimen.

### MEDICATIONS

#### *Doxycycline*

Used as a treatment, but contraindicated during pregnancy

#### *Azithromycin or amoxicillin*

Prescribed during pregnancy

#### *Erythromycin*

Administered to all infants following delivery. This is the medication of choice for ophthalmia neonatorum. This antibiotic is both bacteriostatic and bactericidal, and thus provides prophylaxis against *Neisseria gonorrhoeae* and *Chlamydia trachomatis*.

### CLIENT EDUCATION

- Doxycycline might reduce the effectiveness of oral contraceptives. 
- If continued sexual activity is desired, be aware of the sexually transmitted infection status of any sexual partners, and use a barrier contraceptive each time you have sex.
- All states have a reportable diseases list. Chlamydia is a commonly reported condition. It is the responsibility of the provider to report cases of these diseases to the local health department.

## Gonorrhea

*Neisseria gonorrhoeae* is the causative agent of gonorrhea. Gonorrhea is a bacterial infection that is primarily spread by genital-to-genital contact. However, it also can be spread by anal-to-genital or oral-to-genital contact. It can also be transmitted to a newborn during delivery.

- Females frequently have no manifestations. If gonorrhea is left untreated in females, it can cause tubal scarring and can lead to PID, which can cause infertility.
- The CDC recommends yearly screening for all sexually active females younger than 25 years as well as older females who have risk factors (new or multiple sex partners). All pregnant clients at risk should be screened at the first prenatal visit and rescreened in the third trimester if at continued high risk.
- If left untreated, the neonate experiences ophthalmia neonatorum, which can cause blindness.

## ASSESSMENT

### RISK FACTORS

- Multiple sexual partners
- Unprotected sexual practices
- Age younger than 25, if sexually active

### EXPECTED FINDINGS

- If anal lesions present: anal itching or irritation, rectal bleeding, diarrhea, painful defecation
- If oral lesions present: ulcerations of the lips, tender gums, pharyngitis

#### *Male*

- Dysuria
- Testicular edema or pain
- Penile discharge (white, green, yellow, or clear), sometimes profuse

#### *Female*

- Often no manifestations, but can experience:
  - Dysuria
  - Vaginal bleeding between periods
  - Dysmenorrhea

### PHYSICAL ASSESSMENT FINDINGS

- Yellowish-green vaginal discharge
- Easily induced endocervical bleeding

### LABORATORY TESTS

- Endocervical culture preferred for female clients
- Urine cultures
- Anal or oral cultures

## PATIENT-CENTERED CARE

### NURSING CARE

- Provide client education regarding disease transmission.
- Identify and treat all sexual partners.
- Administer erythromycin to all infants following delivery. This is the medication of choice for ophthalmia neonatorum. This antibiotic is both bacteriostatic and bactericidal, and thus provides prophylaxis against *Neisseria gonorrhoeae* and *Chlamydia trachomatis*.
- All states have a reportable diseases list. Gonorrhea is a commonly reported condition. It is the responsibility of the provider to report cases of these diseases to the local health department.

### MEDICATIONS

CDC recommends treatment for chlamydia as well for those who test positive for gonorrhea.

PREGNANCY: Ceftriaxone IM and azithromycin PO

## CHAPTER 10 *Early Onset of Labor*

Understanding the importance of identifying the onset of early labor in a client who is pregnant is crucial for maternal and fetal well-being. This chapter includes preterm labor, premature rupture of membranes, and preterm premature rupture of membranes.

### *Preterm labor*

Preterm labor is uterine contractions and cervical changes that occur between 20 and 36 weeks and 6 days of gestation. Preterm labor can be categorized as very preterm (less than 32 weeks of gestation), moderately preterm (32 to 34 weeks of gestation), and late preterm (34 to 36 weeks of gestation). Shorter gestation is associated with increased neonatal risks.

### ASSESSMENT

#### RISK FACTORS

- Infections of the urinary tract or vagina, HIV, active herpes infection, or chorioamnionitis (infection of the amniotic sac)
- Previous preterm birth
- Multifetal pregnancy
- Smoking
- Substance use
- Violence or abuse
- Lack of prenatal care
- Uterine abnormalities
- Low prepregnancy weight

#### EXPECTED FINDINGS

- Uterine contractions
- Pressure in the pelvis and menstrual-like cramping
- Persistent low backache
- Gastrointestinal cramping, sometimes with diarrhea
- Urinary frequency
- Vaginal discharge

#### PHYSICAL ASSESSMENT FINDINGS

- Increase, change, odor or blood in vaginal discharge
- Change in cervical dilation
- Regular uterine contractions with a frequency of every 10 min or greater, lasting 1 hr or longer
- Premature rupture of membranes
- Discomfort (dull lower abdominal pain or back pain, pelvic pressure or heaviness)

#### LABORATORY TESTS

- Fetal fibronectin
- Cervical cultures
- CBC
- Urinalysis

#### DIAGNOSTIC PROCEDURES

- Obtain swab of vaginal secretions for fetal fibronectin. This protein can be expected during early and late pregnancy, but presence between 24 weeks and 34 weeks, 6 days can indicate inflammation, which increases risk for preterm labor within the next 2 weeks. FFN testing combined with cervical measurements is the best way to determine risk for preterm labor.
- Measure for a shortened endocervical length with an ultrasound. Cervical shortening occurs before uterine activity (contractions), so this can be a predictor of risk in conjunction with other findings. Cervical length greater than 30 mm indicates low risk of preterm labor.
- Obtain cervical cultures to check for presence of infectious organisms. Culture and sensitivity results guide prescription of an appropriate antibiotic, if indicated.
- Perform a biophysical profile and/or a nonstress test to provide information about the fetal well-being.

### PATIENT-CENTERED CARE

#### NURSING CARE

Management of a client who is in preterm labor includes focusing on stopping uterine contractions.

##### Activity restriction

- Usually modified bed rest with bathroom privileges. Encourage the client to engage in activities that can be completed in bed or on the couch. Strict bed rest can have adverse effects. Q<sub>EBP</sub>
- Encourage the client to rest in the left lateral position to increase blood flow to the uterus and decrease uterine activity. Q<sub>EBP</sub>
- Tell the client to avoid sexual intercourse.

**Ensuring hydration:** Dehydration stimulates the pituitary gland to secrete an antidiuretic hormone and oxytocin. Preventing dehydration prevents the release of oxytocin, which stimulates uterine contractions.

#### Identifying and treating an infection

- Have the client report any vaginal discharge, noting amount, color, consistency, and odor.
- Monitor vital signs and temperature.

**Chorioamnionitis** should be suspected with the occurrence of elevated temperature and tachycardia.

#### Monitor FHR and contraction pattern.

**Fetal tachycardia**, which is a prolonged increase in the FHR greater than 160/min can indicate infection, is frequently associated with preterm labor.

## MEDICATIONS

### Nifedipine

**CLASSIFICATION AND THERAPEUTIC INTENT:** A calcium channel blocker that is used to suppress contractions by inhibiting calcium from entering smooth muscles

#### NURSING ACTIONS

- Monitor for headache, flushing, dizziness, and nausea. These usually are related to orthostatic hypotension that occurs with administration.
- Should not be administered concurrently with magnesium sulfate, or with or immediately following a beta-adrenergic agonist. **Qs**

#### CLIENT EDUCATION **Qs**

- Slowly change positions from supine to upright, and sit until dizziness disappears.
- Maintain adequate hydration to counter hypotension.

### Magnesium sulfate

**CLASSIFICATION AND THERAPEUTIC INTENT:** A commonly used tocolytic that is a central nervous system depressant and relaxes smooth muscles, thus inhibiting uterine activity by suppressing contractions

#### NURSING ACTIONS

- Contraindications for tocolysis include active vaginal bleeding, dilation of the cervix greater than 6 cm, chorioamnionitis, greater than 34 weeks of gestation, and acute fetal distress. Do not use concurrently with nifedipine. Do not give to clients who have myasthenia gravis.
- Monitor the client closely. Discontinue tocolytic therapy immediately if the client exhibits manifestations of pulmonary edema, which includes chest pain, shortness of breath, respiratory distress, audible wheezing and crackles, and a productive cough containing blood-tinged sputum.

- Monitor for adverse effects (hot flashes, diaphoresis, burning at IV site, nausea, vomiting, drowsiness, blurred vision, headache, non-reactive nonstress test, reduced fetal heart rate variability). Monitor for magnesium sulfate toxicity and discontinue for any of the following adverse effects: loss of deep tendon reflexes, urinary output less than 30 mL/hr or 100 mL/4 hr, respirations less than 12/min, pulmonary edema, severe hypotension, or chest pain. **Qs**
- Administer calcium gluconate or calcium chloride as an antidote for magnesium sulfate toxicity.

**CLIENT EDUCATION:** Notify the nurse of blurred vision, headache, nausea, vomiting, or difficulty breathing.

### Terbutaline

**CLASSIFICATION AND THERAPEUTIC INTENT:** A beta-adrenergic agonist that is used as a tocolytic that relaxes smooth muscles and inhibits uterine activity.

#### NURSING ACTIONS

- Assess for history of cardiac disease, pregestational or gestational diabetes, preeclampsia with severe features of eclampsia, severe gestational hypertension, hyperthyroidism, or significant hemorrhage. If the client has any of these, the medication should not be administered.
- Monitor for chest discomfort, palpitations, dysrhythmia, tachycardia, tremors, nervousness, vomiting, hypokalemia, hyperglycemia, and hypotension.
- Notify the provider of heart rate greater than 130/min, chest pain, cardiac arrhythmias, myocardial infarction, blood pressure less than 90/60 mm Hg, or pulmonary edema.
- Administer 0.25 mg subcutaneously every 4 hr, for up to 24 hr.
- Discontinue if the client can't tolerate adverse effects.

### Indomethacin

**CLASSIFICATION AND THERAPEUTIC INTENT:** Indomethacin is a nonsteroidal anti-inflammatory drug (NSAID) that suppresses preterm labor by blocking the production of prostaglandins. This inhibition of prostaglandins suppresses uterine contractions.

- This medication can cause premature narrowing or closure of the ductus arteriosus in the fetus.

#### NURSING ACTIONS

- Monitor the client closely. Discontinue tocolytic therapy immediately if the client exhibits manifestations of pulmonary edema, which include chest pain, shortness of breath, respiratory distress, audible wheezing and crackles, and a productive cough containing blood-tinged sputum.
- Indomethacin treatment should not exceed 48 hr.
- Indomethacin should only be used if gestational age is less than 32 weeks of gestation.
- Monitor for postpartum hemorrhage related to reduced platelet aggregation.
- Administer indomethacin with food or rectally to decrease gastrointestinal distress.
- Notify the provider if the client reports blurred vision, headache, nausea, vomiting, ringing in the ears, or difficulty breathing.
- Monitor the neonate at birth.

## **Betamethasone**

**CLASSIFICATION AND THERAPEUTIC INTENT:** A glucocorticoid that is administered IM in two injections 24 hr apart, and requires 24 hr to be effective. The therapeutic action is to enhance fetal lung maturity and surfactant production in fetuses between 24 to 34 weeks gestation.

### **NURSING ACTIONS**

- Administer betamethasone 12 mg IM for two doses 24 hr apart.
- Ideally, administer at least 24 hr (but not more than 7 days) before delivery.
- Administer deep IM using ventral gluteal or vastus lateralis muscle.
- Monitor for maternal hyperglycemia.
- Assess the preterm infant's lung sounds.

**CLIENT EDUCATION:** Report findings of pulmonary edema (chest pain, shortness of breath, and crackles).

## *Premature rupture of membranes and preterm premature rupture of membranes*

**Premature rupture of membranes (PROM)** is the spontaneous rupture of the amniotic membranes prior to the onset of true labor. For most clients, PROM signifies the onset of true labor if gestational duration is at term.

**Preterm premature rupture of membranes (PPROM)** is the premature spontaneous rupture of membranes after 20 weeks of gestation and prior to 37 weeks of gestation.

## **ASSESSMENT**

### **RISK FACTORS**

- Infection
- Prior preterm birth
- Shortening of the cervix
- Second/third trimester bleeding.
- Pulmonary or connective tissue disorders
- Low BMI
- Copper or ascorbic acid deficiencies
- Tobacco or substance use

### **EXPECTED FINDINGS**

Client reports a gush or leakage of clear fluid from the vagina.

#### **PHYSICAL ASSESSMENT FINDINGS**

- Presence of clear fluid

#### **Assess for a prolapsed umbilical cord.** *Qs*

- Abrupt FHR variable or prolonged deceleration
- Visible or palpable cord at the introitus

## **LABORATORY TESTS**

A positive nitrazine paper test (blue, pH 6.5 to 7.5) or positive ferning test is conducted on amniotic fluid to verify rupture of membranes.

## **PATIENT-CENTERED CARE**

### **NURSING CARE**

- Nursing management depends on gestational duration, if there is evidence of infection, or an indication of fetal or maternal compromise.
- Prepare for birth if indicated.
- Obtain vaginal/rectal cultures for streptococcus beta-hemolytic.
- Obtain vaginal cultures for chlamydia and *Neisseria gonorrhoeae*.
- Limit vaginal exams.
- Provide reassurance to reduce anxiety.
- Assess vital signs every 2 hr. Notify the provider of a temperature greater than 38° C (100° F).
- Monitor FHR and uterine contractions.
- Encourage hydration.
- Obtain a CBC.
- Anticipate a prescription for 7-day course of broad spectrum antibiotics.

### **CLIENT EDUCATION**

- Perform daily fetal kick counts and to notify the nurse of uterine contractions.
- Adhere to bed rest with bathroom privileges.

## **MEDICATIONS**

### **Ampicillin**

**CLASSIFICATION AND THERAPEUTIC INTENT:** Ampicillin is an antibiotic used to treat infection. It is commonly used to treat chorioamnionitis.

**NURSING ACTIONS:** Obtain vaginal, urine, and blood cultures prior to administration of antibiotic.

### **Betamethasone**

#### **CLASSIFICATION AND THERAPEUTIC INTENT**

- Betamethasone is a glucocorticoid administered IM in two injections, 24 hr apart, and requires 24 hr to be effective. The therapeutic action is to enhance fetal lung maturity and surfactant production.
- A single dose is given with PROM at 24 to 34 weeks of gestation to reduce the risk of perinatal mortality, respiratory distress syndrome, and other morbidities.
- Betamethasone is given to PROM and PPROM clients between 24 and 34 weeks of gestation to reduce the risk of distress syndrome.

## COMPLICATIONS

### Infection

Infection, particularly chorioamnionitis, is the most common complication of PPROM.

### Other complications

Placental abruption, umbilical cord compression or prolapse, fetal pulmonary hypoplasia, and death

## CLIENT EDUCATION

- Depending on gestational age, treatment is conservative, and hospitalization can prolong pregnancy while monitoring for risk factors (infection, vaginal bleeding, fetal complications).
- Adhere to limited activity with bathroom privileges.
- Hydrate.
- Conduct a self-assessment for uterine contractions.
- Record daily kick counts for fetal movement.
- Monitor for foul-smelling vaginal discharge.
- Refrain from inserting anything into the vagina.
- Abstain from intercourse.
- Avoid tub baths.
- Wipe the perineal area from front to back after voiding and fecal elimination.
- Take temperature every 4 hr when awake and report a temperature that is greater than 38° C (100° F).

### Active Learning Scenario

A nurse in a prenatal clinic is reviewing preterm labor with a newly hired nurse. What should the nurse include in the discussion? Use the ATI Active Learning Template: System Disorder to complete this item.

#### ALTERATION IN HEALTH (DIAGNOSIS)

**EXPECTED FINDINGS:** Describe at least six manifestations.

**DIAGNOSTIC PROCEDURES:** Describe at least three.

## Application Exercises

1. A nurse is caring for a client who reports manifestations of preterm labor. Which of the following findings are risk factors of this condition? (Select all that apply.)
  - A. Urinary tract infection
  - B. Multifetal pregnancy
  - C. Hydramnios
  - D. Diabetes mellitus
  - E. Uterine abnormalities
2. A nurse is providing care for a client who is in preterm labor at 32 weeks of gestation. Which of the following medications should the nurse anticipate the provider will prescribe to hasten fetal lung maturity?
  - A. Calcium gluconate
  - B. Indomethacin
  - C. Nifedipine
  - D. Betamethasone
3. A nurse is caring for a client who is receiving nifedipine for prevention of preterm labor. The nurse should monitor the client for which of the following manifestations?
  - A. Blood-tinged sputum
  - B. Dizziness
  - C. Pallor
  - D. Somnolence
4. A nurse is caring for a client who has a prescription for magnesium sulfate. The nurse should recognize that which of the following are contraindications for use of this medication? (Select all that apply.)
  - A. Fetal distress
  - B. Preterm labor
  - C. Vaginal bleeding
  - D. Cervical dilation greater than 6 cm
  - E. Severe gestational hypertension
5. A nurse is reviewing discharge teaching with a client who has premature rupture of membranes at 26 weeks of gestation. Which of the following instructions should the nurse include in the teaching?
  - A. Use a condom with sexual intercourse.
  - B. Avoid bubble bath solution when taking a tub bath.
  - C. Wipe from the back to front when performing perineal hygiene.
  - D. Keep a daily record of fetal kick counts.

## Application Exercises Key

1. A. **CORRECT:** A urinary tract infection is a risk factor of preterm labor.
- B. **CORRECT:** Multifetal pregnancy is a risk factor of preterm labor.
- C. **CORRECT:** Hydramnios (excessive amniotic fluid) is a risk factor for preterm labor.
- D. **CORRECT:** Diabetes mellitus is a risk factor of preterm labor.
- E. **CORRECT:** Uterine abnormalities are a risk factor of preterm labor.

❷ NCLEX® Connection: *Health Promotion and Maintenance, Health Promotion/Disease Prevention*

2. A. Calcium gluconate is administered as an antidote for magnesium sulfate toxicity.
- B. Indomethacin is an NSAID used to suppress preterm labor by blocking prostaglandin production.
- C. Nifedipine is a calcium channel blocker used to suppress uterine contractions.
- D. **CORRECT:** Betamethasone is a glucocorticoid given to clients in preterm labor to hasten surfactant production.

❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Medication Administration*

3. A. Blood-tinged sputum production is an adverse effect associated with indomethacin.
- B. **CORRECT:** Dizziness and lightheadedness are associated with orthostatic hypotension, which occurs when taking nifedipine.
- C. Facial flushing and heat sensation are adverse effects associated with nifedipine.
- D. Nervousness, jitteriness, and sleep disturbances are adverse effects associated with nifedipine.

❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Adverse Effects/Contraindications/Side Effects/Interactions*

4. A. **CORRECT:** Acute fetal distress is a complication that is a contraindication for use of magnesium sulfate therapy.
- B. Preterm labor is an indication for use of magnesium sulfate.
- C. **CORRECT:** Vaginal bleeding is a complication that is a contraindication for magnesium sulfate therapy.
- D. **CORRECT:** Cervical dilation greater than 6 cm is a complication that is a contraindication for magnesium sulfate therapy.
- E. Severe gestational hypertension is an indication for the use of magnesium sulfate.

❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Adverse Effects/Contraindications/Side Effects/Interactions*

5. A. The client who has ruptured membranes should not insert anything into the vagina.
- B. Instruct the client to avoid tub baths and take showers.
- C. Instruct the client to wipe from front to back when performing perineal hygiene.
- D. **CORRECT:** The client should record daily fetal kick counts.

❷ NCLEX® Connection: *Physiological Adaptation, Illness Management*

## Active Learning Scenario Key

*Using the ATI Active Learning Template: System Disorder*

**ALTERATION IN HEALTH (DIAGNOSIS):** Uterine contractions and cervical changes that occur between 20 and 37 weeks of gestation

### EXPECTED FINDINGS

- Persistent low backache
- Pressure in the pelvis and cramping
- Gastrointestinal cramping, sometimes with diarrhea
- Urinary frequency
- Vaginal discharge
- Increase, change, or blood in vaginal discharge
- Change in cervical dilation
- Regular uterine contractions with a frequency of every 10 min or greater, lasting 1 hr or longer
- Premature rupture of membranes

### DIAGNOSTIC PROCEDURES

- Test for fetal fibronectin
- Ultrasound to measure endocervical length
- Cervical culture to detect presence of infectious organisms
- Biophysical profile
- Nonstress test
- Home uterine activity monitoring for uterine contractions

❷ NCLEX® Connection: *Physiological Adaptation, Illness Management*

# CHAPTER 9

UNIT 1

ANTEPARTUM NURSING CARE  
SECTION: COMPLICATIONS OF PREGNANCY

CHAPTER 9

## Medical Conditions

Unexpected medical conditions can occur during pregnancy. Awareness, early detection, and interventions are crucial components to ensure fetal well-being and maternal health.

Unexpected medical conditions include cervical insufficiency, hyperemesis gravidarum, anemia, gestational diabetes mellitus, and gestational hypertension.

### ***Cervical insufficiency (premature cervical dilatation)***

Cervical insufficiency is a variable condition whereby expulsion of the products of conception occurs. It is thought to be related to tissue changes and alterations in the length of the cervix.

#### **ASSESSMENT**

#### **RISK FACTORS**

- History of cervical trauma (cervical tears from previous deliveries, excessive dilations, curettage for biopsy, and surgical procedures involving the cervix), short labors, pregnancy loss in early gestation, or advanced cervical dilation at earlier weeks of gestation
- In utero exposure to diethylstilbestrol, ingested by the client during pregnancy
- Congenital structural defects of the uterus or cervix

#### **EXPECTED FINDINGS**

Increase in pelvic pressure or urge to push

#### **PHYSICAL ASSESSMENT FINDINGS**

- Pink-stained vaginal discharge or bleeding
- Possible gush of fluid (rupture of membranes)
- Uterine contractions with the expulsion of the fetus
- Postoperative (cerclage) monitoring for uterine contractions, rupture of membranes, and manifestations of infection

#### **DIAGNOSTIC AND THERAPEUTIC PROCEDURES**

- An **ultrasound** showing a short cervix (less than 25 mm in length), presence of cervical funneling (beaking), or effacement of the cervical os indicates reduced cervical competence.
- **Prophylactic cervical cerclage** is the surgical reinforcement of the cervix with a heavy ligature that is placed submucosally around the cervix to strengthen it and prevent premature cervical dilation. Best results occur if this is done at 12 to 14 weeks of gestation. The cerclage is removed at 36 weeks of gestation or when spontaneous labor occurs.

#### **PATIENT-CENTERED CARE**

#### **NURSING CARE**

- Evaluate the client's support systems and availability of assistance if activity restrictions or bed rest are prescribed.
- Assess vaginal discharge.
- Monitor client reports of pressure and contractions.
- Check vital signs.

#### **CLIENT EDUCATION**

##### **DISCHARGE INSTRUCTIONS**

- Adhere to activity restriction or bed rest.
- Increase hydration to promote a relaxed uterus. (Dehydration stimulates uterine contractions.)
- Avoid intercourse.
- Monitor for cervical/uterine changes.
- Cervical cerclage might be required (indicated for clients who are experiencing singleton pregnancy), often placed at 12 to 14 weeks gestation and removed at 37 to 38 weeks gestation.

##### **HEALTH PROMOTION AND DISEASE PREVENTION:**

Report findings to the provider (preterm labor, rupture of membranes, infection, strong contractions less than 5 min apart, severe perineal pressure, urge to push).

##### **NURSING ACTIONS**

- Follow up for observation and supervision.
- Plan for removal of the cerclage between 37 and 38 weeks of gestation.

# *Hyperemesis gravidarum*

- Hyperemesis gravidarum is excessive nausea and vomiting (possibly related to elevated hCG levels) that is prolonged past 16 weeks of gestation or that is excessive and causes weight loss, dehydration, nutritional deficiencies, electrolyte imbalances, and ketonuria.
- There is a risk to the fetus for intrauterine growth restriction, small for gestational age, or preterm birth if the condition persists.

## **ASSESSMENT**

### RISK FACTORS

- Maternal age younger than 30 years
- Multifetal gestation
- Gestational trophoblastic disease
- Psychosocial issues and high levels of emotional stress
- Clinical hyperthyroid disorders
- Diabetes
- Gastrointestinal disorders
- Family history of hyperemesis

### EXPECTED FINDINGS

#### PHYSICAL ASSESSMENT FINDINGS

- Excessive vomiting for prolonged periods
- Dehydration with possible electrolyte imbalance
- Weight loss
- Increased pulse rate
- Decreased blood pressure
- Poor skin turgor and dry mucous membranes

### LABORATORY TESTS

- **Urinalysis** for ketones and acetones (breakdown of protein and fat) is the most important initial laboratory test: Elevated urine specific gravity
- **Chemistry profile** revealing electrolyte imbalances
  - Sodium, potassium, and chloride reduced from low intake
  - Metabolic acidosis (secondary to starvation)
  - Metabolic alkalosis due to excessive vomiting
  - Elevated liver enzymes
  - Bilirubin level
- **Thyroid test** indicating hyperthyroidism
- **Complete blood count** (CBC): Elevated Hct concentration because inability to retain fluid results in hemoconcentration

## **PATIENT-CENTERED CARE**

### NURSING CARE

- Monitor I&O.
- Assess skin turgor and mucous membranes.
- Monitor vital signs.
- Monitor weight.
- Have the client remain NPO until vomiting stops.

## MEDICATIONS

- Give IV lactated Ringer's for hydration.
- Give pyridoxine (vitamin B<sub>6</sub>) and other vitamin supplements as tolerated. American College of Obstetricians and Gynecologists recommend the use of pyridoxine alone or in combination with doxylamine as the initial medication management because these medications are considered both safe and effective.
- Use antiemetic medications (metoclopramide) cautiously for uncontrollable nausea and vomiting.
- Use corticosteroids to treat refractory hyperemesis gravidarum.

## **CLIENT EDUCATION**

#### DISCHARGE INSTRUCTIONS

- Advance to a diet of clear liquids and bland foods once the vomiting has stopped.
- Advance the client's diet as tolerated, with frequent small meals. Start with dry toast, crackers, or cereal; then move to a soft diet; and finally to a normal diet as tolerated. 
- In severe cases, enteral nutrition per feeding tube or total parental nutrition can be considered.

# *Iron-deficiency anemia*

Iron-deficiency anemia occurs during pregnancy due to inadequacy in maternal iron stores and consuming insufficient amounts of dietary iron.

## **ASSESSMENT**

### RISK FACTORS

- Less than 2 years between pregnancies
- Heavy menses
- Diet low in iron
- Unhealthy weight loss programs

### EXPECTED FINDINGS

- Fatigue and weakness
- Craving unusual food (pica)

### LABORATORY TESTS

- **Hgb** less than 11 mg/dL in the first and third trimesters and less than 10.5 mg/dL in the second trimester
- **Hct** less than 33.0%
- **Blood ferritin** less than 12 mcg/L in presence of low Hgb

## PATIENT-CENTERED CARE

### NURSING CARE

- The recommended iron intake for pregnant clients is 27 mg/day. Prenatal vitamins typically contain 30 mg iron. If maternal iron deficiency anemia is present, increased dosages of 60 to 120 mg/day can be required.
- Increase dietary intake of foods rich in iron (legumes, dried fruit, dark green leafy vegetables, and meat).
- Educate the client about ways to minimize gastrointestinal adverse effects.

### MEDICATIONS

#### *Ferrous sulfate iron supplements*

##### CLIENT EDUCATION

- Take the supplement on an empty stomach and take with orange juice to increase absorption.
- Adhere to a diet rich in vitamin C-containing foods to increase absorption.
- Increase roughage and fluid intake in diet to assist with discomforts of constipation.

#### *Parenteral iron therapy*

For pregnant clients who cannot tolerate oral iron. Severe anemic clients can receive blood transfusions.

## *Gestational diabetes mellitus*

- Gestational diabetes mellitus (GDM) is an impaired tolerance to glucose with the first onset or recognition during pregnancy. The ideal blood glucose level during pregnancy should range between 60 and 99 mg/dL before meals or fasting, and less than or equal to 120 mg/dL 2 hr after meals.
- Findings of diabetes mellitus can disappear a few weeks following delivery. However, approximately 50% of clients will develop type II diabetes mellitus later in life.

##### INCREASED RISKS TO FETUS

- Macrosomia, birth trauma, electrolyte imbalances, and neonatal hypoglycemia
- Infections** (urinary and vaginal), related to increased glucose in the urine and decreased resistance because of altered carbohydrate metabolism
- Hydramnios**, which can cause overdistention of the uterus, placental abruption, preterm labor, and postpartum hemorrhage
- Ketoacidosis** from diabetogenic effect of pregnancy (increased insulin resistance), untreated hyperglycemia, or inappropriate insulin dosing
- Hypoglycemia**, caused by overdosing in insulin, skipped or late meals, or increased exercise
- Hyperglycemia**, which can cause excessive fetal growth (macrosomia)

## ASSESSMENT

### RISK FACTORS

- Obesity
- Hypertension
- Glycosuria
- Maternal age older than 25 years
- Family history of diabetes mellitus
- Previous delivery of an infant that was large or stillborn

### EXPECTED FINDINGS

**Hypoglycemia:** nervousness, headache, weakness, irritability, hunger, blurred vision

**Hyperglycemia:** polydipsia, polyphagia, polyuria, nausea, abdominal pain, flushed dry skin, fruity breath

##### PHYSICAL ASSESSMENT FINDINGS

- Hypoglycemia
- Shaking
- Clammy pale skin
- Shallow respirations
- Rapid pulse
- Hyperglycemia
- Vomiting
- Excess weight gain during pregnancy

### LABORATORY TESTS

- Glucola screening test/1-hr glucose tolerance test:** 50 g oral glucose load, followed by plasma glucose analysis 1 hr later performed at 24 to 28 weeks of gestation; fasting not necessary; a positive blood glucose screening is 130 to 140 mg/dL or greater; additional testing with a 3-hr oral glucose tolerance test (OGTT) is indicated QEBP
- Oral glucose tolerance test** following overnight fasting, avoidance of caffeine, and abstinence from smoking for 12 hr prior to testing; a fasting glucose is obtained, a 100 g glucose load is given, and serum glucose levels are determined at 1, 2, and 3 hr following glucose ingestion
- Presence of ketones in urine** to assess severity of ketoacidosis

### DIAGNOSTIC PROCEDURES

- Biophysical profile to ascertain fetal well-being if nonstress test is nonreactive
- Amniocentesis with amniotic fluid phosphatidylglycerol measured to determine fetal lung maturity
- Nonstress test to assess fetal well-being

## PATIENT-CENTERED CARE

---

### NURSING CARE

---

- Monitor the client's blood glucose.
- Monitor the fetus.

### MEDICATIONS

---

In contrast to clients who have type I diabetes mellitus, clients who have GDM are managed initially with diet and exercise alone. If glucose levels are persistently high, insulin is begun.

Oral hypoglycemic therapy is an alternative to insulin in clients who have GDM who require medication in addition to diet for blood glucose control. Most oral hypoglycemic agents are contraindicated for gestational diabetes mellitus, but there is limited use of glyburide. The provider will need to make the determination if these medications can be used.

### CLIENT EDUCATION

---

- Perform daily kick counts.
- Adhere to the appropriate diet, including standard diabetic diet and restricted carbohydrate intake. Dietary counseling by a registered dietitian should occur.
- Exercise.
- Perform self-administration of insulin.
- Understand the need for postpartum laboratory testing to include OGTT and blood glucose levels.

## *Gestational hypertension*

---

- Hypertensive disease in pregnancy is divided into clinical subsets of the disease based on end-organ effects and progresses along a continuum from gestational hypertension; preeclampsia without severe features; preeclampsia with severe features; and eclampsia.
- Vasospasm contributing to poor tissue perfusion is the underlying mechanism for the manifestations of pregnancy hypertensive disorders.
- Gestational hypertensive disease and chronic hypertension can occur simultaneously.
- Gestational hypertensive diseases are associated with placental abruption, kidney failure, hepatic rupture, preterm birth, and fetal and maternal death.

**Gestational hypertension (GH)**, which begins after the 20th week of pregnancy, describes hypertensive disorders of pregnancy whereby the client has an elevated blood pressure at 140/90 mm Hg or greater recorded on two different occasions, at least 4 hr apart. There is no proteinuria. The presence of edema is no longer considered in the definition of hypertensive disease of pregnancy. Blood pressure returns to baseline by 12 weeks postpartum.

**Preeclampsia** is GH with the addition of proteinuria of greater than or equal to 1+. Report of transient headaches might occur along with episodes of irritability. Edema can be present.

**Severe preeclampsia** consists of blood pressure that is 160/110 mm Hg or greater, proteinuria greater than 3+, oliguria, elevated blood creatinine greater than 1.1 mg/dL, cerebral or visual disturbances (headache and blurred vision), hyperreflexia with possible ankle clonus, pulmonary or cardiac involvement, extensive peripheral edema, hepatic dysfunction, epigastric and right upper-quadrant pain, and thrombocytopenia.

**Eclampsia** is severe preeclampsia manifestations with the onset of seizure activity or coma. Eclampsia is usually preceded by headache, severe epigastric pain, hyperreflexia, and hemoconcentrations, which are warning manifestations of probable convulsions.

**HELLP syndrome** is a variant of GH in which hematologic conditions coexist with severe preeclampsia involving hepatic dysfunction. HELLP syndrome is diagnosed by laboratory tests, not clinically.

- **H: Hemolysis** resulting in anemia and jaundice
- **EL: Elevated liver enzymes** resulting in elevated alanine aminotransferase (ALT) or aspartate transaminase (AST), epigastric pain, and nausea and vomiting
- **LP: Low platelets** (less than 100,000/mm<sup>3</sup>), resulting in thrombocytopenia, abnormal bleeding and clotting time, bleeding gums, petechiae, and possibly disseminated intravascular coagulopathy

## ASSESSMENT

---

### RISK FACTORS

---

No single profile identifies risks for gestational hypertensive disorders, but some high risks include the following.

- Maternal age younger than 19 or older than 40 years
- First pregnancy
- Extreme obesity
- Multifetal gestation
- Chronic renal disease
- Chronic hypertension
- Familiar history of preeclampsia
- Diabetes mellitus
- Rheumatoid arthritis
- Systemic lupus erythematosus

### EXPECTED FINDINGS

---

- Severe continuous headache
- Nausea
- Blurring of vision
- Flashes of lights or dots before the eyes

## **PHYSICAL ASSESSMENT FINDINGS**

- Hypertension
- Proteinuria
- Periorbital, facial, hand, and abdominal edema
- Pitting edema of lower extremities
- Vomiting
- Oliguria
- Hyperreflexia
- Scotoma
- Epigastric pain
- Right upper quadrant pain
- Dyspnea
- Diminished breath sounds
- Seizures
- Jaundice
- Manifestations of progression of hypertensive disease with indications of worsening liver involvement, kidney failure, worsening hypertension, cerebral involvement, and developing coagulopathies

## **LABORATORY FINDINGS**

- Elevated liver enzymes (LDH, AST)
- Increased creatinine
- Increased plasma uric acid
- Thrombocytopenia
- Hgb (decreased in HELLP, increased in preeclampsia)
- Hyperbilirubinemia

## **LABORATORY TESTS**

- Liver enzymes
- Blood creatinine, BUN, uric acid
- CBC
- Clotting studies
- Chemistry profile

## **DIAGNOSTIC PROCEDURES**

- Dipstick testing of urine for proteinuria
- 24-hr urine collection for protein and creatinine clearance
- Nonstress test, contraction stress test, biophysical profile, and serial ultrasounds to assess fetal status
- Doppler blood flow analysis to assess fetal well-being
- Daily kick counts

## **PATIENT-CENTERED CARE**

### **NURSING CARE**

- Assess level of consciousness.
- Obtain pulse oximetry.
- Monitor urine output.
- Obtain daily weights.
- Monitor vital signs with careful attention to blood pressure measurement (using proper size cuff, not talking to client during measurement).
- Encourage lateral positioning.
- Perform NST and daily kick counts.
- Instruct the client to monitor I&O.

## **MEDICATIONS**

It is recommended that daily low dose aspirin therapy be initiated late in the first trimester for clients who have a history of early onset preeclampsia.

### ***Antihypertensive medications***

- Methyldopa
- Nifedipine
- Hydralazine
- Labetalol

**CLIENT EDUCATION:** Avoid ACE inhibitors and angiotensin II receptor blockers.

### ***Anticonvulsant medications: Magnesium sulfate***

Medication of choice for prophylaxis or treatment to depress the CNS and prevent seizures in the client who has eclampsia and severe preeclampsia.

#### **NURSING ACTIONS**

- Use an infusion control device to maintain a regular flow rate.
- Monitor blood pressure, pulse, respiratory rate, deep-tendon reflexes, level of consciousness, urinary output (indwelling urinary catheter for accuracy), presence of headache, visual disturbances, epigastric pain, uterine contractions, and fetal heart rate and activity.
- Monitor for manifestations of magnesium sulfate toxicity. **Qs**
  - Absence of patellar deep tendon reflexes
  - Urine output less than 30 mL/hr
  - Respirations less than 12/min
  - Decreased level of consciousness
  - Cardiac dysrhythmias
- If magnesium toxicity is suspected:
  - Immediately discontinue infusion.
  - Administer antidote calcium gluconate or calcium chloride. **Qs**
  - Prepare for actions to prevent respiratory or cardiac arrest.

**CLIENT EDUCATION:** There can be initial feelings of flushing, heat, sedation, diaphoresis, and burning at IV site with the magnesium sulfate bolus.

## **CLIENT EDUCATION**

### **DISCHARGE INSTRUCTIONS**

- Remain on bed rest and in the side-lying position.
- Perform diversional activities (TV, visits from family or friends, gentle exercise).
- Avoid foods that are high in sodium.
- Avoid alcohol and tobacco and limit caffeine intake.
- Drink six to eight 8-ounce glasses of water per day.
- Maintain a dark quiet environment to avoid stimuli that can precipitate a seizure.
- Maintain a patent airway in the event of a seizure.
- Take antihypertensive medications as prescribed.

## Application Exercises

1. A nurse is caring for a client who is at 14 weeks of gestation and has hyperemesis gravidarum. The nurse should identify that which of the following are risk factors for the client? (Select all that apply.)

  - A. Diabetes
  - B. Multifetal pregnancy
  - C. Maternal age greater than 40
  - D. Gestational trophoblastic disease
  - E. Oligohydramnios
  
2. A nurse is caring for a client who has suspected hyperemesis gravidarum and is reviewing the client's laboratory reports. Which of the following findings is a manifestation of this condition?

  - A. Hgb 12.2 g/dL
  - B. Urine ketones present
  - C. Alanine aminotransferase 20 IU/L
  - D. Blood glucose 114 mg/dL
  
3. A nurse is administering magnesium sulfate IV for seizure prophylaxis to a client who has severe preeclampsia. Which of the following indicates magnesium sulfate toxicity? (Select all that apply.)

  - A. Respirations less than 12/min
  - B. Urinary output less than 25 mL/hr
  - C. Hyperreflexic deep-tendon reflexes
  - D. Decreased level of consciousness
  - E. Flushing and sweating
  
4. A nursing is caring for a client who is receiving IV magnesium sulfate. Which of the following medications should the nurse anticipate administering if magnesium sulfate toxicity is suspected?

  - A. Nifedipine
  - B. Pyridoxine
  - C. Ferrous sulfate
  - D. Calcium gluconate
  
5. A nurse is reviewing a new prescription for ferrous sulfate with a client who is at 12 weeks of gestation. Which of the following statements by the client indicates understanding of the teaching?

  - A. "I will take this pill with my breakfast."
  - B. "I will take this medication with a glass of milk."
  - C. "I plan to drink more orange juice while taking this pill."
  - D. "I plan to add more calcium-rich foods to my diet while taking this medication."

## Active Learning Scenario

A nurse is preparing to teach a client who is at 20 weeks of gestation and is scheduled to undergo a prophylactic cervical cerclage. What information should the nurse include in the teaching? Use the ATI Active Learning Template: Therapeutic Procedure to complete this item.

### DESCRIPTION OF PROCEDURE

**POTENTIAL COMPLICATIONS:** Identify two.

**CLIENT EDUCATION:** Describe at least four instructions to give the client.

## Application Exercises Key

1. A. **CORRECT:** Diabetes is a risk factor for hyperemesis gravidarum.
- B. **CORRECT:** Multifetal pregnancy is a risk factor for hyperemesis gravidarum.
- C. Maternal age less than 30 is a risk factor for hyperemesis gravidarum.
- D. **CORRECT:** Gestational trophoblastic disease is a risk factor for hyperemesis gravidarum.
- E. Oligohydramnios is not a risk factor for hyperemesis gravidarum.

❷ NCLEX® Connection: *Health Promotion and Maintenance, Health Promotion/Disease Prevention*

2. A. Altered hematocrit is a manifestation of hyperemesis gravidarum due to the hemoconcentration that occurs with dehydration.
- B. **CORRECT:** The presence of ketones in the urine is associated with the breakdown of proteins and fats that occurs in a client who has hyperemesis gravidarum.
- C. Liver enzymes are elevated in a client who has hyperemesis gravidarum. This finding is within the expected reference range.
- D. Decreased blood glucose is anticipated in a client who has hyperemesis gravidarum. This result is within the expected reference range.

❷ NCLEX® Connection: *Reduction of Risk Potential, Laboratory Values*

3. A. **CORRECT:** A respiratory rate less than 12/min is a manifestation of magnesium sulfate toxicity.
- B. **CORRECT:** Urinary output less than 25 mL/hr is a manifestation of magnesium sulfate toxicity.
- C. The absence of patellar deep-tendon reflexes is a manifestation of magnesium sulfate toxicity.
- D. **CORRECT:** Decreased level of consciousness is a manifestation of magnesium sulfate toxicity.
- E. Flushing and sweating are adverse effects of magnesium sulfate but are not manifestations of toxicity.

❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Expected Actions/Outcomes*

4. A. Nifedipine is an antihypertensive medication that can be administered to clients who have gestational hypertension.
- B. Pyridoxine (vitamin B<sub>6</sub>) is a vitamin supplement prescribed for clients who have hyperemesis gravidarum.
- C. Ferrous sulfate is a medication used in the treatment of iron deficiency anemia.
- D. **CORRECT:** Calcium gluconate is the antidote for magnesium sulfate.

❷ NCLEX® Connection: *Physiological Adaptation, Expected Actions/Outcomes*

5. A. Ferrous sulfate should be taken on an empty stomach.
- B. Milk will decrease the absorption of ferrous sulfate.
- C. **CORRECT:** A diet with increased vitamin C improves the absorption of ferrous sulfate.
- D. Although a diet of calcium-rich foods is appropriate for the client during pregnancy, it does not improve the effectiveness of ferrous sulfate.

❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Medication Administration*

## Active Learning Scenario Key

*Using the ATI Active Learning Template: Therapeutic Procedure*

**DESCRIPTION OF PROCEDURE:** Surgical reinforcement of the cervix with a heavy ligature (suture) that is placed submucosally around the cervix to strengthen it and prevent premature cervical dilation.

### POTENTIAL COMPLICATIONS

- Uterine contractions
- Rupture of membranes
- Infection

### CLIENT EDUCATION

- Remain on activity restrictions/bed rest as prescribed.
- Increase hydration to promote a relaxed uterus.
- Refrain from sexual intercourse.
- Findings to report to the provider include preterm labor, rupture of membranes, manifestations of infection, strong contractions less than 5 min apart, perineal pressure, and the urge to push.
- Plan for removal of the cerclage between 37 and 38 weeks of gestation.

❷ NCLEX® Connection: *Reduction of Risk Potential, Therapeutic Procedures*

# CHAPTER 10

UNIT 1

ANTEPARTUM NURSING CARE  
SECTION: COMPLICATIONS OF PREGNANCY

## CHAPTER 10 Early Onset of Labor

Understanding the importance of identifying the onset of early labor in a client who is pregnant is crucial for maternal and fetal well-being. This chapter includes preterm labor, premature rupture of membranes, and preterm premature rupture of membranes.

### Preterm labor

Preterm labor is uterine contractions and cervical changes that occur between 20 and 36 weeks and 6 days of gestation. Preterm labor can be categorized as very preterm (less than 32 weeks of gestation), moderately preterm (32 to 34 weeks of gestation), and late preterm (34 to 36 weeks of gestation). Shorter gestation is associated with increased neonatal risks.

### ASSESSMENT

#### RISK FACTORS

- Infections of the urinary tract or vagina, HIV, active herpes infection, or chorioamnionitis (infection of the amniotic sac)
- Previous preterm birth
- Multifetal pregnancy
- Smoking
- Substance use
- Violence or abuse
- Lack of prenatal care
- Uterine abnormalities
- Low prepregnancy weight

#### EXPECTED FINDINGS

- Uterine contractions
- Pressure in the pelvis and menstrual-like cramping
- Persistent low backache
- Gastrointestinal cramping, sometimes with diarrhea
- Urinary frequency
- Vaginal discharge

#### PHYSICAL ASSESSMENT FINDINGS

- Increase, change, odor or blood in vaginal discharge
- Change in cervical dilation
- Regular uterine contractions with a frequency of every 10 min or greater, lasting 1 hr or longer
- Premature rupture of membranes
- Discomfort (dull lower abdominal pain or back pain, pelvic pressure or heaviness)

### LABORATORY TESTS

- Fetal fibronectin
- Cervical cultures
- CBC
- Urinalysis

### DIAGNOSTIC PROCEDURES

- Obtain swab of vaginal secretions for fetal fibronectin. This protein can be expected during early and late pregnancy, but presence between 24 weeks and 34 weeks, 6 days can indicate inflammation, which increases risk for preterm labor within the next 2 weeks. FFN testing combined with cervical measurements is the best way to determine risk for preterm labor.
- Measure for a shortened endocervical length with an ultrasound. Cervical shortening occurs before uterine activity (contractions), so this can be a predictor of risk in conjunction with other findings. Cervical length greater than 30 mm indicates low risk of preterm labor.
- Obtain cervical cultures to check for presence of infectious organisms. Culture and sensitivity results guide prescription of an appropriate antibiotic, if indicated.
- Perform a biophysical profile and/or a nonstress test to provide information about the fetal well-being.

### PATIENT-CENTERED CARE

#### NURSING CARE

Management of a client who is in preterm labor includes focusing on stopping uterine contractions.

##### Activity restriction

- Usually modified bed rest with bathroom privileges. Encourage the client to engage in activities that can be completed in bed or on the couch. Strict bed rest can have adverse effects. 
- Encourage the client to rest in the left lateral position to increase blood flow to the uterus and decrease uterine activity. 
- Tell the client to avoid sexual intercourse.

**Ensuring hydration:** Dehydration stimulates the pituitary gland to secrete an antidiuretic hormone and oxytocin. Preventing dehydration prevents the release of oxytocin, which stimulates uterine contractions.

##### Identifying and treating an infection

- Have the client report any vaginal discharge, noting amount, color, consistency, and odor.
- Monitor vital signs and temperature.

**Chorioamnionitis** should be suspected with the occurrence of elevated temperature and tachycardia.

##### Monitor FHR and contraction pattern.

**Fetal tachycardia**, which is a prolonged increase in the FHR greater than 160/min can indicate infection, is frequently associated with preterm labor.

## MEDICATIONS

---

### *Nifedipine*

---

**CLASSIFICATION AND THERAPEUTIC INTENT:** A calcium channel blocker that is used to suppress contractions by inhibiting calcium from entering smooth muscles

#### NURSING ACTIONS

- Monitor for headache, flushing, dizziness, and nausea. These usually are related to orthostatic hypotension that occurs with administration.
- Should not be administered concurrently with magnesium sulfate, or with or immediately following a beta-adrenergic agonist. **Qs**

#### CLIENT EDUCATION **Qs**

- Slowly change positions from supine to upright, and sit until dizziness disappears.
- Maintain adequate hydration to counter hypotension.

### *Magnesium sulfate*

---

**CLASSIFICATION AND THERAPEUTIC INTENT:** A commonly used tocolytic that is a central nervous system depressant and relaxes smooth muscles, thus inhibiting uterine activity by suppressing contractions

#### NURSING ACTIONS

- Contraindications for tocolysis include active vaginal bleeding, dilation of the cervix greater than 6 cm, chorioamnionitis, greater than 34 weeks of gestation, and acute fetal distress. Do not use concurrently with nifedipine. Do not give to clients who have myasthenia gravis.
- Monitor the client closely. Discontinue tocolytic therapy immediately if the client exhibits manifestations of pulmonary edema, which includes chest pain, shortness of breath, respiratory distress, audible wheezing and crackles, and a productive cough containing blood-tinged sputum.
- Monitor for adverse effects (hot flashes, diaphoresis, burning at IV site, nausea, vomiting, drowsiness, blurred vision, headache, non-reactive nonstress test, reduced fetal heart rate variability). Monitor for magnesium sulfate toxicity and discontinue for any of the following adverse effects: loss of deep tendon reflexes, urinary output less than 30 mL/hr or 100 mL/4 hr, respirations less than 12/min, pulmonary edema, severe hypotension, or chest pain. **Qs**
- Administer calcium gluconate or calcium chloride as an antidote for magnesium sulfate toxicity.

**CLIENT EDUCATION:** Notify the nurse of blurred vision, headache, nausea, vomiting, or difficulty breathing.

### *Terbutaline*

---

**CLASSIFICATION AND THERAPEUTIC INTENT:** A beta-adrenergic agonist that is used as a tocolytic that relaxes smooth muscles and inhibits uterine activity.

#### NURSING ACTIONS

- Assess for history of cardiac disease, pregestational or gestational diabetes, preeclampsia with severe features of eclampsia, severe gestational hypertension, hyperthyroidism, or significant hemorrhage. If the client has any of these, the medication should not be administered.
- Monitor for chest discomfort, palpitations, dysrhythmia, tachycardia, tremors, nervousness, vomiting, hypokalemia, hyperglycemia, and hypotension.
- Notify the provider of heart rate greater than 130/min, chest pain, cardiac arrhythmias, myocardial infarction, blood pressure less than 90/60 mm Hg, or pulmonary edema.
- Administer 0.25 mg subcutaneously every 4 hr, for up to 24 hr.
- Discontinue if the client can't tolerate adverse effects.

### *Indomethacin*

---

**CLASSIFICATION AND THERAPEUTIC INTENT:** Indomethacin is a nonsteroidal anti-inflammatory drug (NSAID) that suppresses preterm labor by blocking the production of prostaglandins. This inhibition of prostaglandins suppresses uterine contractions.

- This medication can cause premature narrowing or closure of the ductus arteriosus in the fetus.

#### NURSING ACTIONS

- Monitor the client closely. Discontinue tocolytic therapy immediately if the client exhibits manifestations of pulmonary edema, which include chest pain, shortness of breath, respiratory distress, audible wheezing and crackles, and a productive cough containing blood-tinged sputum.
- Indomethacin treatment should not exceed 48 hr.
- Indomethacin should only be used if gestational age is less than 32 weeks of gestation.
- Monitor for postpartum hemorrhage related to reduced platelet aggregation.
- Administer indomethacin with food or rectally to decrease gastrointestinal distress.
- Notify the provider if the client reports blurred vision, headache, nausea, vomiting, ringing in the ears, or difficulty breathing.
- Monitor the neonate at birth.

## **Betamethasone**

**CLASSIFICATION AND THERAPEUTIC INTENT:** A glucocorticoid that is administered IM in two injections 24 hr apart, and requires 24 hr to be effective. The therapeutic action is to enhance fetal lung maturity and surfactant production in fetuses between 24 to 34 weeks gestation.

### **NURSING ACTIONS**

- Administer betamethasone 12 mg IM for two doses 24 hr apart.
- Ideally, administer at least 24 hr (but not more than 7 days) before delivery.
- Administer deep IM using ventral gluteal or vastus lateralis muscle.
- Monitor for maternal hyperglycemia.
- Assess the preterm infant's lung sounds.

**CLIENT EDUCATION:** Report findings of pulmonary edema (chest pain, shortness of breath, and crackles).

## *Premature rupture of membranes and preterm premature rupture of membranes*

**Premature rupture of membranes (PROM)** is the spontaneous rupture of the amniotic membranes prior to the onset of true labor. For most clients, PROM signifies the onset of true labor if gestational duration is at term.

**Preterm premature rupture of membranes (PPROM)** is the premature spontaneous rupture of membranes after 20 weeks of gestation and prior to 37 weeks of gestation.

## **ASSESSMENT**

### **RISK FACTORS**

- Infection
- Prior preterm birth
- Shortening of the cervix
- Second/third trimester bleeding.
- Pulmonary or connective tissue disorders
- Low BMI
- Copper or ascorbic acid deficiencies
- Tobacco or substance use

### **EXPECTED FINDINGS**

Client reports a gush or leakage of clear fluid from the vagina.

#### **PHYSICAL ASSESSMENT FINDINGS**

- Presence of clear fluid

#### **Assess for a prolapsed umbilical cord.** Qs

- Abrupt FHR variable or prolonged deceleration
- Visible or palpable cord at the introitus

## **LABORATORY TESTS**

A positive nitrazine paper test (blue, pH 6.5 to 7.5) or positive ferning test is conducted on amniotic fluid to verify rupture of membranes.

## **PATIENT-CENTERED CARE**

### **NURSING CARE**

- Nursing management depends on gestational duration, if there is evidence of infection, or an indication of fetal or maternal compromise.
- Prepare for birth if indicated.
- Obtain vaginal/rectal cultures for streptococcus beta-hemolytic.
- Obtain vaginal cultures for chlamydia and *Neisseria gonorrhoeae*.
- Limit vaginal exams.
- Provide reassurance to reduce anxiety.
- Assess vital signs every 2 hr. Notify the provider of a temperature greater than 38° C (100° F).
- Monitor FHR and uterine contractions.
- Encourage hydration.
- Obtain a CBC.
- Anticipate a prescription for 7-day course of broad spectrum antibiotics.

### **CLIENT EDUCATION**

- Perform daily fetal kick counts and to notify the nurse of uterine contractions.
- Adhere to bed rest with bathroom privileges.

## **MEDICATIONS**

### **Ampicillin**

**CLASSIFICATION AND THERAPEUTIC INTENT:** Ampicillin is an antibiotic used to treat infection. It is commonly used to treat chorioamnionitis.

**NURSING ACTIONS:** Obtain vaginal, urine, and blood cultures prior to administration of antibiotic.

### **Betamethasone**

#### **CLASSIFICATION AND THERAPEUTIC INTENT**

- Betamethasone is a glucocorticoid administered IM in two injections, 24 hr apart, and requires 24 hr to be effective. The therapeutic action is to enhance fetal lung maturity and surfactant production.
- A single dose is given with PROM at 24 to 34 weeks of gestation to reduce the risk of perinatal mortality, respiratory distress syndrome, and other morbidities.
- Betamethasone is given to PROM and PPROM clients between 24 and 34 weeks of gestation to reduce the risk of distress syndrome.

## COMPLICATIONS

### Infection

Infection, particularly chorioamnionitis, is the most common complication of PPROM.

### Other complications

Placental abruption, umbilical cord compression or prolapse, fetal pulmonary hypoplasia, and death

## CLIENT EDUCATION

- Depending on gestational age, treatment is conservative, and hospitalization can prolong pregnancy while monitoring for risk factors (infection, vaginal bleeding, fetal complications).
- Adhere to limited activity with bathroom privileges.
- Hydrate.
- Conduct a self-assessment for uterine contractions.
- Record daily kick counts for fetal movement.
- Monitor for foul-smelling vaginal discharge.
- Refrain from inserting anything into the vagina.
- Abstain from intercourse.
- Avoid tub baths.
- Wipe the perineal area from front to back after voiding and fecal elimination.
- Take temperature every 4 hr when awake and report a temperature that is greater than 38° C (100° F).

### Active Learning Scenario

A nurse in a prenatal clinic is reviewing preterm labor with a newly hired nurse. What should the nurse include in the discussion? Use the ATI Active Learning Template: System Disorder to complete this item.

#### ALTERATION IN HEALTH (DIAGNOSIS)

**EXPECTED FINDINGS:** Describe at least six manifestations.

**DIAGNOSTIC PROCEDURES:** Describe at least three.

## Application Exercises

1. A nurse is caring for a client who reports manifestations of preterm labor. Which of the following findings are risk factors of this condition? (Select all that apply.)
  - A. Urinary tract infection
  - B. Multifetal pregnancy
  - C. Hydramnios
  - D. Diabetes mellitus
  - E. Uterine abnormalities
2. A nurse is providing care for a client who is in preterm labor at 32 weeks of gestation. Which of the following medications should the nurse anticipate the provider will prescribe to hasten fetal lung maturity?
  - A. Calcium gluconate
  - B. Indomethacin
  - C. Nifedipine
  - D. Betamethasone
3. A nurse is caring for a client who is receiving nifedipine for prevention of preterm labor. The nurse should monitor the client for which of the following manifestations?
  - A. Blood-tinged sputum
  - B. Dizziness
  - C. Pallor
  - D. Somnolence
4. A nurse is caring for a client who has a prescription for magnesium sulfate. The nurse should recognize that which of the following are contraindications for use of this medication? (Select all that apply.)
  - A. Fetal distress
  - B. Preterm labor
  - C. Vaginal bleeding
  - D. Cervical dilation greater than 6 cm
  - E. Severe gestational hypertension
5. A nurse is reviewing discharge teaching with a client who has premature rupture of membranes at 26 weeks of gestation. Which of the following instructions should the nurse include in the teaching?
  - A. Use a condom with sexual intercourse.
  - B. Avoid bubble bath solution when taking a tub bath.
  - C. Wipe from the back to front when performing perineal hygiene.
  - D. Keep a daily record of fetal kick counts.

## Application Exercises Key

1. A. **CORRECT:** A urinary tract infection is a risk factor of preterm labor.
- B. **CORRECT:** Multifetal pregnancy is a risk factor of preterm labor.
- C. **CORRECT:** Hydramnios (excessive amniotic fluid) is a risk factor for preterm labor.
- D. **CORRECT:** Diabetes mellitus is a risk factor of preterm labor.
- E. **CORRECT:** Uterine abnormalities are a risk factor of preterm labor.

❷ NCLEX® Connection: *Health Promotion and Maintenance, Health Promotion/Disease Prevention*

2. A. Calcium gluconate is administered as an antidote for magnesium sulfate toxicity.
- B. Indomethacin is an NSAID used to suppress preterm labor by blocking prostaglandin production.
- C. Nifedipine is a calcium channel blocker used to suppress uterine contractions.
- D. **CORRECT:** Betamethasone is a glucocorticoid given to clients in preterm labor to hasten surfactant production.

❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Medication Administration*

3. A. Blood-tinged sputum production is an adverse effect associated with indomethacin.
- B. **CORRECT:** Dizziness and lightheadedness are associated with orthostatic hypotension, which occurs when taking nifedipine.
- C. Facial flushing and heat sensation are adverse effects associated with nifedipine.
- D. Nervousness, jitteriness, and sleep disturbances are adverse effects associated with nifedipine.

❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Adverse Effects/Contraindications/Side Effects/Interactions*

4. A. **CORRECT:** Acute fetal distress is a complication that is a contraindication for use of magnesium sulfate therapy.
- B. Preterm labor is an indication for use of magnesium sulfate.
- C. **CORRECT:** Vaginal bleeding is a complication that is a contraindication for magnesium sulfate therapy.
- D. **CORRECT:** Cervical dilation greater than 6 cm is a complication that is a contraindication for magnesium sulfate therapy.
- E. Severe gestational hypertension is an indication for the use of magnesium sulfate.

❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Adverse Effects/Contraindications/Side Effects/Interactions*

5. A. The client who has ruptured membranes should not insert anything into the vagina.
- B. Instruct the client to avoid tub baths and take showers.
- C. Instruct the client to wipe from front to back when performing perineal hygiene.
- D. **CORRECT:** The client should record daily fetal kick counts.

❷ NCLEX® Connection: *Physiological Adaptation, Illness Management*

## Active Learning Scenario Key

*Using the ATI Active Learning Template: System Disorder*

**ALTERATION IN HEALTH (DIAGNOSIS):** Uterine contractions and cervical changes that occur between 20 and 37 weeks of gestation

### EXPECTED FINDINGS

- Persistent low backache
- Pressure in the pelvis and cramping
- Gastrointestinal cramping, sometimes with diarrhea
- Urinary frequency
- Vaginal discharge
- Increase, change, or blood in vaginal discharge
- Change in cervical dilation
- Regular uterine contractions with a frequency of every 10 min or greater, lasting 1 hr or longer
- Premature rupture of membranes

### DIAGNOSTIC PROCEDURES

- Test for fetal fibronectin
- Ultrasound to measure endocervical length
- Cervical culture to detect presence of infectious organisms
- Biophysical profile
- Nonstress test
- Home uterine activity monitoring for uterine contractions

❷ NCLEX® Connection: *Physiological Adaptation, Illness Management*

When reviewing the following chapters, keep in mind the relevant topics and tasks of the NCLEX outline, in particular:

## *Health Promotion and Maintenance*

---

**ANTE/INTRA/POSTPARTUM AND NEWBORN CARE:** Provide care and education to an antepartum client or client in labor.

## *Basic Care and Comfort*

---

**NON-PHARMACOLOGICAL COMFORT INTERVENTIONS:**  
Incorporate alternative/complementary therapies into client plan of care.

## *Pharmacological and Parenteral Therapies*

---

**ADVERSE EFFECTS/CONTRAINdications/SIDE EFFECTS/INTERACTIONS:** Identify a contraindication to the administration of a medication to the client.

**DOSAGE CALCULATION:** Use clinical decision making/critical thinking when calculating dosages.

**MEDICATION ADMINISTRATION:** Educate client about medications.

## *Reduction of Risk Potential*

---

**DIAGNOSTIC TESTS:** Monitor results of maternal and fetal diagnostic tests.

**POTENTIAL FOR COMPLICATIONS OF DIAGNOSTIC TESTS/TREATMENTS/PROCEDURES:**  
Evaluate responses to procedures and treatments.

**THERAPEUTIC PROCEDURES:** Assess client response to recovery from local, regional, or general anesthesia.

## *Physiological Adaptation*

---

**ALTERATIONS IN BODY SYSTEMS:** Provide care for client experiencing complications of pregnancy/labor and/or delivery.

**UNEXPECTED RESPONSE TO THERAPIES:** Recognize signs and symptoms of client complications and intervene.

# CHAPTER 11 *Labor and Delivery Processes*

An intrapartum nurse should care for three clients during each labor and delivery: the fetus, mother, and family unit. (11.1)

## ASSESSMENT

An intrapartum nurse should collect assessment data on maternal and fetal well-being during labor, the progress of labor, and psychosocial and cultural factors that affect labor. **Q<sub>PCC</sub>**

## 11.1 Stages of labor

FIRST STAGE 12.5 hr duration			SECOND STAGE P: 30 min to 2 hr M: 5 to 30 min	THIRD STAGE 5 to 30 min	FOURTH STAGE 1 to 2 hr
LATENT PHASE P: 6 hr M: 4 hr	ACTIVE PHASE P: 3 hr M: 2 hr	TRANSITION* 20 to 40 min			
Cervical dilation: <b>0 cm</b>	<b>3 cm</b>	<b>4 cm</b>	<b>7 cm</b>	<b>8 cm</b>	<b>10 cm</b>
Onset of labor	Contractions <ul style="list-style-type: none"> <li>More regular, moderate to strong</li> <li>Frequency: 2 to 3' min</li> <li>Duration: 40 to 70 seconds</li> </ul>	Contractions <ul style="list-style-type: none"> <li>Strong to very strong</li> <li>Frequency: 2 to 3' min</li> <li>Duration: 45 to 90 seconds</li> </ul>	Full dilation Progresses to intense contractions every 1 to 2 min	Delivery of the neonate	Delivery of placenta
Contractions <ul style="list-style-type: none"> <li>Irregular, mild to moderate</li> <li>Frequency: 5 to 30 min</li> <li>Duration: 30 to 45 seconds</li> </ul>			Birth		Maternal stabilization of vital signs
Complete dilation					
Some dilation and effacement Talkative and eager	Rapid dilation and effacement Some fetal descent Feelings of helplessness Anxiety and restlessness increase as contractions become stronger	Tired, restless, and irritable Feeling out of control, client often states, "cannot continue" Can have nausea and vomiting Urge to push Increased rectal pressure and feelings of needing to have a bowel movement Increased bloody show Most difficult part of labor	Pushing results in birth of fetus	Placental separation and expulsion Schultze presentation: shiny fetal surface of placenta emerges first Duncan presentation: dull maternal surface of placenta emerges first	Achievement of vital sign homeostasis Lochia scant to moderate rubra

**P = primigravida M = multigravida**

\*Some references only recognize two phases in the first stage of labor: latent (0 to 5 cm) and active (6 to 10 cm).

**Cervical ripening:** Cervix becomes soft (opens) and partially effaced, and can begin to dilate

**Rupture of membranes:** Spontaneous rupture of membranes can initiate labor or can occur anytime during labor, most commonly during the transition phase.

- Labor usually occurs within 24 hr of the rupture of membranes.
- Prolonged rupture of membranes greater than 24 hr before delivery of fetus can lead to an infection.
- Immediately following the rupture of membranes, a nurse should assess the FHR for abrupt decelerations, which are indicative of fetal distress to rule out umbilical cord prolapse. **Qs**

**Assessment of amniotic fluid:** Completed once the membranes rupture

- Amniotic fluid should be watery, clear, and have a slightly yellow tinge.
- Odor should not be foul.
- Volume is between 700 and 1,000 mL.
- Use nitrazine paper to confirm that amniotic fluid is present.
  - **Amniotic fluid is alkaline:** Nitrazine paper is deep blue, indicating pH of 6.5 to 7.5.
  - **Urine is slightly acidic:** Nitrazine paper remains yellow.

## FIVE P'S

There are five factors that affect and define the labor and birth process: **passenger** (fetus and placenta), **passageway** (birth canal), **powers** (contractions), **position** (of the woman), and **psychological** response.

### Passenger

Consists of the fetus and the placenta. The size of the fetal head, fetal presentation, fetal lie, fetal attitude, and fetal position affect the ability of the fetus to navigate the birth canal. The placenta can be considered a passenger because it also must pass through the canal.

**Presentation:** The part of the fetus that is entering the pelvic inlet first and leads through the birth canal during labor. It can be the back of the head (occiput), chin (mentum), shoulder (scapula), or breech (sacrum or feet).

**Lie:** The relationship of the maternal longitudinal axis (spine) to the fetal longitudinal axis (spine)

- **Transverse:** Fetal long axis is horizontal, forms a right angle to maternal axis, and will not accommodate vaginal birth. The shoulder is the presenting part and can require delivery by cesarean birth if the fetus does not rotate spontaneously.
- **Parallel or longitudinal:** Fetal long axis is parallel to maternal long axis, either a cephalic or breech presentation. Breech presentation can require a cesarean birth.

**Attitude:** Relationship of fetal body parts to one another

- **Fetal flexion:** Chin flexed to chest, extremities flexed into torso
- **Fetal extension:** Chin extended away from chest, extremities extended

**Fetopelvic or fetal position:** The relationship of the presenting part of the fetus (sacrum, mentum, or occiput), preferably the occiput, in reference to its directional position as it relates to one of the four maternal pelvic quadrants. It is labeled with three letters.

- **Right (R) or left (L):** The first letter references the side of the maternal pelvis.
- **Occiput (O), sacrum (S), mentum (M), or scapula (Sc):** The second letter references the presenting part of the fetus.
- **Anterior (A), posterior (P), or transverse (T):** The third letter references the part of the maternal pelvis.

**Station:** Measurement of fetal descent in centimeters with station 0 being at the level of an imaginary line at the level of the ischial spines, minus stations superior to the ischial spines, and plus stations inferior to the ischial spines.

### Passageway

The birth canal that is composed of the bony pelvis, cervix, pelvic floor, vagina, and introitus (vaginal opening). The size and shape of the bony pelvis must be adequate to allow the fetus to pass through it. The cervix must dilate and efface in response to contractions and fetal descent.

### Powers

Uterine contractions cause effacement (shortening and thinning of the cervix) during the first stage of labor and dilation of the cervix (enlargement or widening of the cervical opening and canal) that occurs once labor has begun and the fetus is descending. Involuntary urge to push and voluntary bearing down in the second stage of labor helps in the expulsion of the fetus.

### Position

The client should engage in frequent position changes during labor to increase comfort, relieve fatigue, and promote circulation. Position during the second stage is determined by maternal preference, provider preference, and the condition of the mother and the fetus.

Gravity can aid in the fetal descent in upright, sitting, kneeling, and squatting positions.

### Psychological response

Maternal stress, tension, and anxiety can produce physiological changes that impair the progress of labor.

## PATIENT-CENTERED CARE

### PREPROCEDURE

#### NURSING ACTIONS

- Leopold maneuvers:** Abdominal palpation of the fetal presenting part, lie, attitude, descent, and the probable location where fetal heart tones can be best auscultated on the client's abdomen
- External electronic monitoring (tocotransducer):** Separate transducer applied to the maternal abdomen over the fundus that measures uterine activity
  - Displays uterine contraction patterns
  - Easily applied by the nurse but must be repositioned with maternal movement to ensure proper placement
- External fetal monitoring (EFM):** Transducer applied to the abdomen of the client to assess FHR patterns during labor and birth

#### LABORATORY ANALYSIS

- Group B streptococcus:** Culture is obtained if results are not available from screening at 35 to 37 weeks. If positive, an intravenous prophylactic antibiotic is prescribed. **Qs**
- Urinalysis:** Clean-catch urine sample obtained to assess the client for:
  - Dehydration via specific gravity
  - Ketonuria (impaired nutrition or uncontrolled glucose)
  - Proteinuria, which can be indicative of gestational hypertension or preeclampsia
  - Glucosuria which can be indicative of gestational diabetes
  - Urinary tract infection (UTI) via bacterial count (more common in clients who have diabetes mellitus)
- Blood tests**
  - CBC level
  - ABO typing and Rh-factor if not previously done

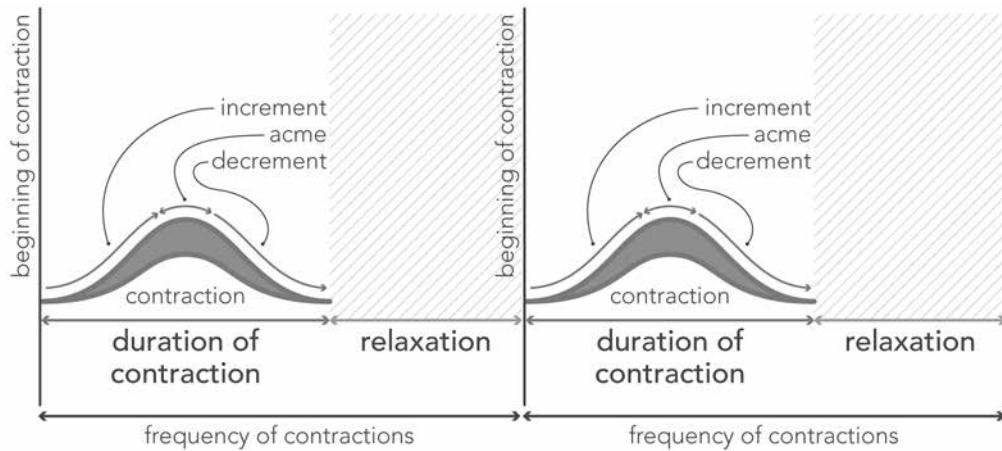

**CLIENT EDUCATION:** The health care team will update you regarding the labor and delivery process. Ask questions for any procedures or information you do not understand.

### INTRAPROCEDURE

#### NURSING ACTIONS

- Assess maternal vital signs** per agency protocol. Check maternal temperature every 2 hr if membranes are ruptured.
- Assess FHR** to determine fetal well-being. This can be performed by use of EFM or spiral electrode that is applied to the fetal scalp. Prior to electrode placement, cervical dilation and rupture of membranes must occur.
- Assess uterine labor contraction characteristics** by palpation (placing a hand over the fundus to assess contraction frequency, duration, and intensity) or by the use of external or internal monitoring. **(11.2)**
  - Frequency:** Established from the beginning of one contraction to the beginning of the next
  - Duration:** Time between the beginning of a contraction to the end of that same contraction
  - Intensity:** Strength of the contraction at its peak, described as mild (slightly tense, like pressing finger to tip of nose), moderate (firm, like pressing finger to chin), or strong (rigid, like pressing finger to forehead)
  - Resting tone of uterine contractions:** Tone of the uterine muscle in between contractions. A prolonged contraction duration (greater than 90 seconds) or too frequent contractions (more than five in a 10-min period) without sufficient time for uterine relaxation (less than 30 seconds) in between can reduce blood flow to the placenta. This can result in fetal hypoxia and decreased FHR. **Qs**
- Intrauterine pressure catheter:** Insert a sterile solid or fluid-filled intrauterine pressure catheter inside the uterus to measure intrauterine pressure.
  - Displays uterine contraction patterns on monitor
  - Requires the membranes to be ruptured and the cervix to be sufficiently dilated

#### 11.2 Contraction pattern

- **Vaginal examination:** Performed digitally by the provider or qualified nurse to assess for the following:
  - Cervical dilation (stretching of cervical os adequate to allow fetal passage) and effacement (cervical thinning and shortening) (11.3)
  - Descent of the fetus through the birth canal as measured by fetal station in centimeters
  - Fetal position, presenting part, and lie
  - Membranes that are intact or ruptured
- **Mechanism of labor in vertex presentation:** The adaptations the fetus makes as it progresses through the birth canal during the birthing process
  - **Engagement:** Occurs when the presenting part, usually biparietal (largest) diameter of the fetal head passes the pelvic inlet at the level of the ischial spines, referred to as station 0.
  - **Descent:** The progress of the presenting part (preferably the occiput) through the pelvis. Measured by station during a vaginal examination as either negative (-) station measured in centimeters if superior to station 0 and not yet engaged, or positive (+) station measured in centimeters if inferior to station 0.
  - **Flexion:** When the fetal head meets resistance of the cervix, pelvic wall, or pelvic floor. The head flexes, bringing the chin close to the chest, presenting a smaller diameter to pass through the pelvis.
  - **Internal rotation:** The fetal occiput ideally rotates to a lateral anterior position as it progresses from the ischial spines to the lower pelvis in a corkscrew motion to pass through the pelvis.
  - **Extension:** The fetal occiput passes under the symphysis pubis, and then the head is deflected anteriorly and is born by extension of the chin away from the fetal chest.
  - **External rotation (restitution):** After the head is born, it rotates to the position it occupied as it entered the pelvic inlet (restitution) in alignment with the fetal body and completes a quarter turn to face transverse as the anterior shoulder passes under the symphysis.
  - **Birth by expulsion:** After birth of the head and shoulders, the trunk of the neonate is born by flexing it toward the symphysis pubis.

### 11.3 Characteristics of true vs. false labor

True labor leads to cervical dilation and effacement.  
 True labor  
 Contractions  
 Can begin irregularly, but become regular in frequency  
 Stronger, last longer, and are more frequent  
 Felt in lower back, radiating to abdomen  
 Walking can increase contraction intensity  
 Continue despite comfort measures  
 Cervix (assessed by vaginal exam)  
 Progressive change in dilation and effacement  
 Moves to anterior position  
 Bloody show  
 Fetus: Presenting part engages in pelvis

## POSTPROCEDURE

### NURSING ASSESSMENTS DURING THE FOURTH STAGE

- Maternal vital signs
- Fundus
- Lochia
- Perineum
- Urinary output
- Maternal/newborn baby-friendly activities

### NURSING ACTIONS DURING THE FOURTH STAGE

- American Academy of Pediatrics and American College of Obstetricians and Gynecologists recommend that blood pressure and pulse be assessed at least every 15 min for the first 2 hr after birth, and that temperature be assessed every 4 hr for the first 8 hr after birth and then at least every 8 hr.
- Assess fundus and lochia every 15 min for the first hour and then according to facility protocol.
- Massage the uterine fundus and/or administer oxytocics as prescribed to maintain uterine tone to prevent hemorrhage. *Qs*
- Assess the client's perineum, and provide comfort measures as indicated.
- Encourage voiding to prevent bladder distention.
- Promote an opportunity for maternal/newborn bonding.
- Offer assistance with breastfeeding, and provide reassurance.

**CLIENT EDUCATION:** Notify the nurse of increased vaginal bleeding or passage of blood clots.

False labor  
 Contractions  
 Painless, irregular frequency, and intermittent  
 Decrease in frequency, duration, and intensity with walking or position changes  
 Felt in lower back or abdomen above umbilicus  
 Often stop with sleep or comfort measures (oral hydration, emptying of the bladder)  
 Cervix (assessed by vaginal exam)  
 No significant change in dilation or effacement  
 Often remains in posterior position  
 No significant bloody show  
 Fetus: Presenting part is not engaged in pelvis

## Application Exercises

1. A client calls a provider's office and reports having contractions for 2 hr that increased with activity and did not decrease with rest and hydration. The client denies leaking of vaginal fluid but did notice blood when wiping after voiding. Which of the following manifestations is the client experiencing?
  - A. Braxton Hicks contractions
  - B. Rupture of membranes
  - C. Fetal descent
  - D. True contractions
2. A nurse is caring for a client having contractions every 8 min that are 30 to 40 seconds in duration. The client's cervix is 2 cm dilated, 50% effaced, and the fetus is at a -2 station with a FHR around 140/min. Which of the following stages and phases of labor is this client experiencing?
  - A. First stage, latent phase
  - B. First stage, active phase
  - C. First stage, transition phase
  - D. Second stage of labor
3. A nurse is caring for a client who is 40 weeks of gestation and reports having large gush of fluid from the vagina while walking from the bathroom. Which of the following actions should the nurse take first?
  - A. Examine the amniotic fluid for meconium.
  - B. Check the FHR.
  - C. Dry the client and make them comfortable.
  - D. Apply a tocotransducer.
4. A nurse is completing an admission assessment for a client who is 39 weeks of gestation and reports fluid leaking from the vagina for 2 days. Which of the following conditions is the client at risk for developing?
  - A. Cord prolapse
  - B. Infection
  - C. Postpartum hemorrhage
  - D. Hydramnios
5. A nurse is caring for a client who is in active labor, irritable, and reports the urge to have a bowel movement. The client vomits and states, "I've had enough. I can't do this anymore." Which of the following stages of labor is the client experiencing?
  - A. Second stage
  - B. Fourth stage
  - C. Transition phase
  - D. Latent phase

## Active Learning Scenario

A manager of a labor and delivery unit is reviewing the procedure for vaginal examinations with a group of newly hired nurses. Use the ATI Active Learning Template: Therapeutic Procedure to complete this item.

**NURSING INTERVENTIONS:** Describe four actions that are preprocedure, intraprocedure, and postprocedure.

**OUTCOMES/EVALUATION:** Describe three assessment findings that can be determined by the procedure.

## Application Exercises Key

1. A. Braxton Hicks contractions decrease with hydration and walking.
- B. Rupture of membranes would be indicated by the presence of a gush of fluid that is unrelated to the client's activity.
- C. Fetal descent is the downward movement of the fetus in the birth canal and cannot be evaluated based on the client's report.
- D. **CORRECT:** True contractions do not go away with hydration or walking. They are regular in frequency, duration, and intensity and become stronger with walking.

❷ NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

2. A. **CORRECT:** In stage 1, latent phase, the cervix dilates from 0 to 3 cm, and contraction duration ranges from 30 to 45 seconds.
- B. In stage 1, active phase, the cervix dilates from 4 to 7 cm, and contraction duration ranges from 40 to 70 seconds.
- C. In stage 1, transition phase, the cervix dilates from 8 to 10 cm, and contraction duration ranges from 45 to 90 seconds.
- D. The second stage of labor consists of the expulsion of the fetus.

❷ NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

3. A. Assess the color, clarity, odor, and amount of amniotic fluid, but this is not the first action to take.
- B. **CORRECT:** The greatest risk to the client and fetus is umbilical cord prolapse, leading to fetal distress following rupture of membranes. The first action to take is to check the FHR for clinical findings of distress.
- C. Provide comfort by drying the client following rupture of the membranes, but this is not the first action to take.
- D. Apply a tocotransducer to the client's uterine contraction pattern after rupture of the membranes, but this is not the first action to take.

❷ NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

4. A. Although cord prolapse is a risk with rupture of membranes, it occurs when the fluid rushes out, rather than trickling or leaking out.
- B. **CORRECT:** Rupture of membranes for longer than 24 hr prior to delivery increases the risk that infectious organisms will enter the vagina and then eventually into the uterus.
- C. The risk for postpartum hemorrhage by this client is not any greater than other clients who are pregnant.
- D. This client is more likely to have oligohydramnios or insufficient amniotic fluid, rather than hydramnios, or excess amniotic fluid.

❷ NCLEX® Connection: Physiological Adaptation, Alterations in Body Systems

5. A. The second stage of labor occurs with the expulsion of the fetus.
- B. The fourth stage of labor is the recovery period, following the delivery of the placenta.
- C. **CORRECT:** The transition phase of labor occurs when the client becomes irritable, feels rectal pressure similar to the need to have a bowel movement, and can become nauseous with emesis.
- D. The latent phase of labor occurs in stage one and coincides with mild contractions. The client is more relaxed, talkative, and eager for labor to progress.

❷ NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

## Active Learning Scenario Key

Using the ATI Active Learning Template: Therapeutic Procedure

### NURSING ACTIONS

- Provide for privacy.
- Explain procedure, and obtain client's permission for the examination.
- Don sterile glove with antiseptic solution or soluble gel for lubrication.
- Position the client to avoid supine hypotension.
- Cleanse the vulva or perineum if needed.
- Insert index and middle finger into the client's vagina.
- Explain findings to the client.
- Document findings, and report to the provider.

### OUTCOMES/EVALUATION

- Cervical dilation, effacement, and position
- Fetal presenting part, position, and station
- Status of membranes
- Characteristics of amniotic fluid if membranes ruptured

❷ NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

## CHAPTER 12 Pain Management

Pain is a subjective and individual experience, and each client's response to the pain of labor is unique. Safety for the mother and fetus must be the first consideration of the nurse when planning pain management measures. *Qs*

### SOURCES OF PAIN DURING LABOR

#### *First stage*

Internal visceral pain that can be felt as back and leg pain

##### PAIN CAUSES

- Dilation, effacement, and stretching of the cervix
- Distention of the lower segment of the uterus
- Contractions of the uterus with resultant uterine ischemia

#### *Second stage*

Pain that is somatic and occurs with fetal descent and expulsion

##### PAIN CAUSES

- Pressure and distention of the vagina and the perineum, described by the client as burning, splitting, and tearing
- Pressure and pulling on the pelvic structures (ligaments, fallopian tubes, ovaries, bladder, and peritoneum)
- Lacerations of soft tissues (cervix, vagina, and perineum)

#### *Third stage*

Pain with the expulsion of the placenta is similar to pain experienced during the first stage.

##### PAIN CAUSES

- Uterine contractions
- Pressure and pulling of pelvic structures

#### *Fourth stage*

Pain is caused by distention and stretching of the vagina and perineum incurred during the second stage with a splitting, burning, and tearing sensation.

### PAIN ASSESSMENT

- Pain level cannot always be assessed by monitoring the outward expressions of a client. Client pain assessment can require persistent questioning and astute observation by the nurse. Cultural beliefs and behaviors of clients during labor and delivery can affect the client's pain management.
- Anxiety and fear are associated with pain. As fear and anxiety increase, muscle tension increases, and thus the experience of pain increases, becoming a cycle of pain. Fear, tension, and pain slow the progression of labor.
- Assess beliefs and expectations related to discomfort, pain relief, and birth plans regarding pain relief methods for clients in labor.
- Assess level, quality, frequency, duration, intensity, and location of pain through verbal and nonverbal cues. Use an appropriate pain scale allowing the client to indicate the severity of their pain on a scale of 0 to 10, with 10 representing the most severe pain.
- INDICATIONS OF PAIN
  - Behavioral manifestations (crying, moaning, screaming, gesturing, writhing, avoidance, withdrawal, inability to follow instructions)
  - Increasing blood pressure, tachycardia, and hyperventilation
  - Nausea and vomiting with an increase in gastric acidity
- Help the client maintain the proper position during administration of pharmacological interventions. Assist the client with positioning for comfort during labor and birth, and following pharmacological interventions.
- Provide client safety after any pharmacological intervention by putting the bed in a low position, maintaining side rails in the up position, placing the call light within the client's reach, and advising the client and their partner to call for assistance if they need to leave the bed or ambulate. *Qs*
- Evaluate the client's response to pain relief methods used (verbal report that pain is relieved or being relieved, appears relaxed between contractions). (12.1)

#### 12.1 Appropriate pain relief measures during labor

	FIRST STAGE	SECOND STAGE	VAGINAL BIRTH	CESAREAN BIRTH
Opioid agonist analgesics	✓			
Opioid agonist-antagonist analgesics	✓			
Epidural (block) analgesia	✓	✓	✓	
Epidural (block) anesthesia			✓	✓
Combined spinal-epidural (CSE) analgesia	✓	✓	✓	
Nitrous oxide	✓	✓	✓	
Local infiltration anesthesia		✓	✓	
Pudendal block		✓	✓	
Spinal (block) anesthesia		✓	✓	✓
General anesthesia				✓

## **NONPHARMACOLOGICAL PAIN MANAGEMENT**

Nonpharmacological pain management measures reduce anxiety, fear, and tension, which are major contributing factors to pain in labor.

### **GATE-CONTROL THEORY OF PAIN**

- Based on the concept that the sensory nerve pathways that pain sensations use to travel to the brain will allow only a limited number of sensations to travel at any given time. By sending alternate signals through these pathways, the pain signals can be blocked from ascending the neurologic pathway and inhibit the brain's perception and sensation of pain.
- Assists in the understanding of how nonpharmacological pain techniques can work to relieve pain.

### **INTERVENTIONS**

#### *Cognitive strategies*

- Childbirth education
- Childbirth preparation methods (Lamaze, patterned breathing exercises) promote relaxation and pain management.
- Doulas can assist clients using methods for nonpharmacological pain management.
- Nursing implications include assessing for findings of hyperventilation (caused by low blood levels of PCO<sub>2</sub> from blowing off too much CO<sub>2</sub>), such as lightheadedness and tingling of the fingers. If this occurs, have the client breathe into a paper bag or their cupped hands.
- Hypnosis
- Biofeedback

#### *Sensory stimulation strategies*

Based on the gate-control theory to promote relaxation and pain relief

- Aromatherapy
- Breathing techniques
- Imagery
- Music
- Use of focal points
- Subdued lighting

#### *Cutaneous stimulation strategies*

Based on the gate-control theory to promote relaxation and pain relief

- Therapeutic touch and massage: back rubs and massage
- Walking
- Rocking
- Effleurage: Light, gentle circular stroking of the client's abdomen with the fingertips in rhythm with breathing during contractions
- Sacral counterpressure: Consistent pressure is applied by the support person using the heel of the hand or fist against the client's sacral area to counteract pain in the lower back

- Application of heat or cold
- Transcutaneous electrical nerve stimulation (TENS) therapy
- Hydrotherapy (whirlpool or shower) increases maternal endorphin levels
- Acupressure
- Frequent maternal position changes to promote relaxation and pain relief
  - Semi-sitting
  - Squatting
  - Kneeling
  - Kneeling and rocking back and forth
  - Supine position only with the placement of a wedge under one of the client's hips to tilt the uterus and avoid supine hypotension syndrome

**CLIENT EDUCATION:** Perform techniques to promote pain management (patterned breathing, progressive relaxation exercises).

## **PHARMACOLOGICAL PAIN MANAGEMENT**

Includes analgesia and local/regional analgesics. To avoid slowing the progress of labor, prior to administering analgesic medications, the nurse should verify that labor is well established by performing a vaginal exam and evaluating uterine contraction pattern. 

Alleviates pain sensations or raises the threshold for pain perception

### **ANALGESIA**

#### *Sedatives (barbiturates)*

Sedatives (secobarbital, pentobarbital, phenobarbital) are not typically used during birth, but they can be used during the early or latent phase of labor to relieve anxiety and induce sleep.

#### **ADVERSE EFFECTS**

- Neonate respiratory depression secondary to the medication crossing the placenta and affecting the fetus. These medications should not be administered if birth is anticipated within 12 to 24 hr. 
- Unsteady ambulation of the client.
- Inhibition of the mother's ability to cope with the pain of labor. Sedatives should not be given if the client is experiencing pain because apprehension can increase and cause the client to become hyperactive and disoriented.

#### **CLIENT EDUCATION**

- The medication will cause drowsiness.
- Request assistance with ambulation.

#### **NURSING ACTIONS**

- Dim the lights, and provide a quiet atmosphere.
- Provide safety for the client by lowering the position of the bed and elevating the side rails.
- Assist the mother to cope with labor. 
- Assess the neonate for respiratory depression.

## Opioid analgesics

Opioid analgesics (meperidine hydrochloride, fentanyl, butorphanol, nalbuphine) act in the CNS to decrease the perception of pain without the loss of consciousness. The client can receive opioid analgesics IM or IV, but the IV route is recommended during labor because the action is quicker. These are usually given during the early part of active labor.

**Butorphanol and nalbuphine** provide pain relief without causing significant respiratory depression in the mother or fetus. Both IM and IV routes are used.

### ADVERSE EFFECTS

- Respiratory depression in the neonate if mother medicated too close to time of delivery
- Reduction of gastric emptying; increased risk for nausea and emesis
- Increased risk for aspiration of food or fluids in the stomach
- Bladder and bowel elimination can be inhibited
- Sedation
- Altered mental status
- Tachycardia
- Hypotension
- Decreased FHR variability
- Allergic reaction

### NURSING ACTIONS

- Prior to administering analgesic medication, verify that labor is well established by performing a vaginal exam.
- Administer antiemetics as prescribed.
- Monitor maternal vital signs, uterine contraction pattern, and continuous FHR monitoring. Assess maternal vital signs and fetal heart rate and pattern and documented before and after administration of opioids for pain relief.
- Assess for adverse reactions (difficulty breathing) and be prepared to administer antidotes whenever medications are administered.

Naloxone, an opioid antagonist, should be readily available for reversal of opioid-induced respiratory depression. **Qs**

### CLIENT EDUCATION

- The medication will cause drowsiness.
- Request assistance with ambulation.

## Metoclopramide

Can control nausea and anxiety. Does not relieve pain and is used as an adjunct with opioids.

**ADVERSE EFFECTS:** Dry mouth and sedation

### NURSING ACTIONS

- Provide ice chips or mouth swabs.
- Provide safety measures for the client.

## Epidural and spinal regional analgesia

Consists of using analgesics such as fentanyl and sufentanil, which are short-acting opioids that are administered as a motor block into the epidural or intrathecal space without anesthesia. These opioids produce regional analgesia, providing rapid pain relief while still allowing the client to sense contractions and maintain the ability to bear down.

### ADVERSE EFFECTS

- Decreased gastric emptying resulting in nausea and vomiting
- Inhibition of bowel and bladder elimination sensations
- Bradycardia or tachycardia
- Hypotension
- Respiratory depression
- Allergic reaction and pruritus
- Elevated temperature

### NURSING ACTIONS

- Institute safety precautions, such as putting side rails up on the client's bed. The client can experience dizziness and sedation, which increases maternal risk for injury. **Qs**
- Assess for nausea and emesis, and administer antiemetics as prescribed.
- Monitor maternal vital signs per facility protocol.
- Monitor for allergic reaction.
- Continue FHR pattern monitoring.

## PHARMACOLOGICAL ANESTHESIA

- Pharmacological anesthesia eliminates pain perceptions by interrupting the nerve impulses to the brain.
- Anesthesia used in childbirth includes regional blocks and general anesthesia.

### Regional blocks

Regional blocks are most commonly used and consist of pudendal, epidural, spinal, and paracervical nerve block.

### Pudendal block

Consists of a local anesthetic (lidocaine, bupivacaine) administered transvaginally into the space in front of the pudendal nerve. This type of block has no maternal or fetal systemic effects, but it does provide local anesthesia to the perineum, vulva, and rectal areas during delivery, episiotomy, and episiotomy repair. It is administered during the late second stage of labor 10 to 20 min before delivery, providing analgesia prior to spontaneous expulsion of the fetus or forceps-assisted or vacuum-assisted birth. It is suitable during the second and third stages of labor and for repair of episiotomy and lacerations.

- **ADVERSE EFFECTS:** Compromise of maternal bearing down reflex
- **NURSING ACTIONS**
  - Instruct the client about the method.
  - Coach the client about when to bear down.

## Epidural block

Consists of a local anesthetic, bupivacaine, along with an analgesic, morphine or fentanyl, injected into the epidural space at the level of the fourth or fifth vertebrae. This eliminates pain from the level of the umbilicus to the thighs, relieving the discomfort of uterine contractions, fetal descent, and stretching of the perineum. However, this might not remove pressure sensations. It is administered when the client is in active labor and dilated to at least 4 cm. Continuous infusion or intermittent injections can be administered through an indwelling epidural catheter. Patient-controlled epidural analgesia is a technique for labor analgesia and is a favored method of pain management for labor and birth. It is suitable for all stages of labor and types of birth and for repair of episiotomy and lacerations.

- **ADVERSE EFFECTS**

- Maternal hypotension
- Fetal bradycardia
- Fever
- Itching
- Inability to feel the urge to void
- Urinary retention
- Loss of the bearing down reflex

- **NURSING ACTIONS**

- Administer a bolus of IV fluids to help offset maternal hypotension. **Q<sub>EBP</sub>**
- Help position and steady the client into a sitting or side-lying modified Sims' position with the back curved to widen the intervertebral space for insertion of the epidural catheter.
- Encourage the client to remain in the side-lying position after insertion of the epidural catheter to avoid supine hypotension syndrome with compression of the vena cava.
- Coach the client in pushing efforts, and request an evaluation of epidural pain management by anesthesia personnel if pushing efforts are ineffective.
- Monitor maternal blood pressure and pulse, and observe for hypotension, respiratory depression, and decreased oxygen saturation.
- Assess FHR patterns continuously.
- Maintain the IV line, and have oxygen and suction available.
- Assess for orthostatic hypotension. Be prepared to administer an IV vasopressor (such as ephedrine), position the client laterally, increase the rate of IV fluid administration, and initiate oxygen. **Q<sub>s</sub>**
- Provide for client safety, such as by raising the side rails of the bed. Do not allow the client to ambulate unassisted.
- Assess the bladder for distention at frequent intervals, and catheterize if necessary to prevent discomfort and interference with uterine contractions.
- Monitor for the return of sensation and motor control in the client's legs after delivery but prior to standing. Assist the client with standing and walking for the first time after a delivery that included epidural anesthesia.
- **CLIENT EDUCATION:** Use patient-controlled analgesia, if provided.

## Spinal anesthesia (block)

Consists of a local anesthetic that is injected into the subarachnoid space into the spinal fluid at the third, fourth, or fifth lumbar interspace. This can be done alone or in combination with an analgesic such as fentanyl. The spinal block eliminates all sensations from the level of the nipples to the feet. It is commonly used for cesarean births. A low spinal block can be used for a vaginal birth, but it is not used for labor. A spinal block is administered in the late second stage or before cesarean birth.

- **ADVERSE EFFECTS**

- Maternal hypotension
- Fetal bradycardia
- Loss of the bearing down reflex in the client with a higher incidence of operative births
- Potential headache from leakage of cerebrospinal fluid at the puncture site
- Higher incidence of maternal bladder and uterine atony following birth

- **NURSING ACTIONS**

- Assess maternal vital signs every 10 min.
- Manage maternal hypotension by administering an IV fluid bolus as prescribed, positioning the client laterally, increasing the rate of IV fluid administration, and initiating oxygen. **Q<sub>s</sub>**
- Assess uterine contractions.
- Assess level of anesthesia.
- Assess FHR patterns.
- Provide client safety to prevent injury by raising the side rails of the bed, and assisting the client with repositioning.
- Recognize manifestations of impending birth, including sitting on one buttock, making grunting sounds, and bulging of the perineum.
- Encourage interventions to relieve a postpartum headache resulting from a cerebrospinal fluid leak. Interventions include placing the client in a supine position, promoting bed rest in a dark room, and administering oral analgesics, caffeine, and fluids. An autologous blood patch is the most beneficial and reliable relief measure for cerebrospinal fluid leaks.

- **CLIENT EDUCATION:** Bear down for expulsion of the fetus because during a vaginal birth, contractions will not be felt.

## General anesthesia

Rarely used for vaginal or cesarean births when there are no complications present. It is used only in the event of a delivery complication or emergency when there is a contraindication to nerve block analgesia or anesthesia. General anesthesia produces unconsciousness.

### NURSING ACTIONS

- Monitor maternal vital signs.
- Monitor FHR patterns.
- Ensure that the client has had nothing by mouth.
- Ensure that the IV infusion is in place.
- Apply antiembolic stockings or sequential compression devices.
- Premedicate the client with oral antacid to neutralize acidic stomach contents.
- Administer a histamine<sub>2</sub>-receptor antagonist, such as famotidine, to decrease gastric acid production.
- Administer metoclopramide to increase gastric emptying as prescribed.
- Place a wedge under one of the client's hips to displace the uterus.
- Maintain an open airway and cardiopulmonary function.
- Assess the client postpartum for decreased uterine tone, which can lead to hemorrhage and be produced by pharmacological agents used in general anesthesia. **Qs**

**CLIENT EDUCATION:** Facilitate parent-newborn attachment as soon as possible.

### Active Learning Scenario

A nurse in a prenatal clinic is teaching a childbirth education class on methods to promote relaxation and pain management to a group of clients in the third trimester. What nonpharmacological pain management strategies should the nurse include in the discussion? Use the ATI Active Learning Template: Basic Concept to complete this item.

**UNDERLYING PRINCIPLES:** Describe the underlying principle for the use of sensory stimulation and cutaneous strategies.

### RELATED CONTENT

- Describe three sensory stimulation strategies.
- Describe three cutaneous strategies.

## Application Exercises

1. A nurse is caring for a client who is at 40 weeks of gestation and experiencing contractions every 3 to 5 min and becoming stronger. A vaginal exam reveals that the client's cervix is 3 cm dilated, 80% effaced, and -1 station. The client asks for pain medication. Which of the following actions should the nurse take? (Select all that apply.)
  - A. Encourage use of patterned breathing techniques.
  - B. Insert an indwelling urinary catheter.
  - C. Administer opioid analgesic medication.
  - D. Suggest application of cold.
  - E. Provide ice chips.
2. A nurse is caring for a client who is in active labor. The client reports lower-back pain. The nurse suspects that this pain is related to a persistent occiput posterior fetal position. Which of the following nonpharmacological nursing interventions should the nurse recommend to the client?
  - A. Abdominal effleurage
  - B. Sacral counterpressure
  - C. Showering if not contraindicated
  - D. Back rub and massage
3. A nurse is caring for a client following the administration of an epidural block and is preparing to administer an IV fluid bolus. The client's partner asks about the purpose of the IV fluids. Which of the following statements should the nurse make?
  - A. "It is needed to promote increased urine output."
  - B. "It is needed to counteract respiratory depression."
  - C. "It is needed to counteract hypotension."
  - D. "It is needed to prevent oligohydramnios."
4. A nurse is caring for a client who is in the second stage of labor. The client's labor has been progressing, and a vaginal delivery is expected in 20 min. The provider is preparing to administer lidocaine for pain relief and perform an episiotomy. The nurse should know that which of the following types of regional anesthetic block is to be administered?
  - A. Pudendal
  - B. Epidural
  - C. Spinal
  - D. Paracervical
5. A nurse is caring for a client who is using patterned breathing during labor. The client reports numbness and tingling of the fingers. Which of the following actions should the nurse take?
  - A. Administer oxygen via nasal cannula at 2 L/min.
  - B. Apply a warm blanket.
  - C. Assist the client to a side-lying position.
  - D. Place an oxygen mask over the client's nose and mouth.

## Application Exercises Key

1. A. **CORRECT:** The use of patterned breathing techniques can assist with pain management at this time.
- B. There is no indication for the insertion of an indwelling urinary catheter at this time.
- C. **CORRECT:** An opioid analgesic can be safely administered at this time.
- D. **CORRECT:** The use of a non-pharmacological approach, such as the application of cold, is an appropriate intervention at this time.
- E. This action does not address the client's request for assistance with pain management.

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

2. A. Abdominal effleurage is an appropriate pain management technique but does not address the pressure on the pelvis due to the fetal position.
- B. **CORRECT:** Sacral counterpressure to the lower back relieves the pressure exerted on the pelvis and spinal nerves by the fetus.
- C. A shower is an appropriate pain management strategy but does not address the pressure on the pelvis due to the fetal position.
- D. A back rub with massage is an appropriate pain management strategy but does not address the pressure on the pelvis due to the fetal position.

NCLEX® Connection: *Basic Care and Comfort, Non-Pharmacological Comfort Interventions*

3. A. Urinary output is not affected by an epidural block.
- B. Oxygen is administered to counteract respiratory depression that can occur following an epidural block.
- C. **CORRECT:** Maternal hypotension can occur following an epidural block and can be offset by administering an IV fluid bolus.
- D. Oligohydramnios does not occur as a result of an epidural block.

NCLEX® Connection: *Pharmacological and Parenteral Therapies, Medication Administration*

4. A. **CORRECT:** A pudendal block is a transvaginal injection of local anesthetic that anesthetizes the perineal area for the episiotomy and repair, and the expulsion of the fetus.
- B. Epidural blocks are administered during labor and allow the client to participate in the second stage while remaining comfortable.
- C. Spinal blocks are administered in the late second stage but most commonly preceding a cesarean birth.
- D. Paracervical blocks are used early in labor to block pain of uterine contractions but are rarely used today.

NCLEX® Connection: *Reduction of Risk Potential, Therapeutic Procedures*

5. A. The client is experiencing hyperventilation caused by low levels of blood PCO<sub>2</sub>. Supplying additional oxygen will not resolve this issue.
- B. The client is experiencing hyperventilation caused by low levels of blood PCO<sub>2</sub>. Applying a warm blanket will not resolve this issue.
- C. The client is experiencing hyperventilation caused by low blood levels of PCO<sub>2</sub>. Assisting the client to a side-lying position will not resolve this issue.
- D. **CORRECT:** The client is experiencing hyperventilation caused by low blood levels of PCO<sub>2</sub>. Placing an oxygen mask over the client's nose and mouth or having the client breathe into a paper bag will reduce the intake of oxygen, allowing the PCO<sub>2</sub> to rise and alleviate the numbness and tingling.

NCLEX® Connection: *Reduction of Risk Potential, Potential for Complications from Surgical Procedures and Health Alterations*

## Active Learning Scenario Key

Using the ATI Active Learning Template: Basic Concept

Underlying Principles: Gate control theory of pain is based on the concept that the sensory nerve pathways that pain sensations use to travel to the brain will allow only a limited number of sensations to travel at any given time. By sending alternate signals through these pathways, the pain signals can be blocked from ascending the neurologic pathway and inhibit the brain's perception and sensation of pain.

NCLEX® Connection: *Basic Care and Comfort, Non-Pharmacological Comfort Interventions*

**CHAPTER 13** *Fetal Assessment During Labor*

---

The diagnostic procedures mentioned in this chapter include Leopold maneuvers, and fetal heart rate (FHR) pattern and uterine contraction monitoring.

### *Leopold maneuvers*

Leopold maneuvers consist of performing external palpations of the maternal uterus through the abdominal wall to determine the following.

- Presenting part, fetal lie, and fetal attitude
- Degree of descent of the presenting part into the pelvis
- Location of the fetus's back to assess for fetal heart tones
  - **Vertex presentation:** Fetal heart tones should be assessed below the client's umbilicus in either the right- or left-lower quadrant of the abdomen.
  - **Breech presentation:** Fetal heart tones should be assessed above the client's umbilicus in either the right- or left-upper quadrant of the abdomen.

### **CONSIDERATIONS**

#### **PREPARATION OF THE CLIENT**

- Ask the client to empty the bladder before beginning the assessment.
- Place the client in the supine position with a pillow under the head, and have both knees slightly flexed.
- Place a small, rolled towel under the client's right or left hip to displace the uterus off the major blood vessels to prevent supine hypotensive syndrome.

#### **ONGOING CARE**

- Identify the fetal part occupying the fundus. The head should feel round, firm, and move freely. The breech should feel irregular and soft. This maneuver identifies the fetal lie (longitudinal or transverse) and presenting part (cephalic or breech).
- Locate and palpate the smooth contour of the fetal back using the palm of one hand and the irregular small parts of the hands, feet, and elbows using the palm of the other hand. This maneuver validates the presenting part.

- Determine the part that is presenting over the true pelvis inlet by gently grasping the lower segment of the uterus between the thumb and fingers. If the head is presenting and not engaged, determine whether the head is flexed or extended. This maneuver assists in identifying the descent of the presenting part into the pelvis.
- Face the client's feet and outline the fetal head using the palmar surface of the fingertips on both hands to palpate the cephalic prominence. If the cephalic prominence is on the same side as the small parts, the head is flexed with vertex presentation. If the cephalic prominence is on the same side as the back, the head is extended with a face presentation. This maneuver identifies the fetal attitude.

#### **INTERVENTIONS**

- Auscultate the FHR post-maneuvers to assess the fetal tolerance to the procedure.
- Document the findings from the maneuvers.

### *Intermittent auscultation and uterine contraction palpation*

Intermittent auscultation of the FHR is a low-technology method that can be performed during labor using a hand-held Doppler ultrasound device, ultrasound stethoscope, or fetoscope to assess FHR. In conjunction, palpation of contractions at the fundus for frequency, intensity, duration, and resting tone is used to evaluate fetal well-being. During labor, uterine contractions compress the uteroplacental arteries, temporarily stopping maternal blood flow into the uterus and intervillous spaces of the placenta, decreasing fetal circulation and oxygenation. Circulation to the uterus and placenta resumes during uterine relaxation between contractions. For low-risk labor and delivery, this procedure allows the client freedom of movement and can be done at home or a birthing center.

#### **Guidelines for intermittent auscultation or continuous electronic fetal monitoring**

- During latent phase: every 30 to 60 min
- During active phase: every 15 to 30 min
- During second stage: every 5 to 15 min

### **INDICATIONS**

- Determine active labor
- Rupture of membranes, spontaneously or artificially
- Preceding and subsequent to ambulation
- Prior to and following administration of or a change in medication analgesia
- At peak action of anesthesia
- Following vaginal examination
- Following expulsion of an enema
- After urinary catheterization
- Abnormal or excessive uterine contractions

## CONSIDERATIONS

### PREPARATION OF THE CLIENT

- Based on findings obtained using Leopold maneuvers, auscultate the FHR using listening device.
- Palpate the uterine fundus to assess uterine activity.
- Count FHR for 30 to 60 seconds between contractions to determine baseline rate.
- Auscultate FHR before, during, and after a contraction to determine FHR in response to the contractions.

### ONGOING CARE

Identify FHR patterns and characteristics of uterine contractions.

### INTERVENTIONS

- It is the responsibility of the nurse to assess FHR patterns and characteristics of uterine contractions, implement nursing interventions, and report nonreassuring patterns or abnormal uterine contractions to the provider.
- Cultural considerations, as well as the emotional, educational, and comfort needs of the client and the family must be incorporated into the plan of care while continuing to assess the FHR pattern's response to uterine contractions during the labor process. 

The method and frequency of fetal surveillance during labor will vary and depend on maternal/fetal risk factors as well as the preference of the facility, provider, and client.

## INTERPRETATION OF FINDINGS

- A normal, reassuring FHR is 110 to 160/min with increases and decreases from baseline.
- Tachycardia is a FHR greater than 160/min for 10 min or longer.
- Bradycardia is a FHR less than 110/min for 10 min or longer.

## *Continuous electronic fetal monitoring*

Continuous external fetal monitoring is accomplished by securing an ultrasound transducer over the client's abdomen, which records the FHR pattern, and a tocotransducer on the fundus that records the uterine contractions.

### ADVANTAGES

- Monitoring is noninvasive and reduces risk for infection.
- Membranes do not have to be ruptured.
- Cervix does not have to be dilated.
- Placement of transducers can be performed by the nurse.
- Provides permanent record of FHR and uterine contraction tracing.

### DISADVANTAGES

- Contraction intensity is not measurable.
- Movement of the client requires frequent repositioning of transducers.
- Quality of recording is affected by client obesity and fetal position.

## INDICATIONS

- Multiple gestations
- Oxytocin infusion (augmentation or induction of labor)
- Placenta previa
- Fetal bradycardia
- Maternal complications (gestational diabetes mellitus, gestational hypertension, kidney disease)
- Intrauterine growth restriction
- Post-date gestation
- Active labor
- Meconium-stained amniotic fluid
- Abruptio placentae: suspected or actual
- Abnormal nonstress test or contraction stress test
- Abnormal uterine contractions
- Fetal distress

## CONSIDERATIONS

### PREPARATION OF THE CLIENT

- Based on findings obtained using Leopold maneuvers, auscultate FHR using listening device.
- Palpate the fundus to identify uterine activity for proper placement of the tocotransducer to monitor uterine contractions.

### ONGOING CARE

- Provide education regarding the procedure to the client and the client's partner during placement and adjustments of the fetal monitor equipment. Client and family teaching is important when an electronic fetal monitor is used. Explain the purpose and reassure that use of monitoring does not necessarily imply fetal jeopardy.
- Encourage frequent maternal position changes, which can require adjustments of the transducers with position changes.
- If the client needs to void and can ambulate, and it is not contraindicated, the nurse can disconnect the external monitor for the client to use the bathroom.
- If disconnecting the FHR monitor is contraindicated or an internal FHR monitor is being used, the nurse can bring the client a bedpan.

## INTERPRETATION OF FINDINGS

- A normal fetal heart rate baseline at term is 110 to 160/min excluding accelerations, decelerations, and periods of marked variability within a 10 min window. At least 2 min of baseline segments in a 10 min window should be present. A single number should be documented instead of a baseline range.
- Fetal heart rate baseline variability is described as fluctuations in the FHR baseline that are irregular in frequency and amplitude. Expected variability should be moderate variability. Classification of variability is as follows.
  - Absent or undetectable variability (considered nonreassuring)
  - Minimal variability (detectable but equal to or less than 5/min)
  - Moderate variability (6 to 25/min)
  - Marked variability (greater than 25/min)
- Changes in fetal heart rate patterns are categorized as episodic or periodic changes. Episodic changes are not associated with uterine contractions, and periodic changes occur with uterine contractions. These changes include accelerations and decelerations.

## THREE-TIER SYSTEM

Current recommendations for fetal monitoring include a three-tier fetal heart rate interpretation system.

### Category I

All of the following are included in the fetal heart rate tracing:

- Baseline fetal heart rate of 110 to 160/min
- Baseline fetal heart rate variability: moderate
- Accelerations: present or absent
- Early decelerations: present or absent
- Variable or late decelerations: absent

### Category II

Category II tracings include all fetal heart rate tracings not categorized as Category I or Category III. Examples of Category II fetal heart rate tracings contain any of the following:

#### Baseline rate

- Tachycardia
- Bradycardia not accompanied by absent baseline variability

#### Baseline FHR variability

- Minimal baseline variability
- Absent baseline variability not accompanied by recurrent decelerations
- Marked baseline variability

### Episodic or periodic decelerations

- Prolonged fetal heart rate deceleration equal or greater than 2 min but less than 10 min
- Recurrent late decelerations with moderate baseline variability
- Recurrent variable decelerations with minimal or moderate baseline variability
- Variable decelerations with additional characteristics, including “overshoots,” “shoulders,” or slow return to baseline fetal heart rate

**Accelerations:** Absence of induced accelerations after fetal stimulation

### Category III

Category III fetal heart rate tracings include either:

- Sinusoidal pattern
- Absent baseline fetal heart rate variability and any of the following.
  - Recurrent variable decelerations
  - Recurrent late decelerations
  - Bradycardia

Each uterine contraction is comprised of the following.

- **Increment:** the beginning of the contraction as intensity is increasing
- **Acme:** the peak intensity of the contraction
- **Decrement:** the decline of the contraction intensity as the contraction is ending

Nonreassuring FHR patterns are associated with fetal hypoxia and include the following.

- Fetal bradycardia
- Fetal tachycardia
- Absence of FHR variability
- Late decelerations
- Variable decelerations

## FHR PATTERNS

### Accelerations

Variable transitory increase in the FHR above baseline

#### CAUSES/COMPLICATIONS

- Healthy fetal/placental exchange
- Intact fetal central nervous system (CNS) response to fetal movement
- Vaginal exam
- Uterine contractions
- Fetal scalp stimulation
- Vibroacoustic stimulation
- Fundal pressure

#### NURSING INTERVENTIONS

- Be reassuring.
- No interventions required.
- Indicate reactive nonstress test.

## Fetal bradycardia

FHR less than 110/min for 10 min or more

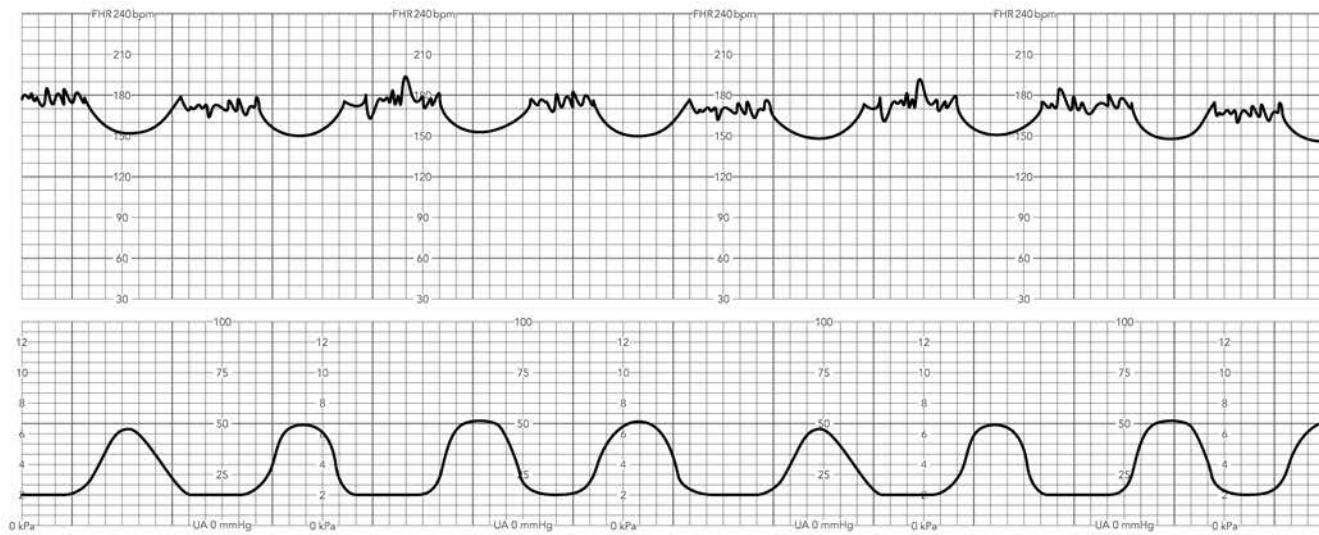

### CAUSES/COMPLICATIONS

- Uteroplacental insufficiency
- Umbilical cord prolapse
- Maternal hypotension
- Prolonged umbilical cord compression
- Fetal congenital heart block
- Anesthetic medications
- Viral infection
- Maternal hypoglycemia
- Fetal heart failure
- Maternal hypothermia

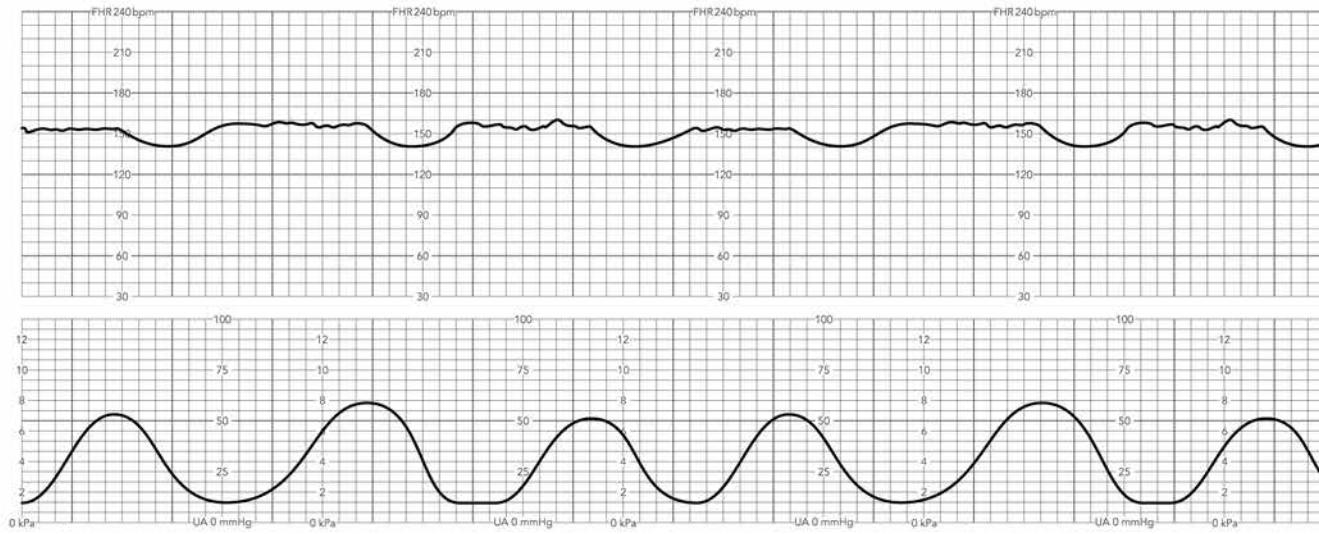

### NURSING INTERVENTIONS

- Discontinue oxytocin if being administered.
- Assist the client to a side-lying position.
- Administer oxygen by mask at 10 L/min via nonrebreather face mask.
- Insert an IV catheter if one is not in place and administer maintenance IV fluids.
- Administer a tocolytic medication.
- Notify the provider.

### 13.1 Early decelerations

### 13.2 Late decelerations

## Fetal tachycardia

FHR greater than 160/min for 10 min or more

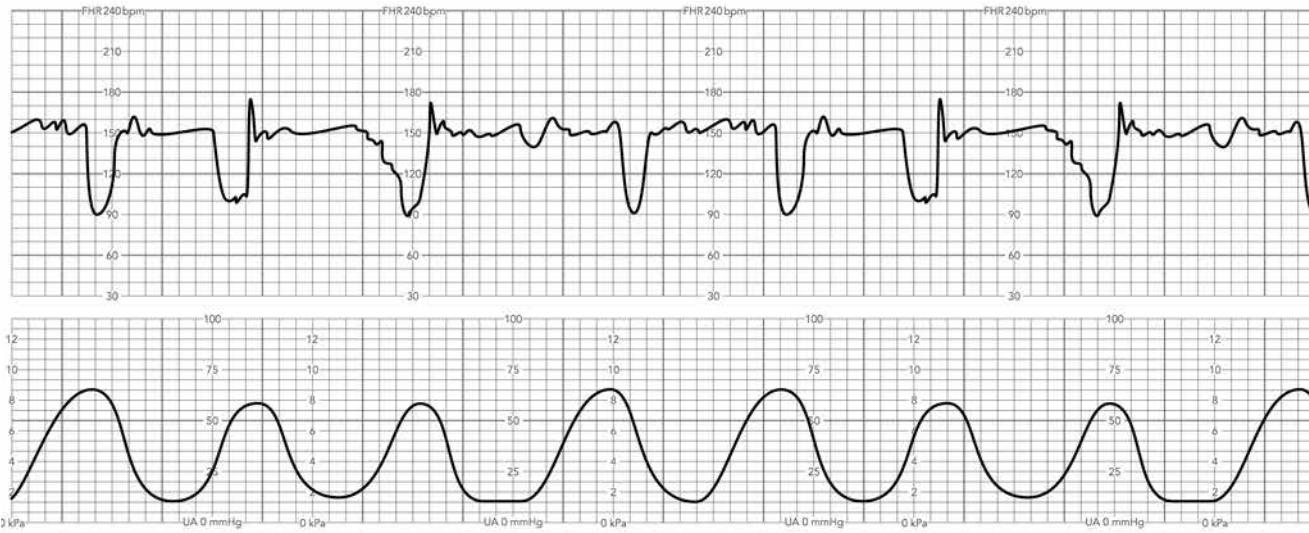

### CAUSES/COMPLICATIONS

- Maternal infection, chorioamnionitis
- Fetal anemia
- Fetal cardiac dysrhythmias
- Maternal use of cocaine or methamphetamines
- Maternal dehydration
- Maternal or fetal infection
- Maternal hyperthyroidism

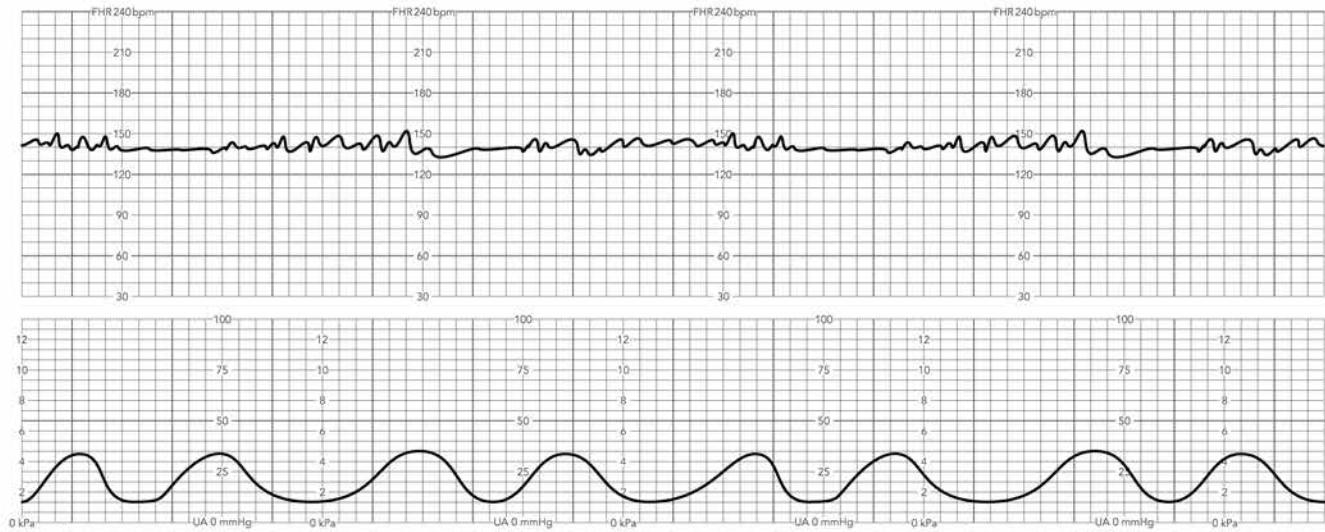

### NURSING INTERVENTIONS

- Administer prescribed antipyretics for maternal fever, if present.
- Administer oxygen by mask at 10 L/min via nonrebreather face mask.
- Administer IV fluid bolus.

### 13.3 Variable decelerations

### 13.4 Minimal variability

## ***Decrease or loss of FHR variability***

---

Decrease or loss of irregular fluctuations in the baseline of the FHR

### **CAUSES/COMPLICATIONS**

- Medications that depress the CNS (barbiturates, tranquilizers, general anesthetics)
- Fetal hypoxemia and metabolic acidemia
- Fetal sleep cycle (minimal variability sleep cycles usually do not last longer than 30 min)
- Congenital abnormalities

### **NURSING INTERVENTIONS**

- Stimulate the fetal scalp.
- Assist provider with application of scalp electrode.
- Place client in left-lateral position.

## ***Early deceleration of FHR***

---

Slowing of FHR at the start of contraction with return of FHR to baseline at end of contraction

### **CAUSES/COMPLICATIONS**

- Compression of the fetal head resulting from uterine contraction
- Uterine contractions
- Vaginal exam
- Fundal pressure

**NURSING INTERVENTIONS:** No intervention required.

## ***Late deceleration of FHR***

---

Slowing of FHR after contraction has started with return of FHR to baseline well after contraction has ended

### **CAUSES/COMPLICATIONS**

- Uteroplacental insufficiency causing inadequate fetal oxygenation
- Maternal hypotension, placenta previa, abruptio placentae, uterine tachysystole with oxytocin
- Preeclampsia
- Late- or post-term pregnancy
- Maternal diabetes mellitus

### **NURSING INTERVENTIONS**

- Place client in side-lying position.
- Insert an IV catheter if not in place, and increase rate of IV fluid administration.
- Discontinue oxytocin if being infused.
- Administer oxygen by mask at 8 to 10 L/min via nonrebreather face mask.
- Elevate the client's legs.
- Notify the provider.
- Prepare for an assisted vaginal birth or cesarean birth.

## ***Variable deceleration of FHR***

---

Transitory, abrupt slowing of FHR 15/min or more below baseline for at least 15 seconds, variable in duration, intensity, and timing in relation to uterine contraction

### **CAUSES/COMPLICATIONS**

- Umbilical cord compression
- Short cord
- Prolapsed cord
- Nuchal cord (around fetal neck)

### **NURSING INTERVENTIONS**

- Reposition client from side to side or into knee-chest.
- Discontinue oxytocin if being infused.
- Administer oxygen by mask at 8 to 10 L/min via nonrebreather face mask.
- Perform or assist with a vaginal examination.
- Assist with an amnioinfusion if prescribed.

## ***Continuous internal fetal monitoring***

---

Continuous internal fetal monitoring with a scalp electrode is performed by attaching a small spiral electrode to the presenting part of the fetus to monitor the FHR. The electrode wires are then attached to a leg plate that is placed on the client's thigh and then attached to the fetal monitor.

## ***INDICATIONS***

---

Continuous internal fetal monitoring can be used in conjunction with an intrauterine pressure catheter (IUPC), which is a solid or fluid-filled transducer placed inside the client's uterine cavity to monitor the frequency, duration, and intensity of contractions.

### **ADVANTAGES**

- Early detection of abnormal FHR patterns suggestive of fetal distress.
- Accurate assessment of FHR variability.
- Accurate measurement of uterine contraction intensity.
- Allows greater maternal freedom of movement because tracing is not affected by fetal activity, maternal position changes, or obesity.

### **DISADVANTAGES**

- Membranes must have ruptured to use internal monitoring.
- Cervix must be adequately dilated to a minimum of 2 to 3 cm.
- Presenting part must have descended to place electrode.
- Potential risk of injury to fetus if electrode is not properly applied.
- A provider, nurse practitioner/midwife, or specially trained registered nurse must perform this procedure.
- Potential risk of infection to the client and the fetus.

## CONSIDERATIONS

### PREPARATION OF THE CLIENT

- Ensure electronic fetal monitoring equipment is functioning properly.
- Use aseptic techniques when assisting with procedures.

### ONGOING CARE

- Monitor maternal vital signs, and obtain maternal temperature every 1 to 2 hr.
- Encourage frequent repositioning of the client. If the client is lying supine, place a wedge under one of the client's hips to tilt the uterus.

## COMPLICATIONS

- Misinterpretation of FHR patterns
- Maternal or fetal infection
- Fetal trauma if fetal monitoring electrode or IUPC are inserted into the vagina improperly
- Supine hypotension secondary to internal monitor placement

### Active Learning Scenario

A nurse in labor and delivery is reviewing intermittent fetal auscultation and uterine contraction palpation with a newly licensed nurse. What information should the nurse include in the teaching? Use the ATI Active Learning Template: Therapeutic Procedure to complete this item.

**INDICATIONS:** Describe four situations when this procedure should be performed.

**OUTCOMES/EVALUATION:** Describe normal expected FHR findings.

### NURSING INTERVENTIONS

- Preprocedure: Describe the three types of devices that are used to auscultate FHR.
- Intraprocedure: Identify the time frame for counting FHR to determine the baseline rate and when auscultation should take place.

## Application Exercises

1. A nurse is caring for a client who is in active labor. The cervix is dilated to 5 cm, and the membranes are intact. Based on the use of external electronic fetal monitoring, the nurse notes a FHR of 115 to 125/min with occasional increases up to 150 to 155/min that last for 25 seconds and have moderate variability. There is no slowing of the FHR from the baseline. This client is exhibiting manifestations of which of the following? (Select all that apply.)
  - A. Moderate variability
  - B. FHR accelerations
  - C. FHR decelerations
  - D. Normal baseline FHR
  - E. Fetal tachycardia
2. A nurse is teaching a client about the benefits of internal fetal heart monitoring. Which of the following statements should the nurse include? (Select all that apply.)
  - A. "It is considered a noninvasive procedure."
  - B. "It can detect abnormal fetal heart tones early."
  - C. "It can determine the amount of amniotic fluid you have."
  - D. "It allows for accurate readings with maternal movement."
  - E. "It can measure uterine contraction intensity."
3. A nurse is reviewing the electronic monitor tracing of a client who is in active labor. A fetus receives more oxygen when which of the following appears on the tracing?
  - A. Peak of the uterine contraction
  - B. Moderate variability
  - C. FHR acceleration
  - D. Relaxation between uterine contractions
4. A nurse is caring for a client who is in labor and observes late decelerations on the electronic fetal monitor. Which of the following is the first action the nurse should take?
  - A. Assist the client into the left-lateral position.
  - B. Apply a fetal scalp electrode.
  - C. Insert an IV catheter.
  - D. Perform a vaginal exam.
5. A nurse is performing Leopold maneuvers on a client who is in labor. Which of the following techniques should the nurse use to identify the fetal lie?
  - A. Apply palms of both hands to sides of uterus.
  - B. Palpate the fundus of the uterus.
  - C. Grasp lower uterine segment between thumb and fingers.
  - D. Stand facing client's feet with fingertips outlining cephalic prominence.

## Application Exercises Key

1. A. **CORRECT:** There is moderate variability of 20/min. (6 to 25/min is expected reference range.)
- B. **CORRECT:** FHR accelerations are present with increases up to 150 to 155/min lasting for 25 seconds.
- C. There are no FHR decelerations because the FHR does not slow down.
- D. **CORRECT:** There is a normal baseline FHR of 115 to 125/min that falls within the expected reference range of 110 to 160/min.
- E. There is no evidence of fetal tachycardia because the FHR is within the expected reference range of 115 to 125/min.

NCLEX® Connection: Reduction of Risk Potential, Diagnostic Tests

2. A. A disadvantage of internal fetal monitoring is that it is an invasive procedure.
- B. **CORRECT:** A benefit of internal fetal monitoring is that it can detect abnormal fetal heart tones early.
- C. Internal fetal monitoring cannot determine the amount of amniotic fluid.
- D. **CORRECT:** A benefit of internal fetal monitoring is that it allows for accurate readings with maternal movement which external monitoring needs adjusting when the client moves.
- E. **CORRECT:** A benefit of internal fetal monitoring is that it can measure uterine contraction intensity which external monitoring cannot.

NCLEX® Connection: Reduction of Risk Potential, Diagnostic Tests

3. A. Compression of the arteries to the uteroplacental intervillous spaces is most acute at the peak (acme) of the uterine contraction, resulting in a decrease in fetal circulation and oxygenation.
- B. Moderate variability indicates fluctuations in the fetal heart and is not an indication the fetus is receiving more oxygen.
- C. FHR accelerations indicate an intact fetal CNS and is not an indication the fetus is receiving more oxygen.
- D. **CORRECT:** A fetus is most oxygenated during the relaxation period between contractions. During contractions, the arteries to the uteroplacental intervillous spaces are compressed, resulting in a decrease in fetal circulation and oxygenation.

NCLEX® Connection: Reduction of Risk Potential, Diagnostic Tests

4. A. **CORRECT:** The greatest risk to the fetus during late decelerations is uteroplacental insufficiency. The initial nursing action should be to place the client into the left-lateral position to increase uteroplacental perfusion.
- B. The application of a fetal scalp electrode will assist in the assessment of fetal well-being, but this is not the first action to take.
- C. Inserting an IV catheter is an intervention for late decelerations, but this is not the first action to take.
- D. The nurse may perform a vaginal exam to assess dilation, but this is not the first action to take.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

5. A. Using the palms of the hands on the sides of the uterus to identify the fetal back and small body parts verifies the presenting part.
- B. **CORRECT:** Palpating the fundus of the uterus identifies the fetal part that is present, indicating the fetal lie (longitudinal or transverse).
- C. The descent of the presenting part into the pelvis is determined by gently grasping the lower uterine segment between the thumb and fingers.
- D. Fetal attitude is identified by facing the client's feet and outlining the cephalic prominence (fetal head) using the fingertips of both hands.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

## Active Learning Scenario Key

Using the ATI Active Learning Template: Therapeutic Procedure

### INDICATIONS

- Determine active labor
- Rupture of membranes, spontaneously or artificially
- Preceding and subsequent to ambulation
- Prior to and following administration of or a change in medication analgesia
- At the peak action of anesthesia
- Following vaginal examination
- Following expulsion of an enema
- After urinary catheterization
- Abnormal or excessive uterine contractions

OUTCOMES/EVALUATION: A normal, reassuring FHR is 110 to 160/min with increases and decreases from baseline.

### NURSING INTERVENTIONS

#### Preprocedure

- Hand-held Doppler ultrasound
- Ultrasound stethoscope
- Fetoscope

#### Intraprocedure

- Count FHR for 30 to 60 seconds between contractions to determine baseline rate.
- Auscultate FHR before, during, and after a contraction to determine FHR in response to the contractions.

NCLEX® Connection: Reduction of Risk Potential, Diagnostic Tests

CHAPTER 14 **Nursing Care During Stages of Labor**

Labor occurs in four stages. It is the responsibility of a nurse to care for, monitor, and provide interventions for the client during each stage.

**NURSING RESPONSIBILITIES****ASSESSMENT**

- Assess the client's labor status prior to admission to the birthing facility. During this time, conduct an admission history, review of antepartum care, and review of the birth plan.
  - Obtain laboratory reports.
  - Monitor baseline fetal heart tones and uterine contraction patterns for 20 to 30 min.
  - Obtain maternal vital signs.
  - Check the status of the amniotic membranes.
- Orient the client and their partner to the unit during admission.
- Perform maternal and fetal assessments continuously throughout the labor process and immediately after birth.
- Avoid vaginal examinations in the presence of vaginal bleeding or until placenta previa or abruptio placentae is ruled out. If necessary, vaginal examinations should be done by the provider.
- Cervical dilation is the single most important indicator of the progress of labor.
- Progress of labor is affected by size of fetal head, fetal presentation, fetal lie, fetal attitude, and fetal position.
- The frequency, duration, and strength (intensity) of the uterine contractions cause fetal descent and cervical dilation

**14.1 Stages of labor**

FIRST STAGE			SECOND STAGE	THIRD STAGE	FOURTH STAGE
Latent Phase	Active Phase	Transition*			
Onset of labor			Full dilation Progresses to intense contractions every 1 to 2 min	Delivery of the neonate	Delivery of placenta
Contractions <ul style="list-style-type: none"> <li>• Irregular, mild to moderate</li> <li>• Frequency: 5 to 30 min</li> <li>• Duration: 30 to 45 seconds</li> <li>• Dilation: 0 to 3 cm</li> </ul>	Contractions <ul style="list-style-type: none"> <li>• More regular, moderate to strong</li> <li>• Frequency: 3 to 5 min</li> <li>• Duration: 40 to 70 seconds</li> <li>• Dilation: 4 to 7 cm</li> </ul>	Contractions <ul style="list-style-type: none"> <li>• Strong to very strong</li> <li>• Frequency: 2 to 3 min</li> <li>• Duration: 45 to 90 seconds</li> </ul>	Birth		Maternal stabilization of vital signs

Complete dilation

\*Some references only recognize two phases in the first stage of labor: latent (0 to 5 cm) and active (6 to 10 cm).

**PATIENT-CENTERED CARE**

Provide culturally competent care that respects and is compatible with the client's culture. (These are commonalities, and not meant to overgeneralize.) 

**Hispanic:** Might prefer mother to be present rather than partner

**African American:** Might prefer female family members for support

**Asian American:** Might prefer mother to be present; partner not an active participant; labor in silence; cesarean birth undesirable

**Native American:** Might prefer female nursing personnel; family involved in birth; use of herbs during labor; squatting position for birth

**European American:** Birth is public concern; focus on technology; partner expected to be involved; provider seen as head of health care team

**FIRST STAGE**

Lasts from onset of regular uterine contractions to full effacement and dilation of cervix (longer than second and third stages combined)

**ASSESSMENT**

- Perform Leopold maneuvers.
- Perform a vaginal examination as indicated (if no evidence of progress) to allow the examiner to assess whether client is in true labor and whether membranes have ruptured.
  - Encourage the client to take slow, deep breaths prior to the vaginal exam.
  - Monitor cervical dilation and effacement.
  - Monitor station and fetal presentation.
  - Prepare for impending delivery as the presenting part moves into positive stations and begins to push against the pelvic floor (crowning).

- Assessments related to possible rupture of membranes
  - When there is suspected rupture of membranes, first assess the FHR to ensure there is no fetal distress from possible umbilical cord prolapse, which can occur with the gush of amniotic fluid. *Qs*
  - Verify presence of alkaline amniotic fluid using nitrazine paper (turns blue, pH 6.5 to 7.5).
  - A sample of the fluid can be obtained and viewed on a slide under a microscope. Amniotic fluid will exhibit a frond-like ferning pattern. Assess the amniotic fluid for color and odor.
    - Expected findings are clear, the color of water, and free of odor.
    - Abnormal findings include the presence of meconium, abnormal color (yellow, green), and a foul odor.
- Perform bladder palpation on a regular basis to prevent bladder distention, which can impede fetal descent through the birth canal and cause trauma to the bladder.
  - Clients might not feel the urge to void secondary to the labor process or anesthesia.
  - Encourage the client to void frequently.
- Perform a temperature assessment every 4 hr (every 2 hr if membranes have ruptured).

## NURSING ACTIONS

Teach the client and their partner about what to expect during labor and implementing relaxation measures: breathing (deep cleansing breaths help divert focus away from contractions), effleurage (gentle circular stroking of the abdomen in rhythm with breathing during contractions), diversional activities (distraction, concentration on a focal point, or imagery).

- Encourage upright positions, application of warm/cold packs, ambulation, or hydrotherapy if not contraindicated to promote comfort.
- Encourage voiding every 2 hr.

### DURING THE ACTIVE PHASE

- Provide client/fetal monitoring.
- Encourage frequent position changes.
- Encourage voiding at least every 2 hr.
- Encourage deep cleansing breaths before and after modified paced breathing.
- Encourage relaxation.
- Provide nonpharmacological comfort measures.
- Provide pharmacological pain relief as prescribed.

### DURING THE TRANSITION PHASE\*

- Continue to encourage voiding every 2 hr.
- Continue to monitor and support the client and fetus.
- Encourage a rapid pant-pant-blow breathing pattern if the client has not learned a particular breathing pattern.
- Discourage pushing efforts until the cervix is fully dilated.
- Listen for client statements expressing the need to have a bowel movement. This sensation is a finding of complete dilation and fetal descent.
- Prepare the client for the birth.
- Observe for perineal bulging or crowning (appearance of the fetal head at the perineum).
- Encourage the client to begin bearing down with contractions once the cervix is fully dilated.
- \*Some references only recognize two phases in the first stage of labor: latent (0 to 5 cm) and active (6 to 10 cm).

## SECOND STAGE

Lasts from the time the cervix is fully dilated to the birth of the fetus

### ASSESSMENT

Begins with complete dilation and effacement

- Blood pressure, pulse, and respiration measurements every 5 to 30 min
- Uterine contractions
- Pushing efforts by client
- Increase in bloody show
- Shaking of extremities
- FHR every 5 to 15 min (depending on fetal risk status) and immediately following birth

Assessment for perineal lacerations, which usually occur as the fetal head is expulsed. Perineal lacerations are defined in terms of depth.

- **First degree:** Laceration extends through the skin of the perineum and does not involve the muscles.
- **Second degree:** Laceration extends through the skin and muscles into the perineum but not the anal sphincter.
- **Third degree:** Laceration extends through the skin, muscles, perineum, and external anal sphincter muscle.
- **Fourth degree:** Laceration extends through skin, muscles, anal sphincter, and the anterior rectal wall.

### 14.2 Assessment in the first stage

	LATENT PHASE	ACTIVE PHASE	TRANSITION PHASE*
<i>Blood pressure, pulse, and respiration measurements</i>	every 30 to 60 min	every 30 min	every 15 to 30 min
<i>Contraction monitoring</i>	every 30 to 60 min	every 15 to 30 min	every 10 to 15 min
<i>FHR monitoring (expected range 110 to 160/min)</i>	every 30 to 60 min	every 15 to 30 min	every 15 to 30 min

\*Some references only recognize two phases in the first stage of labor: latent (0 to 5 cm) and active (6 to 10 cm).

## NURSING ACTIONS

- Continue to monitor the client/fetus.
- Assist in positioning the client for effective pushing.
- Assist in partner involvement with pushing efforts and in encouraging bearing down efforts during contractions.
- Promote rest between contractions.
- Provide comfort measures such as cold compresses.
- Cleanse the client's perineum as needed if fecal material is expelled during pushing.
- Prepare for episiotomy, if needed.
- Provide feedback on labor progress to the client.
- Prepare for care of neonate. A nurse trained in neonatal resuscitation should be present at delivery.
  - Check oxygen flow and tank on warmer.
  - Preheat radiant warmer.
  - Lay out newborn stethoscope and bulb syringe.
  - Have resuscitation equipment in working order (resuscitation bag, laryngoscope) and emergency medications available.
  - Check suction apparatus.

## THIRD STAGE

Lasts from the birth of the fetus until the placenta is delivered

## ASSESSMENT

- Blood pressure, pulse, and respiration measurements every 15 min
- Clinical findings of placental separation from the uterus as indicated by
  - Fundus firmly contracting
  - Swift gush of dark blood from introitus
  - Umbilical cord appears to lengthen as placenta descends
  - Vaginal fullness on exam
- Assignment of 1 and 5 min Apgar scores to the neonate

## NURSING ACTIONS

- Instruct the client to push once findings of placental separation are present. Keep client/parents informed of progress of placental expulsion and perineal repair if appropriate.
- Administer oxytocics as prescribed to stimulate the uterus to contract and thus prevent hemorrhage.
- Administer analgesics.
- Gently cleanse the perineal area with warm water and apply a perineal pad or ice pack to the perineum.
- Promote baby-friendly activities between the family and the newborn, which facilitates the release of endogenous maternal oxytocin. Examples of such activities include introducing the parents to the baby and facilitating the attachment process by promoting skin-to-skin contact immediately following the birth. Allow private time and encourage breastfeeding. **Q<sub>PCC</sub>**

## FOURTH STAGE

Begins with the delivery of the placenta and includes at least the first 2 hr after birth

## ASSESSMENT

- Maternal vital signs
- Fundus
- Lochia
- Urinary output
- Baby-friendly activities of the family

## NURSING ACTIONS

- Assess maternal blood pressure and pulse every 15 min for the first 2 hr and determine the temperature at the beginning of the recovery period, then assess every 4 hr for the first 8 hr after birth, then at least every 8 hr.
- Assess fundus and lochia every 15 min for the first hour and then according to facility protocol.
- Massage the uterine fundus and/or administer oxytocics to maintain uterine tone and to prevent hemorrhage. **Q<sub>S</sub>**
- Encourage voiding to prevent bladder distention.
- Assess episiotomy or laceration repair for erythema.
- Promote an opportunity for parental-newborn bonding.
- After they have had a chance to bond with their baby and eat, most new mothers are ready for a nap or at least a quiet period of rest.

## Application Exercises

- 1.** A nurse is caring for a client and partner during the second stage of labor. The client's partner asks the nurse to explain how to know when crowning occurs. Which of the following responses should the nurse make?

  - A. "The placenta will protrude from the vagina."
  - B. "Your partner will report a decrease in the intensity of contractions."
  - C. "The vaginal area will bulge as the baby's head appears."
  - D. "Your partner will report less rectal pressure."
  
- 2.** A nurse is caring for a client who is in the transition phase of labor and reports that they need to have a bowel movement with the peak of contractions. Which of the following actions should the nurse make?

  - A. Assist the client to the bathroom.
  - B. Prepare for an impending delivery.
  - C. Prepare to remove a fecal impaction.
  - D. Encourage the client to take deep, cleansing breaths.
  
- 3.** A nurse is caring for a client in the third stage of labor. Which of the following findings indicate placental separation? (Select all that apply.)

  - A. Lengthening of the umbilical cord
  - B. Swift gush of clear amniotic fluid
  - C. Softening of the lower uterine segment
  - D. Appearance of dark blood from the vagina
  - E. Fundus firm upon palpation
  
- 4.** A nurse is planning care for a newly admitted client who reports, "I am in labor and I have been having vaginal bleeding for 2 weeks." Which of the following should the nurse include in the plan of care?

  - A. Inspect the introitus for a prolapsed cord.
  - B. Perform a test to identify the ferning pattern.
  - C. Monitor station of the presenting part.
  - D. Defer vaginal examinations.
  
- 5.** A nurse is caring for a client who is in the first stage of labor and is encouraging the client to void every 2 hr. Which of the following statements should the nurse make?

  - A. "A full bladder increases the risk for fetal trauma."
  - B. "A full bladder increases the risk for bladder infections."
  - C. "A distended bladder will be traumatized by frequent pelvic exams."
  - D. "A distended bladder reduces pelvic space needed for birth."

## Active Learning Scenario

A nurse is caring for a client in the fourth stage of labor. What actions should the nurse take? Use the ATI Active Learning Template: Basic Concept to complete this item.

**UNDERLYING PRINCIPLES:** Describe.

**NURSING INTERVENTIONS:** Describe four.

## Application Exercises Key

1. A. The appearance of the placenta occurs after crowning and the birth of the neonate.
- B. Crowning occurs with an increase in the intensity of contractions and the urge to push.
- C. **CORRECT:** Crowning is bulging of the perineum and the appearance of the fetal head.
- D. Crowning occurs with an increase in rectal pressure as the fetal head descends onto the perineum.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

2. A. The urge to have a bowel movement indicates fetal descent and complete dilation. Assisting the client to the bathroom is not an appropriate action in view of the impending birth.
- B. **CORRECT:** The urge to have a bowel movement indicates fetal descent and complete dilation. Preparing for an imminent birth is appropriate.
- C. The nurse cleanses the perineal area to remove fecal matter that can be expelled due to the descent of the fetus. The nurse does not prepare to remove an impaction.
- D. Deep cleansing breaths are encouraged between contractions. The client will be encouraged to push because the sensation of a bowel movement indicates complete dilation and fetal descent.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

3. A. **CORRECT:** The umbilical cord lengthens as the placenta is being expelled.
- B. A sudden gush of clear amniotic fluid occurs when membranes rupture.
- C. Softening of the lower uterine segment is not an indication of placental separation.
- D. **CORRECT:** A gush of dark blood from the introitus is an indication of placental separation.
- E. **CORRECT:** The uterus contracts firmly with placental separation.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

4. A. Active vaginal bleeding is not an indication of ruptured membranes. Therefore, do not anticipate cord prolapse.
- B. A test for ferning is performed if there is suspected amniotic fluid and there is no indication of ruptured membranes.
- C. Station is monitored by vaginal examination, which should not be performed if there is vaginal bleeding, which can be related to placenta previa or abruptio placentae.
- D. **CORRECT:** Vaginal examinations should not be performed until placenta previa or abruptio placentae has been ruled out as the cause of vaginal bleeding.

NCLEX® Connection: Physiological Adaptation, Unexpected Response to Therapies

5. A. A full bladder does not place the fetus at risk for trauma.
- B. Urinary stasis, which occurs due to long periods between voiding, increases the risk for bladder infections.
- C. The urethra can be traumatized by frequent pelvic exams.
- D. **CORRECT:** A distended bladder reduces pelvic space, impedes fetal descent, and places the bladder at risk for trauma during the labor process.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

## Active Learning Scenario Key

Using the ATI Active Learning Template: Basic Concept

UNDERLYING PRINCIPLES: The focus of care in the fourth stage is to maintain uterine tone and to prevent hemorrhage.

### NURSING INTERVENTIONS

- Assess vital signs, fundus, and lochia every 15 min for the first 2 hr, then according to facility protocol.
- Massage the uterus.
- Encourage voiding to prevent bladder distention.
- Promote parental-newborn bonding.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

## *Therapeutic Procedures to Assist with Labor and Delivery*

In this chapter, the various therapeutic procedures to assist with labor and delivery will be discussed.

The therapeutic procedures that will be reviewed include external cephalic version, Bishop score, cervical ripening, induction of labor, augmentation of labor, amniotomy, amnioinfusion, vacuum-assisted delivery, forceps-assisted delivery, episiotomy, cesarean birth, and vaginal birth after cesarean birth.

### *External cephalic version*

External cephalic version is an ultrasound-guided hands-on procedure to externally manipulate the fetus into a cephalic lie. The procedure is performed at 37 to 38 weeks of gestation in an inpatient setting. There is a high risk of placental abruption, umbilical cord compression, and emergent cesarean birth with this procedure. Contraindications to performing a version include uterine anomalies, previous cesarean birth, cephalopelvic disproportion, placenta previa, multifetal gestation, oligohydramnios, third-trimester bleeding, uteroplacental insufficiency, or nuchal cord.

### **INDICATIONS**

**POTENTIAL DIAGNOSES:** A malpositioned fetus in a breech or transverse position late in gestation.

### **CONSIDERATIONS**

#### **PREPARATION OF THE CLIENT**

- Have the client sign an informed consent form.
- The provider will perform ultrasound screening prior to the procedure to evaluate fetal position, locate the umbilical cord, assess placental placement to rule out placenta previa, determine the amount of amniotic fluid, determine fetal age, assess for the presence of anomalies, evaluate pelvic adequacy for delivery, and/or guide the direction of the fetus during the procedure.
- Perform a nonstress test to evaluate fetal well-being.
- Ensure that Rho(D) immune globulin was administered at 28 weeks of gestation if the mother is Rh-negative.
- Administer IV fluid and tocolytics to relax uterus to permit easier manipulation.

#### **ONGOING CARE**

- Continuously monitor FHR patterns to assess for bradycardia and variable decelerations during the version and for 1 hr following the procedure.
- Monitor vital signs.
- Assess for hypotension to determine whether vena cava compression is occurring. *Qs*
- Monitor for client report of pain.
- Rh-negative clients should receive Rho(D) immune globulin to suppress the maternal immune response to fetal Rh-positive blood after the procedure in case minimal bleeding occurs.

#### **INTERVENTIONS**

- Monitor fetal activity, fetal heart rate, and the fetal heart rate pattern.
- Monitor uterine activity, contraction frequency, duration, and intensity.
- Monitor for rupture of membranes.
- Monitor for bleeding until maternal condition is stable.
- Monitor for a decrease in fetal activity.

### *Bishop score*

- A Bishop score is used to determine maternal readiness for labor by evaluating whether the cervix is favorable by rating the following.
  - Cervical dilation
  - Cervical effacement
  - Cervical consistency (firm, medium, or soft)
  - Cervical position (posterior, midposition, or anterior)
  - Station of presenting part
- The five factors are assigned a numerical value of 0 to 3, and the total score is calculated.

### **INDICATIONS**

**POTENTIAL DIAGNOSES:** Any condition in which augmentation or induction of labor is indicated.

**CLIENT READINESS:** A Bishop score for a client at 39 weeks of gestation should be a score of 8 or more, which is indicative of a successful induction.

### *Cervical ripening*

Cervical ripening by various methods increases cervical readiness for labor through promotion of cervical softening, dilation, and effacement.

- Cervical ripening can eliminate the need for oxytocin administration to induce labor, lower the dosage of oxytocin needed, and promote a more successful induction.
- Administration of a low-dose infusion of oxytocin is used for cervical priming.

#### **MECHANICAL AND PHYSICAL METHODS**

- A balloon catheter is inserted into the intracervical canal to dilate the cervix.
- Membrane stripping and an amniotomy can be performed.

- Hygroscopic dilators can be inserted to absorb fluid from surrounding tissues and then enlarge. Fresh dilators can be inserted if further dilation is required.
  - Laminaria tents are made from desiccated seaweed.
  - Synthetic dilators contain magnesium sulfate.

**CHEMICAL AGENTS** based on prostaglandins are used to soften and thin the cervix. They can be in the form of oral medication or vaginal suppositories/gels.

- Misoprostol: prostaglandin E<sub>1</sub>
- Dinoprostone: prostaglandin E<sub>2</sub>

## INDICATIONS

**POTENTIAL DIAGNOSES:** Any condition in which augmentation or induction of labor is indicated.

### CLIENT PRESENTATION

- Failure of the cervix to dilate and efface
- Failure of labor to progress

## CONSIDERATIONS

### NURSING ACTIONS

Ongoing care includes the nurse assessing for

- Urinary retention
- Rupture of membranes
- Uterine tenderness or pain
- Contractions
- Vaginal bleeding
- Fetal distress

### INTERVENTIONS

- Obtain the client's informed consent form.
- Obtain baseline data on fetal and maternal well-being.
- Assist the client to void prior to the procedure.
- Document the number of dilators and/or sponges inserted during the procedure.
- The client should remain in a side-lying position.
- Assist with augmentation or induction of labor as prescribed.
- Monitor FHR and uterine activity after administration of cervical-ripening agents.
- Notify the provider if uterine tachysystole or fetal distress is noted.
- Monitor for potential adverse effects (nausea, vomiting, diarrhea, fever, uterine tachysystole).
- Proceed with caution in clients who have glaucoma, asthma, and cardiovascular or renal disorders.

## COMPLICATIONS

### Tachysystole

**NURSING ACTIONS:** Administer subcutaneous injection of terbutaline.

### Fetal distress

### NURSING ACTIONS

- Apply O<sub>2</sub> via face mask at 10 L/min.
- Position the client on the left side.
- Increase rate of IV fluid administration.
- Notify the provider.

## Induction of labor

Induction of labor is the deliberate initiation of uterine contractions to stimulate labor before spontaneous onset to bring about the birth by chemical or mechanical means.

### METHODS

- Mechanical or chemical approaches
- Administration of IV oxytocin
- Nipple stimulation to trigger the release of endogenous oxytocin

## INDICATIONS

Any condition in which augmentation or induction of labor is indicated. Elective induction for nonmedical indications must meet the criteria of at least 39 weeks of gestation. Elective inductions that do not meet recommended criteria can result in increased risk for infection, premature delivery, longer labor, and need for cesarean birth.

### CLIENT PRESENTATION

- Postterm pregnancy (greater than 42 weeks of gestation)
- Dystocia (prolonged, difficult labor) due to inadequate uterine contractions
- Prolonged rupture of membranes, which predisposes the client and fetus to risk of infection
- Intrauterine growth restriction
- Maternal medical complications
  - Rh-isoimmunization
  - Diabetes mellitus
  - Pulmonary disease
  - Gestational hypertension
- Fetal demise
- Chorioamnionitis

## CONSIDERATIONS

### CLIENT PREPARATION

- Prepare the client for cervical ripening.
  - Obtain the client's informed consent form.
  - If cervical-ripening agents are used, baseline data on fetal and maternal well-being should be obtained.
  - Monitor FHR and uterine activity after administration of cervical-ripening agents.
  - Notify the provider of uterine tachysystole or fetal distress.
- Prepare the client for misoprostol administration.
  - Misoprostol is a tablet inserted vaginally to ripen the cervix.
  - Encourage the client to void prior to the procedure.
- Prepare the client for oxytocin administration.
  - Prior to the administration of oxytocin, it is essential that the nurse confirm that the fetus is engaged in the birth canal at a minimum of station 0.
  - Initiate oxytocin no sooner than 4 hr after the administration of misoprostol, and 6 to 12 hr after dinoprostone gel instillation or removal of a dinoprostone insert.

- Use the infusion port closest to the client for administration. Oxytocin should be connected to the main IV line and administered as an intermittent IV bolus via an infusion pump.
- An intrauterine pressure catheter (IUPC) can be used to monitor frequency, duration, and intensity of contractions.
- When oxytocin is administered, assessments include maternal blood pressure, pulse, and respirations every 30 to 60 min and with every change in dose.
- Monitor the FHR and contraction pattern every 15 min in the first stage of labor, every 5 min in the second stage of labor, and with every change in dose.
- Assess fluid intake and urinary output.
- A Bishop score rating should be obtained prior to starting any labor induction protocol.

#### ONGOING CARE

- Assist with or perform administration of labor induction agents.
- Increase oxytocin until desired contraction pattern is obtained and then maintain the dose if there is
  - Contraction frequency of 2 to 3 min
  - Contraction duration of 80 to 90 seconds
  - Contraction intensity of 40 to 90 mm Hg on IUPC or strong to palpation
  - Uterine resting tone of 10 to 15 mm Hg on IUPC
  - Cervical dilation of 1 cm/hr
  - Reassuring FHR between 110 to 160/min
- Discontinue oxytocin if uterine tachysystole occurs. Clinical findings of uterine tachysystole include the following. *Qs*
  - Contraction frequency more often than every 2 min
  - Contraction duration longer than 90 seconds
  - Contraction intensity that results in pressures greater than 90 mm Hg as shown by IUPC
  - Uterine resting tone greater than 20 mm Hg between contractions
  - No relaxation of uterus between contractions

## COMPLICATIONS

### *Nonreassuring FHR*

- Abnormal baseline less than 110 or greater than 160/min
- Loss of variability
- Late or prolonged decelerations

#### NURSING ACTIONS

- Notify the provider.
- Position the client in a side-lying position to increase uteroplacental perfusion.
- Keep the IV line open and increase the rate of IV fluid administration to 200 mL/hr unless contraindicated.
- Administer O<sub>2</sub> by a face mask at 8 to 10 L/min.
- Administer the tocolytic terbutaline 0.25 mg subcutaneously to diminish uterine activity.
- Monitor FHR and patterns in conjunction with uterine activity.
- Document responses to interventions.
- If unable to restore reassuring FHR, prepare for an emergency cesarean birth.

## *Augmentation of labor*

Augmentation of labor is the stimulation of hypotonic contractions once labor has spontaneously begun, but progress is inadequate.

Some providers favor active management of labor to establish effective labor with the aggressive use of oxytocin or rupture of membranes.

**RISK FACTORS REQUIRING AUGMENTATION OF LABOR:** Administration procedures, nursing assessments and interventions, and possible procedure complications are the same for labor induction.

## *Amniotomy*

- An amniotomy is the artificial rupture of the amniotic membranes (AROM) by the provider using a hook, clamp, or other sharp instrument.
- Labor typically begins within 12 hr after the membranes rupture and can decrease the duration of labor by up to 2 hr.
- The client is at an increased risk for cord prolapse or infection.

## INDICATIONS

- Labor progression is too slow and augmentation or induction of labor is indicated.
- An amnioinfusion is indicated for cord compression.

## CONSIDERATIONS

#### ONGOING CARE

- Ensure that the presenting part of the fetus is engaged prior to an amniotomy to prevent cord prolapse.
- Monitor FHR prior to and immediately following AROM to assess for cord prolapse as evidenced by variable or late decelerations.
- Assess and document characteristics of amniotic fluid including color, odor, and consistency.

#### INTERVENTIONS

- Document the time of rupture.
- Obtain temperature every 2 hr.
- Provide comfort measures (frequently changing pads, perineal cleansing).

## ***Amnioinfusion***

An amnioinfusion of normal saline or lactated Ringer's is instilled into the amniotic cavity through a transcervical catheter introduced into the uterus to supplement the amount of amniotic fluid. The instillation reduces the severity of variable decelerations caused by cord compression.

### **INDICATIONS**

#### POTENTIAL DIAGNOSES

- Oligohydramnios (scant amount or absence of amniotic fluid) caused by any of the following
  - Uteroplacental insufficiency
  - Premature rupture of membranes
  - Postmaturity of the fetus
- Fetal cord compression secondary to postmaturity of fetus (macrosomic, large body), which places the fetus at risk for variable deceleration from cord compression

### **CONSIDERATIONS**

#### INTERVENTIONS

- Assist with the amniotomy if membranes have not already ruptured. Membranes must have ruptured to perform an amnioinfusion.
- Warm fluid using a blood warmer prior to infusion. Fluid should be room temperature.
- Perform nursing measures to maintain comfort and dryness because the infused fluid will leak continuously.
- Monitor the client to prevent uterine overdistention and increased uterine tone, which can initiate, accelerate, or intensify uterine contractions and cause nonreassuring FHR changes.
- Continually assess intensity and frequency of uterine contractions.
- Continually monitor FHR.
- Monitor fluid output from vagina to prevent uterine overdistention.

## ***Vacuum-assisted delivery***

A vacuum-assisted birth involves the use of a cuplike suction device that is attached to the fetal head. Traction is applied during contractions to assist in the descent and birth of the head, after which, the vacuum cup is released and removed preceding delivery of the fetal body.

Follow recommendations by the manufacturer for product use to ensure safety.

#### CONDITIONS FOR USE

- Vertex presentation
- Cervical dilation of 10 cm
- Absence of cephalopelvic disproportion
- Ruptured membranes

#### ASSOCIATED RISKS

- Scalp lacerations
- Subdural hematoma of the neonate
- Cephalohematoma
- Maternal lacerations to the cervix, vagina, or perineum

### **INDICATIONS**

- Maternal exhaustion and ineffective pushing efforts
- Fetal distress during second stage of labor
- Generally not used to assist birth before 34 weeks gestation

### **CONSIDERATIONS**

#### PREPARATION OF THE CLIENT

- Provide the client and their partner with support and education regarding the procedure.
- Assist the client into the lithotomy position to allow for sufficient traction of the vacuum cup when it is applied to the fetal head.
- Assess and record FHR before and during vacuum assistance.
- Assess for bladder distention, and catheterize if necessary.

ONGOING CARE: Prepare for a forceps-assisted birth if a vacuum-assisted birth is not successful.

#### INTERVENTIONS

- Alert postpartum care providers that vacuum assistance was used.
- Observe the neonate for lacerations, cephalohematomas, or subdural hematomas after delivery.
- Check the neonate for caput succedaneum. Caput succedaneum is swelling of the scalp in a newborn that usually disappears within 3 to 5 days.

## ***Forceps-assisted birth***

A forceps-assisted birth consists of using an instrument with two curved spoon-like blades to assist in the delivery of the fetal head. Traction is applied during contractions.

### **INDICATIONS**

#### CLIENT PRESENTATION

- Prolonged second stage of labor and need to shorten duration (maternal exhaustion)
- Fetal distress during labor
- Abnormal presentation or a breech position requiring delivery of the head
- Arrest of rotation

### **CONSIDERATIONS**

#### PREPARATION OF THE CLIENT

- Explain the procedure to the client and their partner.
- Assist the client into the lithotomy position.
- Assess to ensure that the client's bladder is empty, and catheterize if necessary.
- Assess to ensure that the fetus is engaged and that membranes have ruptured.

ONGOING CARE: Assist with the procedure as necessary.

## INTERVENTIONS

- Assess and record FHR before, during, and after forceps assistance.
- Compression of the cord between the fetal head and forceps will cause a decrease in the FHR.
  - If a FHR decrease occurs, the forceps are removed and reapplied.
- Observe the neonate for bruising and abrasions at the site of forceps application after birth. Assess for facial palsy.
- Check the client for any possible injuries after birth.
  - Vaginal or cervical lacerations indicated by bleeding in spite of contracted uterus
  - Urine retention resulting from bladder or urethral injuries
  - Hematoma formation in the pelvic soft tissues resulting from blood vessel damage
- Report to the postpartum nursing caregivers that forceps or vacuum-assisted delivery methods were used.

## COMPLICATIONS

- Lacerations of the cervix
- Lacerations of the vagina and perineum
- Injury to the bladder
- Facial nerve palsy of the neonate
- Facial bruising on the neonate
- Subdural hematoma in the neonate

## *Episiotomy*

An episiotomy is an incision made into the perineum to enlarge the vaginal opening to facilitate birth and minimize soft tissue damage.

## INDICATIONS

- Shorten the second stage of labor
- Facilitate forceps-assisted or vacuum-assisted delivery
- Prevent cerebral hemorrhage in a fragile preterm fetus
- Facilitate birth of a macrosomic (large) infant

## CONSIDERATIONS

The site and direction of the incision designates the type of episiotomy.

- A **median (midline) episiotomy** extends from the vaginal outlet toward the rectum, and is the most commonly used.
  - Effective
  - Easily repaired
  - Generally least painful
  - Associated with a higher incidence of third- and fourth-degree lacerations
- A **mediolateral episiotomy** extends from the vaginal outlet posterolateral, either to the left or right of the midline, and is used when posterior extension is likely.
  - Third-degree laceration can occur.
  - Blood loss is greater, and the repair is more difficult and painful.
  - Local anesthetic is administered to the perineum prior to the incision.

**ONGOING CARE:** Encourage alternate labor positions to reduce pressure on the perineum and promote perineal stretching to reduce the necessity for an episiotomy.

## *Cesarean birth*

- A cesarean birth is the delivery of the fetus through a transabdominal incision of the uterus to preserve the life or health of the client and fetus when there is evidence of complications.
- Incisions are made vertically and horizontally into the lower segment of the uterus. Horizontal is the optimal incision.

## INDICATIONS

### POTENTIAL DIAGNOSES

- Malpresentation, particularly breech presentation
- Cephalopelvic disproportion
- Nonreassuring fetal heart tones
- Placental abnormalities
- Placenta previa
- Abruptio placentae
- High-risk pregnancy
  - Positive HIV status
  - Hypertensive disorders (preeclampsia, eclampsia)
  - Diabetes mellitus
  - Active genital herpes lesions
- Previous cesarean birth
- Dystocia
- Multiple gestations
- Umbilical cord prolapse
- Congenital malformations
- Maternal cardiac or respiratory disease

## CONSIDERATIONS

### PREPROCEDURE

#### NURSING ACTIONS

- Assess and record FHR and vital signs.
- Assist with obtaining an ultrasound to determine whether a cesarean birth is indicated.
- Position the client in a supine position with a wedge under one hip to prevent compression of the vena cava.
- Insert an indwelling urinary catheter.
- Ensure the client has signed the informed consent form.
- Apply a sequential compression device.
- Administer preoperative medications.
- Prepare the surgical site.
- Insert an IV catheter, and initiate administration of IV fluids.
- Determine whether the client has had nothing by mouth since midnight before the procedure. If the client has, notify the anesthesiologist.
- Ensure that preoperative diagnostic tests are complete, including an Rh-factor test.
- Explain the procedure to the client and their partner.
- Provide emotional support.

## INTRAPROCEDURE

---

- Assist in positioning the client on the operating table.
- Continue to monitor FHR.
- Continue to monitor vital signs, IV fluids, and urinary output.
- Conduct instrument and sponge counts per protocol.

## POSTPROCEDURE

---

- Monitor for evidence of infection and excessive bleeding at the incision site.
- Assess the uterine fundus for firmness or tenderness.
- Assess the lochia for amount and characteristics.

A tender uterus and foul-smelling lochia can indicate endometritis.

- Assess for productive cough or chills, which could be a manifestation of pneumonia.
- Assess for indications of thrombophlebitis, which include tenderness, pain, and heat on palpation.
- Monitor I&O.
- Monitor vital signs per protocol.
- Provide pain relief and antiemetics as prescribed.
- Encourage the client to turn, cough, and deep breathe to prevent pulmonary complications.
- Encourage splinting of the incision with pillows.
- Encourage ambulation to prevent thrombus formation.
- Assess the client for burning and pain on urination, which could be suggestive of a urinary tract infection.

## COMPLICATIONS

---

### MATERNAL

- Aspiration
- Amniotic fluid pulmonary embolism
- Wound infection
- Wound dehiscence
- Severe abdominal pain
- Thrombophlebitis
- Hemorrhage
- Urinary tract infection
- Injuries to the bladder or bowel
- Anesthesia associated complications

### FETAL

- Premature birth of fetus if gestational age is inaccurate
- Fetal injuries during surgery

## *Vaginal birth after cesarean (VBAC)*

---

A vaginal birth after cesarean birth is when the client delivers vaginally after having had a previous cesarean birth.

## INDICATIONS

---

**CLIENT PRESENTATION:** Selection criteria for VBAC

- No other uterine scars or history of previous rupture
- One or two previous low transverse cesarean births
- Clinically adequate pelvis
- Clients who have had a prior cesarean for dysfunctional labor, breech presentation, or abnormal FHR pattern, which are considered nonrecurring events
- Providers immediately available throughout active labor capable of monitoring labor and performing an emergency cesarean birth if necessary
- No current contraindications
  - Large for gestational age newborn
  - Malpresentation
  - Cephalopelvic disproportion
  - Previous classical vertical uterine incision

## CONSIDERATIONS

---

### PREPROCEDURE

---

#### NURSING ACTIONS

- Review medical records for evidence of a previous low-segment transverse cesarean incision.
- Explain the procedure to the client and their partner.

### INTRAPROCEDURE

---

- Assess and record FHR during the labor.
- Assess and record contraction patterns for strength, duration, and frequency of contractions.
- Assess for evidence of uterine rupture.
- Promote relaxation and breathing techniques during labor.
- Provide analgesia as prescribed and requested.

### POSTPROCEDURE

---

Nursing interventions for a vaginal delivery after a cesarean birth are the same as for a vaginal delivery.

## Application Exercises

1. A nurse is caring for a client who is 42 weeks of gestation and is having an ultrasound. For which of the following conditions should the nurse plan for an amnioinfusion? (Select all that apply.)

  - A. Oligohydramnios
  - B. Hydramnios
  - C. Fetal cord compression
  - D. Hydration
  - E. Fetal immaturity
  
2. A nurse is caring for a client who has been in labor for 12 hr with intact membranes. The nurse performs a vaginal examination to ensure which of the following prior to the performance of the amniotomy?

  - A. Fetal engagement
  - B. Fetal lie
  - C. Fetal attitude
  - D. Fetal position
  
3. A nurse is caring for a client who had no prenatal care, is Rh-negative, and will undergo an external version at 38 weeks of gestation. Which of the following medications should the nurse plan to administer prior to the version?

  - A. Prostaglandin gel
  - B. Magnesium sulfate
  - C. Rho(D) immune globulin
  - D. Oxytocin
  
4. A nurse is caring for a client who is receiving oxytocin for induction of labor and has an intrauterine pressure catheter (IUPC) placed to monitor uterine contractions. For which of the following contraction patterns should the nurse discontinue the infusion of oxytocin?

  - A. Frequency of every 2 min
  - B. Duration of 90 to 120 seconds
  - C. Intensity of 60 to 90 mm Hg
  - D. Resting tone of 15 mm Hg
  
5. A nurse educator in the labor and delivery unit is reviewing the use of chemical agents to promote cervical ripening with a group of newly licensed nurses. Which of the following statements by a nurse indicates understanding of the teaching?

  - A. "They are tablets administered vaginally."
  - B. "They act by absorbing fluid from tissues."
  - C. "They promote dilation of the os."
  - D. "They include an amniotomy."

## Active Learning Scenario

A nurse is planning care for a client who experienced a cesarean birth. What should the nurse include in the plan of care? Use the ATI Active Learning Template: Therapeutic Procedure to complete this item.

### DESCRIPTION OF PROCEDURE

**INDICATIONS:** Describe at least four.

**NURSING INTERVENTIONS:** Describe four that are preprocedure.

**POTENTIAL COMPLICATIONS:** Describe two that are maternal and two that are fetal.

## Application Exercises Key

1. A. **CORRECT:** Oligohydramnios is an indication for an amnioinfusion because inadequate amniotic fluid can contribute to intrauterine growth restriction of the fetus, restrict fetal movement, and cause fetal distress during labor.  
B. Hydramnios is excessive amniotic fluid.  
C. **CORRECT:** Oligohydramnios results in fetal cord compression, which decreases fetal oxygenation. Amnioinfusion prevents cord compression.  
D. Amnioinfusion does not increase hydration. IV fluids or oral intake would provide hydration.  
E. Fetal immaturity is not a reason for performing an amnioinfusion.
- ❷ NCLEX® Connection: *Physiological Adaptation, Unexpected Response to Therapies*
2. A. **CORRECT:** Prior to the performance of an amniotomy, it is imperative that the fetus is engaged at 0 station and at the level of the maternal ischial spines to prevent prolapse of the umbilical cord.  
B. Fetal lie pertains to the axis of the maternal spine in relation to the fetal spine and is determined by Leopold maneuvers.  
C. Fetal attitude is the relationship of the fetal extremities and chin to the fetal torso. It is determined by Leopold maneuvers.  
D. Fetal position refers to the direction of a reference point in the fetal presenting part to the maternal pelvis. It is not a criterion when performing an amniotomy.
- ❷ NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*
3. A. Prostaglandin gel is a cervical ripening agent and is not administered prior to an external version.  
B. Magnesium sulfate is a tocolytic, which can be administered prior to the version. However, because the client had no prenatal care and is Rh-negative, there is another medication to anticipate administering.  
C. **CORRECT:** Rho(D) immune globulin is administered to an Rh-negative client at 28 weeks of gestation. Because this client had no prenatal care, it should be given prior to the version to prevent isoimmunization.  
D. Oxytocin is administered to increase contraction frequency, intensity and duration. It is not administered prior to an external version.
- ❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Medication Administration*
4. A. This contraction pattern does not require discontinuing the infusion of oxytocin.  
B. **CORRECT:** Oxytocin is discontinued if uterine tachysystole occurs with contraction duration longer than 90 seconds.  
C. This contraction pattern does not require discontinuing the infusion of oxytocin.  
D. This contraction pattern does not require discontinuing the infusion of oxytocin.
- ❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Medication Administration*
5. A. **CORRECT:** Chemical agents that promote cervical ripening include medications administered vaginally.  
B. Hygroscopic dilators, which are a mechanical method to promote cervical ripening, act by absorbing fluid from surrounding tissues to enlarge the cervical opening.  
C. Mechanical and physical methods promote cervical ripening by dilation.  
D. An amniotomy is a mechanical method to promote cervical ripening.
- ❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Medication Administration*

## Active Learning Scenario Key

*Using the ATI Active Learning Template: Therapeutic Procedure*

**DESCRIPTION OF PROCEDURE:** Delivery of the fetus through a transabdominal incision of the uterus to preserve the life or health of the client and fetus when there is evidence of complications; incisions are made vertically and horizontally into the lower segment of the uterus, with horizontally being the optimal incision.

### INDICATIONS

- Malpresentation, breech
- Cephalopelvic disproportion
- Fetal distress
- Placenta previa
- Abruptio placentae
- HIV-positive status
- Dystocia
- Multiple gestations
- Umbilical cord prolapse
- Preeclampsia
- Eclampsia
- Active herpes lesions
- Previous cesarean birth

### NURSING INTERVENTIONS

- Assess and record FHR, vital signs.
- Assist with ultrasound.
- Position client in a supine position with a wedge under one hip.
- Insert an indwelling urinary catheter.
- Administer preoperative medications.
- Prepare the surgical site.
- Insert an IV catheter, and administer IV fluids.
- Obtain signed informed consent form.
- Determine client's NPO status.
- Verify preoperative testing results.
- Provide emotional support.

### POTENTIAL COMPLICATIONS

#### Maternal

- Aspiration
- Amniotic fluid pulmonary embolism
- Wound infection
- Wound dehiscence
- Severe abdominal pain
- Thrombophlebitis
- Hemorrhage
- Urinary tract infection
- Injury to bladder or bowel
- Anesthesia-associated complications

#### Fetal

- Premature birth
- Fetal injury during surgery

❷ NCLEX® Connection: *Reduction of Risk Potential, Therapeutic Procedures*

## *Complications Related to the Labor Process*

Complications occurring during the labor process are emergent and require immediate intervention in order to improve maternal fetal outcomes. This chapter explores prolapsed umbilical cord, meconium-stained amniotic fluid, fetal distress, dystocia (dysfunctional labor), precipitous labor, uterine rupture, and anaphylactoid syndrome of pregnancy (amniotic fluid embolism).

### Prolapsed umbilical cord

A prolapsed umbilical cord occurs when the umbilical cord is displaced, preceding the presenting part of the fetus, or protruding through the cervix. This results in cord compression and compromised fetal circulation.

### **ASSESSMENT**

#### RISK FACTORS

- Rupture of amniotic membranes
- Abnormal fetal presentation (any presentation other than vertex [occiput as presenting part])
- Transverse lie: Presenting part not engaged, which leaves room for the cord to descend
- Small-for-gestational-age fetus
- Unusually long umbilical cord
- Multifetal pregnancy
- Unengaged presenting part
- Hydramnios or polyhydramnios

#### EXPECTED FINDINGS

Client reports that they feel something coming through the vagina.

#### PHYSICAL ASSESSMENT FINDINGS

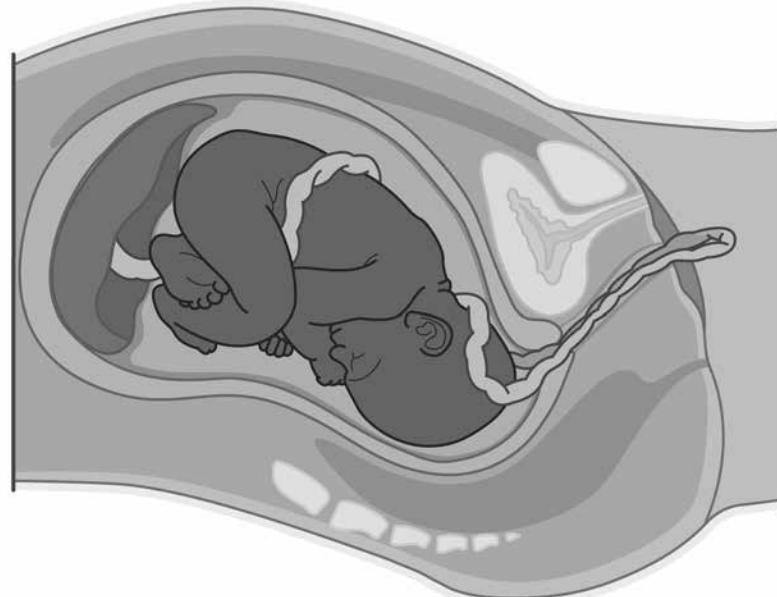

- Visualization or palpation of the umbilical cord protruding from the introitus
- FHR monitoring shows variable or prolonged deceleration
- Excessive fetal activity followed by cessation of movement; suggestive of severe fetal hypoxia

### **PATIENT-CENTERED CARE**

#### NURSING CARE

- Call for assistance immediately.
- Do not leave the client.
- Notify the provider.
- Using a sterile-gloved hand, insert two fingers into the vagina, and apply finger pressure on either side of the cord to the fetal presenting part to elevate it off of the cord. Stay in this position until the delivery of the baby. **Qs**
- Reposition the client in a knee-chest, Trendelenburg, or a side-lying position with a rolled towel under the client's right or left hip to relieve pressure on the cord. **QEBP**
- Apply a warm, sterile, saline-soaked towel to the visible cord to prevent drying and to maintain blood flow.
- Provide continuous electronic monitoring of FHR for variable decelerations, which indicate fetal asphyxia and hypoxia.
- Administer oxygen at 8 to 10 L/min via a face mask to improve fetal oxygenation.
- Initiate IV access, and administer IV fluid bolus.
- Prepare for an immediate vaginal birth if cervix is fully dilated or cesarean section if it is not.
- Inform and educate the client and their partner about the interventions.

#### 16.1 Prolapsed cord

# *Meconium-stained amniotic fluid*

- Meconium passage in the amniotic fluid during the antepartum period prior to the start of labor is typically not associated with an unfavorable fetal outcome.
- The fetus has had an episode of loss of sphincter control, allowing meconium to pass into amniotic fluid.

## **ASSESSMENT**

### RISK FACTORS

- There is an increased incidence for meconium in the amniotic fluid after 38 weeks of gestation due to fetal maturity of normal physiological functions.
- Umbilical cord compression results in fetal hypoxia that stimulates the vagal nerve in mature fetuses.
- Hypoxia stimulates the vagal nerve, which induces peristalsis of the fetal gastrointestinal tract and relaxation of the anal sphincter.

### EXPECTED FINDINGS

#### PHYSICAL ASSESSMENT FINDINGS

- Amniotic fluid can vary in color: black to greenish, or yellow, though meconium-stained amniotic fluid is often green. Consistency can be thin or thick.
- Criteria for evaluation of meconium-stained amniotic fluid
  - Often present in breech presentation, and might not indicate fetal hypoxia
  - Present with no changes in FHR
  - Stained fluid accompanied by variable or late decelerations in FHR (ominous finding)

### DIAGNOSTIC PROCEDURES

Electronic fetal monitoring

## **PATIENT-CENTERED CARE**

### NURSING CARE

- Document color and consistency of stained amniotic fluid.
- Notify neonatal resuscitation team to be present at birth.
- Gather equipment needed for neonatal resuscitation.
- Follow designated suction protocol.
  - Assess neonate's respiratory efforts, muscle tone, and heart rate.
  - Suction mouth and nose using bulb syringe if respiratory efforts are strong, muscle tone good, and heart rate greater than 100/min.
  - Suction below the vocal cords using an endotracheal tube before spontaneous breaths occur if respirations are depressed, muscle tone decreased, and heart rate less than 100/min.

# *Fetal distress*

Fetal distress is present when

- The FHR is below 110/min or above 160/min.
  - The FHR shows decreased or no variability.
  - There is fetal hyperactivity or no fetal activity.
- Additional manifestations of fetal distress are late decelerations associated with absent or minimal variability, recurrent variables, and prolonged decelerations.

## **ASSESSMENT**

**EXPECTED FINDINGS:** Nonreassuring FHR pattern with decreased or no variability

#### DIAGNOSTIC PROCEDURES

- Monitor uterine contractions.
- Monitor FHR.
- Monitor findings of ultrasound and any other prescribed diagnostics.

#### RISK FACTORS

- Fetal anomalies
- Uterine anomalies
- Complications of labor and birth

## **PATIENT-CENTERED CARE**

### NURSING CARE

- Monitor vital signs and FHR.
- Position the client in a left side-lying position. (Other possible positions include knee-chest and Trendelenburg.)
- Administer 8 to 10 L/min of oxygen via a face mask.
- Discontinue oxytocin if being administered.
- Increase IV fluid rate to treat hypotension if indicated.
- Prepare the client for an emergency cesarean birth if indicated.

# *Dystocia (dysfunctional labor)*

- Dystocia, or dysfunctional labor, is a difficult or abnormal labor related to the five P's of labor (passenger, passageway, powers, position, and psychologic response).
- Atypical uterine contraction patterns prevent the normal process of labor and its progression. Contractions can be hypotonic (weak, inefficient, or completely absent) or hypertonic (excessively frequent, uncoordinated, and of strong intensity with inadequate uterine relaxation) with failure to efface and dilate the cervix.

## ASSESSMENT

### RISK FACTORS

- Short stature, overweight status
- Age greater than 40 years
- Uterine abnormalities
- Pelvic soft tissue obstructions or pelvic contracture
- Cephalopelvic disproportion (fetal head is larger than maternal pelvis)
- Congenital anomalies
- Fetal macrosomia
- Fetal malpresentation, malposition
- Multifetal pregnancy
- Hypertonic or hypotonic uterus
- Maternal fatigue, fear, or dehydration
- Inappropriate timing of anesthesia or analgesics

### EXPECTED FINDINGS

#### PHYSICAL ASSESSMENT FINDINGS

- Lack of progress in dilatation, effacement, or fetal descent during labor.
  - A **hypotonic uterus** is easily indent-able, even at peak of contractions.
  - A **hypertonic uterus** cannot be indented, even between contractions.
- Client is ineffective in pushing with no voluntary urge to bear down.
  - Persistent occiput posterior presentation is when the fetal occiput is directed toward the posterior maternal pelvis rather than the anterior pelvis.
  - Persistent occiput posterior position prolongs labor and the client reports greater back pain as the fetus presses against the maternal sacrum.

### DIAGNOSTIC AND THERAPEUTIC PROCEDURES

- Ultrasound
- Amniotomy or stripping of membranes if not ruptured
- Oxytocin infusion
- Vacuum-assisted birth
- Cesarean birth

## PATIENT-CENTERED CARE

### NURSING CARE

#### *Dysfunctional labor*

- Assist with application of fetal scalp electrode and/or intrauterine pressure catheter.
- Assist with amniotomy (artificial rupture of membranes).
- Encourage client to engage in regular voiding to empty the bladder.
- Encourage position changes to aid in fetal descent or to open up the pelvic outlet. Assist the client to a position on both hands and knees to help the fetus to rotate from a posterior to anterior position.
- Encourage ambulation to enhance the progression of labor.
- Encourage hydrotherapy and other relaxation techniques to aid in the progression of labor.
- Apply counterpressure using fist or heel of hand to sacral area to alleviate discomfort.
- Assist the client into a beneficial position for pushing and coach them about how to bear down with contractions.
- Prepare for a possible forceps-assisted, vacuum-assisted, or cesarean birth.
- Continue monitoring FHR in response to labor.

#### *Hypertonic contractions*

- Maintain hydration.
- Promote rest and relaxation, and provide comfort measures between contractions.
- Place the client in a lateral position, and provide oxygen by mask.

### MEDICATIONS

Administer analgesics if prescribed (for rest from hypertonic contractions).

#### *Oxytocin*

**THERAPEUTIC INTENT:** Used to augment labor and strengthen uterine contractions

**NURSING ACTIONS:** Administer if prescribed to augment labor. Oxytocin is not administered for hypertonic contractions.

## Precipitous labor

Precipitous labor is defined as labor that lasts 3 hr or less from the onset of contractions to the time of delivery.

### ASSESSMENT

#### RISK FACTORS

##### Hypertonic uterine dysfunction

- Nonproductive, uncoordinated, painful, uterine contractions during labor that are too frequent and too long in duration and do not allow for relaxation of the uterine muscle between contractions (uterine tetany).
- Hypertonic contractions do not contribute to the progression of labor (cervical effacement, dilation, and fetal descent).
- Hypertonic contractions can result in uteroplacental insufficiency leading to fetal hypoxia.

##### Oxytocin stimulation

- Administered to augment or induce labor by increasing intensity and duration of contractions.
- Oxytocin stimulation can lead to hypertonic uterine contractions.

**Multiparous client:** Can move through the stages of labor more rapidly.

#### EXPECTED FINDINGS

##### DURING LABOR

- Low backache
- Abdominal pressure and cramping
- Increased or bloody vaginal discharge
- Palpable uterine contractions
- Progress of cervical dilation and effacement
- Diarrhea
- Fetal presentation, station, and position
- Status of amniotic membranes (membranes can be intact or ruptured)

##### PHYSICAL ASSESSMENT FINDINGS (POSTBIRTH)

- Assess maternal perineal area for indications of trauma or lacerations.
- Assess neonate's color and for indications of hypoxia.
- Assess for indications of trauma to presenting part of neonate, especially on cephalic presentation.

### PATIENT-CENTERED CARE

#### NURSING CARE

- Do not leave the client unattended.
  - Provide reassurance and emotional support to help the client remain calm.
  - Prepare for emergency delivery of the neonate.
- Encourage the client to pant with an open mouth between contractions to control the urge to push.
- Encourage the client to maintain a side-lying position to optimize uteroplacental perfusion and fetal oxygenation. 

- Prepare for rupturing of membranes upon crowning (fetal head visible at perineum) if not already ruptured.
- Do not attempt to stop delivery.
- Control rapid delivery by applying light pressure to the perineal area and fetal head, gently pressing upward toward the vagina. This eases the rapid expulsion of the fetus and prevents cerebral damage to the newborn and perineal lacerations to the client.
  - Deliver the fetus between contractions assuring the cord is not around the fetal neck.
  - If the cord is around the fetal neck, attempt to gently slip it over the head. If not possible, clamp the cord with two clamps and cut between the clamps.
- Suction mucus from the fetal mouth and nose with a bulb syringe when the head appears.
- Next, deliver the anterior shoulder located under the maternal symphysis pubis: next, the posterior shoulder; and then allow the rest of the fetal body to slip out.
- Assess for complications of precipitous labor.
  - **MATERNAL**
    - Cervical, vaginal, or perineal lacerations
    - Resultant tissue trauma secondary to rapid birth
    - Uterine rupture
    - Amniotic fluid embolism
    - Postpartum hemorrhage
  - **FETAL**
    - Fetal hypoxia due to hypertonic contractions or umbilical cord around fetal neck
    - Fetal intracranial hemorrhage due to head trauma from rapid birth

## Uterine rupture

- Complete rupture involves the uterine wall, peritoneal cavity, and/or broad ligament. Internal bleeding is present.
- Incomplete rupture occurs with dehiscence at the site of a prior scar (cesarean birth, surgical intervention). Internal bleeding might not be present.
- This is a rare but life-threatening obstetric injury.

### ASSESSMENT

#### RISK FACTORS

- Congenital uterine abnormality
- Uterine trauma due to accident or surgery (previous multiple cesarean births)
- Overdistention of the uterus from a fetus who is large for gestational age, a multifetal gestation, or polyhydramnios
- Tachysystole of the uterus, either spontaneous or from oxytocin administration
- External or internal fetal version done to correct malposition of the fetus
- Forceps-assisted birth
- Multigravida clients

## **EXPECTED FINDINGS**

---

- Client reports sensation of “ripping,” “tearing,” or sharp pain.
- Client reports abdominal pain, uterine tenderness.

### **PHYSICAL ASSESSMENT FINDINGS**

- Nonreassuring FHR with indications of distress (bradycardia, variable and late decelerations, and absent or minimal variability)
- Change in uterine shape and fetal parts palpable
- Cessation of contractions and loss of fetal station
- Manifestations of hypovolemic shock: tachypnea, hypotension, pallor, and cool, clammy skin

## **PATIENT-CENTERED CARE**

---

### **NURSING CARE**

---

- Administer IV fluids.
- Administer oxygen.
- Administer blood product transfusions if prescribed.
- Prepare the client for an immediate cesarean birth, which can involve a laparotomy and/or hysterectomy.
- Inform the client and their partner about the treatment.

## *Anaphylactoid syndrome of pregnancy (amniotic fluid embolism)*

---

- An amniotic fluid embolism occurs when there is a rupture in the amniotic sac or maternal uterine veins accompanied by high intrauterine pressure that causes infiltration of the amniotic fluid into the maternal circulation. The amniotic fluid then travels to and obstructs pulmonary vessels and causes respiratory distress and circulatory collapse. It can occur during labor, birth, or within 30 min following birth.
- Meconium-stained amniotic fluid or fluid containing particulate matter can cause devastating maternal damage because it readily clogs the pulmonary veins completely.
- Serious coagulation problems, such as disseminated intravascular coagulopathy (DIC), can occur.

## **ASSESSMENT**

---

### **RISK FACTORS**

---

- Placenta previa or abruption
- Preeclampsia
- Eclampsia
- Hypertensive disorders
- Oxytocin administration
- Diabetes mellitus
- Cesarean birth
- Labor induction
- Forceps-assisted birth
- Uterine rupture
- Cervical laceration
- Meconium-stained amniotic fluid

## **EXPECTED FINDINGS**

---

Report of sudden chest pain and/or sudden shortness of breath

### **PHYSICAL ASSESSMENT FINDINGS**

- **Indications of respiratory distress**
  - Restlessness
  - Cyanosis
  - Dyspnea
  - Pulmonary edema
  - Respiratory arrest
- **Indications of coagulation failure**
  - Bleeding from incisions and venipuncture sites
  - Petechiae and ecchymosis
  - Uterine atony
- **Indications of circulatory collapse**
  - Tachycardia
  - Hypotension
  - Shock
  - Cardiac arrest

## **PATIENT-CENTERED CARE**

---

### **NURSING CARE**

---

- Administer oxygen via a mask at 8 to 10 L/min.
- Assist with intubation and mechanical ventilation as indicated.
- Perform cardiopulmonary resuscitation if necessary.
- Administer IV fluids.
- Position the client on one side with the pelvis tilted at a 30° angle to displace the uterus.
- Administer blood products to correct coagulation failure.
- Insert an indwelling urinary catheter, and measure hourly urine output.
- Monitor maternal and fetal status.
- Prepare the client for an emergency cesarean birth if the fetus is not yet delivered.

## Application Exercises

1. A nurse is caring for a client who is in labor and experiencing incomplete uterine relaxation between hypertonic contractions. The nurse should identify that this contraction pattern increases the risk for which of the following complications?
  - A. Prolonged labor
  - B. Reduced fetal oxygen supply
  - C. Delayed cervical dilation
  - D. Increased maternal stress
  
2. A nurse is caring for a client who is in active labor and reports severe back pain. During assessment, the fetus is noted to be in the occiput posterior position. Which of the following maternal positions should the nurse suggest to the client to facilitate normal labor progress?
  - A. Hands and knees
  - B. Lithotomy
  - C. Trendelenburg
  - D. Supine with a rolled towel under one hip
  
3. A nurse is caring for a client who is in labor. With the use of Leopold maneuvers, it is noted that the fetus is in a breech presentation. For which of the following possible complications should the nurse observe?
  - A. Precipitous labor
  - B. Premature rupture of membranes
  - C. Postmaturity syndrome
  - D. Prolapsed umbilical cord
  
4. A nurse is caring for a client who is at 42 weeks of gestation and in active labor. Which of the following findings is the fetus at risk for developing?
  - A. Intrauterine growth restriction
  - B. Hyperglycemia
  - C. Meconium aspiration
  - D. Polyhydramnios
  
5. A nurse is caring for a client in active labor. When last examined 2 hr ago, the client's cervix was 3 cm dilated, 100% effaced, membranes intact, and the fetus was at a -2 station. The client suddenly states, "My water broke." The monitor reveals a FHR of 80 to 85/min, and the nurse performs a vaginal examination, noticing clear fluid and a pulsing loop of umbilical cord in the client's vagina. Which of the following actions should the nurse perform first?
  - A. Place the client in the Trendelenburg position.
  - B. Apply pressure to the presenting part with the fingers.
  - C. Administer oxygen at 10 L/min via a face mask.
  - D. Initiate IV fluids.

## Active Learning Scenario

A nurse is caring for a client and observes meconium-stained amniotic fluid upon rupture of the client's membranes. What actions should the nurse take? Use the ATI Active Learning Template: System Disorder to complete this item.

**EXPECTED FINDINGS:** Describe at least two observations the nurse should make.

**RISK FACTORS:** Describe two.

**NURSING CARE:** Describe three actions the nurse should take.

## Application Exercises Key

1. A. Precipitous labor, not prolonged labor, is often the result of hypertonic contractions and inadequate uterine relaxation between contractions.
- B. **CORRECT:** Inadequate uterine relaxation results in reduced oxygen supply to the fetus.
- C. Hypertonic contractions and inadequate relaxation of the uterus between contractions does not delay cervical dilation.
- D. A contraction pattern of hypertonic contractions and inadequate relaxation between contractions will increase maternal distress, but this is not an adverse effect.

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

2. A. **CORRECT:** Having the client assume a position on both hands and knees can help the fetus rotate from a posterior to an anterior position.
- B. The lithotomy position is when the client lies on the back with both knees elevated and does not facilitate labor progression.
- C. The Trendelenburg position requires the client to lie on the back and does not assist in the rotation of the fetus.
- D. The supine position with a rolled towel under one hip can assist in preventing vena cava syndrome but does not assist in the rotation of the fetus.

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

3. A. Breech presentation would most likely cause dystocia (prolonged, difficult labor) rather than a precipitous labor.
- B. Breech presentation has no effect on rupture of the membranes.
- C. Breech presentation is not associated with postmaturity syndrome.
- D. **CORRECT:** A prolapsed umbilical cord is a potential complication for a fetus in a breech presentation.

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

4. A. Intrauterine growth restriction occurs earlier in the pregnancy and not at this point.
- B. A postterm neonate is at risk for hypoglycemia, not hyperglycemia.
- C. **CORRECT:** Postterm neonates are at risk for aspiration of meconium.
- D. Postterm pregnancies result in oligohydramnios, not polyhydramnios.

NCLEX® Connection: *Health Promotion and Maintenance, Health Screening*

5. A. The nurse should place the client in the Trendelenburg position. However, another action/assessment is the priority.
- B. **CORRECT:** According to evidence-based practice apply pressure to the presenting part with the fingers.
- C. The nurse should administer oxygen at 10 L/min via a face mask. However, another action/assessment is the priority.
- D. The nurse should initiate IV fluids. However, another action/assessment is the priority.

NCLEX® Connection: *Physiological Adaptation, Medical Emergencies*

## Active Learning Scenario Key

Using the ATI Active Learning Template: System Disorder

### EXPECTED FINDINGS

- Color and consistency
- FHR pattern (presence of decelerations)

### RISK FACTORS

- After 38 weeks gestation
- Episodes of fetal hypoxia due to cord compression

### NURSING CARE

- Document color and consistency of amniotic fluid.
- Notify neonatal resuscitation team to be present at birth.
- Gather equipment needed for neonatal resuscitation and make available.
- Follow designated suction protocol.
  - Assess neonate's respiratory efforts, muscle tone, and heart rate.
  - If respiratory efforts are strong, muscle tone good, and heart rate greater than 100/min, suction mouth and nose using bulb syringe.
  - If respirations are depressed, muscle tone decreased, and heart rate less than 100/min, suction below the vocal cords using an endotracheal tube before spontaneous breaths occur.

NCLEX® Connection: *Physiological Adaptation, Medical Emergencies*

When reviewing the following chapters, keep in mind the relevant topics and tasks of the NCLEX outline, in particular:

### *Health Promotion and Maintenance*

---

**ANTE/INTRA/POSTPARTUM AND NEWBORN CARE:** Provide postpartum care and education.

**DEVELOPMENTAL STAGES AND TRANSITIONS:**  
Assist client to cope with life transitions.

**HEALTH PROMOTION/DISEASE PREVENTION:** Educate client about health promotion and maintenance recommendations.

### *Pharmacological and Parenteral Therapies*

---

**ADVERSE EFFECTS/CONTRAINdicATIONS/SIDE EFFECTS/INTERACTIONS:** Provide information to the client on common side effects/adverse effects/potential interactions of medications and inform the client when to notify the primary health care provider.

**EXPECTED ACTIONS/OUTCOMES:** Evaluate client response to medication.

**MEDICATION ADMINISTRATION:** Review pertinent data prior to medication administration.

### *Reduction of Risk Potential*

---

**CHANGES/ABNORMALITIES IN VITAL SIGNS:** Assess and respond to changes in client vital signs.

**LABORATORY VALUES:** Educate client about the purpose and procedure of prescribed laboratory tests.

**POTENTIAL FOR COMPLICATIONS FROM SURGICAL PROCEDURES AND HEALTH ALTERATIONS:** Apply knowledge of pathophysiology to monitoring for complications.

## *Physiological Adaptation*

---

**ALTERATIONS IN BODY SYSTEMS:** Provide care for client experiencing complications of pregnancy/labor and/or delivery.

**HEMODYNAMICS:** Manage the care of a client with alteration in hemodynamics, tissue perfusion and/or hemostasis.

# *Postpartum Physiological Adaptations*

It is important to provide comfort measures for the client during the fourth stage of labor. This recovery period starts with delivery of the placenta and includes at least the first 2 hr after birth. Also during this stage, parent-newborn bonding should begin to occur.

The main goal during the immediate postpartum period is to prevent postpartum hemorrhage. Other goals include assisting in a client's recovery, identifying deviations in the expected recovery process, providing comfort measures and pharmacological pain relief, providing client education about newborn and self-care, and providing baby-friendly activities to promote infant/family bonding.

## PHYSICAL CHANGES

The postpartum period, also known as the puerperium, includes physiological and psychological adjustments. This period is the interval between birth and the return of the reproductive organs to their nonpregnant state. Although traditionally this has been considered to last 6 weeks, this time frame varies among postpartum clients.

- Physiological changes consist of uterine involution; lochia flow; cervical involution; decrease in vaginal distention; alteration in ovarian function and menstruation; and cardiovascular, urinary tract, breast, and gastrointestinal tract changes.
- The greatest risks during the postpartum period are hemorrhage, shock, and infection.
- Oxytocin, a hormone released from the pituitary gland, coordinates and strengthens uterine contractions.
  - Breastfeeding stimulates the release of endogenous oxytocin from the pituitary gland.
  - Exogenous oxytocin can be administered postpartum to improve the quality of the uterine contractions. A firm and contracted uterus prevents excessive bleeding and hemorrhage.
  - Uncomfortable uterine cramping is referred to as afterpains.

- After delivery of the placenta, hormones (estrogen, progesterone, and placental enzyme insulinase) decrease, thus resulting in decreased blood glucose, estrogen, and progesterone levels.
  - Decreased estrogen is associated with breast engorgement, diaphoresis (profuse perspiration), and diuresis (increased formation and excretion of urine) of excess extracellular fluid accumulated during pregnancy.
  - Decreased estrogen diminishes vaginal lubrication. Local dryness and intercourse discomfort can persist until ovarian function returns and menstruation resumes.
  - Decreased progesterone results in an increase in muscle tone throughout the body.
  - Decreased placental enzyme insulinase results in reversal of the diabetogenic effects of pregnancy, which lowers blood glucose levels immediately in the puerperium.
  - Human chorionic gonadotropin (hCG) disappears from the blood quickly, but some can be detected for up to 4 weeks postpartum.
- Lactating and nonlactating clients differ in the timing of the first ovulation and the resumption of menstruation.
  - In lactating clients, the blood prolactin levels remain elevated and suppress ovulation.
    - The return of ovulation is influenced by breastfeeding frequency, the length of each feeding, and the use of supplementation.
    - The infant's suck is also believed to affect prolactin levels.
    - Length of time to the first postpartum ovulation is approximately 6 months.
  - In nonlactating clients, prolactin declines and reaches the prepregnant level by the third week postpartum.
    - Ovulation occurs 7 to 9 weeks after birth.
    - Menses resume by 12 weeks postpartum.

## ASSESSMENT

Postpartum assessments immediately following delivery include monitoring vital signs, uterine firmness and its location in relation to the umbilicus, uterine position in relation to the midline of the abdomen, and amount of vaginal bleeding.

- American Academy of Pediatrics and American College of Obstetricians and Gynecologists recommends that blood pressure and pulse be assessed at least every 15 min for the first 2 hr after birth. Temperature should be assessed every 4 hr for the first 8 hr after birth and then at least every 8 hr.

A focused postpartum physical assessment should include assessing the client's

- **B: Breasts**
- **U: Uterus** (fundal height, uterine placement, and consistency)
- **B: Bowel** and GI function
- **B: Bladder** function
- **L: Lochia** (color, odor, consistency, and amount [COCA])
- **E: Episiotomy** (edema, ecchymosis, approximation)
- Vital signs, to include pain assessment
- Teaching needs

## LABORATORY TESTS

- Can include urinalysis and CBC with monitoring of Hgb, Hct, and WBC and platelet counts.
- If the rubella and Rh status are unknown, tests should be performed to determine their status.

## Uterus

Physical changes of the uterus include involution of the uterus. Involution occurs with contractions of the uterine smooth muscle, whereby the uterus returns to its prepregnant state. The uterus also rapidly decreases in size from approximately 1,000 g at the end of the third stage of labor to 60 to 80 g at 6 weeks postpartum with the fundal height steadily descending into the pelvis approximately one fingerbreadth (1 cm) per day. (17.1)

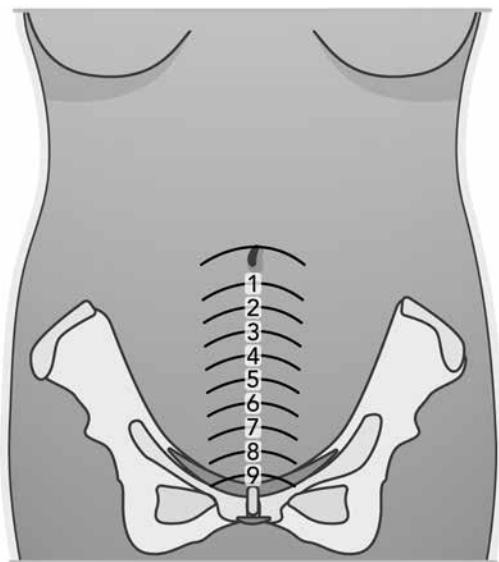

- At the end of the third stage of labor, the uterus should be palpable at midline and 2 cm below the umbilicus.
- 1 hr after delivery, the fundus (top portion of the uterus) should rise to the level of the umbilicus.
- Every 24 hr, the fundus should descend approximately 1 to 2 cm. It should be halfway between the symphysis pubis and the umbilicus by the sixth postpartum day.
- After about 2 weeks, the uterus should lie within the true pelvis and should not be palpable.

## ASSESSMENT

Assess the fundal height, uterine placement, and uterine consistency at least every 8 hr after the recovery period has ended.

- Explain the procedure to the client.
- Position the client supine with their knees slightly flexed so that the fundal height is not influenced by positioning.
- Apply clean gloves and a lower perineal pad, and observe lochia flow as the fundus is palpated.

### 17.1 Uterine involution

- Cup one hand just above the symphysis pubis to support the lower segment of the uterus, and with the other hand, palpate the abdomen to locate the fundus. Never palpate the fundus without cupping the uterus.
- Document the fundal height, location, and uterine consistency.
  - Determine the fundal height by placing fingers on the abdomen and measuring how many fingerbreadths (centimeters) fit between the fundus and the umbilicus above, below, or at the umbilical level.
  - Determine whether the fundus is midline in the pelvis or displaced laterally (caused by a full bladder).
  - Determine whether the fundus is firm or boggy. If the fundus is boggy (not firm), lightly massage the fundus in a circular motion. Q<sub>EBP</sub>
  - If the uterus does not firm after massaging, keep massaging and notify the provider.
- Document the position and location of the uterus by the number of fingerbreadths and according to agency policy.
  - If above the umbilicus, document as +1, U+1, 1/U.
  - If below the umbilicus, document as -1, U-1, U/1.

## PATIENT-CENTERED CARE

- Administer oxytocics intramuscularly or IV after the placenta is delivered to promote uterine contractions and to prevent hemorrhage.
  - Oxytocics include oxytocin, methylergonovine, and carboprost. Misoprostol, a prostaglandin, also can be administered.
- Monitor for adverse effects of medications.
  - Oxytocin and misoprostol can cause hypotension.
  - Methylergonovine, ergonovine, and carboprost can cause hypertension.
- Encourage early breastfeeding for a client who is lactating. This will stimulate the production of natural oxytocin and prevent hemorrhage.
- Encourage emptying of the bladder to prevent possible uterine displacement and atony.

## Lochia

Lochia is post-birth uterine discharge that contains blood, mucus, and uterine tissue. The amount of lochia is similar to a heavy menstrual period about 2 hr after delivery, then decreases gradually at a consistent rate.

### Three stages of lochia

**Lochia rubra:** Dark red color, bloody consistency, fleshy odor, can contain small clots, transient flow increases during breastfeeding and upon rising. Lasts 1 to 3 days after delivery.

**Lochia serosa:** Pinkish brown color and serosanguineous consistency. Can contain small clots and leukocytes. Lasts from approximately day 4 to day 10 after delivery.

**Lochia alba:** Yellowish white creamy color, fleshy odor. Can consist of mucus and leukocytes. Lasts from approximately day 10 up to 8 weeks postpartum.

## ASSESSMENT

- Lochia amount is assessed by the quantity of saturation on the perineal pad as being
  - Scant: less than 2.5 cm
  - Light: 2.5 to 10 cm
  - Moderate: more than 10 cm
  - Heavy: one pad saturated within 2 hr
  - Excessive blood loss: one pad saturated in 15 min or less, or pooling of blood under buttocks (17.2) Qs
- Assess the lochia for normal color, amount, odor, and consistency.
  - Assess lochia frequently to determine the amount of bleeding. Check at least every 15 min for the first hour after delivery, then every 1 hr for the next 4 hr, and then every 4 to 8 hr depending on facility policy.
  - Lochia typically trickles from the vaginal opening but flows more steadily during uterine contractions.
  - Assess for pooled lochia on the pad under the client, which they might not feel. This can identify heavy bleeding, which can be unnoticed.
  - Massaging the uterus or ambulation can result in a gush of lochia with the expression of clots and dark blood that has pooled in the vagina, but should soon decrease back to a trickle of bright red lochia when in the early puerperium.
  - Soiled pads can be weighed to give a better estimation as to the extent of bleeding.
  - If a cesarean section was performed, the amount of bleeding will be decreased because the provider cleans out the uterus after surgery.

## PATIENT-CENTERED CARE

Nursing interventions for abnormal lochia include notifying the provider and performing prescribed interventions based on the cause of the abnormality.

### Manifestations of abnormal lochia

- Excessive spurting of bright red blood from the vagina, possibly indicating a cervical or vaginal tear
- Numerous large clots and excessive blood loss (saturation of one pad in 15 min or less), which can indicate hemorrhage
- Foul odor, which is suggestive of infection
- Persistent heavy lochia rubra in the early postpartum period beyond day 3, which can indicate retained placental fragments
- Continued flow of lochia serosa or alba beyond the normal length of time can indicate endometritis, especially if it is accompanied by fever, pain, or abdominal tenderness.

## CLIENT EDUCATION

- Change pads frequently.
- Perform hand hygiene after perineal care and changing of soiled pads.
- Do not use tampons due to the increased risk for infection.

## Cervix, vagina, and perineum

### PHYSICAL CHANGES

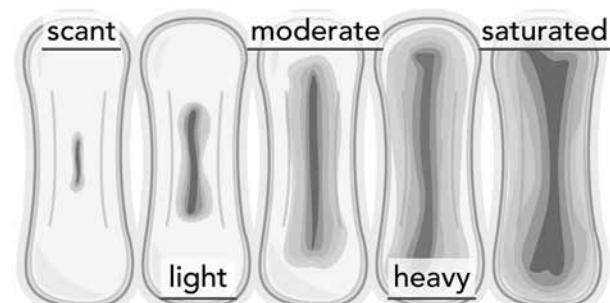

- The cervix is soft directly after birth and can be edematous, bruised, and have small lacerations.
  - Within 2 to 3 days postpartum, it shortens, regains its form, and becomes firm, with the os gradually closing.
  - Lacerations to the cervix can decrease the amount of cervical mucus.
  - External os will no longer have a round-dimple shape and will have a slit-like appearance.
- The vagina, which has distended, gradually returns to its prepregnancy size with the reappearance of rugae and a thickening of the vaginal mucosa.
  - Muscle tone is never restored completely.
  - Breastfeeding increases the incidence of vaginal dryness and atrophy.
- The soft tissues of the perineum can be erythematous and edematous, especially in areas of an episiotomy or lacerations.
  - Hematomas or hemorrhoids can be present.
  - Pelvic floor muscles can be overstretched and weak.

## ASSESSMENT

Assess for cervical, vaginal, and perineal healing.

- Observe the perineum for erythema, edema, and hematoma.
- Assess episiotomy and lacerations for approximation, drainage, quantity, and quality. A bright red trickle of blood from the episiotomy site in the early postpartum period is a normal finding.
- Initial healing occurs in 2 to 3 weeks, and complete healing occurs within 4 to 6 months.

### 17.2 Vaginal bleeding

## PATIENT-CENTERED CARE

### *Perineal tenderness, laceration, and episiotomy*

- Promote measures to help soften the client's stools.
- Promote comfort measures.
  - Apply ice/cold packs to the perineum for the first 24 hr to reduce edema and provide anesthetic effect. Do not apply directly to the perineum.
  - Heat therapies (hot packs), moist heat, and sitz baths can be used to increase circulation and promote healing and comfort.
  - Encourage sitz baths at a hot or cool temperature for at least 20 min for at least twice a day. 
  - Administer analgesics, such as nonopioids (acetaminophen), nonsteroidal anti-inflammatories (ibuprofen), and opioids (codeine, hydrocodone) for pain and discomfort.
  - Opioid analgesia can be administered via a patient-controlled analgesia (PCA) pump after cesarean birth. Continuous epidural infusions can also be used for pain control after cesarean birth.
  - Apply topical anesthetics (benzocaine spray) to the client's perineal area as needed or witch hazel compresses or hemorrhoidal creams to the rectal area for hemorrhoids.
- Educate the client about proper cleansing to prevent infection.

#### CLIENT EDUCATION

- Wash both hands thoroughly before and after voiding.
- Use a squeeze bottle filled with warm water or antiseptic solution after each voiding to cleanse the perineal area.
- Blot the perineal area to clean it after toileting, starting from front to back (urethra to anus).
- Use topical antiseptic cream or spray sparingly.
- Change the perineal pad by removing the front part first, peeling it toward the back after voiding or defecating.

## Breasts

Physical changes of the breasts include the secretion of colostrum, which occurs during pregnancy and 2 to 3 days immediately after birth. Milk is produced 3 to 5 days after the delivery of the newborn.

## ASSESSMENT

The nurse should perform a physical assessment of the client's breasts, and determine the client's choice regarding breastfeeding.

- Colostrum (early milk) transitions to mature milk by about 72 to 96 hr after birth; this transition is referred to as the milk coming in.
- Engorgement (fullness) of the breast tissue is a result of lymphatic circulation, milk production, and temporary vein congestion. The breast will appear tight, tender, warm, and full.
  - Inform clients who do not plan to breastfeed that this will resolve on its own, but breast binders or support bras can be used, or an ice pack or cabbage leaves can be applied.
  - Inform clients who plan to breastfeed that breast care and frequent feedings will prevent or manage engorgement.
- Observe for erythema, breast tenderness, cracked nipples, and indications of mastitis (infection in a milk duct of the breast with concurrent flu-like manifestations).
- Determine the client's ability to assist the newborn with latching on, and ensure the newborn has latched on correctly to prevent sore nipples.
- Ineffective newborn feeding patterns are related to maternal dehydration, maternal discomfort, newborn positioning, or difficulty with the newborn latching onto the breast.

## PATIENT-CENTERED CARE

- Promote early breastfeeding within the first 1 to 2 hr after birth.
- Encourage early demand feeding for the client who chooses to breastfeed. This will also stimulate the production of natural oxytocin and help prevent uterine hemorrhage.
- Assist the client into a comfortable position, and have them try various positions during breastfeeding. The four traditional positions for breastfeeding are football hold (under the arm), cradle, across the lap (modified cradle), and side-lying. Explain how varying positions can prevent nipple soreness. (17.3)
- Teach the client the importance of proper latch techniques (the newborn takes in part of the areola and nipple, not just the tip of the nipple) to prevent nipple soreness.
- Inform the client that breastfeeding causes the release of oxytocin, which stimulates uterine contractions. This is a normal occurrence and beneficial to uterine tone.
- Advise clients who do not plan to breastfeed to not stimulate the breast or express breast milk.

### 17.3 Breastfeeding positions

#### Football hold

#### Cradle

#### Modified cradle

The mother positions the baby as in the cradle position shown above, but reverses the function of each arm.

#### Side-lying

## Cardiovascular system and fluid and hematologic status

### PHYSICAL CHANGES

#### In the cardiovascular system during the postpartum period

- The cardiovascular system undergoes a decrease in blood volume during the postpartum period related to
  - Blood loss during childbirth (average blood loss is 300 to 500 mL [10% of blood volume] in an uncomplicated vaginal delivery and 500 to 1,000 mL [15% to 30% of blood volume] for a cesarean birth).
  - Diaphoresis and diuresis occur within the first 2 to 5 days after delivery, and rid the body of the excess fluid accumulated during the last part of pregnancy.
  - Weight loss (due to lochia, delivery, and diuresis) of about 19 lb [8.6 kg] during the first 5 days after delivery.
- Hypovolemic shock does not usually occur in response to the normal blood loss of labor and birth because of the expanded blood volume of pregnancy and the readjustment in the maternal vasculature, which occurs in response to the following.
  - Elimination of the placenta
  - Rapid reduction in the size of the uterus, putting more blood into the maternal systemic circulation

#### In blood values, coagulation factors, and fibrinogen levels during the puerperium

- Hematocrit levels drop moderately for 3 to 4 days then begin to increase and reach nonpregnant levels by 8 weeks postpartum.
- During the first 4 to 7 days after birth, WBC values between 20,000 and 25,000/mm<sup>3</sup> are common. This is called postpartum leukocytosis, and it is how the body prevents infection and aids in healing.
- Coagulation factors and fibrinogen levels increase during pregnancy and remain elevated in the immediate postpartum period. Hypercoagulability predisposes the postpartum client to thrombus formation and thromboembolism.

### VITAL SIGN CHANGES

- Blood pressure is usually unchanged with an uncomplicated pregnancy but can have an insignificant, slight transient increase. Significant decrease from baseline could indicate bleeding. Significant increase could indicate postpartum hypertension.
- Possible orthostatic hypotension within the first 48 hr postpartum can occur immediately after standing up with manifestations of faintness or dizziness resulting from splanchnic (viscera/internal organs) engorgement that can occur after birth. Encourage the client to sit on the side of the bed prior to standing up.

- Elevation of pulse, stroke volume, and cardiac output for the first hour postpartum occurs and then gradually decreases to a prepregnant state baseline by 6 to 8 weeks. Due to elevations in stroke volume during the first 2 days after delivery, the heart rate can be as low as 40/min. This is called puerperal bradycardia and this is common finding. Tachycardia in the postpartum period should be evaluated.
- Elevation of temperature to 38° C (100.4° F) resulting from dehydration after labor during the first 24 hr can occur, but should return to normal after 24 hr postpartum. Elevation after 24 hr or that persists after 2 days could indicate infection.

## ASSESSMENT

- Assess for cardiovascular and vital sign changes and monitor blood component changes. Compare with baseline pregnancy vital signs.
- Assess pedal pulses, skin turgor, and the legs and feet for edema.
- Inspect the legs for redness, swelling, and warmth, which are additional indications of venous thrombosis.

## PATIENT-CENTERED CARE

Nursing actions for alterations in findings include notifying the provider and performing prescribed interventions based on the cause of the alteration.

- Encourage adequate fluid intake.
- Encourage early ambulation to prevent venous stasis and thrombosis.
- Apply antiembolism stockings to the lower extremities if the client is at high risk for developing venous stasis and thrombosis. Remove the stockings as soon as the client is ambulating.
- Administer medications as prescribed.

## *Gastrointestinal system and bowel function*

Operative vaginal birth (forceps-and vacuum-assisted) and anal sphincter lacerations increase the risk of temporary postpartum anal incontinence that usually resolves within 6 months.

### PHYSICAL CHANGES IN THE GASTROINTESTINAL SYSTEM

- Increased appetite following delivery
- Constipation
- Hemorrhoids

## ASSESSMENT

The nurse should assess the gastrointestinal system including bowel function.

- Assess for reports of hunger. Expect the client to have a good appetite.
- Assess for bowel sounds and the return of normal bowel function. Spontaneous bowel movement might not occur for 2 to 3 days after delivery secondary to decreased intestinal muscle tone during labor and puerperium, prelabor diarrhea, dehydration, or medication adverse effects.
- Assess for discomfort with defecation due to perineal tenderness, episiotomy, lacerations, or hemorrhoids.
- Assess the rectal area for varicosities (hemorrhoids).

## PATIENT-CENTERED CARE

- Encourage interventions to promote bowel function (early ambulation, increased fluids, and intake of high-fiber foods).
- Administer stool softeners (docusate sodium) to prevent constipation.
- Enemas and suppositories are contraindicated for clients who have third- or fourth-degree perineal lacerations. Qs
- Flatus is common after a cesarean birth. Encourage the client to ambulate or rock in a chair to promote passage of flatus, and to avoid gas-forming foods. Anti-flatulence medications can be required.

## *Urinary system and bladder function*

The urinary system can show evidence of the following.

- Urinary retention secondary to loss of bladder elasticity and tone and/or loss of bladder sensation resulting from trauma, medications, or anesthesia. A distended bladder as a result of urinary retention can cause infection, uterine atony, and displacement to one side. The ability of the uterus to contract is also lessened.
- Postpartal diuresis with increased urinary output begins within 12 hr of delivery.

## ASSESSMENT

Assess the urinary system and bladder function.

- Assess the client's ability to void (perineal/urethral edema can cause pain and difficulty in voiding during the first 24 to 48 hr).
- Assess bladder elimination pattern. Excessive urine diuresis (more than 3,000 mL/day) is normal within the first 2 to 3 days after delivery.
- Assess for evidence of a distended bladder.
  - Fundal height above the umbilicus or baseline level
  - Fundus displaced from the midline over to the side
  - Bladder bulges above the symphysis pubis
  - Excessive lochia
  - Tenderness over the bladder area
- Frequent voiding of less than 150 mL of urine is indicative of urinary retention with overflow.

## PATIENT-CENTERED CARE

- Assist the client to void within 6 to 8 hr after delivery. If unable to void, catheterization can be required.
- Encourage the client to empty their bladder frequently to prevent possible displacement of the uterus and atony.
- Measure the client's first few voidings after delivery to assess for bladder emptying.
- Encourage the client to increase their oral fluid intake to replace fluids lost at delivery and to prevent or correct dehydration.
- Catheterize if necessary for bladder distention if the client is unable to void to ensure complete emptying of the bladder and allow uterine involution.

## Musculoskeletal system

Physical changes of the musculoskeletal system involve a reversal of the musculoskeletal adaptations that occurred during pregnancy. By 6 to 8 weeks after birth:

- The joints return to their prepregnant state and are completely restabilized. The feet, however, can remain permanently increased in size.
- Muscle tone begins to be restored throughout the body with the removal of progesterone's effect following delivery of the placenta. The rectus abdominis muscles of the abdomen and the pubococcygeus muscle tone are restored following placental expulsion and return to the prepregnant state about 6 weeks postpartum.

## ASSESSMENT

- Assess the musculoskeletal system for changes.
- Assess the abdominal wall for diastasis recti (separation of the rectus muscle). It usually resolves within 6 weeks.

## PATIENT-CENTERED CARE

Prevent falls by encouraging the client to wear nonskid slippers or socks, assisting the client with getting out of bed, and instructing the client to call for assistance initially when getting out of bed.

## CLIENT EDUCATION

- Perform postpartum strengthening exercises, starting with simple exercises, and then gradually progressing to more strenuous ones.
- Following cesarean birth, postpone abdominal exercises until about 4 to 6 weeks after delivery, or follow recommendations of the provider.
- Use good body mechanics and proper posture.
- Ambulate soon after delivery.
- Perform Kegel exercises to strengthen pelvic muscles.

## Immune system

Review the status of the following.

**Rubella:** A client who is nonimmune to rubella or has a negative or low titer is administered a subcutaneous injection of rubella vaccine or a measles, mumps, and rubella (MMR) vaccine during the postpartum period to protect a subsequent fetus from malformations. The client should not get pregnant for 4 weeks (28 days) following the immunization. *Qs*

**Rh:** All Rh-negative clients who have newborns who are Rh-positive must be given Rho(D) immune globulin administered IM within 72 hr of the newborn being born to suppress antibody formation in the mother.

• Test the client who receives both a live virus vaccine, such as the rubella vaccine, and Rho(D) immune globulin after 3 months to determine whether immunity to rubella has been developed. *QEBP*

**Varicella:** If the client has no immunity, varicella vaccine is administered before discharge. The client should not get pregnant for 1 month following the immunization. A second dose of vaccine is given at 4 to 8 weeks.

**Tetanus-diphtheria-acellular pertussis vaccine:** The vaccine is recommended for clients who have not previously received it. It is also recommended for people who are going to be around the baby frequently if they have not received the vaccine previously. Administer prior to discharge or as soon as possible in the postpartum period. Breastfeeding is not contraindicated.

## Comfort level

### ASSESSMENTS AND INTERVENTIONS

- Assess pain related to episiotomy, lacerations, incisions, afterpains, and sore nipples.
- Assess location, type, and quality of the pain to guide nursing interventions and client education.
- Administer pain medications as prescribed.
- Teach nonpharmacological measures (distraction, imagery, heating pads, position changes, cold packs).

## **Psychosocial**

During the postpartum period, a client can experience many different emotions due to hormonal changes. Monitor for conditions such as postpartum blues and depression during the postpartum period.

### **ASSESSMENTS AND INTERVENTIONS**

- Allow verbalization of feelings.
- Assess emotional status.
- Observe for bonding with infant.
- Monitor for manifestations of postpartum blues or depression.
  - Decreased appetite
  - Difficulty sleeping
  - Decreased interactions with others
  - Lack of communication

### **PATIENT-CENTERED CARE**

- Encourage skin-to-skin contact with their baby after delivery.
- Document interactions and bonding concerns.
- Encourage rooming in with the baby in the client's room at all times.
- Provide support, and initiate referrals as needed for counseling.

### **Active Learning Scenario**

A nurse on the postpartum unit is leading a discussion with a group of clients about perineal care after delivery. What education should the nurse include in the discussion? Use the ATI Active Learning Template: Basic Concept to complete this item.

**UNDERLYING PRINCIPLES:** Describe three concepts that are the basis for perineal hygiene.

### **NURSING INTERVENTIONS**

- Describe four actions the client should take to prevent infection.
- Describe four actions the nurse can take to promote client comfort.

## **Application Exercises**

1. A nurse is performing a fundal assessment for a client who is 2 days postpartum and observes the perineal pad for lochia. The pad is saturated approximately 12 cm with lochia that is bright red and contains small clots. Which of the following findings should the nurse document?
  - A. Moderate lochia rubra
  - B. Excessive lochia serosa
  - C. Light lochia rubra
  - D. Scant lochia serosa
2. During ambulation to the bathroom, a postpartum client experiences a gush of dark red blood that soon stops. On assessment, a nurse finds the uterus to be firm, midline, and at the level of the umbilicus. Which of the following findings should the nurse interpret this data as being?
  - A. Evidence of a possible vaginal hematoma
  - B. An indication of a cervical or perineal laceration
  - C. A normal postural discharge of lochia
  - D. Abnormally excessive lochia rubra flow
3. A nurse is completing postpartum discharge teaching to a client who had no immunity to varicella and was given the varicella vaccine. Which of the following statements by the client indicates understanding of the teaching?
  - A. "I will need to use contraception for 3 months before considering pregnancy."
  - B. "I need a second vaccination at my postpartum visit."
  - C. "I was given the vaccine because my baby is O-positive."
  - D. "I will be tested in 3 months to see if I have developed immunity."
4. A nurse is assessing a postpartum client for fundal height, location, and consistency. The fundus is noted to be displaced laterally to the right, and there is uterine atony. The nurse should identify which of the following conditions as the cause of the uterine atony?
  - A. Poor involution
  - B. Urinary retention
  - C. Hemorrhage
  - D. Infection
5. A nurse is providing education to a client who is 2 hr postpartum and has perineal laceration. Which of the following information should the nurse include? (Select all that apply.)
  - A. Use a perineal squeeze bottle to cleanse the perineum.
  - B. Sit on the perineum while resting in bed.
  - C. Apply a topical anesthetic cream or spray to the perineum.
  - D. Wipe the perineum thoroughly with a back-and-forth motion.
  - E. Apply cold or ice packs to the perineum.

## Application Exercises Key

1. A. **CORRECT:** The client has moderate lochia rubra containing small clots, which is an expected finding for the second day postpartum.
  - B. Excessive lochia serosa is indicated by saturation of a perineal pad in 15 min or less, or pooling of blood under the buttocks.
  - C. Light lochia rubra is a perineal pad that is saturated less than 10 cm with lochia.
  - D. Scant lochia serosa (less than 2.5 cm on perineal pad) is pinkish brown in color and serosanguineous in consistency. It occurs on day 4 to 12 following delivery.
- NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care
2. A. A client who has a vaginal hematoma is expected to report excessive pain or vaginal pressure.
  - B. Excessive spurting of bright red blood from the vagina indicates a possible cervical or perineal laceration.
  - C. **CORRECT:** Lochia typically trickles from the vaginal opening but flows more steadily during uterine contractions. Massaging the uterus or ambulation can result in a gush of lochia with the expression of clots and dark blood that has been pooled in the vagina, but it should soon decrease back to a trickle of bright red lochia in the early puerperium.
  - D. Excessive blood loss consists of one pad saturated in 15 min or less or the pooling of blood under the buttocks, which is not affected by the client's postural changes.
- NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care
3. A. A client is instructed to not get pregnant for 1 month following administration of varicella vaccine.
  - B. **CORRECT:** A second varicella immunization is needed at 4 to 8 weeks following delivery by clients who had no history of immunity.
  - C. Rho(D) immune globulin is administered to an Rh-negative client who has an Rh-positive newborn.
  - D. A client requires testing for immunity at 3 months following administration of rubella vaccine and Rho(D) immune globulin.
- NCLEX® Connection: Pharmacological and Parenteral Therapies, Medication Administration
4. A. Poor involution is the result of uterine atony and does not cause it.
  - B. **CORRECT:** Urinary retention can result in a distention of the bladder. A distended bladder can cause uterine atony and lateral displacement from the midline.
  - C. Hemorrhage is the result of uterine atony and does not cause it.
  - D. Infection does not cause uterine displacement or atony and would be characterized by foul-smelling vaginal discharge and elevated temperature.
- NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care
5. A. **CORRECT:** Use a perineal squeeze bottle filled with warm water to cleanse the perineum and promote healing.
  - B. Sitting supine on the perineum while resting in bed will apply more pressure to the area. Instead, the client should lay on one side when possible.
  - C. **CORRECT:** The application of a topical anesthetic cream or spray to the perineum will promote comfort.
  - D. The client should blot the perineum to dry it from front to back using toilet paper or wipes.
  - E. **CORRECT:** The application of cold or ice packs to the perineum will promote comfort and decrease swelling.
- NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

## Active Learning Scenario Key

Using the ATI Active Learning Template: Basic Concept

### UNDERLYING PRINCIPLES

- Increase tissue perfusion.
- Prevent infection.
- Promote comfort.

### NURSING INTERVENTIONS

- Prevent infection.
  - Wash hands thoroughly before and after voiding.
  - Use a squeeze bottle with warm water or antiseptic solution after each voiding.
  - Clean the perineal area from front to back.
  - Blot dry; do not wipe.
  - Use topical application of antiseptic cream or spray sparingly.
  - Change perineal pad from front to back after voiding and defecating.
- Promote comfort.
  - Apply ice or cold packs to the perineum.
  - Encourage sitz baths at least twice a day.
  - Administer analgesics.
  - Apply topical anesthetics to perineal area or witch hazel compresses to the rectal area.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

## CHAPTER 18 Baby-Friendly Care

Bonding and integration of an infant into the family structure should start during pregnancy, and continue into the fourth stage of labor and throughout hospitalization.

Assessment of bonding and integration of an infant into the family structure requires that a nurse understand the normal postpartum psychological changes the client undergoes in the attainment of the maternal role and the recognition of deviations. Baby-friendly care can be promoted by delaying nursing procedures during the first hour after birth and through the first attempt of the client to breastfeed to allow for immediate parent-infant contact.

A client's emotional and physical condition (unwanted pregnancy, adolescent pregnancy, history of depression, difficult pregnancy and birth) and the newborn's physical condition (prematurity, congenital anomalies) after birth can affect the family's bonding process. Culture, age, and socioeconomic status are factors that can influence the bonding process. Bonding can be delayed secondary to maternal or neonatal factors.

### PSYCHOSOCIAL AND MATERNAL ADAPTATION

Psychosocial adaptation and maternal adjustment begin during pregnancy as the client goes through commitment, attachment, and preparation for the birth of the newborn.

- During the first 2 to 6 weeks after birth, the client goes through a period of acquaintance with the newborn, as well as physical restoration. During this time the client also focuses on competently caring for the newborn.
- Finally, the act of achieving maternal identity is accomplished around 4 months following birth.
- These stages can overlap, and are variable based on maternal, infant, and the environmental factors.

### PHASES OF MATERNAL ROLE ATTAINMENT

**Dependent:** taking-in phase

- First 24 to 48 hr
- Focus on meeting personal needs
- Rely on others for assistance
- Excited, talkative
- Need to review birth experience with others

**Dependent-independent:** taking-hold phase

- Begins on day 2 or 3
- Lasts 10 days to several weeks
- Focus on baby care and improving caregiving competency
- Want to take charge but need acceptance from others
- Want to learn and practice
- Dealing with physical and emotional discomforts, can experience "baby blues"

**Interdependent:** letting-go phase

- Focus on family as a unit
- Resumption of role (intimate partner, individual)

### ASSESSMENT

Nursing assessments include noting the client's condition after birth, observing the maternal adaptation process, assessing maternal emotional readiness to care for the infant, and assessing how comfortable the client appears in providing infant care.

- Assess for behaviors that facilitate and indicate parent-infant bonding.
  - Considers the infant a family member
  - Holds the infant face-to-face (en face position), maintaining eye contact
  - Assigns meaning to the infant's behavior and views this positively
  - Identifies the infant's unique characteristics and relates them to those of other family members
  - Names the infant, indicating bonding is occurring
  - Touches the infant and maintains close physical proximity and contact
  - Provides physical care for the infant (feeding, diapering)
  - Responds to the infant's cries
  - Smiles at, talks to, and sings to the infant
- Assess for behaviors that impair and indicate a lack of parent-infant bonding.
  - Apathy when the infant cries
  - Disgust when the infant voids, stools, or spits up
  - Expresses disappointment in the infant
  - Turns away from the infant
  - Does not seek close physical proximity to the infant
  - Does not talk about the infant's unique features
  - Handles the infant roughly
  - Ignores the infant entirely
  - Does not include the infant in the family context
  - Perceives infant behavior as uncooperative
- Assess for manifestations of mood swings, conflict about maternal role, or personal insecurity.
  - Feelings of being "down"
  - Feelings of inadequacy
  - Feelings of anxiety
  - Emotional lability with frequent crying
  - Flat affect and being withdrawn
  - Feeling unable to care for the infant

#### NURSING ACTIONS

- Facilitate the bonding process by placing the infant skin-to-skin or in the en face position with the client immediately after birth.
- Promote rooming-in as a quiet and private environment that enhances the family bonding process.
- Promote early initiation of breastfeeding, and encourage the client to recognize infant readiness cues. Offer assistance as needed.
- Teach the client about infant care to facilitate bonding as the client's confidence improves.
- Encourage parents to bond with the infant through cuddling, bathing, feeding, diapering, and watching the infant.
- Provide frequent praise, support, and reassurance to the client as they move toward independence in caring for the infant and adjusting to their parental role.
- Encourage parents to express feelings, fears, and anxieties about caring for the infant.

#### CO-PARENT ADAPTATION

Co-parent adaptation occurs through bonding with the infant through the following behaviors.

- Using skin-to-skin contact, holding the infant, and engaging in eye-to-eye contact with the infant.
- Observing the infant for similarities to the parent's own features.
- Talking, singing, and reading to the infant.

#### TRANSITION

Research on the transition to fatherhood has revealed the following phases.

**Expectations and intentions:** Desires to be deeply and emotionally connected with the infant.

**Confronting reality:** Understands that reality does not always meet expectations. Commonly expressed emotions include feeling sad, frustrated, and jealous. Can feel like they are unable to talk with the other parent, who is consumed with infant caregiving and their own transition to parenthood.

**Creating the role of the involved father:** Decides to become actively involved in the care of the infant.

**Reaping rewards:** Rewards include infant smiles and a sense of completeness and meaning.

#### ASSESSMENT

Nursing assessment of paternal adaptation includes observing for the characteristics of infant bonding.

#### NURSING ACTIONS

- Provide education about infant care with each parent or caregiver, and encourage a hands-on approach.
- Assist the co-parent to transition to the parental role by providing guidance and encouraging equal participation in infant care.
- Encourage the parents to verbalize concerns and expectations related to infant care.

#### SIBLING ADAPTATION

The addition of an infant into the family unit affects everyone in the family, including siblings who can experience a temporary separation from parents. Siblings become aware of changes in the parents' behavior because the infant requires much more of parents' time.

#### ASSESSMENT

Nursing assessment of sibling adaptation to the infant includes the following.

- Assess for positive responses from the sibling.
  - Interest and concern for the infant
  - Increased independence
- Assess for adverse responses from the sibling.
  - Indications of sibling rivalry and jealousy
  - Regression in toileting and sleep habits
  - Aggression toward the infant
  - Increased attention-seeking behaviors and whining

#### NURSING ACTIONS

- Take the sibling on a tour of the obstetric unit.
- Encourage the parents to do the following.
  - Let the sibling be one of the first to see the infant.
  - Provide a gift from the infant to give the sibling.
  - Arrange for one parent to spend time with the sibling while the other parent is caring for the infant.
  - Allow older siblings to help in providing care for the infant.
  - Provide preschool-aged siblings with a doll to care for.

#### COMPLICATIONS

#### NURSING ACTIONS

- Emphasize verbal and nonverbal communication skills between the client, caregivers, and the infant.
- Provide continued assessment of the client's parenting abilities, as well as any other caregivers for the infant.
- Encourage continued support of grandparents and other family members.
- Provide home visits and group sessions for discussion regarding infant care and parenting problems.
- Give the client and caregivers information about social networks that provide a support system where they can seek assistance.
- Notify programs that provide prompt and effective community interventions to prevent more serious problems from occurring.

## Application Exercises

- 1.** A nurse concludes that the parent of a newborn is not showing positive indications of parent-infant bonding. The parent appears very anxious and nervous when asked to bring the newborn to the other parent. Which of the following actions should the nurse use to promote parent-infant bonding?

  - A. Hand the parent the newborn, and suggest that they change the diaper.
  - B. Ask the parent why they are so anxious and nervous.
  - C. Tell the parent that they will grow accustomed to the newborn.
  - D. Provide education about infant care when the parent is present.
- 2.** A client in the early postpartum period is very excited and talkative. They repeatedly tell the nurse every detail of the labor and birth. Because the client will not stop talking, the nurse is having difficulty completing the postpartum assessments. Which of the following action should the nurse take?

  - A. Come back later when the client is more cooperative.
  - B. Give the client time to express feelings.
  - C. Tell the client they need to be quiet so the assessment can be completed.
  - D. Redirect the client's focus so that they will become quiet.
- 3.** A nurse is caring for a client who is 1 day postpartum. The nurse is assessing for maternal adaptation and parent-infant bonding. Which of the following behaviors by the client indicates a need for the nurse to intervene? (Select all that apply.)

  - A. Demonstrates apathy when the newborn cries
  - B. Touches the newborn and maintains close physical proximity
  - C. Views the newborn's behavior as uncooperative during diaper changing
  - D. Identifies and relates newborn's characteristics to those of family members
  - E. Interprets the newborn's behavior as meaningful and a way of expressing needs
- 4.** A nurse is caring for a client who is 2 days postpartum. The client states, "My 4-year old son was toilet trained and now he is frequently wetting himself." Which of the following statements should the nurse provide to the client?

  - A. "Your son was probably not ready for toilet training and should wear training pants."
  - B. "Your son is showing an adverse sibling response."
  - C. "Your son may need counseling."
  - D. "You should try sending your son to preschool to resolve the behavior."
- 5.** A nurse in the delivery room is planning to promote parent-infant bonding for a client who just delivered. Which of the following is the priority action by the nurse?

  - A. Encourage the parents to touch and explore the neonate's features.
  - B. Limit noise and interruption in the delivery room.
  - C. Place the neonate at the client's breast.
  - D. Position the neonate skin-to-skin on the client's chest.

### Active Learning Scenario

A nurse is leading a parenting class on paternal adaptation for expectant clients and their partners. What concepts on paternal adaptation should the nurse include in the presentation? Use ATI Active Learning Template: Basic Concept to complete this item.

**RELATED CONTENT:** Describe three ways the father develops a parent-infant bond.

#### UNDERLYING PRINCIPLES

- Describe three stages of paternal transition to parenthood.
- Describe three stages of the development of the father-infant bond.

**NURSING INTERVENTIONS:** Describe three actions to assist in the father-infant bonding process.

## Application Exercises Key

1. A. It is not helpful to push the parent into newborn care activities without first providing education.
- B. This is a nontherapeutic statement and presumes the nurse knows what the parent is feeling.
- C. This is a nontherapeutic statement and offers the nurse's opinion.
- D. **CORRECT:** Nursing interventions to promote paternal bonding include providing education about newborn care and encouraging the parent to take a hands-on approach.

NCLEX® Connection: Psychosocial Integrity, Family Dynamics

2. A. Continue activities while encouraging the client to talk.
- B. **CORRECT:** Recognize that the client is in the taking-in phase, which begins immediately following birth and lasts a few hours to a couple of days.
- C. It is not necessary for the client to stop talking while completing the needed assessments.
- D. The client is in the taking-in phase, which includes talking about the birth experience. The client should be encouraged.

NCLEX® Connection: Psychosocial Integrity, Therapeutic Communication

3. A. **CORRECT:** This behavior demonstrates a lack of interest in the newborn and impaired parent-infant bonding.
- B. Touching the newborn and maintaining close proximity are indications of effective parent-infant bonding.
- C. **CORRECT:** A client's view of their newborn as being uncooperative during diaper changing is a sign of impaired parent-infant bonding.
- D. Endowing the newborn with family characteristics indicates effective parent-infant bonding.
- E. Recognizing the newborn's behavior as meaningful and a way to express needs is an indication of effective parent-infant bonding.

NCLEX® Connection: Psychosocial Integrity, Family Dynamics

4. A. This is not an appropriate intervention because it overlooks the child's emotional response to a new family member.
- B. **CORRECT:** Adverse responses by a sibling to a new infant can include regression in toileting habits.
- C. Recommending that the child receive counseling is not an appropriate nursing intervention for a child who is demonstrating an adverse sibling response.
- D. Recommending that the child be sent to preschool is not an appropriate nursing intervention for a child who is demonstrating an adverse sibling response.

NCLEX® Connection: Psychosocial Integrity, Therapeutic Communication

5. A. This is an appropriate action, but another intervention is the priority.
- B. This is an appropriate action, but another intervention is the priority.
- C. This is an appropriate action, but another intervention is the priority.
- D. **CORRECT:** Placing the neonate in the en face position on the client's chest immediately after birth is the priority nursing intervention to promote parent-infant bonding.

NCLEX® Connection: Psychosocial Integrity, Family Dynamics

## Active Learning Scenario Key

Using the ATI Active Learning Template: Basic Concept

### RELATED CONTENT

- Development of parent-infant bond
- Touching, holding, skin-to-skin contact, and maintaining eye-to-eye contact
- Recognizing personal features in the infant, and validating his claim to the infant
- Talking, reading, singing, and verbally interacting with the newborn

### UNDERLYING PRINCIPLES

Stages of paternal transition to parenthood

- Expectations: Having preconceived ideas about fatherhood
- Reality: Recognizing expectations might not be met, facing these feelings, and then embracing the need to become actively involved in parenting
- Transition to mastery: Taking an active role in parenting

Development of the father-infant bond

- Making a commitment and assuming responsibility for parenting
- Becoming connected and having feelings of attachment to the newborn
- Modifying lifestyle to make room to care for the newborn

### NURSING INTERVENTIONS

- Provide education about newborn care when the father is present.
- Encourage the father to take a hands-on role in care when present.
- Provide guidance.
- Involve the father as a full partner, not a helper, in the parenting process.
- Encourage the couple to verbalize concerns and expectations about newborn care.

NCLEX® Connection: Psychosocial Integrity, Family Dynamics

# CHAPTER 19

UNIT 3

POSTPARTUM NURSING CARE  
SECTION: ROUTINE POSTPARTUM CARE

CHAPTER 19

## *Client Education and Discharge Teaching*

Discharge teaching is an important aspect of postpartum care. It is important for a client to be able to perform self-care and recognize effects that suggest possible complications prior to discharge.

Discharge planning should be initiated at admission with time spent during the hospitalization on providing client education regarding postpartum self-care.

A nurse should use a variety of teaching strategies to promote learning. Return demonstrations are important to ensure that adequate learning has taken place.

### **ASSESSING A CLIENT'S KNOWLEDGE OF POSTPARTUM CARE**

- Inquire about the client's current knowledge regarding self-care.
- Assess the client's home support system and who will be there to assist. Include support persons in the educational process.
- Determine the client's readiness for learning and their ability to verbalize or demonstrate the information that has been given.

### **NURSING INTERVENTIONS FOR POSTPARTUM CARE**

Provide client teaching on self-care.

#### ***Perineal care***

##### **CLIENT EDUCATION**

- Cleanse the perineal area from front to back with warm water after each voiding and bowel movement.
- Blot perineal area from front to back.
- Remove and apply perineal pads from front to back.

#### **Breast care**

##### **Clients who plan to breastfeed**

- Emphasize the importance of hand hygiene prior to breastfeeding to prevent infection.
- **CLIENT EDUCATION**
  - Wear a well-fitting, nonbinding bra if breast support is needed. Do not use an underwire bra, which can cause clogged milk ducts.
  - Allow the infant to nurse on demand, which would be about 8 to 12 times in 24-hr period. Allow the infant to feed until the breast softens. Offer the second breast to the infant before completing the feeding, and start each feeding with a different breast.
  - To relieve breast engorgement, take a warm shower or apply warm compresses before breastfeeding to promote letdown and milk flow. Empty each breast completely at feedings, using a pump if needed after the infant has finished feeding. Apply cool compresses after feedings.
  - Apply breast creams as prescribed and wear breast shells in the bra to soften the nipples if they are irritated and cracked.
  - For flat or inverted nipples, use a breast shell between feedings.
  - For sore nipples, apply a small amount of breast milk to the nipple and allow it to air dry after breastfeeding.
  - Drink adequate fluids to satisfy the thirst.

##### **Clients who do not plan to breastfeed**

- Suppression of lactation is necessary for clients who are not breastfeeding.
- **CLIENT EDUCATION**
  - Wear a well-fitting, supportive bra continuously for the first 72 hr.
  - Avoid breast stimulation and running warm water over the breasts for prolonged periods until no longer lactating.
  - For breast engorgement, which can occur on the third or fifth postpartum day, apply cold compresses 15 min on and 45 min off. Fresh, cold cabbage leaves can be placed inside the bra. Mild analgesics or anti-inflammatory medication can be taken for pain and discomfort of breast engorgement.

## **Activity**

---

- Discuss the client's usual activity level to determine what tasks might be strenuous for the client.
- Encourage the client to be willing to accept help from others.
- Teach the client how to perform pelvic tilt exercises to strengthen back muscles and relieve strain on the lower back. These exercises involve alternately arching and straightening the back.

### **CLIENT EDUCATION**

- Regain pelvic floor muscle control by performing Kegel exercises. The same muscles are used when starting and stopping the flow of urine.
- Begin simple exercises soon after birth and progress to more strenuous activities.
- Following cesarean birth, postpone abdominal exercises for approximately 4 to 6 weeks.
- Following vaginal birth, limit stair climbing for the first few weeks postpartum.
- Following cesarean birth, wait until the 4- to 6-week follow-up visit before performing strenuous exercise, heavy lifting, or excessive stair climbing. A general rule is to climb no more than one flight of stairs once a day and to not lift more than 10 lb for the first 2 weeks.
- Plan at least one daily rest period; rest when the infant naps.

## **Nutrition**

---

- Encourage nonlactating clients to consume 1,800 to 2,200 kcal/day.
- Instruct the lactating client to increase their caloric intake and to include calcium-enriched foods in the diet.
  - The American Academy of Pediatrics recommends that clients who are lactating add an additional 450 to 500 calories/day to their prepregnancy diet.
- Iron supplements can be prescribed for clients who have low hemoglobin and hematocrit levels.

### **CLIENT EDUCATION**

- Consume a nutritious diet including all food groups and high in protein, which will aid in tissue repair.
- Continue taking prenatal vitamins until 6 weeks following birth.

## **Sexual activity**

---

- Clients can safely resume sexual intercourse by the second to fourth week after birth, when bleeding has stopped and perineum has healed. Over-the-counter lubricants might be needed during the first 6 weeks to 6 months.
- Physiological reactions to sexual activity can be slower and less intense for the first 3 months following birth.

## **Contraception**

---

Discuss the use of contraception upon resumption of sexual activity and inform the client that pregnancy can occur while breastfeeding even though menses has not returned.

### **CLIENT EDUCATION**

- If breastfeeding, do not take oral contraceptives until milk production is well established (usually 6 weeks).
- Menses for nonlactating clients might not resume until around 4 to 10 weeks. However, ovulation can occur as early as 1 month after delivery.
- Menses for lactating clients might not resume for 6 months or until cessation of breastfeeding.

## **INDICATIONS OF POTENTIAL COMPLICATIONS**

---

- Postpartum complications include hemorrhage, infection of the breasts, wounds, incisions, and postpartum depression. Refer to **CHAPTER 16: COMPLICATIONS OF THE POSTPARTUM PERIOD**.
- Ensure the client has an appointment set for a postpartum follow-up visit or a number to call and schedule an appointment. Following a vaginal delivery, the follow-up visit should take place in 4 to 6 weeks; following a cesarean birth, the visit should take place in 2 weeks. Write the date and time of the follow-up appointment in the discharge instructions.

**CLIENT EDUCATION:** Report indications of potential complications to the provider.

- **Chills or fever** greater than 38° C (100.4° F) after 24 hr
- **Change in vaginal discharge** with increased amount, large clots, change to a previous lochia color, such as bright red bleeding, and a foul odor **Qs**
- **NORMAL LOCHIAL FLOW PATTERNS**
  - Rubra: Dark red vaginal drainage for 1 to 3 days
  - Serosa: Brownish red or pink vaginal drainage from days 3 to 10
  - Alba: Yellowish white vaginal discharge after day 10 to 8 weeks
- **Episiotomy, laceration, or incisional pain** that does not resolve with analgesics, foul-smelling drainage, redness, or edema
- **Pain or tenderness in the abdominal or pelvic areas** that does not resolve with analgesics
- **Breast(s) with localized areas of pain and tenderness** with firmness, heat, and swelling, and/or nipples with cracks, redness, bruising, blisters, or fissures
- **Calves with localized pain, tenderness, redness, and swelling.** A lower extremity with either areas of redness and warmth or tenderness
- **Urination with burning, pain, frequency, urgency**
- **Indications of possible depression**, including apathy toward the infant, cannot provide self- or infant-care, or has feelings that they might hurt themselves or the infant.

## Application Exercises

1. A nurse is conducting a home visit for a client who is 1 week postpartum and breastfeeding. The client reports breast engorgement. Which of the following recommendations should the nurse make?

  - A. "Apply cold compresses between feedings."
  - B. "Take a warm shower right after feedings."
  - C. "Apply breast milk to the nipples and allow them to air dry."
  - D. "Use the various infant positions for feedings."
2. A nurse is providing discharge instructions for a client. At 4 weeks postpartum, the client should contact the provider for which of the following client findings?

  - A. Scant, nonodorous white vaginal discharge
  - B. Uterine cramping during breastfeeding
  - C. Sore nipple with cracks and fissures
  - D. Decreased response with sexual activity
3. A nurse is providing discharge teaching for a nonlactating client. Which of the following instructions should the nurse include in the teaching?

  - A. "Wear a supportive bra continuously for the first 72 hours."
  - B. "Pump your breast every 4 hours to relieve discomfort."
  - C. "Use breast shells throughout the day to decrease milk supply."
  - D. "Apply warm compresses until milk suppression occurs."
4. A nurse is providing discharge instructions to a postpartum client following a cesarean birth. The client reports leaking urine every time they sneeze or cough. Which of the following interventions should the nurse suggest?

  - A. Sit-ups
  - B. Pelvic tilt exercises
  - C. Kegel exercises
  - D. Abdominal crunches
5. A nurse is providing care to four clients on the postpartum unit. Which of the following clients is at greatest risk for developing a postpartum infection?

  - A. A client who has an episiotomy that is erythematous and has extended into a third-degree laceration
  - B. A client who does not wash their hands between perineal care and breastfeeding
  - C. A client who is not breastfeeding and is using measures to suppress lactation
  - D. A client who has a cesarean incision that is well-approximated with no drainage

### Active Learning Scenario

A nurse is reviewing discharge teaching with a client who is not breastfeeding. What information should the nurse include in the teaching? Use the ATI Active Learning Template: Basic Concept to complete this item.

#### UNDERLYING PRINCIPLES

- Nutrition: Describe the nutrition and fluid plan the client should use.
- Resumption of sexual intercourse: Describe appropriate actions by the client.
- Indications of complications to report to the provider: List two that the client should report.

## Application Exercises Key

1. A. **CORRECT:** Cold compresses applied to the breasts after the feedings can help with breast engorgement.
- B. Taking a warm shower prior to feedings, not immediately after, can assist with the letdown reflex and milk flow.
- C. Applying breast milk to the nipples and air drying is recommended for the client who has sore nipples, but it has no effect on breast engorgement.
- D. Using the various positions for feedings helps to prevent nipple soreness but has no effect on breast engorgement.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

2. A. Lochia alba, a white vaginal discharge, is normal from the 11th day postpartum to approximately 6 weeks following birth.
- B. Oxytocin, which is released with breastfeeding, causes the uterus to contract and can cause discomfort.
- C. **CORRECT:** A sore nipple that has cracks and fissures is an indication of mastitis.
- D. Physiological reactions to sexual activity can be slower and less intense for the first 3 months following birth.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

3. A. **CORRECT:** Instruct the client to wear a well-fitting support bra continuously for the first 72 hr.
- B. Do not recommend using a breast pump for the nonlactating client.
- C. Recommend using a breast shell for clients who have flat or inverted nipples.
- D. Instruct the nonlactating client to avoid application of warm compresses. Cold compresses can be applied to relieve discomfort.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

4. A. Sit-ups should not be performed until after the postpartum follow-up appointment.
- B. Pelvic tilt exercises consist of the alternate arching and straightening of the back to strengthen the back muscles and relieve back discomfort.
- C. **CORRECT:** Kegel exercises consist of the voluntary contraction and relaxation of the pubococcygeus muscle to strengthen the pelvic muscles, which will assist the client in decreasing urinary stress incontinence that occurs with sneezing and coughing.
- D. Abdominal crunches should not be performed until after the postpartum follow-up appointment.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

5. A. An episiotomy with a laceration is at risk for an infection, but there is a client who is at greater risk for a postpartum infection.
- B. **CORRECT:** The client who does not wash their hands between perineal care and breastfeeding is at an increased risk for developing mastitis. Therefore, they are most at risk for developing a postpartum infection.
- C. A client who is suppressing lactation (increases the risk of milk stasis) is at risk for an infection, but there is a client who is at greater risk for a postpartum infection.
- D. A client who has an abdominal incision is at risk for an infection, but there is a client who is at greater risk for a postpartum infection.

NCLEX® Connection: Physiological Adaptation, Illness Management

## Active Learning Scenario Key

Using the ATI Active Learning Template: Basic Concept

### UNDERLYING PRINCIPLES

#### Nutrition

- Eat a diet that includes all food groups and higher protein content.
- Drink fluids to satisfy thirst.
- Consume 1,800 to 2,200 kcal/day.

#### Sexual intercourse

- Clients can safely resume sexual activity by the second to fourth week after birth, when bleeding has stopped and perineum has healed.
- Over-the-counter lubricants might be needed.
- Physiological reactions to sexual activity can be slower and less intense.

#### Indications of complications

- Chills or fever greater than 38° C (100.4° F) for 2 or more days.
- Change in vaginal discharge with increased amount, large clots, change to previous lochia color, foul odor.
- Episiotomy, laceration, or incisional pain that does not resolve with analgesics; foul-smelling drainage; redness; and/or edema.
- Pain or tenderness in the abdominal or pelvic area that does not resolve with analgesics.
- Breasts with localized areas of pain and tenderness with firmness, heat, and swelling and/or nipples with cracks or fissures.
- Calves with localized pain and tenderness, redness, and swelling. Lower extremity with either areas of redness and warmth.
- Urination with burning, pain, frequency, urgency.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

## Postpartum Disorders

Postpartum disorders are unexpected events or occurrences that can happen during the postpartum period. It is imperative for a nurse to have a thorough understanding of each disorder and initiate appropriate nursing interventions to achieve positive outcomes.

Postpartum disorders reviewed in this chapter include superficial and deep-vein thrombosis, pulmonary embolus, coagulopathies (idiopathic thrombocytopenic purpura and disseminated intravascular coagulation), postpartum hemorrhage, uterine atony, subinvolution of the uterus, inversion of the uterus, retained placenta, lacerations, and hematomas.

### Deep-vein thrombosis

- Thrombophlebitis refers to a thrombus that is associated with inflammation.
- Thrombophlebitis of the lower extremities can be of superficial or deep veins, which are most often of the femoral, saphenous, or popliteal veins. The postpartum client is at greatest risk for a deep-vein thrombosis (DVT) that can lead to a pulmonary embolism.

### ASSESSMENT

#### RISK FACTORS

- Pregnancy
- Cesarean birth (doubles the risk)
- Operative vaginal birth
- Pulmonary embolism or varicosities
- Immobility
- Obesity
- Smoking
- Multiparity
- Age greater than 35 years
- History of thromboembolism

#### EXPECTED FINDINGS

Leg pain and tenderness

#### **PHYSICAL ASSESSMENT FINDINGS**

- Unilateral area of swelling, warmth, and redness
- Hardened vein over the thrombosis
- Calf tenderness

#### DIAGNOSTIC PROCEDURES

##### **NONINVASIVE**

- Doppler ultrasound scanning
- Computed tomography
- Magnetic resonance imaging

### **PATIENT-CENTERED CARE**

#### NURSING CARE

##### *Prevention of thrombophlebitis*

- Maintain sequential compression device until ambulation established.
- If bed rest is prolonged longer than 8 hr, use active and passive range of motion to promote circulation in the legs if warranted.
- Initiate early and frequent ambulation postpartum.
- Measure the lower extremities for fitted elastic thromboembolic hose to lower extremities.

##### **CLIENT EDUCATION**

- Avoid prolonged periods of standing, sitting, or immobility.
- Elevate both legs when sitting.
- Avoid crossing the legs, which will reduce the circulation and exacerbate venous stasis.
- Maintain fluid intake of 2 to 3 L each day from food and beverage sources to prevent dehydration, which causes circulation to be sluggish.
- Discontinue smoking.

##### *Management of thrombophlebitis*

- Facilitate bed rest and elevation of the client's extremity above the level of the heart. (Avoid using a knee gatch or pillow under knees.) Encourage the client to change positions frequently.
- Administer intermittent or continuous warm moist compresses.
- Do **NOT** massage the affected limb to prevent thrombus from dislodging and becoming an embolus.
- Measure the client's leg circumferences.
- Provide thigh-high antiembolism stockings for the client at high risk for venous insufficiency.
- Administer analgesics (nonsteroidal anti-inflammatory agents).
- Administer anticoagulants for DVT.

## MEDICATIONS

---

### *Heparin*

---

CLASSIFICATION: Anticoagulant

THERAPEUTIC INTENT: Given IV to prevent formation of other clots and to prevent enlargement of the existing clot.

#### NURSING ACTIONS

- Initially, IV heparin is administered by continuous infusion for 3 to 5 days with doses adjusted according to coagulation studies. Protamine sulfate, the heparin antidote, should be readily available to counteract the development of heparin-induced antiplatelet antibodies.
- Monitor aPTT (1.5 to 2.5 times the control level of 30 to 40 seconds).

CLIENT EDUCATION: Report bleeding from the gums or nose, increased vaginal bleeding, blood in the urine, and frequent bruising.

### *Warfarin*

---

CLASSIFICATION: Anticoagulant

THERAPEUTIC INTENT: Used for treatment of clots. It is administered orally and is continued by the client for approximately 3 months.

#### NURSING ACTIONS

- Phytonadione, the warfarin antidote, should be readily available for prolonged clotting times.
- Monitor PT (1.5 to 2.5 times the control level of 11 to 12.5 seconds) and INR of 2 to 3.

#### CLIENT EDUCATION

- Watch for bleeding from the gums or nose, increased vaginal bleeding, blood in the urine, and frequent bruising. **Qs**
- Use birth control to avoid pregnancy due to the teratogenic effects of warfarin. Oral contraceptives are contraindicated because of the increased risk for thrombosis.

## CLIENT EDUCATION

---

### PRECAUTIONS WHILE RECEIVING ANTICOAGULANTS

- Avoid taking aspirin or ibuprofen (increases bleeding tendencies).
- Use an electric razor for shaving.
- Avoid alcohol use (inhibits warfarin).
- Brush teeth gently using a soft toothbrush.
- Avoid rubbing or massaging legs.
- Avoid periods of prolonged sitting or crossing legs.

## *Pulmonary embolus*

---

- An embolus occurs when fragments or an entire clot dislodges and moves into circulation.
- A pulmonary embolism is a complication of DVT that occurs if the embolus moves into the pulmonary artery or one of its branches and lodges in a lung, occluding the vessel and obstructing blood flow to the lungs.
- Acute pulmonary embolus is an emergent situation.

## ASSESSMENT

---

### RISK FACTORS

Risk factors are the same as those for DVT.

### EXPECTED FINDINGS

---

- Apprehension
- Pleuritic chest pain
- Dyspnea
- Tachypnea
- Hemoptysis
- Tachycardia
- Cough
- Syncope
- Crackles with breath sounds
- Elevated temperature
- Hypoxia

### DIAGNOSTIC AND THERAPEUTIC PROCEDURES

---

- Ventilation/perfusion lung scan
- Magnetic resonance angiography
- Spiral computed tomography
- Pulmonary angiogram
- Embolectomy to surgically remove the embolus

## PATIENT-CENTERED CARE

---

### NURSING CARE

- Place the client in a semi-Fowler's position with the head of the bed elevated to facilitate breathing.
- Administer oxygen by mask.

### MEDICATIONS

---

- Medications prescribed include the medications listed under DVT.
- Thrombolytic therapy to break up blood clots can be prescribed.
  - Alteplase, streptokinase:** Similar adverse effects and contraindications as anticoagulants.

# Coagulopathies

- **Idiopathic thrombocytopenic purpura (ITP)** is a coagulopathy that is an autoimmune disorder in which the life span of platelets is decreased by antiplatelet antibodies. This can result in severe hemorrhage following a cesarean birth or lacerations.
- **Disseminated intravascular coagulation (DIC)** is a coagulopathy in which clotting and anticoagulation mechanisms occur at the same time. The client is at risk for both internal and external bleeding, as well as damage to organs resulting from ischemia caused by microclots.
- Coagulopathies are suspected when the usual measures to stimulate uterine contractions fail to stop vaginal bleeding.

## ASSESSMENT

### RISK FACTORS

**ITP:** genetic in origin

**DIC:** can occur secondary to other complications to include the following

- Abruptio placenta (most common cause)
- Amniotic fluid embolism
- Missed abortion
- Fetal death in utero (fetus has died but is retained in the uterus for at least 6 weeks)
- Severe preeclampsia or eclampsia (gestational hypertension), HELLP syndrome
- Septicemia
- Cardiopulmonary arrest
- Hemorrhage
- Hydatidiform mole

### EXPECTED FINDINGS

#### PHYSICAL ASSESSMENT FINDINGS

- Unusual spontaneous bleeding from the gums and nose (epistaxis)
- Oozing, trickling, or flow of blood from incision, lacerations, or episiotomy
- Petechiae and ecchymoses
- Excessive bleeding from venipuncture, injection sites, or slight traumas
- Hematuria
- Gastrointestinal bleeding
- Tachycardia, hypotension, and diaphoresis

### LABORATORY TESTS

- CBC with differential
- Blood typing and crossmatch

#### CLOTTING FACTORS

- Platelet levels (thrombocytopenia): decreased
- Fibrinogen levels: decreased
- PT: prolonged
- Fibrin split product levels: increased
- D-dimer test (specific fibrin degradation fragment): increased

## PATIENT-CENTERED CARE

### NURSING CARE

- Assess skin, venipuncture, injection sites, lacerations, and episiotomy for bleeding.
- Monitor vital signs and hemodynamic status.
- Monitor urinary output, usually by insertion of an indwelling urinary catheter.
- Transfuse platelets, clotting factors, other blood products, or volume expanders.
- Assist in preparing the client for a splenectomy if ITP does not respond to medical management and provide postsurgical care.
- Ensure optimal oxygenation.

**DIC:** Focus is on assessing for and correcting the underlying cause (removal of dead fetus or placental abruption, treatment of infection, preeclampsia, or eclampsia).

- Administer fluid volume replacement, which can include blood and blood products.
- Administer pharmacological interventions, including antibiotics, vasoactive medications, and uterotonic agents.
- Administer supplemental oxygen.
- Provide protection from injury.

### THERAPEUTIC PROCEDURES

- Correction of the underlying cause
- Splenectomy: can be performed by the provider if ITP does not respond to medical management
- Surgical intervention (hysterectomy) for DIC: performed by the provider as indicated

## Postpartum hemorrhage

Postpartum hemorrhage is considered to occur if the client loses more than 500 mL blood after a vaginal birth or more than 1,000 mL blood after a cesarean birth. Two complications that can occur following postpartum hemorrhage include hypovolemic shock and anemia.

## ASSESSMENT

### RISK FACTORS

- Uterine atony or history of uterine atony
- Overdistended uterus
- Prolonged labor, oxytocin-induced labor
- High parity
- Ruptured uterus
- Complications during pregnancy (placenta previa, abruptio placenta)
- Precipitous delivery
- Administration of magnesium sulfate therapy during labor
- Lacerations and hematomas
- Inversion of uterus
- Subinvolution of the uterus
- Retained placental fragments
- Coagulopathies (DIC)

## **EXPECTED FINDINGS**

---

Increase or change in lochial pattern (return to previous stage, large clots)

### **PHYSICAL ASSESSMENT FINDINGS**

- Uterine atony (hypotonic or boggy)
- Blood clots larger than a quarter
- Perineal pad saturation in 15 min or less
- Constant oozing, trickling, or frank flow of bright red blood from the vagina
- Tachycardia and hypotension
- Pallor of skin and mucous membranes; cool, and clammy with loss of turgor
- Oliguria

## **LABORATORY TESTS**

---

- Hgb and Hct
- Coagulation profile (PT)
- Blood type and crossmatch

## **PATIENT-CENTERED CARE**

---

### **NURSING CARE**

---

- Firmly massage the uterine fundus.
- Monitor vital signs.
- Assess for source of bleeding.
  - Assess fundus for height, firmness, and position. If uterus is boggy, massage fundus to increase muscle contraction.
  - Assess lochia for color, quantity, and clots.
  - Assess for clinical findings of bleeding from lacerations, episiotomy site, or hematomas.
- Assess bladder for distention. Insert an indwelling urinary catheter to assess kidney function and obtain an accurate measurement of urinary output.
- Maintain or initiate IV fluids to replace fluid volume loss with IV isotonic solutions, such as lactated Ringer's or 0.9% sodium chloride; colloid volume expanders, such as albumin; and blood products (packed RBCs and fresh frozen plasma).
- Provide oxygen at 10 to 12 L/min via nonrebreather facemask, and monitor oxygen saturation.
- Elevate the client's legs to a 20° to 30° angle to increase circulation to essential organs.

## **MEDICATIONS**

---

### **Oxytocin**

---

**CLASSIFICATION:** Uterine stimulant

**THERAPEUTIC INTENT:** Promotes uterine contractions

### **NURSING ACTIONS**

- Assess uterine tone and vaginal bleeding.
- Monitor for adverse reactions of water intoxication (lightheadedness, nausea, vomiting, headache, malaise). These reactions can progress to cerebral edema with seizures, coma, and death.

## ***Methylergonovine***

---

**CLASSIFICATION:** Uterine stimulant

**THERAPEUTIC INTENT:** Controls postpartum hemorrhage

### **NURSING ACTIONS**

- Assess uterine tone and vaginal bleeding. Do not administer to clients who have hypertension.
- Monitor for adverse reactions, including hypertension, nausea, vomiting, and headache.

## ***Misoprostol***

---

**CLASSIFICATION:** Uterine stimulant

**THERAPEUTIC INTENT:** Controls postpartum hemorrhage.

**NURSING ACTIONS:** Assess uterine tone and vaginal bleeding.

## ***Carboprost tromethamine***

---

**CLASSIFICATION:** Uterine stimulant

**THERAPEUTIC INTENT:** Controls postpartum hemorrhage

### **NURSING ACTIONS**

- Assess uterine tone and vaginal bleeding.
- Monitor for adverse reactions, including fever, hypertension, chills, headache, nausea, vomiting, and diarrhea.

## **CLIENT EDUCATION**

---

Limit physical activity to conserve strength, to increase iron and protein intake to promote the rebuilding of RBC volume, and to take iron with vitamin C to enhance absorption.

## ***Uterine atony***

---

Uterine atony results from the inability of the uterine muscle to contract adequately after birth. This can lead to postpartum hemorrhage.

## **ASSESSMENT**

---

### **RISK FACTORS**

---

- Retained placental fragments
- Prolonged or precipitous labor
- Oxytocin induction or augmentation of labor
- Overdistention of the uterine muscle (multiparity, multiple gestations, polyhydramnios [hydramnios], macrosomic fetus)
- Magnesium sulfate administration as a tocolytic
- Anesthesia and analgesia administration
- Trauma during labor and birth from operative delivery (forceps- or vacuum-assisted birth, cesarean birth)

## **EXPECTED FINDINGS**

---

Increased vaginal bleeding

### **PHYSICAL ASSESSMENT FINDINGS**

- Uterus that is larger than normal and boggy with possible lateral displacement on palpation
- Prolonged lochial discharge
- Irregular or excessive bleeding
- Tachycardia and hypotension
- Pallor of skin and mucous membranes; cool, and clammy with loss of turgor

## **DIAGNOSTIC PROCEDURES**

---

- Bimanual compression or manual exploration of the uterine cavity for retained placental fragments by the provider
- Surgical management, such as a hysterectomy

## **PATIENT-CENTERED CARE**

---

### **NURSING CARE**

---

- Ensure that the urinary bladder is empty.
- Monitor the following.
  - Fundal height, consistency, and location
  - Lochia for quantity, color, and consistency
- Perform fundal massage if indicated.
  - If the uterus becomes firm, continue assessing hemodynamic status.
  - If uterine atony persists, anticipate surgical intervention, such as a hysterectomy.
- Express clots that can have accumulated in the uterus, but only after the uterus is firmly contracted. It is critical not to express clots prior to the uterus becoming firmly contracted, because pushing on an uncontracted uterus can invert the uterus and result in extensive hemorrhage. 
- Monitor vital signs.
- Maintain or initiate IV fluids.

### **MEDICATIONS**

---

As noted for postpartum hemorrhage

### **CLIENT EDUCATION**

---

- Rapid intervention is required. The health care team will explain the purpose of the interventions as they are performed.
- After becoming stable, limit physical activity to conserve strength. Increase iron and protein intake to promote the rebuilding of RBC volume.

## ***Subinvolution of the uterus***

---

Subinvolution is when the uterus remains enlarged with continued lochial discharge and can result in postpartum hemorrhage.

## **ASSESSMENT**

---

### **RISK FACTORS**

---

- Pelvic infection and endometritis
- Retained placental fragments not completely expelled from the uterus

## **EXPECTED FINDINGS**

---

- Prolonged vaginal bleeding
- Irregular or excessive vaginal bleeding

### **PHYSICAL ASSESSMENT FINDINGS**

- Uterus that is enlarged and higher than normal in the abdomen relative to the umbilicus
- Boggy uterus
- Prolonged lochia discharge with irregular or excessive bleeding

## **LABORATORY TESTS**

---

Blood, intracervical, and intrauterine bacterial cultures to check for evidence of infection and endometritis

## **THERAPEUTIC PROCEDURES**

---

Dilation and curettage (D&C) is performed by the provider to remove retained placental fragments or to debride placenta insertion site, if indicated.

## **PATIENT-CENTERED CARE**

---

### **NURSING CARE**

---

- Monitor fundal position and consistency.
- Monitor lochia for color, amount, consistency, and odor.
- Monitor vital signs.
- Encourage the client to use activities that can enhance uterine involution.
  - Breastfeeding
  - Early and frequent ambulation
  - Frequent voiding

## MEDICATIONS

---

### Methylergonovine

CLASSIFICATION: Uterine stimulant

THERAPEUTIC INTENT: To promote uterine contractions and expel the retained fragments of placenta

#### NURSING ACTIONS

- Assess uterine tone and vaginal bleeding.
- Assess for signs of infection such as increased uterine tenderness.

**Antibiotic therapy** can be prescribed to prevent or treat infection.

## *Inversion of the uterus*

---

Inversion of the uterus is the turning inside out of the uterus and can be partial or complete. Uterine inversion is an emergency situation that can result in postpartum hemorrhage and requires immediate intervention.

## ASSESSMENT

---

### RISK FACTORS

---

- Retained placenta
- Tocolysis
- Fetal macrosomia
- Nulliparity
- Uterine atony
- Vigorous fundal pressure
- Abnormally adherent placental tissue
- Fundal implantation of the placenta
- Excessive traction applied to the umbilical cord
- Short umbilical cord
- Prolonged labor

## EXPECTED FINDINGS

---

Pain in lower abdomen

#### PHYSICAL ASSESSMENT FINDINGS

- Vaginal bleeding: hemorrhage
  - Complete inversion as evidenced by the fundus presenting as a mass in the vagina
  - Prolapsed inversion as evidenced by a large, red, rounded mass that protrudes 20 to 30 cm outside the introitus
  - Incomplete inversion as evidenced by the palpation of a smooth mass through the dilated cervix
- Dizziness
- Low blood pressure, increased pulse (shock)
- Pallor

## THERAPEUTIC PROCEDURES

---

Manual replacement of the uterus into the uterine cavity and repositioning of the uterus by the provider

## PATIENT-CENTERED CARE

---

### NURSING CARE

- Assess for an inverted uterus.
  - Visualize the introitus.
  - Perform a pelvic exam.
- Maintain IV fluids.
- Administer oxygen.
- Stop oxytocin if it is being administered at the time uterine inversion occurred.
- Avoid excessive traction on the umbilical cord.
- Anticipate surgery if nonsurgical interventions and management are unsuccessful.

## MEDICATIONS

---

### Terbutaline

CLASSIFICATION: Tocolytic

THERAPEUTIC INTENT: To relax the uterus prior to the provider's attempt at replacement of the uterus into the uterine cavity and uterus repositioning

#### NURSING ACTIONS

Following replacement of the uterus into the uterine cavity

- Closely observe the client's response to treatment and assess for stabilization of hemodynamic status.
- Avoid aggressive fundal massage.
- Administer oxytocics as prescribed.
- Administer broad-spectrum antibiotics for infection prophylaxis.

## *Retained placenta*

---

The placenta or fragments of the placenta remain in the uterus and prevent the uterus from contracting, which can lead to uterine atony or subinvolution. A placenta that has not been delivered within 30 min of the birth is a retained placenta.

## ASSESSMENT

---

### RISK FACTORS

---

- Partial separation of a normal placenta
- Entrapment of a partially or completely separated placenta by a constricting ring of the uterus
- Excessive traction on the umbilical cord prior to complete separation of the placenta
- Placental tissue that is abnormally adherent to the uterine wall
- Preterm births between 20 and 24 weeks of gestation

## EXPECTED FINDINGS

---

#### PHYSICAL ASSESSMENT FINDINGS

- Uterine atony, subinvolution, or inversion
- Excessive bleeding or blood clots larger than a quarter
- Return of lochia rubra once lochia has progressed to serosa alba
- Malodorous lochia or vaginal discharge
- Elevated temperature

## LABORATORY TESTS

Hgb and Hct

## DIAGNOSTIC PROCEDURES

- Manual separation and removal of the placenta is done by the provider.
- D&C if oxytocics are ineffective in expelling the placental fragments.

## PATIENT-CENTERED CARE

### NURSING CARE

- Monitor the uterus for fundal height, consistency, and position.
- Monitor lochia for color, amount, consistency, and odor.
- Monitor vital signs.
- Maintain or initiate IV fluids.
- Anticipate surgical interventions (D&C, hysterectomy) if postpartum bleeding is present and continues.

### MEDICATIONS

#### Oxytocin

To expel retained fragments of the placenta

CLASSIFICATION: Uterine stimulant

THERAPEUTIC INTENT: Promotes uterine contractions and expels the retained fragments of placenta

#### NURSING ACTIONS

- Assess uterine tone and vaginal bleeding.
- Monitor for adverse reactions of water intoxication (lightheadedness, nausea, vomiting, headache, malaise), which can progress to cerebral edema with seizures, coma, and death.

## CLIENT EDUCATION

After becoming stable, limit physical activity to conserve strength. Increase iron and protein intake to promote the rebuilding of RBC volume.

## *Lacerations and hematomas*

- Lacerations that occur during labor and birth consist of the tearing of soft tissues in the birth canal and adjacent structures including the cervical, vaginal, vulvar, perineal, and/or rectal areas.
- An episiotomy can extend and become a third- or fourth-degree laceration.
- A hematoma is a collection of clotted blood within tissues that can appear as a bulging bluish mass. Hematomas can occur in the pelvic region or higher in the vagina or broad ligament.
- Pain, rather than noticeable bleeding, is the distinguishable clinical finding of hematomas.
- The client is at risk for hemorrhage or infection due to a laceration or hematoma.

## ASSESSMENT

### RISK FACTORS

- Operative vaginal birth (forceps-assisted, vacuum-assisted birth)
- Precipitous birth
- Cephalopelvic disproportion
- Size (macrosomic infant) and abnormal presentation or position of the fetus
- Prolonged pressure of the fetal head on the vaginal mucosa
- Previous scarring of the birth canal from infection, injury, or operation

## EXPECTED FINDINGS

#### Laceration

- Sensation of oozing or trickling of blood
- Excessive rubra lochia (with or without clots)

#### Hematoma

- Pain
- Pressure sensation in rectum (urge to defecate) or vagina
- Difficulty voiding

#### PHYSICAL ASSESSMENT FINDINGS

- **Laceration**
  - Vaginal bleeding even though the uterus is firm and contracted
  - Continuous slow trickle of bright red blood from vagina, laceration, episiotomy
- **Hematoma:** Bulging, bluish mass or area of red-purple discoloration on vulva, perineum, or rectum

## PATIENT-CENTERED CARE

### NURSING CARE

- Assess pain.
- Visually or manually inspect the vulva, perineum, and rectum for lacerations and/or hematomas.
- Evaluate lochia.
- Continue to assess vital signs and hemodynamic status.
- Attempt to identify the source of the bleeding.
- Assist the provider with repair procedures.
- Use ice packs to treat small hematomas.
- Administer pain medication.
- Encourage sitz baths and frequent perineal hygiene.

### THERAPEUTIC PROCEDURES

- Repair and suturing of the episiotomy or lacerations is done by the provider.
- Ligation of the bleeding vessel or surgical incision for evacuation of the clotted blood from the hematoma is done by the provider.

#### Active Learning Scenario

A nurse is planning care for a client who has a deep-vein thrombosis (DVT). What interventions should the nurse include in the plan of care? Use the ATI Active Learning Template: System Disorder to complete this item.

**ALTERATION IN HEALTH (DIAGNOSIS):**  
Describe the disease process and location.

**RISK FACTORS:** Describe four risk factors for the disorder.

**CLIENT EDUCATION:** Describe four teaching points for prevention of a DVT.

**MEDICATIONS:** Describe two medications and their related laboratory tests.

### Application Exercises

1. A nurse is caring for a client who is postpartum. The nurse should identify which of the following findings as an early indicator of hypovolemia caused by hemorrhage?
  - Increasing pulse and decreasing blood pressure
  - Dizziness and increasing respiratory rate
  - Cool, clammy skin, and pale mucous membranes
  - Altered mental status and level of consciousness
2. A nurse educator on the postpartum unit is reviewing risk factors for postpartum hemorrhage with a group of nurses. Which of the following factors should the nurse include in the teaching? (Select all that apply.)
  - Precipitous delivery
  - Obesity
  - Inversion of the uterus
  - Oligohydramnios
  - Retained placental fragments
3. A nurse on the postpartum unit is assessing a client who is being admitted with a suspected deep-vein thrombosis (DVT). Which of the following clinical findings should the nurse expect? (Select all that apply.)
  - Calf tenderness to palpation
  - Mottling of the affected extremity
  - Elevated temperature
  - Area of warmth
  - Report of nausea
4. A nurse is planning care for a client who is postpartum and has thrombophlebitis. Which of the following nursing interventions should the nurse include in the plan of care?
  - Apply cold compresses to the affected extremity.
  - Massage the affected extremity.
  - Allow the client to ambulate.
  - Measure leg circumferences.
5. A nurse is caring for a client who has disseminated intravascular coagulation (DIC). Which of the following antepartum complications should the nurse understand is a risk factor for this condition?
  - Preeclampsia
  - Thrombophlebitis
  - Placenta previa
  - Hyperemesis gravidarum

## Application Exercises Key

1. A. **CORRECT:** A rising pulse rate and decreasing blood pressure are often the first indications of inadequate blood volume.
- B. Dizziness and increased respiratory rate are findings that occur in hypovolemia, but they are not the earliest indicators.
- C. Skin that is cool, clammy, and pale, along with pale mucous membranes, are changes that occur in the physical status of a client who has decreased blood volume, but they are not the first indicators of inadequate blood volume.
- D. Altered mental status and changes in level of consciousness are late manifestations of decreased blood volume, which leads to hypoxia and low oxygen saturation.

❷ NCLEX® Connection: Physiological Adaptation, Alterations in Body Systems

2. A. **CORRECT:** Rapid, precipitous delivery is a risk factor for postpartum hemorrhage.
- B. Obesity is not a risk factor for postpartum hemorrhage.
- C. **CORRECT:** Inversion of the uterus is a risk factor for postpartum hemorrhage.
- D. Oligohydramnios does not place a client at risk for postpartum hemorrhage.
- E. **CORRECT:** Retained placental fragments is a risk factor for postpartum hemorrhage.

❷ NCLEX® Connection: Reduction of Risk Potential, Potential for Complications from Surgical Procedures and Health Alterations

3. A. **CORRECT:** A client report of calf tenderness to palpation is an expected finding in a client who has a DVT.
- B. Mottling of the affected extremity is not an expected finding in a client who has a DVT.
- C. **CORRECT:** Elevated temperature is an expected finding in a client who has a DVT.
- D. **CORRECT:** An area of warmth over the thrombus is an expected finding in a client who has a DVT.
- E. A report of nausea is not an expected finding in a client who has a DVT.

❷ NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

4. A. Plan to apply warm compresses to the affected extremity.
- B. Do not massage the affected extremity. This action can result in dislodgement of the clot.
- C. Encourage the client to rest with the affected extremity elevated.
- D. **CORRECT:** Plan to measure the circumference of the leg to assess for changes in the client's condition.

❷ NCLEX® Connection: Physiological Adaptation, Unexpected Response to Therapies

5. A. **CORRECT:** DIC can occur secondary in a client who has preeclampsia.
- B. Thrombophlebitis is not a risk factor for DIC.
- C. Placenta previa is not a risk factor for DIC.
- D. Hyperemesis gravidarum is not a risk factor for DIC.

❷ NCLEX® Connection: Physiological Adaptation, Hemodynamics

## Active Learning Scenario Key

Using the ATI Active Learning Template: System Disorder

**ALTERATION IN HEALTH (DIAGNOSIS):** DVT is a thrombus that is associated with inflammation. It can occur in a superficial or deep vein (femoral, saphenous, or popliteal).

### RISK FACTORS

- Pregnancy
- Immobility
- Obesity
- Smoking
- Cesarean birth
- Multiparity
- Age older than 35 years
- History of previous thromboembolism

### CLIENT EDUCATION

- Wear antiembolic stockings until ambulation established.
- Perform active range of motion when on bed rest for longer than 8 hr.
- Initiate early and frequent postpartum ambulation.
- Avoid prolonged periods of standing, sitting, or immobility.
- Elevate the legs when sitting.
- Avoid crossing legs.
- Maintain 2 to 3 L of daily fluid intake from food and beverage sources.
- Discontinue smoking.

### MEDICATIONS

- Heparin: aPTT
- Warfarin: PT and INR

❷ NCLEX® Connection: Physiological Adaptation, Alterations in Body Systems

## *Postpartum Infections*

Postpartum infections are complications that can occur up to 28 days following childbirth, or a spontaneous or induced abortion. Fever of 38° C (100.4° F) or higher after the first 24 hr, or for 2 days during the first 10 days of the postpartum period is indicative of a postpartum infection and requires further investigation. The infection can be present in the bladder, uterus, wound, or breast of a postpartum client. The major complication of puerperal infection is septicemia.

Uterine infection, wound infection, mastitis, and a urinary tract infection are examples of postpartum infections. Early identification and prompt treatment are necessary to promote positive outcomes.

### *Infections (endometritis, mastitis, and wound infections)*

The immediate postpartum period following birth is a time of increased risk for all clients for micro-organisms entering the reproductive tract and migrating into the blood and other parts of the body, which can result in life-threatening septicemia.

**Uterine infection** is also referred to as **endometritis**.

- Endometritis is an infection of the uterine lining or endometrium. It is the most frequently occurring puerperal infection.
- Endometritis usually begins on the third to fourth postpartum day, generally starting as a localized infection at the placental attachment site and spreading to include the entire uterine endometrium.

Sites of **wound infections** include cesarean incisions, episiotomies, lacerations, and any trauma wounds present in the birth canal following labor and birth.

**Mastitis** is an infection of the breast involving the interlobular connective tissue and is usually unilateral. Mastitis can progress to an abscess if untreated.

- It can occur as early as the seventh postpartum day. It usually occurs during the first 6 weeks of breastfeeding, but can occur at any time during breastfeeding.
- *Staphylococcus aureus* is usually the infecting organism.

## ASSESSMENT

### RISK FACTORS

- Urinary tract infection, mastitis, pneumonia, or history of previous venous thrombus
- History of diabetes mellitus, immunosuppression, anemia, or malnutrition
- History of alcohol or substance use disorder
- Cesarean birth
- Prolonged rupture of membranes
- Retained placental fragments and manual extraction of the placenta
- Bladder catheterization
- Chorioamnionitis
- Internal fetal/uterine pressure monitoring
- Multiple vaginal examinations after rupture of membranes
- Prolonged labor
- Postpartum hemorrhage
- Operative vaginal birth
- Epidural analgesia/anesthesia
- Hematomas
- Episiotomy or lacerations

### *Mastitis*

- Milk stasis, which can be caused by a blocked duct, engorgement, or a bra with an underwire
- Nipple trauma and cracked or fissured nipples
- Poor breastfeeding technique with improper latching of the infant onto the breast, which can lead to sore and cracked nipples
- Decrease in breastfeeding frequency due to supplementation with bottle feeding
- Contamination of breasts due to poor hygiene

## EXPECTED FINDINGS

### **Puerperal infections**

- Flu-like manifestations (body aches, chills, fever, malaise)
- Anorexia and nausea

### **Endometritis**

- Pelvic pain
- Chills
- Fatigue
- Loss of appetite

### **Mastitis**

- Painful or tender localized hard mass and reddened area, usually on one breast
- Influenza-like manifestations (chills, fever, headache, body ache)
- Fatigue

## **PHYSICAL ASSESSMENT FINDINGS**

### **• Puerperal infections**

- Elevated temperature of at least 38° C (100.4° F) for 2 or more consecutive days
- Tachycardia

### **• Endometritis**

- Uterine tenderness and enlargement
- Dark, profuse lochia
- Lochia that is either malodorous or purulent
- Temperature greater than 38° C (100.4° F)
- Tachycardia

### **• Wound infection**

- Wound warmth, erythema, tenderness, pain, edema, seropurulent drainage, and wound dehiscence (separation of wound or incision edges) or evisceration (protrusion of internal contents through the separated wound edges)
- Temperature greater than 38° C (100.4° F) for 2 or more consecutive days

### **• Mastitis:** Axillary adenopathy in the affected side (enlarged tender axillary lymph nodes) with an area of inflammation that can be red, swollen, warm, and tender

## **LABORATORY TESTS**

- Blood, intracervical, or intrauterine bacterial cultures to reveal the offending organism
- WBC count: leukocytosis
- RBC sedimentation rate: distinctly increased
- RBC count: anemia

## **PATIENT-CENTERED CARE**

## **NURSING CARE**

- Obtain frequent vital signs.
- Assess pain.
- Assess fundal height, position, and consistency.
- Observe lochia for color, quantity, and consistency.
- Inspect incisions, episiotomy, and lacerations.
- Inspect breasts.

### ***Puerperal infections***

- Use aseptic technique for appropriate procedures; perform proper hand hygiene; and don gloves for labor, birth, and postpartum care.
- Maintain or initiate IV access.
- Administer IV broad-spectrum antibiotic therapy (penicillins, cephalosporins, clindamycin, gentamicin).
- Provide comfort measures (warm blankets, cool compresses), depending on findings.

### **CLIENT EDUCATION**

- Report signs of worsening conditions.
- Adhere to the treatment plan with the completion of a full course of antibiotics.
- Preventative measures include thorough handwashing and good perineal hygiene.
- A diet high in protein promotes tissue healing.

### ***Endometritis***

- Collect vaginal and blood cultures.
- Administer IV antibiotics.
- Administer analgesics.

### **CLIENT EDUCATION**

- Perform effective hand hygiene techniques.
- Maintain interaction with the infant to facilitate bonding.

### ***Wound infection***

- Perform wound care.
- Administer IV antibiotics.
- Provide or encourage comfort measures (sitz baths, perineal care, warm or cold compresses).

**CLIENT EDUCATION:** Good hygiene techniques include changing perineal pads from front to back, and performing thorough hand hygiene prior to and after perineal care.

### ***Mastitis***

Administer antibiotics.

**CLIENT EDUCATION:** Breast hygiene can prevent and manage mastitis.

- Thoroughly wash hands prior to breastfeeding.
- Maintain cleanliness of breasts with frequent changes of breast pads.
- Allow nipples to air-dry.
- Proper infant positioning and latching-on techniques include both the nipple and the areola. Release the infant's grasp on the nipple prior to removing the infant from the breast.
- Completely empty the breasts with each feeding to prevent milk stasis, which provides a medium for bacterial growth.
- Use ice packs or warm packs on affected breasts for discomfort.
- Continue breastfeeding frequently (at least every 2 to 4 hr), especially on the affected side.
- Manually express breast milk or use a breast pump if breastfeeding is too painful.
- Breastfeed or pump frequently, emptying the affected side.
- Rest, take analgesics, and maintain fluid intake of at least 3,000 mL per day.
- Wear a well-fitting bra for support. The bra should not have an underwire because that increases the risk for infection.
- Report redness and fever.
- Complete the entire course of antibiotics as prescribed.

## MEDICATIONS

---

### *For endometritis*

---

#### **Clindamycin**

#### **Cephalosporins, penicillins, and gentamicin**

CLASSIFICATION: Antibiotic

THERAPEUTIC INTENT: Treatment of bacterial infections

#### CLIENT EDUCATION

- Take all the medication as prescribed.
- Notify the provider of the development of watery, bloody diarrhea.
- Notify the provider if breastfeeding.

## THERAPEUTIC PROCEDURES

---

The provider might need to open and drain the wound or perform wound debridement if indicated.

## ***Urinary tract infection***

---

- Urinary tract infections (UTIs) are a common postpartum infection secondary to bladder trauma incurred during the delivery or a break in aseptic technique during bladder catheterization.
- A potential complication of a UTI is the progression to pyelonephritis with permanent kidney damage leading to kidney failure.

## ASSESSMENT

---

### RISK FACTORS

---

- Postpartal hypotonic bladder or urethra (urinary stasis and retention)
- Epidural anesthesia
- Urinary bladder catheterization
- Frequent pelvic examinations
- Genital tract injuries
- History of UTIs
- Cesarean birth

## EXPECTED FINDINGS

---

- Reports of urgency, frequency, dysuria, and discomfort in the pelvic area
- Fever
- Chills
- Malaise

#### PHYSICAL ASSESSMENT FINDINGS

- Change in vital signs, elevated temperature
- Urine (cloudy, blood-tinged, malodorous, sediment visible)
- Urinary retention
- Pain in the suprapubic area
- Pain at the costovertebral angle (pyelonephritis)

## DIAGNOSTIC PROCEDURES

---

Urinalysis for WBCs, RBCs, protein, bacteria

## PATIENT-CENTERED CARE

---

### NURSING CARE

---

- Obtain a random or clean-catch urine sample.
- Administer antibiotics, and teach the client the importance of completing the entire course of antibiotics as prescribed.
- Acetaminophen is taken to reduce discomfort and pain associated with a urinary tract infection.
- Teach the client proper perineal hygiene, such as wiping from front to back.
- Encourage the client to increase their fluid intake to 3,000 mL/day to dilute the bacteria and flush the bladder.

## Application Exercises

1. A nurse on the postpartum unit is caring for four clients. Which of the following clients should the nurse recognize as the greatest risk for development of a postpartum infection?

  - A. A client who experienced a precipitous labor less than 3 hr in duration
  - B. A client who had premature rupture of membranes and prolonged labor
  - C. A client who delivered a large for gestational age infant
  - D. A client who had a boggy uterus that was not well-contracted
  
2. A nurse is teaching a client who is breastfeeding and has mastitis. Which of the following responses should the nurse make?

  - A. "Limit the amount of time the infant nurses on each breast."
  - B. "Nurse the infant only on the unaffected breast until resolved."
  - C. "Completely empty each breast at each feeding or use a pump."
  - D. "Wear a tight-fitting bra until lactation has ceased."
  
3. A nurse is reviewing discharge teaching with a client who has a urinary tract infection. Which of the following statements by the client indicates understanding of the teaching? (Select all that apply.)

  - A. "I will perform perineal care and apply a perineal pad in a back-to-front direction."
  - B. "I will drink grape juice to make my urine more acidic."
  - C. "I will drink large amounts of fluids to flush the bacteria from my urinary tract."
  - D. "I will go back to breastfeeding after I have finished taking the antibiotic."
  - E. "I will take Tylenol for any discomfort."
  
4. A nurse is caring for a client who has mastitis. Which of the following is the typical causative agent of mastitis?

  - A. *Staphylococcus aureus*
  - B. *Chlamydia trachomatis*
  - C. *Klebsiella pneumonia*
  - D. *Clostridium perfringens*
  
5. A nurse is discussing risks factors for urinary tract infections with a newly licensed nurse. Which of the following conditions should the nurse include in the teaching? (Select all that apply).

  - A. Epidural anesthesia
  - B. Urinary bladder catheterization
  - C. Frequent pelvic examinations
  - D. History of UTIs
  - E. Vaginal birth

## Active Learning Scenario

A nurse educator is reviewing care of a client who has endometritis with a group of newly hired nurses. What information should the nurse educator include in the teaching? Use the ATI Active Learning Template: System Disorder to complete this item.

### ALTERATION IN HEALTH (DIAGNOSIS)

**EXPECTED FINDINGS:** Describe at least six.

**NURSING CARE:** Describe at least three nursing interventions.

## Application Exercises Key

1. A. A precipitous labor places the client at risk for trauma and lacerations during delivery, but there is another client who is at greater risk for postpartum infection.
- B. **CORRECT:** Premature rupture of membranes with prolonged labor poses the greatest risk for developing a postpartum infection because the birth canal was open, allowing pathogens to enter.
- C. Delivery of a large infant places the client at risk for a postpartum infection, but there is another client who is at greater risk.
- D. A boggy uterus that did not remain well-contracted places the client at risk for a postpartum infection, but there is another client who is at greater risk.

NCLEX® Connection: Physiological Adaptation, Alterations in Body Systems

2. A. Frequent, on-demand breastfeeding should be encouraged to promote milk flow.
- B. The client should be instructed to continue breastfeeding, especially on the affected side.
- C. **CORRECT:** Instruct the client to completely empty each breast at each feeding to prevent milk stasis, which provides a medium for bacterial growth.
- D. The client should wear a well-fitting bra, not one that is too tight or a binder.

NCLEX® Connection: Physiological Adaptation, Illness Management

3. A. Perineal cleansing and pad application should be done front to back, not back to front.
- B. Grape juice does not make urine acidic.
- C. **CORRECT:** Increased fluid intake can help to flush the bacteria from the urinary tract.
- D. Breastfeeding does not have to be delayed until the course of antibiotics is completed.
- E. **CORRECT:** Acetaminophen is taken to reduce discomfort and pain associated with a urinary tract infection.

NCLEX® Connection: Physiological Adaptation, Illness Management

4. A. **CORRECT:** *Staphylococcus aureus*, *Escherichia coli*, and *streptococcus* are usually the infecting agents that enter the breast due to sore or cracked nipples, which results in mastitis.
- B. *Chlamydia trachomatis* is an STI but not the causative agent of mastitis.
- C. *Klebsiella pneumonia* is a causative agent of pneumonia.
- D. *Clostridium perfringens* can cause wound infections but is not a causative agent of mastitis.

NCLEX® Connection: Physiological Adaptation, Illness Management

5. A. **CORRECT:** Epidural anesthesia is a risk factor for a UTI.
- B. **CORRECT:** Urinary bladder catheterization is a risk factor for a UTI.
- C. **CORRECT:** A history of frequent pelvic examinations is a risk factor for a UTI.
- D. **CORRECT:** A history of UTIs is a risk factor for developing UTIs.
- E. Cesarean birth places a client at risk for development of a UTI.

NCLEX® Connection: Physiological Adaptation, Illness Management

## Active Learning Scenario Key

Using the ATI Active Learning Template: System Disorder

**ALTERATION IN HEALTH (DIAGNOSIS):** Endometritis is an infection of the uterine lining or endometrium. It usually begins on the second to fifth postpartum day as a localized infection at the placental attachment site and spreads to include the entire endometrium. It is the most frequently occurring puerperal infection.

### EXPECTED FINDINGS

- Uterine tenderness and enlargement
- Dark, profuse lochia
- Malodorous or purulent lochia
- Temperature greater than 38° C (100.4° F) on the third or fourth postpartum day
- Tachycardia
- Pelvic pain
- Chills
- Fatigue, loss of appetite

### NURSING CARE

- Collect vaginal and blood cultures.
- Administer IV antibiotics.
- Administer analgesics.
- Teach client hand hygiene techniques.
- Encourage client interaction with their infant to facilitate bonding.

NCLEX® Connection: Physiological Adaptation, Illness Management

# CHAPTER 22

UNIT 3

POSTPARTUM NURSING CARE

SECTION: COMPLICATIONS OF THE POSTPARTUM PERIOD

## CHAPTER 22 Postpartum Depression

Postpartum blues can occur in up to 85% of clients during the first few days after birth and generally continues for up to 10 days. It is characterized by mood swings, tearfulness, insomnia, lack of appetite, and a feeling of letdown. A parent can experience an intense fear, anxiety, anger, and inability to cope with the slightest problems and become despondent. Postpartum blues typically resolves in 10 days without intervention.

Postpartum depression occurs within 12 months of delivery and is characterized by persistent feelings of sadness and intense mood swings. It occurs in 10% to 15% of new parents and usually does not resolve without intervention. It is similar to nonpostpartum mood disorders.

Postpartum psychosis develops within the first 2 to 3 weeks of the postpartum period. Clients who have a history of bipolar disorder are at a higher risk. Clinical findings are severe and can include confusion, disorientation, hallucinations, delusions, obsessive behaviors, and paranoia. The client might attempt to harm themselves or their infant.

A nurse should monitor clients for suicidal or delusional thoughts. The nurse should monitor infants for failure to thrive secondary to an inability of the parent to provide care.

## ASSESSMENT

### RISK FACTORS

- Hormonal changes with a rapid decline in estrogen and progesterone levels
- Individual socioeconomic factors
- Decreased social support system
- Anxiety about assuming new role as a parent
- Unintended pregnancy
- History of previous depressive disorder
- Low self-esteem
- History of partner violence
- Medical conditions (thyroid imbalance, diabetes, infertility)
- Complications with breastfeeding
- Parent of multiples

### EXPECTED FINDINGS

#### *Postpartum blues*

- Feelings of sadness
- Lack of appetite
- Sleep pattern disturbances
- Feeling of inadequacies
- Crying easily for no apparent reason
- Restlessness, insomnia, fatigue
- Headache
- Anxiety, anger, sadness

PHYSICAL ASSESSMENT FINDINGS: Crying

#### *Postpartum depression*

- Feelings of guilt and inadequacies
- Irritability
- Anxiety
- Fatigue persisting beyond a reasonable amount of time
- Feeling of loss
- Lack of appetite
- Persistent feelings of sadness
- Intense mood swings
- Sleep pattern disturbances

PHYSICAL ASSESSMENT FINDINGS

- Crying
- Weight loss
- Flat affect
- Irritability
- Rejection of the infant
- Severe anxiety and panic attack

#### *Postpartum psychosis*

- Pronounced sadness
- Disorientation
- Confusion
- Paranoia

PHYSICAL ASSESSMENT FINDINGS: Behaviors indicating hallucinations or delusional thoughts of self-harm or harming the infant

## PATIENT-CENTERED CARE

### NURSING CARE

- Monitor interactions between the client and their infant. Encourage bonding activities.
- Monitor the client's mood and affect.
- Reinforce that feeling down in the postpartum period is normal and self-limiting. Encourage the client to notify the provider if the condition persists.
- Encourage the client to communicate feelings, validate and address personal conflicts, and reinforce personal power and autonomy.
- Reinforce the importance of compliance with any prescribed medication regimen.
- Contact a community resource to schedule a follow-up visit after discharge for clients who are at high risk for postpartum depression.
- Ask the client if they have thoughts of self-harm, suicide, or harming their infant. Provide for the safety of the infant and client as the priority of care.

### MEDICATIONS

- **Antidepressants** can be prescribed by the provider if indicated.
- **Antipsychotics** and **mood stabilizers** can be prescribed for clients who have postpartum psychosis.

### CLIENT EDUCATION

#### CARE AFTER DISCHARGE

- Get plenty of rest and to nap when the infant sleeps.
- Remember the importance of taking time out for self.
- Schedule a follow-up visit prior to the traditional postpartum visit if at risk for developing postpartum depression.
- Consider community resources (La Leche League, community mental health centers).
- Seek counseling, and consider social agencies as indicated.

### Application Exercises

1. A nurse is assessing a postpartum client who is exhibiting tearfulness, insomnia, lack of appetite, and a feeling of letdown. Which of the following conditions are associated with these manifestations?
  - Postpartum fatigue
  - Postpartum psychosis
  - Letting-go phase
  - Postpartum blues
2. A nurse is caring for a postpartum client who delivered their third infant 2 days ago. Which of the following manifestations could indicate postpartum depression? (Select all that apply.)
  - Fatigue
  - Insomnia
  - Euphoria
  - Flat affect
  - Delusions
3. A nurse is assessing a client who has postpartum depression. The nurse should expect which of the following manifestations? (Select all that apply.)
  - Paranoia that their infant will be harmed
  - Concerns about lack of income to pay bills
  - Anxiety about assuming a new role as a parent
  - Rapid decline in estrogen and progesterone
  - Feeling of inadequacy with the new role as a parent
4. A nurse is caring for a client who has postpartum psychosis. Which of the following actions is the nurse's priority?
  - Reinforce the need to take antipsychotics as prescribed.
  - Ask the client if they have thoughts of harming themselves or their infant.
  - Monitor the infant for indications of failure to thrive.
  - Review the client's medical record for a history of bipolar disorder.

### Active Learning Scenario

A nurse manager is reviewing the facility's protocol for the care of a client who has postpartum depression. What information should the nurse manager include in the protocol? Use the ATI Active Learning Template: System Disorder to complete this item.

#### ALTERATION IN HEALTH (DIAGNOSIS)

#### MEDICATIONS

**NURSING CARE:** Describe four nursing interventions.

**CLIENT EDUCATION:** Describe two teaching points for the client.

## Application Exercises Key

1. A. Postpartum fatigue results from the work of labor. It is normally self-limiting.
- B. The client who has postpartum psychosis will exhibit pronounced feelings of sadness, confusion, disorientation, hallucinations, delusions, and paranoia, and might attempt to harm themselves or their infant.
- C. The letting-go phase is the phase in which the client assumes their position at home and their new maternal role, focusing on the forward movement of the family unit.
- D. **CORRECT:** Postpartum blues are characterized by tearfulness, insomnia, lack of appetite, and feeling let-down.

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

2. A. **CORRECT:** Fatigue is a finding suggestive of postpartum depression.
- B. **CORRECT:** Insomnia is a finding suggestive of postpartum depression.
- C. Persistent sadness, rather than euphoria, is associated with postpartum depression.
- D. **CORRECT:** A flat affect is a finding suggestive of postpartum depression.
- E. Delusions are a finding suggestive of postpartum psychosis.

NCLEX® Connection: *Health Promotion and Maintenance, Health Screening*

3. A. Paranoia is a finding associated with postpartum psychosis.
- B. **CORRECT:** Feelings of financial inadequacy to provide for family is a finding associated with postpartum depression.
- C. **CORRECT:** Anxiety about assuming a new role as a parent is a finding associated with postpartum depression.
- D. **CORRECT:** The rapid decline in estrogen and progesterone is a finding associated with postpartum depression.
- E. **CORRECT:** Feeling of inadequacies with the new role as a mother is a finding associated with postpartum depression.

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

4. A. Reinforce the need to take antipsychotics as prescribed to manage the manifestations of postpartum psychosis; however, there is another action that is priority.
- B. **CORRECT:** Identify that the greatest risk to the client and the infant is self-harm or harm directed toward the infant. Therefore, the priority action to take is to directly ask the client if they have thoughts of self-harm, suicide, or harming the infant.
- C. Monitor the infant for indications of failure to thrive as the client who has postpartum psychosis might be unable to provide care for the infant; however, there is another action that is priority.
- D. Review the client's medical record for a history of bipolar disorder as this is associated with an increased risk for postpartum psychosis; however, there is another action that is priority.

NCLEX® Connection: *Health Promotion and Maintenance, Health Screening*

## Active Learning Scenario Key

*Using the ATI Active Learning Template: System Disorder*

**ALTERATION IN HEALTH (DIAGNOSIS):** Postpartum depression occurs within 6 months of delivery. It is characterized by persistent feelings of sadness and intense mood swings. It occurs in 10% to 15% of new mothers and usually does not resolve without intervention. It is similar to nonpostpartum mood disorders.

**MEDICATIONS:** Antidepressants

**NURSING CARE**

- Monitor client-infant interactions; encourage bonding activities.
- Monitor the client's mood and affect.
- Encourage verbalization of feelings; validate and address person conflicts; reinforce personal power and autonomy.
- Reinforce compliance with medication regimen.
- Provide referral, and schedule appointment with an appropriate community resource.
- Monitor the client for indications of postpartum psychosis. Prioritize care to ensure the safety of the client and her infant.

**CLIENT EDUCATION**

- Get plenty of rest; nap when the infant sleeps.
- Make time for self.
- Seek counseling, and use resources provided by referred community agencies.

NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

When reviewing the following chapters, keep in mind the relevant topics and tasks of the NCLEX outline, in particular:

### *Health Promotion and Maintenance*

---

**ANTE/INTRA/POSTPARTUM AND NEWBORN CARE:**  
Assist client with performing/learning newborn care.

**TECHNIQUES OF PHYSICAL ASSESSMENT:** Perform comprehensive health assessments.

### *Basic Care and Comfort*

---

**NON-PHARMACOLOGICAL COMFORT INTERVENTIONS:**  
Apply knowledge of pathophysiology to non-pharmacological comfort/palliative care interventions.

**NUTRITION AND ORAL HYDRATION:** Monitor the client's nutritional status.

### *Reduction of Risk Potential*

---

**CHANGES/ABNORMALITIES IN VITAL SIGNS:** Apply knowledge of client pathophysiology when measuring vital signs.

**LABORATORY VALUES:** Monitor client laboratory values.

**SYSTEM SPECIFIC ASSESSMENTS:** Assess the client for signs of hypoglycemia or hyperglycemia.

CHAPTER 23 **Newborn Assessment**

Understanding physiologic responses of a newborn to birth and physical assessment findings are imperative for providing nursing care following the birth of a newborn. Key areas to know about include Apgar scoring, physical examination of the newborn, New Ballard Score (gestational age assessment), normal newborn vital signs and measurements, classifications of a newborn by gestational age and weight, diagnostic and therapeutic procedures, and complications of a newborn.

**PHYSIOLOGIC RESPONSE OF NEWBORN TO BIRTH**

- Adjustments to extrauterine life occur as a newborn's respiratory and circulatory systems are required to rapidly adjust to life outside of the uterus.
- The establishment of respiratory function with the cutting of the umbilical cord is the most critical extrauterine adjustment as air inflates the lungs with the first breath.
- Circulatory changes occur due to changes in pressures of the cardiovascular system related to cutting of the umbilical cord as a newborn begins breathing independently. The three shunts (ductus arteriosus, ductus venosus, foramen ovale) functionally close during a newborn's transition to extrauterine life with the flow of oxygenated blood in the lungs and readjustment of atrial blood pressure in the heart.

**23.1 Apgar scoring**

An Apgar score is assigned based on a quick review of systems that is completed at 1 and 5 min of life. This allows the nurse to rapidly assess extrauterine adaptation and intervene with appropriate nursing actions.

- 0 to 3 indicates severe distress
- 4 to 6 indicates moderate difficulty
- 7 to 10 indicates minimal or no difficulty with adjusting to extrauterine life

**PHYSICAL ASSESSMENT OF NEWBORN FOLLOWING BIRTH**

**Apgar scoring** and a brief physical exam is done immediately following birth to rule out abnormalities. (23.1)

**EQUIPMENT FOR NEWBORN ASSESSMENT**

**Bulb syringe:** Used for suctioning excess mucus from the mouth and nose.

**Stethoscope with a pediatric head:** Used to evaluate heart rate, breath sounds, and bowel sounds.

**Axillary thermometer:** Used to monitor temperature and prevent hypothermia. Rectal temperatures are avoided because they can injure the delicate rectal mucosa; an initial rectal temperature can be obtained to evaluate for anal abnormalities.

**Blood pressure cuff:** Electronic method. Blood pressure can be done in all four extremities if evaluating the newborn for cardiac problems.

**Scale with protective cover in place:** Scale should be at 0; weight should include pounds, ounces, and grams.

**Tape measure in centimeters:** Measure from crown to heel of foot for length. Measure head circumference at greatest diameter (occipital to frontal). Measure chest circumference beginning at the nipple line, and abdominal circumference above the umbilicus.

**Clean gloves:** Worn for all physical assessments until discharge.

**INITIAL ASSESSMENT**

Perform a quick initial assessment to review the newborn's systems and to observe for life-threatening abnormalities and respiratory issues.

**External assessment:** Skin color, peeling, birthmarks, foot creases, breast tissue, nasal patency, and meconium staining (can indicate fetal hypoxia)

**Chest:** Point of maximal impulse location; ease of breathing; auscultation for heart rate and quality of tones; and respirations for crackles, wheezes, and equality of bilateral breath sounds

APGAR SCORE	0	1	2
HEART RATE	Absent	Slow, less than 100/min	Greater than 100/min
RESPIRATORY RATE	Absent	Slow, weak cry	Good cry
MUSCLE TONE	Flaccid	Some flexion of extremities	Well-flexed
REFLEX IRRITABILITY	None	Grimace	Cry
COLOR	Blue, pale	Pink body, cyanotic hands and feet (acrocyanosis)	Completely pink

**Abdomen:** Rounded abdomen and umbilical cord with one vein and two arteries

**Neurologic:** Muscle tone and reflex reaction (Moro reflex); palpation for the presence and size of fontanels and sutures; assessment of fontanels for fullness or bulge

**Other observations:** Inspection for gross structural malformations

#### EXPECTED REFERENCE RANGES

**Weight:** 2,500 to 4,000 g (5.5 to 8.8 lb)

**Length:** 45 to 55 cm (18 to 22 in)

**Head circumference:** 32 to 36.8 cm (12.6 to 14.5 in)

**Chest circumference:** 30 to 33 cm (12 to 13 in)

### GESTATIONAL AGE ASSESSMENT

A gestational age assessment is performed on newborns within the first 48 hr following birth. Neonatal morbidity and mortality are related to gestational age and birth weight. The gestational age assessment involves taking measurements of the newborn and the use of the New Ballard Score. This score provides an estimation of gestational age and a baseline to assess growth and development.

#### New Ballard Score

A newborn maturity rating score used to assesses neuromuscular and physical maturity

- Each individual assessment parameter displays at least six ranges of development along a continuum.
- Each range of development within an assessment is assigned a number value from -1 to 5. The totals are added to give a maturity rating in weeks gestation (e.g., a score of 35 indicates 38 weeks of gestation).

#### NEUROMUSCULAR MATURITY

- Posture ranging from fully extended to fully flexed (0 to 4).
- Square window formation with the neonate's wrist (-1 to 4).
- Arm recoil, where the neonate's arm is passively extended and spontaneously returns to flexion (0 to 4).
- Popliteal angle, which is the degree of the angle to which the newborn's knees can extend (-1 to 5).
- Scarf sign, which is crossing the neonate's arm over the chest (-1 to 4).
- Heel to ear, which is how far the neonate's heels reach to their ears (-1 to 4).

#### PHYSICAL MATURITY

- Skin texture, ranging from sticky and transparent, to leathery, cracked, and wrinkled (-1 to 5).
- Lanugo presence and amount, ranging from none, sparse, abundant, thinning, bald, or mostly bald (-1 to 4).
- Plantar surface creases, ranging from less than 40 mm to creases over the entire sole (-1 to 4).
- Breast tissue amount, ranging from imperceptible, to full areola with a 5 to 10 mm bud (-1 to 4).

- Eyes and ears for amount of eye opening and ear cartilage present (-1 to 4).
- Genitalia development, ranging from flat smooth scrotum to pendulous testes with deep rugae for males (-1 to 4), and prominent clitoris with flat labia to the labia majora covering the labia minora and clitoris for females (-1 to 4).

#### CLASSIFICATION

Following physical assessment, classification of the newborn by gestational age and birth weight is determined.

**Appropriate for gestational age (AGA):** Weight is between the 10th and 90th percentile.

**Small for gestational age (SGA):** Weight is less than the 10th percentile.

**Large for gestational age (LGA):** Weight is greater than the 90th percentile.

**Low birth weight (LBW):** Weight of 2,500 g or less at birth.

**Intrauterine growth restriction (IUGR):** Growth rate does not meet expected norms.

**Term:** Birth between the beginning of week 37 and prior to the end of 42 weeks of gestation.

- Early term is defined as occurring from 37  $\frac{1}{2}$  weeks through 38  $\frac{1}{2}$  weeks.
- Late term is defined as occurring from 41  $\frac{1}{2}$  weeks through 42  $\frac{1}{2}$  weeks.

**Preterm or premature:** Born prior to 37 weeks of gestation.

**Postterm (postdate):** Born after the completion of 42 weeks of gestation.

**Postmature:** Born after the completion of 42 weeks of gestation with evidence of placental insufficiency.

### VITAL SIGNS

Vital signs are checked in the following sequence: respirations, heart rate, blood pressure, and temperature. The nurse observes the respiratory rate first before the newborn becomes active or agitated by use of the stethoscope, thermometer, and/or blood pressure cuff.

**Respiratory rate** varies from 30 to 60 breaths/min with short periods of apnea (less than 15 seconds) occurring most frequently during the rapid eye movement sleep cycle. Periods of apnea lasting longer than 15 seconds should be evaluated. Crackles and wheezing are manifestations of fluid or infection in the lungs. Grunting and nasal flaring are clinical findings of respiratory distress.

**Normal heart rate** ranges from 110 to 160/min with brief fluctuations above and below this range depending on activity level (crying, sleeping). Apical pulse rate is assessed for 1 full minute, preferably when the newborn is sleeping. The pediatric stethoscope head is placed on the fourth or fifth intercostal space at the left midclavicular line over the apex of the newborn's heart. Heart murmurs are documented and reported.

**Blood pressure** should be 60 to 80 mm Hg systolic and 40 to 50 mm Hg diastolic.

**Normal temperature range** is 36.5° C to 37.5° C (97.7° F to 99.5° F), with 37° C (98.6° F) being average. The newborn is at risk for hypothermia and hyperthermia until thermoregulation (ability to produce heat and maintain normal body temperature) stabilizes. If the newborn becomes chilled (cold stress), oxygen demands can increase and acidosis can occur.

A more extensive physical exam is performed on the neonate within 24 hr of birth. Vital signs are obtained. A head-to-toe assessment is performed. Neurologic and behavioral assessments are completed by eliciting reflexes and observing responses. Laboratory data is monitored.

## PHYSICAL EXAM FROM HEAD TO TOE

### Posture

- Lying in a curled-up position with arms and legs in moderate flexion
- Resistant to extension of extremities

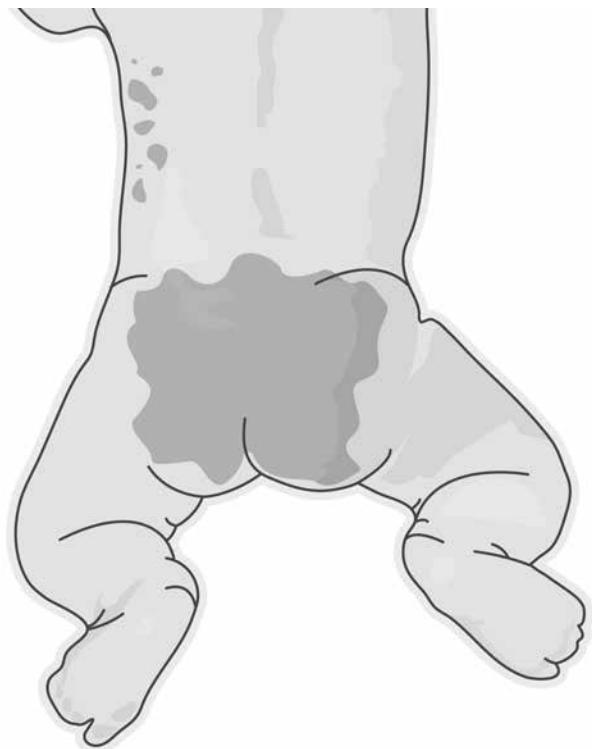

### Skin

- Skin color should be initially deep red to purple, with acrocyanosis (bluish tint to hands and feet). Skin color should fade to a color congruent to the newborn genetic background. Secondary to increased bilirubin, jaundice can appear on the third day of life, but then decrease spontaneously.
- Skin turgor should be quick, indicating that the newborn is well hydrated. The skin should spring back immediately when pinched.
- Texture should be dry, soft, and smooth, showing good hydration. Cracks in hands and feet can be present. In full-term newborns, desquamation (peeling) occurs a few days after birth.
- Vernix caseosa (protective, thick, cheesy covering) amounts vary, with more present in creases and skin folds.
- Lanugo (fine downy hair) varies regarding the amount present. It is usually found on the pinnae of ears, forehead, and shoulders.

### NORMAL DEVIATIONS

- **Milia** (small raised pearly or white spots on the nose, chin, and forehead) can be present. These spots disappear spontaneously without treatment (parents should not squeeze the spots).
- **Mongolian spots** (spots of pigmentation that are blue, gray, brown, or black) are commonly noted on the back and buttocks. These spots are more commonly present on newborns who have dark skin and can be linked to genetics. Be sure the parents are aware of Mongolian spots, and document location and presence. (23.2)
- **Telangiectatic nevi** (stork bites) are flat pink or red marks that easily blanch and are found on the back of the neck, nose, upper eyelids, and middle of the forehead. They usually fade by the second year of life. (23.3)

### 23.2 Mongolian spots

### 23.3 Telangiectatic nevi

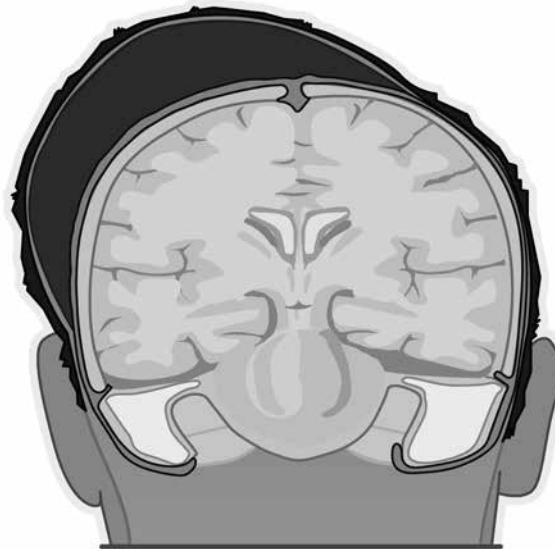

- **Nevus flammeus** (port wine stain) is a capillary angioma below the surface of the skin that is purple or red, varies in size and shape, is commonly seen on the face, and does not blanch or disappear.
- **Erythema toxicum** (erythema neonatorum) is a pink rash that appears suddenly anywhere on the body of a term newborn during the first 3 weeks. This is frequently referred to as newborn rash. No treatment is required.

## **Head**

- Head should be 2 to 3 cm larger than chest circumference. If the head circumference is greater than or equal to 4 cm larger than the chest circumference, this can be an indication of **hydrocephalus** (excessive cerebral fluid within the brain cavity surrounding the brain). If the head circumference is less than or equal to 32 cm, this can be an indication of **microcephaly** (abnormally small head).
- Anterior fontanel should be palpable and approximately 5 cm on average and diamond shaped. Posterior fontanel is smaller and triangle-shaped. Fontanels should be soft and flat. Fontanels can bulge when the newborn cries, coughs, or vomits, but should be flat when the newborn is quiet. Bulging fontanels at rest can indicate increased intracranial pressure, infection, or hemorrhage. Depressed fontanels can indicate dehydration.
- Sutures should be palpable, separated, and can be overlapping (molding), a normal occurrence resulting from head compression during labor.
- **Caput succedaneum** (localized swelling of the soft tissues of the scalp caused by pressure on the head during labor) is an expected finding that can be palpated as a soft edematous mass and can cross over the suture line. Caput succedaneum usually resolves in 3 to 4 days and does not require treatment. (23.4)

**23.4 Caput succedaneum**

- **Cephalohematoma** is a collection of blood between the periosteum and the skull bone that it covers. It does not cross the suture line. It results from trauma during birth such as pressure of the fetal head against the maternal pelvis in a prolonged difficult labor or forceps delivery. It appears in the first 1 to 2 days after birth and resolves in 2 to 8 weeks. (23.5)

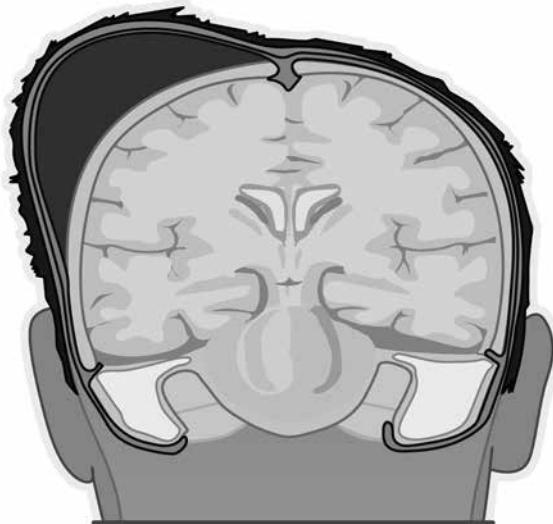

## **Eyes**

- Assess eyes for symmetry in size and shape.
- Each eye from the inner to outer canthus and the space between the eyes should equal one-third the distance across both eyes to rule out chromosomal abnormalities, such as Down syndrome.
- Eyes are usually blue or gray following birth.
- Lacrimal glands are immature, with minimal or no tears.
- Subconjunctival hemorrhages can result from pressure during birth.
- Pupillary and red reflex are present.
- Eyeball movement will demonstrate random, jerky movements.

## **Ears**

- When examining the placement of ears, draw an imaginary line through the inner to the outer canthus of the newborn's eye. The line should be even with the top notch of the newborn's ear, where the ear meets the scalp. Ears that are low-set can indicate a chromosome abnormality, such as Down syndrome, or a kidney disorder.
- Cartilage should be firm and well formed. Lack of cartilage indicates prematurity.
- The newborn should respond to voices and other sounds.
- Inspect ears for skin tags.

**23.5 Cephalohematoma**

## Nose

- The nose should be midline, flat, and broad with lack of a bridge.
- Some mucus should be present, but with no drainage.
- Newborns are obligate nose breathers and do not develop the response of opening the mouth with a nasal obstruction until 3 weeks after birth. Therefore, a nasal blockage can result in flaring of the nares, cyanosis, or asphyxia.
- Newborns sneeze to clear nasal passages.

## Mouth

- Assess for palate closure and strength of sucking.
- Lip movements should be symmetrical.
- Saliva should be scant. Excessive saliva can indicate a tracheoesophageal fistula.
- Epstein's pearls (small whitish-yellow cysts found on the gums and at the junction of the soft and hard palates) are expected findings. They result from the accumulation of epithelial cells and disappear a few weeks after birth.
- Tongue should move freely, be symmetrical in shape, and not protrude. (A protruding tongue can be an indication of Down syndrome.)
- Soft and hard palate should be intact.
- Gray-white patches on the tongue and gums can indicate thrush, a fungal infection caused by Candida albicans, sometimes acquired from the mother's vaginal secretions.

## Neck

- Neck should be short, thick, surrounded by skin folds, and exhibit no webbing.
- Neck should move freely from side to side and up and down.
- Absence of head control can indicate prematurity or Down syndrome.

## Chest

- Chest should be barrel-shaped.
- Respirations are primarily diaphragmatic.
- Clavicles should be intact.
- Retractions should be absent.
- Nipples should be prominent, well formed, and symmetrical.
- Breast nodules can be 3 to 10 mm.

## Abdomen

- Umbilical cord should be odorless and exhibit no intestinal structures.
- Abdomen should be round, dome-shaped, and nondistended.
- Bowel sounds should be present within a few minutes following birth.

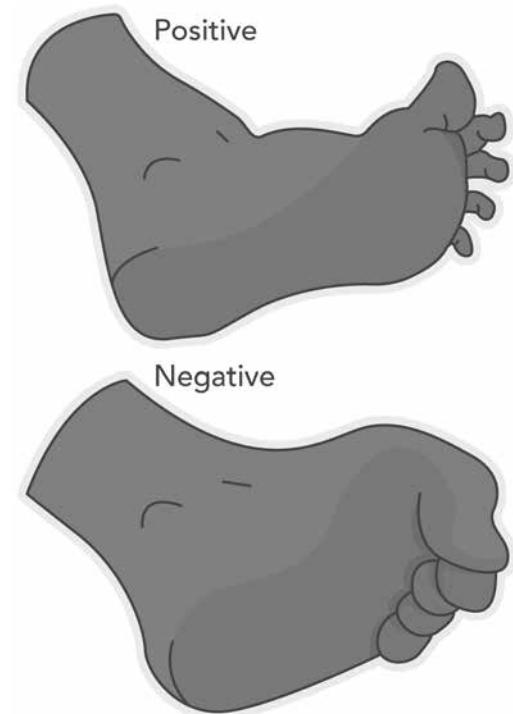

## Anogenital

- Anus should be present, patent, and not covered by a membrane.
- Meconium should be passed within 24 to 48 hr after birth.
- Genitalia of a male newborn should include rugae on the scrotum.
- Testes should be present in the scrotum.
- Male urinary meatus should be located at penile tip.
- Genitalia of a female should include labia majora covering the labia minora and clitoris, and are usually edematous.
- Vaginal blood-tinged discharge can occur in female newborns, which is caused by maternal pregnancy hormones. This is an expected finding.
- A hymenal tag should be present.
- Urine should be passed within 24 hr after birth. Uric acid crystals will produce a rust color in the urine the first couple of days of life.

## Extremities

- Assess for full range, symmetry of motion, and spontaneous movements.
- Extremities should be flexed.
- Assess for bowed legs and flat feet, which should be present because lateral muscles are more developed than the medial muscles.
- No click should be heard when abducting the hips.
- Gluteal folds should be symmetrical.
- Soles should be well-lined over two-thirds of the feet.
- Nail beds should be pink, and no extra digits are present.

### 23.6 Babinski reflex

## **Spine**

Spine should be straight, flat, midline, and easily flexed.

## **Reflexes**

### **Sucking and rooting reflex**

- **EXPECTED FINDING:** Elicit by stroking the cheek or edge of mouth. Newborn turns the head toward the side that is touched and starts to suck.
- **EXPECTED AGE:** Usually disappears after 3 to 4 months but can persist up to 1 year

### **Palmar grasp**

- **EXPECTED FINDING:** Elicit by placing examiner's finger in palm of newborn's hand. The newborn's fingers curl around examiner's fingers.
- **EXPECTED AGE:** Lessens by 3 to 4 months

### **Plantar grasp**

- **EXPECTED FINDING:** Elicit by placing examiner's finger at base of newborn's toes. The newborn responds by curling toes downward.
- **EXPECTED AGE:** Birth to 8 months

### **Moro reflex**

- **EXPECTED FINDING:** Elicit by allowing the head and trunk of the newborn in a semisitting position to fall backward to an angle of at least 30°. The newborn will symmetrically extend and then abduct the arms at the elbows and fingers spread to form a "C."
- **EXPECTED AGE:** Complete response can be seen until 8 weeks, body jerk only until 8 to 18 weeks, and then absent by 6 months.

### **Tonic neck reflex (fencer position)**

- **EXPECTED FINDING:** With newborn in supine, neutral position, examiner turns newborn's head quickly to one side. The newborn's arm and leg on that side extend and opposing arm and leg flex.
- **EXPECTED AGE:** Birth to 3 to 4 months

### **Babinski reflex**

- **EXPECTED FINDING:** Elicit by stroking outer edge of sole of the foot, moving up toward toes. Toes will fan upward and out. (23.6)
- **EXPECTED AGE:** Birth to 1 year

### **Stepping**

- **EXPECTED FINDING:** Elicit by holding the newborn upright with feet touching a flat surface. The newborn responds with stepping movements.
- **EXPECTED AGE:** Birth to 4 weeks

## **Senses**

**Vision:** The newborn should be able to focus on objects 8 to 12 inches away from face. This is approximately the distance from the mother's face when the newborn is breastfeeding. The eyes are sensitive to light, so newborns prefer dim lighting. Pupils are reactive to light, and the blink reflex is easily stimulated. The newborn can track high-contrast objects and prefers black and white patterns. Term newborns can see objects as far away as 2.5 feet. Within 2 to 3 months, they can discriminate colors.

**Hearing:** Hearing is similar to that of an adult once the amniotic fluid drains from the ears. Newborns exhibit selective listening to familiar voices and rhythms of intrauterine life. The newborn turns toward the general direction of a sound.

**Touch:** Newborns should respond to tactile messages of pain and touch. The mouth, hands, and soles of the feet are the areas most sensitive to touch in the newborn.

**Taste:** Newborns can taste and prefer sweet to salty, sour, or bitter.

**Smell:** Newborns have a highly developed sense of smell, prefer sweet smells, and can recognize the mother's smell.

**Habituation:** This is a protective mechanism whereby the newborn becomes accustomed to environmental stimuli. Response to a constant or repetitive stimulus is decreased. This allows the newborn to select stimuli that promotes continued learning, avoiding overload.

**!** Provide education to the parent and family about the neonate's appearance, and give reassurance about expected findings that the family can be concerned about (milia, Epstein's pearls, caput succedaneum).

## **PAIN ASSESSMENT**

Measure newborn pain using a combination of behavioral observation and physiological findings. Several pain scales have been developed as a tool to measure newborn pain.

- CRIES scale
- Scale for Use in Newborns (SUN)
- Neonatal Infant Pain Scale (NIPS)

### **Behavioral responses to pain**

- Alterations in sleep-wake cycles, feeding, or activity
- Fussiness or irritability
- Limb withdrawal; thrashing or fist-clenching; muscle rigidity or flaccidity
- Facial grimacing; chin quivering; furrowed brow; tightly closed eyes; open, square-shaped mouth
- Crying, groaning, or whimpering vocalizations

## Physiologic responses to pain

**Vital signs:** Rapid or shallow respirations; decreased oxygen saturation; increased heart rate and blood pressure

**Skin:** Pallor or flushing; palmar or general diaphoresis

**Laboratory findings:** Hyperglycemia, decreased pH, increased blood corticosteroid levels

**Other:** Increased muscle tone, decreased vagal nerve tone, increased intracranial pressure, dilated pupils

## DIAGNOSTIC AND THERAPEUTIC PROCEDURES FOLLOWING BIRTH

Cord blood is collected at birth. Laboratory tests are conducted to determine ABO blood type and Rh status if the parent's blood type is "O" or they are Rh-negative. A CBC can be done by a capillary stick to evaluate for anemia, polycythemia, infection, or clotting problems. Blood glucose levels are usually evaluated only in newborns who have risk factors for hypoglycemia.

### **EXPECTED LABORATORY VALUES**

- **Hgb:** 14 to 24 g/dL
- **Platelets:** 150,000 to 300,000/mm<sup>3</sup>
- **Hct:** 44% to 64%
- **Glucose:** greater than 40 to 45 mg/dL
- **RBC count:**  $4.8 \times 10^6$  to  $7.1 \times 10^6$
- **Bilirubin**
  - 24 hr: 2 to 6mg/dL
  - 48 hr: 6 to 7 mg/dL
  - 3 to 5 days: 4 to 6 mg/dL
- **WBC count:** 9,000 to 30,000/mm<sup>3</sup>

## COMPLICATIONS

### Airway obstruction related to mucus

**NURSING ACTIONS:** Suction mouth and then nose with a bulb syringe. Mouth should be suctioned first to prevent aspiration as the nose is suctioned.

### Hypothermia

#### **NURSING ACTIONS**

- Monitor axillary temperature. Healthy newborn temperature averages 37° C (98.6° F), with a range of 36.5° C to 37.5° C (97.7° F to 99.5° F).
- If temperature is unstable, place the newborn in a radiant warmer, and maintain skin temperature at approximately 36.5° C (97.7° F). Ideal method for promoting warmth and maintaining neonate's body temperature for a stable newborn is early skin-to-skin contact with parent. If the infant does not remain skin-to-skin with parent during the first 1 to 2 hr after birth, place the thoroughly dried infant under the radiant warmer or in a warm incubator until body temperature stabilizes.
- Assess axillary temperature every hour until stable.
- All exams and assessments should be performed while the newborn is under a radiant warmer or during skin-to-skin contact with the parent.

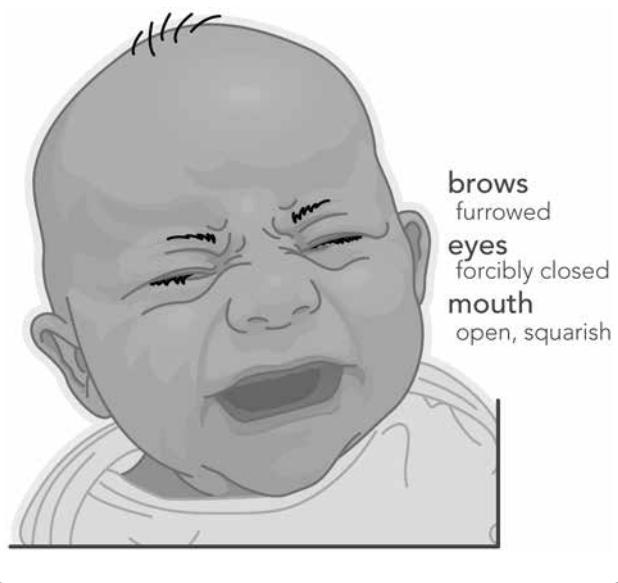

### Inadequate oxygen supply

Related to obstructed airway, poorly functioning cardiopulmonary system, or hypothermia

#### **NURSING ACTIONS**

- Monitor respirations and for indication of cyanosis (changes in skin, mucous membrane color).
- Stabilize the body temperature or clear airway as indicated, administer oxygen, and if needed, prepare for resuscitation.

### **23.7 Pain cues**

## Application Exercises

1. A nurse is caring for a newborn who was born at 38 weeks of gestation, weighs 3,200 g, and is in the 60th percentile for weight. Based on the weight and gestational age, the nurse should classify this neonate as which of the following?

  - A. Low birth weight
  - B. Appropriate for gestational age
  - C. Small for gestational age
  - D. Large for gestational age
  
2. A nurse is completing a newborn assessment and observes small pearly white nodules on the roof of the newborn's mouth. This finding is a characteristic of which of the following conditions?

  - A. Mongolian spots
  - B. Milia spots
  - C. Erythema toxicum
  - D. Epstein's pearls
  
3. A nurse is assessing the reflexes of a newborn. In checking for the Moro reflex, the nurse should perform which of the following?

  - A. Hold the newborn vertically under arms and allow one foot to touch table.
  - B. Stimulate the pads of the newborn's hands with stroking or massage.
  - C. Stimulate the soles of the newborn's feet on the outer lateral surface of each foot.
  - D. Hold the newborn in a semi-sitting position, then allow the newborn's head and trunk to fall backward.
  
4. A nurse is completing an assessment. Which of the following data indicate the newborn is adapting to extrauterine life? (Select all that apply.)

  - A. Expiratory grunting
  - B. Inspiratory nasal flaring
  - C. Apnea for 10-second periods
  - D. Obligatory nose breathing
  - E. Crackles and wheezing
  
5. A nurse is teaching a newly licensed nurse how to bathe a newborn and observes a bluish brown marking across the newborn's lower back. The nurse should include which of the following information in the teaching?

  - A. "This is more commonly seen in newborns who have dark skin."
  - B. "This is a finding indicating hyperbilirubinemia."
  - C. "This is a forceps mark from an operative delivery."
  - D. "This is related to prolonged birth or trauma during delivery."

## Active Learning Scenario

A nurse in the nursery is admitting a newborn 2 hr following birth. What nursing actions should the nurse use to evaluate newborn physical development? Use the ATI Active Learning Template: Growth and Development to complete this item.

### PHYSICAL DEVELOPMENT

- Describe at least three tools for assessment.
- Describe four reflex responses present at birth and how they are elicited.
- Describe newborn heart rate and how it is assessed.

## Application Exercises Key

1. A. A newborn who has a low birth weight would weigh less than 2,500 g.
- B. **CORRECT:** This newborn is classified as appropriate for gestational age because the weight is between the 10th and 90th percentile.
- C. A newborn who is small for gestational age would weigh less than the 10th percentile.
- D. A newborn who is large for gestational age would weigh greater than the 90th percentile.

NCLEX® Connection: *Health Promotion and Maintenance, Health Screening*

2. A. Mongolian spots are areas of darkened pigmentation that occur on the back or sacrum.
- B. Milia are small pearly white bumps that occur on the nose due to clogged sebaceous glands.
- C. Erythema toxicum is a transient maculopapular rash seen in newborns.
- D. **CORRECT:** Epstein's pearls are small yellow-white nodules that appear on the roof of a newborn's mouth.

NCLEX® Connection: *Health Promotion and Maintenance, Health Screening*

3. A. Holding the newborn vertically under the arms and allowing one foot to touch the table elicits the stepping reflex.
- B. Stimulating the pads of the newborn's hands elicits the grasp reflex.
- C. Stimulating the outer lateral portion of the newborn's soles elicits the Babinski reflex.
- D. **CORRECT:** The Moro reflex is elicited by holding the newborn in a semi-sitting position and then allowing the head and trunk to fall backward.

NCLEX® Connection: *Health Promotion and Maintenance, Health Screening*

4. A. Expiratory grunting is a manifestation of respiratory distress.
- B. Nasal flaring is a manifestation of respiratory distress.
- C. **CORRECT:** Periods of apnea lasting less than 15 seconds are an expected finding.
- D. **CORRECT:** Newborns are obligatory nose breathers.
- E. Crackles and wheezing are manifestations of fluid or infection in the lungs.

NCLEX® Connection: *Health Promotion and Maintenance, Health Screening*

5. A. **CORRECT:** Mongolian spots are commonly found over the lumbosacral area of newborns who have dark skin and can be linked to genetics.
- B. Hyperbilirubinemia would present as jaundice.
- C. Forceps marks would most likely present as a cephalohematoma.
- D. Birth trauma would present as ecchymosis.

NCLEX® Connection: *Health Promotion and Maintenance, Health Screening*

## Active Learning Scenario Key

Using the ATI Active Learning Template: Growth and Development

### PHYSICAL DEVELOPMENT

#### Assessment tools

- Brief initial systems assessment
- Gestational age assessment: Physical measurements and New Ballard Score
- Vital signs
- Head-to-toe physical assessment

#### Reflexes

- Sucking and rooting: Turns head to side that is touched and begins to suck when cheek or edge of mouth is stroked.
- Palmar grasp: Grasps object when placed in palm.
- Plantar grasp: Toes curl downward when sole of the foot is touched.
- Moro reflex: Arms and legs symmetrically extend and then abduct while fingers spread to form a "C" when infant's head and trunk are allowed to fall backward at an angle of at least 30°.
- Tonic neck (fencer position): Extends arm and leg on same side when head is turned to that side, and flexes arm and leg of opposite side.
- Babinski: Toes fan upward and out when outer edge of sole of foot is stroked, moving up toward toes.
- Stepping: Makes stepping movements when held upright with feet touching flat surface.

#### Heart rate

- 100 to 160/min with brief fluctuations above and below, depending on activity level.
- When newborn is sleeping, place pediatric stethoscope head on fourth or fifth intercostal space at the left midclavicular line over apex of the heart. Listen for 1 full minute.
- Note any murmurs.

NCLEX® Connection: *Health Promotion and Maintenance, Health Screening*

**CHAPTER 24** *Nursing Care of Newborns*

---

Newborn care consists of stabilization and/or resuscitation. This can include establishing a patent airway, maintaining adequate oxygenation, and thermoregulation for the maintenance of body temperature. A physical assessment (physical examination, measurements, and monitoring laboratory studies) is done every 8 hr or as needed.

Nursing interventions and family teaching (umbilical cord care, prophylactic measures, newborn screening, newborn feedings and bathing, and fostering baby-friendly activities) are integrated into a newborn's plan of care.

## ASSESSMENT

---

### PHYSICAL ASSESSMENT

---

- Vital signs should be checked on admission/birth and every 30 min x 2, every 1 hr x 2, and then every 8 hr.
- Weight should be checked daily at the same time, using the same scale.
- Inspect the umbilical cord. Observe for any bleeding from the cord, and ensure that the cord is clamped securely to prevent hemorrhage.
- In the first 6 to 8 hr of life as body systems stabilize and pass through periods of adjustment, observe for periods of reactivity.
  - **First period of reactivity:** The newborn is alert, exhibits exploring activity, makes sucking sounds, and has a rapid heart rate and respiratory rate. Heart rate can be as high as 160 to 180/min, but will stabilize at a baseline of 100 to 120/min during a period that lasts 30 min after birth.
  - **Period of relative inactivity:** The newborn will become quiet and begin to rest and sleep. The heart rate and respirations will decrease, and this period will last from 60 to 100 min after birth.
  - **Second period of reactivity:** The newborn reawakens, becomes responsive again, and often gags and chokes on mucus that has accumulated in the mouth. This period usually occurs 2 to 8 hr after birth and can last 10 min to several hours.
- Using the facility's preferred pain assessment tool, conduct a pain assessment on the newborn with routine assessments and following painful procedures. 

## LABORATORY TESTS

---

**Hgb and Hct**, if prescribed

**Blood glucose for hypoglycemia**, per facility policy or as prescribed

**Metabolic screening**

- Newborn genetic screening is mandated in all states. A capillary heel stick should be done 24 hr following birth. For results to be accurate, the newborn must have received formula or breast milk for at least 24 hr. If the newborn is discharged before 24 hr of age, the test should be repeated in 1 to 2 weeks.
- All states require testing for phenylketonuria (PKU). PKU is a defect in protein metabolism in which the accumulation of the amino acid phenylalanine can result in mental retardation. (Treatment in the first 2 months of life can prevent mental retardation.)

**Other genetic testing** that can be done includes for galactosemia, cystic fibrosis, maple syrup urine disease, hypothyroidism, and sickle cell disease.

**Serum bilirubin** on all newborns prior to discharge

**Collecting blood samples**

- Heel stick blood samples are obtained by the nurse, who dons clean gloves.
- Warm the newborn's heel first to increase circulation.
- Cleanse the area with an appropriate antiseptic, and allow for drying.
- A spring-activated lancet is used so that the skin incision is made quickly and painlessly.
- The outer aspect of the heel should be used, and the lancet should go no deeper than 2.4 mm to prevent necrotizing osteochondritis resulting from penetration of bone with the lancet.
- Follow facility protocol for specimen collection, equipment to be used, and labeling of specimens.
- Apply pressure with dry gauze (do not use alcohol because it will cause bleeding to continue) until bleeding stops, and cover with an adhesive bandage.
- Cuddle and comfort the newborn when the procedure is completed to reassure the newborn and promote feelings of safety.

## DIAGNOSTIC PROCEDURES

---

**Newborn hearing screening** is required in most states. Newborns are screened so that hearing impairments can be detected and treated early. 

## THERAPEUTIC PROCEDURES

---

**Circumcision** is the surgical removal of the foreskin of the penis.

- The newborn's family makes the choice regarding whether to circumcise, depending on health, hygiene, religion (Jewish male on eighth day after birth), tradition, culture, or social norms. Parents should make a well-informed decision in consultation with the provider.

- Circumcision should not be performed immediately following birth because the newborn's level of vitamin K is at a low point, and the newborn would be at risk for hemorrhage. The newborn is also at increased risk for cold stress.
- Circumcision is usually performed within the first few days of life, but might be postponed due to cultural reasons, or for preterm or ill newborns.

#### HEALTH BENEFITS

- Easier hygiene
- Decreased risk of STIs (HIV, human papillomavirus [HPV])
- Decreased risk of penile cancer and cervical cancer in female partners 

#### POSSIBLE RISKS

- Hemorrhage
- Infection
- Inflammation or stenosis of the urinary meatus
- Urethral fistula
- Adhesions or dehiscence of the skin.
- Concealed penis

#### CONTRAINDICATIONS

- Hypospadias (abnormal positioning of urethra on ventral under-surface of the penis) and epispadias (urethral canal terminates on dorsum of penis) because the prepuce skin can be needed for surgical repair of the defect
- Family history of bleeding disorders
- Newborns who do not receive vitamin K, making them more likely to experience bleeding at the circumcision site

### Preprocedure

#### NURSING ASSESSMENT

Assess the newborn for the following.

- Family history of bleeding tendencies (hemophilia, clotting disorders)
- Hypospadias or epispadias
- Ambiguous genitalia (can include both male and female characteristics)
- Illness or infection

#### NURSING ACTIONS

- Obtained signed informed consent form from parents.
- Gather and prepare supplies.
- Administer medication as prescribed.
- Assist with procedure.
  - Place the newborn on the restraining board, and provide a radiant heat source to prevent cold stress. Do not leave the newborn unattended. Have bulb syringe readily available.
  - Comfort the newborn as needed.
  - Document time and type of circumcision, amount of bleeding, and newborn voiding following procedure.

### Intraprocedure

**ANESTHESIA:** Anesthesia is required for circumcision. Types of anesthesia include a ring block, dorsal-penile nerve block, topical anesthetic (eutectic mixture of local anesthetics), and concentrated oral sucrose. Nonpharmacologic methods (swaddling, nonnutritive sucking) can be used to enhance pain management.

**EQUIPMENT FOR PERFORMING CIRCUMCISION:** Gomco (Yellen) or Mogen clamp, or Plastibell device

- The provider applies the Gomco (Yellen) or Mogen clamp to the penis, loosens the foreskin, and inserts the cone under the foreskin to provide a cutting surface for removal of the foreskin and to protect the penis. Using the clamp reduces the amount of blood lost. The wound is covered with sterile petroleum gauze to prevent infection and control bleeding.
- The provider slides the Plastibell device between the foreskin and the glans of the penis. The provider ties a suture tightly around the foreskin at the coronal edge of the glans. This applies pressure as the excess foreskin is removed from the penis. After 5 to 7 days, the Plastibell drops off, leaving a clean, healed excision. No petroleum is used for circumcision with the Plastibell. **(24.1)**

### Postprocedure

#### NURSING ASSESSMENT

Assess the newborn for the following.

- Bleeding (assess every 15 to 30 min for the first hour and then hourly for the next 4 to 6 hr)
- The first voiding

#### NURSING ACTIONS

- Remove the newborn from the restraining board, and swaddle to provide comfort.
- Monitor for bleeding and voiding per facility protocol. Apply gauze lightly to penis if bleeding or oozing is observed.
- Fan-fold diapers to prevent pressure on the circumcised area.
- Liquid acetaminophen 10 to 15 mg/kg can be administered orally after the procedure and repeated every 4 to 6 hr as prescribed for a maximum of 30 to 45 mg/kg/day.
- Provide discharge instructions to the parents about manifestations of infection, comfort measures, medications, and when to notify the provider.

#### CLIENT EDUCATION

- A signed informed consent is needed.
- The newborn will not be able to be bottle fed for up to 2 to 3 hr prior to the procedure to prevent vomiting and aspiration based. Newborns can breastfeed up until the procedure.
- The newborn is restrained on a board during the procedure.
- Keep the area clean. Change the newborn's diaper at least every 4 hr, and clean the penis with warm water with each diaper change. With clamp procedures, apply petroleum jelly with each diaper change for at least 24 hr after the circumcision to keep the diaper from adhering to the penis.

- Avoid wrapping the penis in tight gauze, which can impair circulation to the glans.
- Do not give a tub bath until the circumcision is healed. Until then, trickle warm water gently over the penis.
- Notify the provider if there is any redness, discharge, swelling, strong odor, tenderness, decrease in urination, or excessive crying from the newborn.
- A film of yellowish mucus can form over the glans by day two. Do not wash it off.
- Avoid using premoistened towelettes to clean the penis because they contain alcohol.
- The newborn can be fussy or can sleep for several hours after the circumcision. Provide comfort measures for 24 to 48 hr, to include acetaminophen as prescribed.
- The circumcision should heal completely within a couple of weeks.
- Report any frank bleeding, foul-smelling drainage, or lack of voiding to the provider.

### **Complications and nursing management**

#### **Hemorrhage**

- Monitor for bleeding.
- Provide gentle pressure on the penis using a small gauze square. Gelfoam powder or sponge can be applied to stop bleeding. If bleeding persists, notify the provider that a blood vessel might need to be ligated. Have a nurse continue to hold pressure until the provider arrives while another nurse prepares the circumcision tray and suture material.

#### **Cold stress/hypoglycemia**

- Monitor for excessive loss of heat resulting in increased respirations and lowered body temperature.
- Swaddle and feed the newborn as soon as the procedure is over.

## **PATIENT-CENTERED CARE**

### **NURSING CARE**

Stabilize and/or give resuscitation to the newborn.

#### **Respiratory complications**

Monitor for clinical findings of respiratory complications.

- **Bradypnea:** respirations less than or equal to 30/min
- **Tachypnea:** respirations greater than or equal to 60/min
- **Abnormal breath sounds:** expiratory grunting, crackles, wheezes
- **Respiratory distress:** nasal flaring, retractions, grunting, gasping, labored breathing

#### **INTERVENTIONS FOR STABILIZATION AND RESUSCITATION OF AIRWAY**

- The newborn is able to clear most secretions in air passages by the cough reflex. Routine suctioning of the mouth, then the nasal passages with a bulb syringe, is done to remove excess mucus in the respiratory tract.
- Newborns delivered by cesarean birth are more susceptible to fluid remaining in the lungs than newborns who were delivered vaginally.

- If bulb suctioning is unsuccessful, use mechanical suction for clearing the airway. Institute emergency procedures if the airway does not clear.
- The bulb syringe should be kept with the newborn, and the newborn's family should be instructed on its use. Family members should be asked to perform a demonstration to show that they understand bulb syringe techniques.
  - Compress bulb before insertion into one side of the mouth.
  - Avoid center of the mouth to prevent stimulating gag reflex.
  - Aspirate mouth first, one nostril, then second nostril.

### **Identification**

Identification (using two identifiers) is applied to the newborn immediately after birth by the nurse. It is an important safety measure to prevent the newborn from being given to the wrong parents, switched, or abducted. **Qs**

- The newborn, client, and client's partner are identified by plastic identification wristbands with permanent locks that must be cut to be removed. Identification bands should include the newborn's name, sex, date, and time of birth, and client's health record number. The newborn should have one band placed on the ankle and one on the wrist. In addition, the newborn's footprints and client's thumb prints are taken. The above information is also included with the footprint sheet.
- Each time the newborn is given to the parents, the identification band should be verified against the client's identification band.
- All facility staff who assist in caring for the newborn are required to wear photo identification badges.

#### **24.1 Circumcision plastibell**

- The newborn is not to be given to anyone who does not have a photo identification badge that distinguishes that person as a staff member of the facility maternal-newborn unit.
- Many facilities have locked maternal-newborn units that require staff to permit entrance or exit. Some facilities have a sensor device on the ID band or umbilical cord clamp that sounds an alarm if the newborn is removed from the facility.

## ***Thermoregulation***

Thermoregulation provides a neutral thermal environment that helps a newborn maintain a normal core temperature with minimal oxygen consumption and caloric expenditure. A newborn has a relatively large surface-to-weight ratio, reduced metabolism per unit area, blood vessels close to the surface, and small amounts of insulation.

- The newborn keeps warm by metabolizing brown fat, which is unique to newborns, but only within a very narrow temperature range. Becoming chilled (cold stress) can increase the newborn's oxygen demands and rapidly use up brown fat reserves. Therefore, monitoring temperature regulation is important.
- Monitor for hypothermia in the newborn.
  - Axillary temperature of less than 36.5° C (97.7° F)
  - Cyanosis
  - Increased respiratory rate
- Core temperature varies within newborns, but it should be kept at approximately 36.5 to 37° C (97.7 to 98.6° F).

## **INTERVENTIONS TO MAINTAIN THERMOREGULATION**

- Heat loss occurs by four mechanisms.
  - Conduction:** Loss of body heat resulting from direct contact with a cooler surface. Preheat a radiant warmer, warm a stethoscope and other instruments, and pad a scale before weighing the newborn. The newborn should be placed directly on the parent's chest and covered with a warm blanket.
  - Convection:** Flow of heat from the body surface to cooler environmental air. Place the bassinet out of the direct line of a fan or air conditioning vent, swaddle the newborn in a blanket, and keep the head covered. Any procedure done with the newborn uncovered should be performed under a radiant heat source. Keep ambient temperature of the nursery or client's room at 22 to 26° C (72 to 78° F).
  - Evaporation:** Loss of heat as surface liquid is converted to vapor. Gently rub the newborn dry with a warm sterile blanket (adhering to standard precautions) immediately after delivery. If thermoregulation is unstable, postpone the initial bath until the newborn's skin temperature is 36.5° C (97.7° F). When bathing, expose only one body part at a time, washing and drying thoroughly.
  - Radiation:** Loss of heat from the body surface to a cooler solid surface that is close to, but not in direct contact. Keep the newborn and examining tables away from windows and air conditioners.
- Temperature stabilizes at 37° C (98.6° F) within 12 hr after birth if chilling is prevented.
- The best method for promoting and maintaining the newborn's temperature is early skin-to-skin contact with the parent.

## ***Bathing***

- Bathing can begin once the newborn's temperature has stabilized to at least 36.5° C (97.7° F). A complete sponge bath should be postponed until thermoregulation stabilizes.
- Gloves should be worn until the newborn's first bath to avoid exposure to body secretions.

## ***Feeding***

Feedings can be started immediately following birth.

- Breastfeeding is initiated as soon as possible after birth as part of baby-friendly initiatives.
- Formula feeding usually is started at about 2 to 4 hr of age.
  - The newborn is fed on demand, which is normally every 3 to 4 hr for bottle-fed newborns and more frequently for breastfed newborns.
  - Monitor and document feedings per facility protocol.

## ***Sleep***

- Sleep-wake states are variations of consciousness in the newborn consisting of six states along a continuum comprised of deep sleep, light sleep, drowsy, quiet alert, active alert, and crying.
- Newborns sleep approximately 16 to 19 hr/day with periods of wakefulness gradually increasing. Newborns are positioned supine, "safe sleep," to decrease the incidence of sudden infant death syndrome (SIDS). *Qs*
  - No bumper pads, loose linens, or toys should be placed in the bassinet.
  - Parents should sleep in close proximity but not in a shared space. Higher incidence rates are noted for SIDS and suffocation with bed sharing/co-sleeping.
  - Educate parents about the need for immunizations as a measure to prevent SIDS.

## ***Elimination***

- Monitor elimination habits.
  - Newborns should void once within 24 hr of birth. They should void 6 to 8 times per 24 hr after day 4.
  - Meconium should be passed within the first 24 hr to 48 hr after birth. The newborn will then continue to pass stool 3 to 4 times a day depending on whether they are being breast- or bottle-fed.
  - The stools of newborns who are breastfed can appear yellow and seedy. They should have at least 3 stools per day for the first month. These stools are lighter in color and looser than the stools of newborns who are formula-fed.
- Monitor and document output.
- Keep the perineal area clean and dry. The ammonia in urine is irritating to the skin and can cause diaper rash.
  - After each diaper change, cleanse the perineal area with clear water or water with a mild soap. Diaper wipes with alcohol should be avoided. Pat dry, and apply triple antibiotic ointment, petroleum jelly, or zinc oxide, depending on facility protocol.

## Infection control

Infection control is essential in preventing cross-contamination from newborn to newborn and between newborns and staff. Newborns are at risk for infection during the first few months of life because of immature immune systems.

- Provide individual bassinets equipped with diapers, T-shirts, and bathing supplies.
- All personnel who care for a newborn should scrub with antimicrobial soap from elbows to finger tips before entering the nursery. In between care of the newborn, the nurse should follow facility hygiene protocols. Cover gowns or special uniforms are used to avoid direct contact with clothes.

## Family education

Provide family education and promote family-newborn attachment. 

- Provide family education while performing all nursing care. Encourage family involvement, allowing the parent and family to perform newborn care with direct supervision and support by the nurse.
- Encourage parents and family to hold the newborn so that they can experience eye-to-eye contact and interaction.
- Foster sibling interaction in newborn care.

## Umbilical cord care

Goal of cord care is to prevent or decrease risk for infection and hemorrhage.

### NURSING ACTIONS

- Cord clamp stays in place for 24 to 48 hr.
- Recommendations for cord care include cleaning the cord with water (using cleanser sparingly if needed to remove debris) during the initial bath of the newborn.
- Assess stump and base of cord for erythema, edema, and drainage with each diaper change.
- The newborn's diaper should be folded down and away from the umbilical stump.
- Bathing infant by submerging in water should not occur until the cord has fallen off.
- Most cords fall off within the first 10 to 14 days.

## MEDICATIONS

### Erythromycin

- Prophylactic eye care is the mandatory instillation of antibiotic ointment into the eyes to prevent ophthalmia neonatorum.
- Infections can be transmitted during descent through the birth canal. Ophthalmia neonatorum is caused by *Neisseria gonorrhoeae* or *Chlamydia trachomatis* and can cause blindness.

### NURSING ACTIONS

- Use a single-dose unit to avoid cross-contamination.
- Apply a 1- to 2-cm ribbon of ointment to the lower conjunctival sac of each eye, starting from the inner canthus and moving outward.
- A possible side effect is chemical conjunctivitis, causing redness, swelling, drainage, and temporarily blurred vision for 24 to 48 hr. Reassure the parents that this will resolve on its own.
- Application can be delayed for 1 hr after birth to facilitate baby-friendly activities during the first period of newborn reactivity.

### Vitamin K (phytonadione)

Administered to prevent hemorrhagic disorders. Vitamin K is not produced in the gastrointestinal tract of the newborn until around day 7. Vitamin K is produced in the colon by bacteria once formula or breast milk is introduced.

**NURSING ACTIONS:** Administer 0.5 to 1 mg intramuscularly into the vastus lateralis (where muscle development is adequate) soon after birth.

### Hepatitis B immunization

Provides protection against hepatitis B

### NURSING ACTIONS

- Recommended to be administered to all newborns.
- Informed consent must be obtained.
- For newborns born to healthy clients, recommended dosage schedule is at birth, 1 month, and 6 months.
- For parents infected with hepatitis B, hepatitis B immunoglobulin and the hepatitis B vaccine is given within 12 hr of birth. The hepatitis B vaccine is given alone at 1 month, 2 months, and 12 months.

**!** It is important **NOT** to give the vitamin K and the hepatitis B injections in the same thigh.

## COMPLICATIONS

### Cold stress

Ineffective thermoregulation can lead to hypoxia, acidosis, and hypoglycemia. Newborns who have respiratory distress are at a higher risk for hypothermia.

#### NURSING ACTIONS

- Monitor for manifestations of cold stress (skin pallor with mottling and cyanotic trunk; tachypnea).
- The newborn should be warmed slowly over a period of 2 to 4 hr. Correct hypoxia by administering oxygen. Correct acidosis and hypoglycemia. 

### Hypoglycemia

- An initial drop in blood glucose after birth is a common occurrence due to the cessation of the maternal supply of glucose.
- Blood glucose levels are not usually assessed in healthy term newborns as they have adequate glycogen stores to compensate for this physiological change.
  - A healthy term newborn can tolerate an initial decrease in their blood glucose level to as low as 30 mg/dL.
- Newborns who have risk factors for hypoglycemia should have a blood glucose level checked within the first hour after birth. This includes newborns who are preterm, small or large for gestational age, and newborns of diabetic clients.
  - Interventions are indicated for at-risk newborns when their blood glucose levels are less than 40 to 45 mg/dL.
- Follow facility protocols regarding frequency of assessing blood glucose levels.

#### NURSING ACTIONS

- Monitor for manifestations of hypoglycemia (jitteriness, tremors, weak or high pitched cry, decreased tone, poor feeding, apnea, respiratory distress, low temperature, seizures, a blood glucose of less than 40 to 45 mg/dL).
- Initiate feedings with breastmilk or formula in clinically stable newborns to maintain or increase blood glucose levels.
- Continue to monitor blood glucose levels and feed every 2 to 3 hr for at least the first 24 hr of life, in at-risk newborns and those who have demonstrated hypoglycemia, as per facility protocol.
- Skin-to-skin contact will promote breastfeeding and thermoregulation to stabilize blood sugar levels.

### Hemorrhage

Due to improper cord care or placement of clamp

#### NURSING ACTIONS

- Ensure that the clamp is tight. If seepage of blood is noted, a second clamp should be applied.
- Notify the provider if bleeding continues.

### Application Exercises

1. A nurse is preparing to administer prophylactic eye ointment to a newborn to prevent ophthalmia neonatorum. Which of the following medications should the nurse anticipate administering?
  - A. Ofloxacin
  - B. Nystatin
  - C. Erythromycin
  - D. Ceftriaxone
2. A newborn was not dried completely after birth. This places the infant at risk for which of the following types of heat loss?
  - A. Conduction
  - B. Convection
  - C. Evaporation
  - D. Radiation
3. A nurse is caring for a newborn immediately following birth. Which of the following nursing interventions is the highest priority?
  - A. Initiating breastfeeding
  - B. Performing the initial bath
  - C. Giving a vitamin K injection
  - D. Covering the newborn's head with a cap
4. A nurse is preparing to administer a vitamin K (phytonadione) injection to a newborn. Which of the following responses should the nurse make to the newborn's parent regarding why this medication is given?
  - A. "It assists with blood clotting."
  - B. "It promotes maturation of the bowel."
  - C. "It is a preventative vaccine."
  - D. "It provides immunity."
5. A nurse is taking a newborn to a parent following a circumcision. Which of the following actions should the nurse take for security purposes?
  - A. Ask the parent to state their full name.
  - B. Look at the name on the newborn's bassinet.
  - C. Match the parent's identification band with the newborn's band.
  - D. Compare name on the bassinet and room number.

## Application Exercises Key

1. A. Ofloxacin is an antibiotic, but it is not used for ophthalmia neonatorum.
- B. Nystatin is used to treat *Candida albicans*, an oral yeast infection.
- C. **CORRECT:** One medication of choice for ophthalmia neonatorum is erythromycin ophthalmic ointment 0.5%. This antibiotic provides prophylaxis against *Neisseria gonorrhoeae* and *Chlamydia trachomatis*.
- D. Ceftriaxone is an antibiotic, but it is not used for ophthalmia neonatorum.

❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Medication Administration*

2. A. Conduction is the loss of heat from the body surface area to cooler surfaces that the newborn can be in contact with.
- B. Convection is the flow of heat from the body surface area to cooler air.
- C. **CORRECT:** Evaporation is the loss of heat that occurs when a liquid is converted to a vapor. In a newborn, heat loss by evaporation occurs as a result of vaporization of the moisture from the skin.
- D. Radiation is the loss of heat to a cooler surface that is not in direct contact with the newborn.

❷ NCLEX® Connection: *Health Promotion and Maintenance, Aging Process*

3. A. Initiating breastfeeding is important following birth, but it is not the priority action.
- B. Initial baths are not given until the newborn's temperature is stable. It is not the priority action.
- C. Vitamin K can be given immediately after birth, but it is not the priority action.
- D. **CORRECT:** The greatest risk to the newborn is cold stress. Therefore, the highest priority intervention is to prevent heat loss. Covering the newborn's head with a cap prevents cold stress due to excessive evaporative heat loss.

❷ NCLEX® Connection: *Management of Care, Establishing Priorities*

4. A. **CORRECT:** Vitamin K is deficient in a newborn because the colon is sterile. Until bacteria are present to stimulate vitamin K production, the newborn is at risk for hemorrhagic disease.
- B. Vitamin K does not assist the bowel to mature.
- C. Vitamin K is not part of the vaccines that are administered.
- D. Vitamin K does not provide immunity.

❷ NCLEX® Connection: *Pharmacological and Parenteral Therapies, Medication Administration*

5. A. Asking the parent to state their full name is not appropriate verification because two identifiers should be used.
- B. Looking at the name on the bassinet is not appropriate verification because two identifiers should be used.
- C. **CORRECT:** Each time the newborn is taken to the parent, the parent's identification band should be verified against the newborn's identification band.
- D. Comparing the name on the bassinet with the room number is not appropriate verification because it does not include two identifiers involving the parent and newborn.

❷ NCLEX® Connection: *Safety and Infection Control, Accident/Error/Injury Prevention*

## Active Learning Scenario

A nurse is conducting a class for parents on care of the newborn. What should the nurse include in this class? Use the ATI Active Learning Template: Basic Concept to complete this item.

**UNDERLYING PRINCIPLES:** Describe three mechanisms that promote airway clearance.

**NURSING INTERVENTIONS:** Describe appropriate bulb syringe technique.

## Active Learning Scenario Key

*Using the ATI Active Learning Template: Basic Concept*

**UNDERLYING PRINCIPLES:** Mechanisms that promote airway clearance

- Infant's cough reflex
- Mechanical suctioning
- Use of the bulb syringe for suctioning

**NURSING INTERVENTIONS:** Bulb syringe technique

- Depress the bulb.
- Insert syringe into side of mouth, avoiding center of the mouth.
- Suction mouth first, then one nostril, then second nostril.

❷ NCLEX® Connection: *Safety and Infection Control, Home Safety*

# CHAPTER 25

UNIT 4

NEWBORN NURSING CARE

SECTION: LOW-RISK NEWBORN

## CHAPTER 25 Newborn Nutrition

Understanding the nutritional needs of newborns (breastfeeding, human pasteurized milk, human donor milk, formula-feeding, bottle-feeding) is essential. This includes nutrition considerations, complications, and interventions.

### NUTRITIONAL NEEDS FOR THE NEWBORN

Desirable growth and development of the newborn is enhanced by good nutrition. Feeding the newborn provides an opportunity for parents to meet the newborn's nutritional needs as well as an opportunity for them to bond with the newborn. Whether the client breastfeeds, uses donor milk, or formula (bottle) feeds, nurses should provide education and support.

- Normal newborn weight loss immediately after birth and subsequent weight gain should be as follows.
  - **Loss of 5% to 10% after birth (regain 10 to 14 days after birth)**
  - **Gain of 110 to 200 g/week for first 3 months**
- During the first 2 days of life, healthy newborns need a fluid intake of 60 to 80 mL/kg/24 hr. From 3 to 7 days, the fluid requirement is 100 to 150 mL/kg/24 hr.
- Adequate caloric intake is essential to provide energy for growth, digestion, metabolic needs, and activity. For the first 3 months, the newborn requires 110 kcal/kg/day. From 3 to 6 months, the requirement decreases to 100 kcal/kg/day. Both breast milk and formula provide 20 kcal/oz.
- Carbohydrates should make up 40% to 50% of the newborn's total caloric intake. The most abundant carbohydrate in breast milk or formula is lactose.
- At least 15% of calories must come from fat (triglycerides). The fat in breast milk is easier to digest than the fat in cow's milk.
- For adequate growth and development, a newborn should receive 9 g per day of protein from birth to 6 months of age.
- Breast milk contains the vitamins necessary to provide adequate newborn nutrition. According to the American Academy of Pediatrics, all infants who are breastfed or partially breastfed should receive 400 IU of vitamin D daily beginning in the first few days of life. Infant formula has vitamins added, but vitamin D supplements also are recommended. Parents who are breastfeeding and do not consume meat, fish, and dairy products should provide vitamin B<sub>12</sub> supplementation to their newborns. 

- The mineral content of commercial newborn formula and breast milk is adequate with the exception of iron and fluoride.
  - Iron is low in all forms of milk, but it is absorbed better from breast milk. Newborns who only breastfeed should be given iron supplements at 4 months of age, and until they are able to consume iron-containing foods. Newborns who are formula-fed should receive iron-fortified newborn formula until 12 months of age.
  - Fluoride levels in breast milk and formulas are low. A fluoride supplement should be considered after 6 months of age, depending on the water supply.
- Solids are not introduced until 6 months of age. If introduced too early, food allergies can develop.

### BREASTFEEDING

Breastfeeding is the optimal source of nutrition for newborns. Breastfeeding is recommended exclusively for the first 6 months of age by the American Academy of Pediatrics. Newborns should be breastfed every 2 to 3 hr. Parents should awaken the newborn to feed at least every 3 hr during the day and at least every 4 hr during the night until the newborn is feeding well and gaining weight adequately. Breastfeeding should occur eight to 12 times within 24 hr. Then, a feed-on-demand schedule can be followed.

- For the first few days after birth, the baby receives colostrum (early milk). Colostrum is secreted from the postpartum client's breasts during postpartum days 1 to 3. It contains immunoglobulin A (IgA), which provides passive immunity to the newborn.
- Nursing interventions can help a new parent be successful in breastfeeding. This includes the provision of adequate calories and fluids to support breastfeeding. The practice of rooming-in (allowing clients and newborns to remain together) should be encouraged as part of baby-friendly initiatives. Lactation consultants can improve success in breastfeeding. Encourage breastfeeding through the first 12 months of life. 

### ADVANTAGES OF BREASTFEEDING

Parents should receive with factual information about the nutritional and immunological needs of their newborn. Present information about both breastfeeding and bottle feeding in a nonjudgmental manner. The optimal time to provide newborn nutritional information is during pregnancy, so that the parents can make a decision prior to hospital admission.

## 25.1 Breastfeeding positions

### Football hold

### Cradle

### Modified cradle

The parent positions the baby as in the cradle position shown above, but reverses the function of each arm.

### Side-lying

### BENEFITS OF BREASTFEEDING

- Reduces the risk of infection by providing IgA antibodies, lysozymes, leukocytes, macrophages, and lactoferrin that prevents infections.
- Promotes rapid brain growth due to large amounts of lactose.
- Provides protein and nitrogen for neurologic cell building and improves the newborn's ability to regulate calcium and phosphorus levels.
- Contains electrolytes and minerals.
- Easy for the newborn to digest.
- Reduces incidence of sudden infant death syndrome (SIDS), allergies, and childhood obesity.
- Promotes maternal-infant bonding and attachment.

**Benefits specific to the infant:** Decreased risk for gastrointestinal infections, celiac disease, asthma, lower respiratory tract infections, otitis media, sudden infant death syndrome (SIDS), obesity in adolescence and adulthood, diabetes mellitus types 1 and 2, and acute lymphocytic and myeloid leukemia

**Benefits specific to the nursing parent:** Decreased postpartum bleeding and more rapid uterine involution; decreased risk for ovarian and breast cancer, diabetes mellitus type 2, hypertension, hypercholesterolemia, cardiovascular disease, and rheumatoid arthritis

**Benefits specific to families and society:** Less expensive than formula, reduces annual health care costs, and reduces environmental effects related to disposal of formula packaging and equipment

### NURSING INTERVENTIONS

- Place the newborn skin-to-skin on the parent's chest immediately after birth. Initiate breastfeeding as soon as possible or within the first 30 min following birth.
- Explain breastfeeding techniques to the parent. Have the parent wash their hands, get comfortable, and have caffeine-free, nonalcoholic fluids to drink during breastfeeding.
- Explain the let-down reflex (stimulation of maternal nipple releases oxytocin that causes the let-down of milk).
- Express a few drops of colostrum or milk and spread it over the nipple to lubricate the nipple and entice the newborn.
- Show the parent the proper latch-on position. Have them support the breast in one hand with the thumb on top and four fingers underneath. With the newborn's mouth in front of the nipple, the newborn can be stimulated to open their mouth by tickling the lower lip with the tip of the nipple. The parent pulls the newborn to the nipple with the newborn's mouth covering all or as much of the areola as possible, as well as the nipple.
- Demonstrate the four basic breastfeeding positions: football hold (under the arm), cradle (most common) or modified cradle (across the lap), and side-lying. (25.1)
- Teach parents to observe the infant for cues of fullness rather than being concerned about the time the feeding takes.

- To prevent nipple trauma, show the parent how to insert a finger in the side of the newborn's mouth to break the suction from the nipple prior to removing the newborn from the breast.
- Promote rooming-in efforts.
- Offer referral to breastfeeding support groups.
- Contact a lactation consultant to offer additional recommendations and support, especially to parents who have concerns about adequate breast milk or parents who have been unsuccessful with breastfeeding in the past.

#### CLIENT EDUCATION

- Uterine cramps are normal during breastfeeding, resulting from oxytocin, and promote uterine involution.
- When the newborn is latched on correctly, the nose, cheeks, and chin will be touching the breast.
- Hunger cues include hand to mouth or hand to hand movements, sucking motions, and rooting reflex. Newborns will nurse on demand after a pattern is established.
- Breastfeed at least 15 to 20 min per breast to ensure that the newborn receives adequate fat and protein, which is richest in the breast milk as it empties the breast. Newborns need to be breastfed at least 8 to 12 times in a 24 hr. period.
- Observe for indications that the newborn has completed the feeding (slowing of newborn suckling, softened breast, sleeping). Offer both breasts to ensure that each breast receives equal stimulation and emptying.
- Burp the newborn when alternating breasts. The newborn should be burped either over the shoulder or in an upright position with the chin supported. Gently pat the newborn on the back to elicit a burp.
- Begin the newborn's next feeding with the breast you stopped feeding with in the previous feeding.
- The newborn is receiving adequate feeding if they are gaining weight, voiding 6 to 8 diapers per day, and are content between feedings.
- Loose, pale, and/or yellow stools are normal during breastfeeding.
- Avoid nipple confusion in the newborn by not offering supplemental formula, pacifier, or soothers until breastfeeding has been established (typically 3 to 4 weeks). Supplementation can be provided using a supplemental device or syringe feeding, if needed. If supplementation is necessary, expressed breast milk is best.
- Always place the newborn on the back after feedings.
- Herbal products (fenugreek, blessed thistle) and prescription medications (metoclopramide) have been reported to increase breast milk production. There is insufficient data to confirm or deny their effect on lactation. Check with a provider before taking over-the-counter or prescription medications. 
- Breast milk can be expressed using hand expression or a pump so the newborn can be fed using bottle or supplemental device.
  - Breast pumps can be manual, electric, or battery-operated and pumped directly into a bottle or freezer bag.
  - One or both breasts can be pumped, and suction is adjustable for comfort.

- Breast milk must be stored according to guidelines for proper containers, labeling, refrigerating, and freezing.
  - Breast milk can be stored at room temperature under very clean conditions for up to 8 hr. It can be refrigerated in sterile bottles for use within 8 days, or can be frozen in sterile containers in the freezer compartment of a refrigerator for up to 6 months. Breast milk can be stored in a deep freezer for 12 months.
  - Thawing the milk in the refrigerator for 24 hr is the best way to preserve the immunoglobulins present in it. It also can be thawed by holding the container under running lukewarm water or placing it in a container of lukewarm water. The bottle should be rotated often, but not shaken when thawing in this manner.
  - Thawing by microwave is contraindicated because it destroys some of the immune factors and lysozymes contained in the milk. Microwave thawing also leads to the development of hot spots in the milk because of uneven heating, which can burn the newborn.
  - Do not refreeze thawed milk.
  - Unused portions of breast milk must be discarded after thawing or warming.

## BOTTLE FEEDING

---

### *Human/donor milk*

---

If a parent is not able to produce breast milk, the recommended alternative is pasteurized donor milk from a milk bank. (Obtain informed consent.) However, it is often not readily accessible, and a commercial infant formula is used.

- Donor milk might be prescribed for infants who have some disorders.
- Caution the client against purchasing donor milk from individuals due to the risk of contamination.

### *Formula*

---

Formula feeding can be an adequate source of nutrition. The newborn should be fed every 3 to 4 hr. Parents should awaken the newborn to feed at least every 3 hr during the day and at least every 4 hr during the night until the newborn is feeding well and gaining weight adequately. Then, a feed-on-demand schedule can be followed.

#### NURSING ACTIONS

- Teach the parents how to prepare formula (mix according to instructions), bottles, and nipples. Review the importance of hand hygiene prior to formula preparation.
- Teach the parents about the different forms of formula (ready-to-feed, concentrated, and powder) and how to prepare each correctly.

#### CLIENT EDUCATION

- Bottles and accessories can be put in the dishwasher, boiled, or washed by hand in hot soapy water using a good bottle and nipple brush.
- Wash the lid of a can of formula with hot soapy water, and shake before opening it.

- Use tap water to mix concentrated or powder formula. If the water source is questionable, tap water should be boiled first.
- Prepared formula can be refrigerated for up to 48 hr.
- Check the flow of formula from the bottle to ensure it is not coming out too slow or too fast.
- Do not use formula past the expiration date on the container.
- Cradle the newborn in the arms in a semi-upright position. The newborn should not be placed in the supine position during bottle feeding because of the danger of aspiration. Newborns who bottle feed do best when held close and at a 45° angle.
- Place the nipple on top of the newborn's tongue.
- Keep the nipple filled with formula to prevent the newborn from swallowing air.
- Always hold the bottle and never prop the bottle for feeding.
- Give the newborn opportunities to burp several times during a feeding.
- Place the newborn on the back after feedings.
- Discard any unused formula remaining in the bottle when the newborn is finished feeding due to the possibility of bacterial contamination. *Qs*
- The newborn is being adequately fed if they are gaining weight; bowel movements are yellow, soft and formed; and they are satisfied between feedings.
  - Infants usually have 6 or more wet diapers a day.
  - Infants who consume breast milk usually have three or more bowel movements a day. Infants who receive formula have less frequent bowel movements.

## RISK FACTORS FOR IMPAIRED NEWBORN NUTRITION

Risk factors for failure to thrive (newborn) can be related to the newborn or parent.

### NEWBORN FACTORS

- Inadequate breastfeeding
- Illness/infection
- Malabsorption
- Other conditions that increase energy needs

### MATERNAL FACTORS

- Inadequate or slow milk production
- Inadequate emptying of the breast
- Inappropriate timing of feeding
- Inadequate breast tissue
- Pain with feeding
- Hemorrhage
- Illness/infection

## MONITORING NEWBORN FOR ADEQUATE GROWTH

- Monitor the newborn for adequate growth and weight gain.
  - Weights are done daily in the newborn nursery. Every newborn should be seen and examined at the provider's office within 3 to 5 days after discharge from the hospital and again at 2 weeks. Growth is assessed by placing the newborn's weight on a growth chart. Adequate growth should be within the 10th to 90th percentile. Poor weight gain is below 10th percentile, and too much weight gain is above 90th percentile.
  - The newborn's length and head circumference are also routinely monitored.
- Assess the parent's ability to feed their newborn, whether by breast or bottle.
- Calculate the newborn's 24-hr I&O, if indicated, to ensure adequate nutrition.

## ASSESSMENT OF NEWBORN NUTRITION

Assessment of newborn nutrition begins during pregnancy and continues after birth by reviewing parent and newborn factors that affect feeding.

### NEWBORN

- Maturity level
- History of labor and delivery
- Birth trauma
- Congenital defects
- Physical stability
- State of alertness
- Presence of bowel sounds

### PARENT

- Previous experience with breastfeeding
- Knowledge about breastfeeding
- Cultural factors
- Feelings about breastfeeding
- Physical features of breasts
- Physical/psychological readiness
- Support of family and significant others

## INTERVENING FOR NEWBORN NUTRITION

Provide the parent with education about feeding-readiness cues exhibited by newborns and encourage the parent to begin feeding the newborn upon cues rather than waiting until the newborn is crying. Cues include the following.

- Hand-to-mouth or hand-to-hand movements
- Sucking motions
- Rooting
- Mouthing

## COMPLICATIONS FOR NEWBORN NUTRITION

There can be special considerations when a newborn has difficulty receiving adequate nutrition. Nursing interventions can often help these newborns receive adequate nutrition.

### NEWBORNS WHO ARE SLEEPY

- Unwrap the newborn.
- Change the newborn's diaper.
- Hold the newborn upright, and turn them from side to side.
- Talk to the newborn.
- Massage the newborn's back, and rub the hands and feet.
- Apply a cool cloth to the newborn's face.

### NEWBORNS WHO ARE FUSSY

- Swaddle the newborn.
- Hold the newborn close, move, and rock them gently.
- Reduce the newborn's environmental stimuli.
- Place the newborn skin-to-skin.

### Failure to thrive

Failure to thrive is slow weight gain. A newborn usually falls below the 5th percentile on the growth chart.

### NEWBORNS WHO ARE BREASTFEEDING

- Evaluate positioning and latch-on during breastfeeding. (25.1)
- Massage the breast during feeding. QEBP
- Determine feeding patterns and length of feedings.
- If the newborn is spitting up, the newborn can have an allergy to dairy products. Determine the maternal intake of dairy products. The parent might need to eliminate dairy from their diet. Instruct them to consume other food sources high in calcium or calcium supplements.

### NEWBORNS WHO ARE FORMULA FEEDING

- Evaluate how much and how often the newborn is feeding.
- If the newborn is spitting up or vomiting, they can have an allergy or intolerance to cow's milk-based formula and can require a soy-based formula.

### Active Learning Scenario

A nurse is teaching about the use of a breast pump and storing breast milk with a group of new parents. What information should the nurse include in the teaching? Use the ATI Active Learning Template: Basic Concept to complete this item.

#### RELATED CONTENT

- List the types of breast pumps.
- Describe use of the pump.

#### NURSING INTERVENTIONS

- Describe storage and freezing of milk.
- Describe procedures for thawing milk.

### Application Exercises

1. A nurse is giving instructions to a parent about how to breastfeed their newborn. Which of the following actions by the parent indicates understanding of the teaching?
  - The parent places a few drops of water on their nipple before feeding.
  - The parent gently removes their nipple from the infant's mouth to break the suction.
  - When they are ready to breastfeed, the parent gently strokes the newborn's neck with a finger.
  - When latched on, the infant's nose, cheek, and chin are touching the breast.
2. A nurse is teaching a group of new parents about proper techniques for bottle feeding. Which of the following instructions should the nurse provide?
  - Burp the newborn at the end of the feeding.
  - Hold the newborn close in a supine position.
  - Keep the nipple full of formula throughout the feeding.
  - Refrigerate any unused formula.
3. A nurse is caring for a newborn. Which of the following actions by the newborn indicates readiness to feed?
  - Spits up clear mucus
  - Attempts to place their hand in their mouth
  - Turns the head toward sounds
  - Lies quietly with their eyes open
4. A nurse is reviewing formula preparation with parents who plan to bottle-feed their newborn. Which of the following information should the nurse include in the teaching? (Select all that apply.)
  - Use a disinfectant wipe to clean the lid of the formula can.
  - Store prepared formula in the refrigerator for up to 72 hr.
  - Place used bottles in the dishwasher.
  - Check the nipple for appropriate flow of formula.
  - Use tap water to dilute concentrated formula.
5. A nurse is reviewing breastfeeding positions with the parent of a newborn. Which of the following positions should the nurse discuss?
  - Over-the-shoulder
  - Supine
  - Chin-supported
  - Cradle

## Application Exercises Key

1. A. The infant is enticed to suck when the parent spreads colostrum on the nipple.
- B. The parent should insert a finger in the side of the newborn's mouth to break the suction before removing their nipple.
- C. The parent should stroke the newborn's lips with the nipple to promote sucking.
- D. **CORRECT:** Effective latching-on includes the infant's nose, cheek and chin touching the parent's breast.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

2. A. The newborn should be burped after each  $\frac{1}{2}$  oz of formula.
- B. The newborn should be cradled in a semi-upright position.
- C. **CORRECT:** The nipple should always be kept full of formula to prevent the newborn from sucking in air during the feeding.
- D. Any unused formula should be discarded due to the possibility of bacterial contamination.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

3. A. Spitting up, coughing, or gagging on mucus is an attempt by the newborn to clear the airway.
- B. **CORRECT:** Readiness-to-feed cues include the newborn making hand-to-mouth and hand-to-hand movements, sucking motions, rooting, and mouthing.
- C. The infant turns their head toward sounds in the environment as a sensory response indicating normal central nervous system functioning.
- D. Lying quietly with eyes open is an alerting behavior, indicating normal newborn reactivity.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

4. A. Chemicals from the disinfectant wipe can remain on the lid during opening and mix with the formula.
- B. Once formula is prepared, it can be refrigerated for up to 48 hr.
- C. **CORRECT:** Bottles can be placed in a dishwasher or washed by hand in hot soapy water using a good bottle brush.
- D. **CORRECT:** The flow of formula from the nipple should be checked to determine that it is not too fast or too slow.
- E. **CORRECT:** Tap water is used to mix concentrated or powder formula. If the water is from a questionable source, it should be boiled first.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

5. A. An over-the-shoulder position can be used when burping the newborn.
- B. The supine position is appropriate for the sleeping newborn.
- C. Holding the newborn upright with the chin supported is a position that can be used when burping the newborn.
- D. **CORRECT:** The cradle position for breastfeeding includes the parent laying the newborn across one forearm with their hand supporting the lower back and buttocks.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

## Active Learning Scenario Key

Using the ATI Active Learning Template: Basic Concept

### RELATED CONTENT

Types of breast pumps

- Manual
- Electric
- Battery-operated

Use of the pump: Pumping of one or both breasts using adjustable suction for comfort to obtain breast milk for storage in a bottle or freezer bag

### NURSING INTERVENTIONS

Storage

- Store at room temperature under very clean conditions for up to 8 hr.
- Refrigerate in sterile bottles for use within 8 days.
- Freeze in sterile containers in the freezer of a refrigerator for up to 6 months.
- Store in a deep freezer for up to 12 months.

Thawing

- Thaw milk in the refrigerator for 24 hr to preserve immunoglobulins.
- Hold container under running lukewarm water or place in a pan of lukewarm water; bottle should be rotated, but not shaken.
- Do not thaw in a microwave.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

# CHAPTER 26

UNIT 4

NEWBORN NURSING CARE

SECTION: LOW-RISK NEWBORN

CHAPTER 26

## Nursing Care and Discharge Teaching

Discharge teaching and newborn care include bathing, umbilical cord care, circumcision, car seat safety, environmental safety, newborn behaviors, feeding, elimination, and clinical findings of illness to report to the provider.

Prior to discharge, a nurse should provide anticipatory guidance to prepare new parents to care for their newborn at home. Clients and newborns are normally discharged 48 hr following a vaginal delivery or 72 hr following a cesarean birth. Serious complications can result if improper discharge instructions are given to the parents prior to taking the newborn home.

A nurse should inquire about the family's experience and knowledge regarding newborn care, anticipate the learning needs of the parents, and assess their readiness for learning to provide education about newborn care.

Parents should be made aware of general guidelines about newborn behavior and care. These guidelines include causes of crying in the newborn, quieting techniques, sleeping patterns, hunger cues, and feeding, bathing, and clothing the newborn.

Parents need to be aware of the importance of well-newborn checkups, immunization schedules, and when to call the provider for manifestations of illness.

Providing a safe protective environment at home should be stressed to new parents and should include instruction about proper car seat usage, which is a very important part of the discharge instruction process. **Qs**

## ASSESSMENT OF FAMILY READINESS FOR HOME CARE OF THE NEWBORN

- Previous newborn experience and knowledge
- Parent-newborn attachment
- Adjustment to the parental role
- Social support
- Educational needs
- Sibling rivalry issues
- Readiness of the parents to have their home and lifestyle altered to accommodate their newborn
- Parents' ability to verbalize and demonstrate newborn care following teaching

## INTERVENTIONS FOR HOME CARE OF THE NEWBORN

Through discussion, pamphlets, and demonstration, provide education to the client and family regarding newborn behavior, quieting techniques, newborn care, findings of newborn well-being and illness, and issues of newborn safety. **Qpcc**

### CRYING

#### CLIENT EDUCATION

- Newborns cry when they are hungry, overstimulated, wet, cold, hot, tired, bored, or need to be burped. In time, parents learn what the newborn's cry means.
- Do not feed the newborn every time they cry. Overfeeding can lead to stomach aches and diarrhea.
- Newborns often have a fussy time of day when they cry for no reason. In this case, it is not always possible to stop a newborn's crying, and the newborn might cry themselves to sleep.

#### Quieting techniques

- Swaddling
- Close skin contact
- Nonnutritive sucking with pacifier
- Rhythmic noises to simulate utero sounds
- Movement (car ride, vibrating chair, infant swing, rocking newborn)
- Placing the newborn on the stomach across a holder's lap while gently bouncing legs
- En face position for eye contact (when parents' and newborns' faces are about 30 cm [12 in] apart and on the same plane)
- Stimulation

### SLEEP-WAKE CYCLE

- Newborns sleep approximately 16 to 19 hr/day with periods of wakefulness gradually increasing.
- Many parents believe that adding solid food to the newborn's diet will help with sleep patterns. During the first 6 months of life, the American Academy of Pediatrics (AAP) recommends only breastfeeding. Most newborns will sleep through the night without a feeding by 4 to 5 months of age. The provider will instruct the parents when to add solid food to the newborn's diet.

## CLIENT EDUCATION

- Placing the newborn in the supine position for sleeping greatly decreases the risk of sudden infant death syndrome.
- Keep the newborn's environment quiet and dark at night.
- Place the newborn in a crib or bassinet to sleep. The newborn should never sleep in the parents' bed due to the risk of suffocation.
- Most newborns get their days and nights mixed up.
  - Basic suggestions for helping develop a predictable routine
    - Bring the newborn out into the center of the action in the afternoon, and keep them there until bedtime.
    - Bathe them right before bedtime so that they feel soothed.
    - Give them their last feeding around 2300, and then place them into a crib or bassinet.
- When awake, the newborn can be placed on the abdomen to promote muscle development for crawling. The infant should be supervised.
- For nighttime feedings and diaper changes, keep a small night-light on to avoid having to turn on bright lights. Speak softly, and handle the newborn gently so that they go back to sleep easily.

## ORAL AND NASAL SUCTIONING

Review correct technique with the parents.

## POSITIONING AND HOLDING OF THE NEWBORN (HEAD SUPPORT)

### CLIENT EDUCATION

- The newborn has minimal head control.
- The head should be supported when the newborn is lifted because the head is larger and heavier than the rest of the body.

### *Basic ways to hold a newborn*

- **Cradle hold:** Cradle the newborn's head in the bend of the elbow. This permits eye-to-eye contact and is a good position for feeding.
- **Upright position:** Hold the newborn upright, and face them toward the holder while supporting the head, upper back, and buttocks.
- **Football hold:** Support half of the newborn's body in the holder's forearm with the newborn's head and neck resting in the palm of the hand. This is a good position for breastfeeding and when shampooing the newborn's hair.

## SWADDLING

Parents should be shown how to swaddle their newborn. Swaddling the newborn snugly in a receiving blanket helps the newborn to feel more secure. Swaddling brings the newborn's extremities in closer to the trunk, which is similar to the intrauterine position. 

## BATHING

- Teach the parents proper newborn bathing techniques by a demonstration. Have the parents return the demonstration.
- After the initial bath, the newborn's face, diaper area, and skin folds are cleansed daily. Complete bathing is performed two to three times per week using a mild soap.

### CLIENT EDUCATION

- Bathing by immersion is not done until the newborn's umbilical cord has fallen off and the circumcision has healed, if applicable. Wash the area around the cord, taking care not to get the cord wet. Move from the cleanest to dirtiest part of the newborn's body, beginning with the eyes, face, and head; proceed to the chest, arms, and legs; and wash the groin area last.
- Bathing should take place at the convenience of the parents, but not immediately after feeding to prevent spitting up and vomiting.
- Organize all equipment so that the newborn is not left unattended. Never leave the newborn alone in the tub or sink.
- Make sure the hot water heater is set at 49° C (120.2° F) or less. The room should be warm, and the bath water should be 38° C (100.4° F). Test water for comfort with your elbow prior to bathing the newborn.
- Avoid drafts or chilling of the newborn. Expose only the body part being bathed, and dry the newborn thoroughly to prevent chilling and heat loss.
- Clean the newborn's eyes using a clean portion of the wash cloth. Use clear water to clean each eye, moving from the inner to the outer canthus.
- Each area of the newborn's body should be washed, rinsed, and dried, with no soap left on the skin.
- Wrap the newborn in a towel, and swaddle them in a football hold to shampoo the head. Rinse shampoo from the newborn's head, and dry to avoid chilling.
- To cleanse an uncircumcised penis, wash with soap and water and rinse the penis. The foreskin should not be forced back or constriction can result.
- To cleanse a circumcised penis, use warm water. Do not use soap until the circumcision is healed.
- Wash the vulva by wiping from front to back to prevent contamination of the vagina or urethra from rectal bacteria.
- Applying a fragrance-free, hypoallergenic, moisturizing emollient immediately after bathing can help prevent dry skin.

## FEEDING/ELIMINATION

### • REFER TO CHAPTER 26: NEWBORN NUTRITION

- Newborns who receive breast milk should have three or more bowel movements per day; formula-fed newborns are less frequent. Newborns who receive breast milk should have six or more wet diapers per day; formula-fed infants have a similar number of voids.

## DIAPERING

- To avoid diaper rash, the newborn's diaper area should be kept clean and dry. Diapers should be changed frequently, and the perineal area cleaned with warm water or wipes and dried thoroughly to prevent skin breakdown.
- Provide instructions regarding perineal cleansing of the vulva, or for the circumcised or uncircumcised penis.

## CORD CARE

- Before discharge, the cord clamp is removed.
- Prevent cord infection by keeping the cord dry, and keep the top of the diaper folded underneath it.

### CLIENT EDUCATION

- Sponge baths are given until the cord falls off, which occurs around 10 to 14 days after birth. Tub bathing and submersion can follow.
- Cord infection (a complication of improper cord care) can result if the cord is not kept clean and dry.
  - Monitor for manifestations of a cord that is moist and red, has a foul odor, or has purulent drainage.
  - Notify the provider immediately if findings of cord infection are present.

## CLOTHING

Instruct the parents about care for and choice of newborn clothing.

### CLIENT EDUCATION

- Choose flame-retardant fabrics.
- Wash clothes separately with mild detergent and hot water.
- Dress newborns lightly for indoors and on hot days. Too many layers of clothing or blankets can make the newborn too hot.
- On cold days, cover the newborn's head when outdoors.
- A general rule is to dress the newborn as the parents would dress themselves.

## HOME SAFETY

Provide community resources to clients who might need ongoing assessment and instruction on newborn care (adolescent parents).

### CLIENT EDUCATION

- Never leave the newborn unattended with pets or other small children.
- Keep small objects (coins) out of the reach of newborns due to choking hazard.
- Never leave the newborn alone on a bed, couch, or table. Newborns move enough to reach the edge and fall off.
- Never place the newborn on the stomach to sleep during the first few months of life. The back-lying position is the position of choice. The newborn can be placed on the abdomen when awake and supervised.

- Never provide a newborn with a soft surface to sleep on (pillows or water bed). The newborn's mattress should be firm. Never put pillows, toys, bumper pads, or loose blankets in a crib. Crib linens should be tight-fitting.
- Do not tie anything around the newborn's neck.
- Monitor the safety of the newborn's crib. The space between the mattress and sides of the crib should be less than 2 fingerbreadths. The slats on the crib should be no more than 5.7 cm (2.25 in) apart.
- The newborn's crib or playpen should be away from window blinds and drapery cords. Newborns can become strangled in them.
- The bassinet or crib should be placed on an inner wall, not next to a window, to prevent cold stress by radiation.
- Smoke detectors should be on every floor of a home and should be checked monthly to ensure that they are working. Batteries should be changed twice a year.
- Eliminate potential fire hazards. Keep a crib and playpen away from heaters, radiators, and heat vents. Linens could catch fire if they come into contact with heat sources.
- Control the temperature and humidity of the newborn's environment by providing adequate ventilation.
- Avoid exposing the newborn to cigarette smoke in a home or elsewhere. Secondhand exposure increases the newborn's risk of developing respiratory illnesses.
- All visitors should wash their hands before touching the newborn. Any individual who has an infection should be kept away from the newborn.
- Carefully handle the newborn. Do not toss the newborn up in the air or swing them by their extremities. Do not shake the newborn.

## CAR SEAT SAFETY

### CLIENT EDUCATION

- Use an approved rear-facing car seat in the back seat, preferably in the middle (away from air bags and side impact), to transport the newborn.
- Keep infants in rear-facing car seats until age 2 or until the child reaches the maximum height and weight for the seat. *Qs*

## NEWBORN WELLNESS CHECKUPS

- Every newborn should be seen and examined at the provider's office within 72 hr (2 to 3 days) after discharge. The AAP recommends wellness checks at 2 to 5 days, 1 month, 2 months, 4 months, 6 months, 9 months, 12 months, 15 months, 18 months, 2 years, 2.5 years, 3 years, 4 years, and every year thereafter.
- Review the schedule for immunizations with the parents. Stress the importance of receiving these immunizations on a schedule for the newborn to be protected against diphtheria, tetanus, pertussis, hepatitis B, *Haemophilus influenzae*, polio, measles, mumps, rubella, influenza, rotavirus, pneumococcal, and varicella.

## MANIFESTATIONS OF ILLNESS TO REPORT

Instruct parents regarding the manifestations of illness and to report them immediately.

- Temperature greater than 38° C (100.4° F) or less than 36.5° C (97.9° F)
- Poor feeding or little interest in food
- Forceful vomiting or frequent vomiting
- Decreased urination
- Diarrhea or decreased bowel movements
- Labored breathing with flared nostrils or an absence of breathing for greater than 15 seconds
- Jaundice
- Cyanosis
- Lethargy
- Inconsolable crying
- Difficulty waking
- Bleeding or purulent drainage around umbilical cord or circumcision
- Drainage developing in eyes

## CARDIOPULMONARY RESUSCITATION

Encourage parents to seek CPR training.

## COMPLICATIONS RELATED TO NEWBORN HOME CARE

Complications stemming from improper understanding of discharge instructions can include the following.

- Infected cord or circumcision from improper care or tub bathing too soon
- Falls, suffocation, strangulation, burns resulting in injuries, fractures, aspiration, or death due to improper safety precautions
- Respiratory infections due to passive smoke or inhaled powders
- Improper or no use of a car seat resulting in injuries or death
- Serious infections due to lack of nonadherence with immunization schedule

### Active Learning Scenario

A nurse is leading a discussion with a group of parents on bathing a newborn. What information should the nurse include in the teaching? Use the ATI Active Learning Template: Basic Concept to complete this item.

### NURSING INTERVENTIONS

- Describe two interventions that relate to general skin care.
- Describe two interventions that relate to promoting infant safety.
- Describe two interventions that relate to the correct order of giving a bath.
- Describe two interventions that prevent complications in the newborn.

## Application Exercises

1. A nurse is reviewing care of the umbilical cord with the parent of a newborn. Which of the following instructions should the nurse include in the teaching?
  - A. Cover the cord with a small gauze square.
  - B. Trickle clean water over the cord with each diaper change.
  - C. Apply hydrogen peroxide to the cord twice a day.
  - D. Keep the diaper folded below the cord.
2. A nurse is reviewing contraindications for circumcision with a newly hired nurse. Which of the following conditions are contraindications? (Select all that apply.)
  - A. Hypospadias
  - B. Hydrocele
  - C. Family history of hemophilia
  - D. Hyperbilirubinemia
  - E. Epispadias
3. A nurse is providing discharge teaching to the parents of a newborn regarding circumcision care. Which of the following statements made by a parent indicates an understanding of the teaching?
  - A. "The circumcision will heal within a couple of days."
  - B. "I should remove the yellow mucus that will form."
  - C. "I will clean the penis with each diaper change."
  - D. "I will give him a tub bath within a couple of days."
4. A nurse is caring for a newborn immediately following a circumcision using a Gomco procedure. Which of the following actions should the nurse implement?
  - A. Apply Gelfoam powder to the site.
  - B. Place the newborn in the prone position.
  - C. Apply petroleum gauze to the site.
  - D. Avoid changing the diaper until the first voiding.
5. A nurse is reviewing car seat safety with the parents of a newborn. Which of the following instructions should the nurse include in the teaching regarding car seat position?
  - A. Front seat, rear-facing
  - B. Front seat, forward-facing
  - C. Back seat, rear-facing
  - D. Back seat, forward-facing

## Application Exercises Key

1. A. Covering the cord with a gauze square prevents the cord from drying and encourages infection.
- B. Water should not be applied to the cord.
- C. The cord should be kept clean and dry. Hydrogen peroxide is not applied to the cord site.
- D. **CORRECT:** Folding the diaper below the cord prevents urine from the diaper penetrating the cord site.

❷ NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

2. A. **CORRECT:** Hypospadias involves a defect in the location of the urethral opening and is a contraindication to circumcision.
- B. Hydrocele, a collection of fluid in the scrotal sac, is not a contraindication to circumcision.
- C. **CORRECT:** A family history of hemophilia is a contraindication for circumcision.
- D. Hyperbilirubinemia is not a contraindication for circumcision.
- E. **CORRECT:** Epispadias involves a defect in the location of the urethral opening and is a contraindication to circumcision.

❷ NCLEX® Connection: *Reduction of Risk Potential, Therapeutic Procedures*

3. A. The circumcision will heal within a couple of weeks.
- B. The yellow mucus should remain in place as part of the healing process.
- C. **CORRECT:** The penis should be cleaned with warm water with each diaper change.
- D. A tub bath should not be given until the circumcision is healed.

❷ NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

4. A. Gelfoam powder is used to control bleeding when there is a risk for hemorrhage.
- B. Newborns should not be placed in the prone position.
- C. **CORRECT:** Petroleum gauze is applied to the site for 24 hr to prevent the skin edges from sticking to the diaper.
- D. Diapers are changed more frequently to inspect the site.

❷ NCLEX® Connection: *Reduction of Risk Potential, Therapeutic Procedures*

5. A. This is not an appropriate position for the car seat.
- B. This is not an appropriate position for the car seat.
- C. **CORRECT:** The newborn should be restrained in a car seat in a rear-facing position in the back seat until 2 years of age.
- D. This is not an appropriate position for the car seat.

❷ NCLEX® Connection: *Safety and Infection Control, Accident/Error/Injury Prevention*

## Active Learning Scenario Key

*Using the ATI Active Learning Template: Basic Concept*

### NURSING INTERVENTIONS

#### Skin Care

- The eyes are cleaned using a clean portion of the wash cloth.
- The newborn should be washed, rinsed, and dried with no soap left on the skin.

#### Infant Safety

- Do not leave the newborn unattended during the bath.
- Hot water heater should be set at 49° C (120.2° F) or less.
- The room should be warm, and the bath water should be at 36.6° to 37.2° C (98° to 99° F).
- Bath water should be tested on the inner wrist prior to use.

#### Order of Giving the Bath

- Move from the cleanest to the dirtiest areas of the newborn's body, which includes starting with the eyes, face, and head; proceeding to the chest, arms, and legs; and washing the groin area last.
- The eyes are cleaned by moving from the inner to the outer canthus.

#### Preventing Complications

- Bathing by immersion is not done until the umbilical cord falls off and the circumcision is healed.
- Do not bathe the newborn immediately after feeding to prevent spitting up and vomiting.
- After cleansing the uncircumcised newborn male, the foreskin should not be forced back.
- In female newborns, wash the vulva by wiping from front to back.

❷ NCLEX® Connection: *Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care*

## CHAPTER 27

UNIT 4 NEWBORN NURSING CARE  
SECTION: COMPLICATIONS OF THE NEWBORN

# CHAPTER 27

## *Assessment and Management of Newborn Complications*

Assessment and management of newborn complications includes assessment, risk factors, and collaborative care. It is essential for a nurse to immediately identify complications and implement appropriate interventions.

Ongoing emotional support to a client and their significant other is also imperative to the plan of care.

Complications include neonatal substance withdrawal, hypoglycemia, respiratory distress syndrome (RDS)/asphyxia/meconium aspiration, preterm newborn, small for gestational age (SGA) newborn, large for gestational age (LGA)/macrosomic newborn, postmature newborn, newborn infection/sepsis (sepsis neonatorum), birth trauma or injury, hyperbilirubinemia, and congenital anomalies.

### *Neonatal substance withdrawal*

Maternal substance use during pregnancy consists of any use of alcohol or drugs. Intrauterine drug exposure can cause anomalies, neurobehavioral changes, and evidence of withdrawal in the neonate. These changes depend on the specific drug or combination of drugs used, dosage, route of administration, metabolism and excretion by the parent and fetus, timing of drug exposure, and length of drug exposure.

- Substance withdrawal in the newborn occurs when the parent uses drugs that have addictive properties during pregnancy. This includes illegal drugs, alcohol, tobacco, and prescription medications.
- Fetal alcohol syndrome (FAS) results from the chronic or periodic intake of alcohol during pregnancy. Alcohol is considered teratogenic, so the daily intake of alcohol increases the risk of FAS. Newborns who have FAS are at risk for specific congenital physical defects and long-term complications.

### LONG-TERM COMPLICATIONS

- Feeding problems
- Central nervous system dysfunction (cognitive impairment, cerebral palsy)
- Attention deficit disorder
- Language abnormalities
- Microcephaly
- Delayed growth and development
- Poor maternal-newborn bonding

### ASSESSMENT

#### RISK FACTORS

- Maternal use of substances prior to knowing they are pregnant
- Maternal substance use during pregnancy

#### EXPECTED FINDINGS

Monitor the neonate for abstinence syndrome (withdrawal) and increased wakefulness using the neonatal abstinence scoring system that assesses for and scores the following.

- **CNS:** High-pitched, shrill cry; incessant crying; irritability; tremors; hyperactivity with an increased Moro reflex; increased deep-tendon reflexes; increased muscle tone; disturbed sleep pattern; hypertonicity; convulsions
- **Metabolic, vasomotor, and respiratory findings:** Nasal congestion with flaring, frequent yawning, skin mottling, retractions, apnea, tachypnea greater than 60/min, sweating, temperature greater than 37.2° C (99° F)
- **Gastrointestinal:** Poor feeding; regurgitation (projectile vomiting); diarrhea; excessive, uncoordinated, constant sucking

**OPIATE WITHDRAWAL:** Manifestations of neonatal abstinence syndrome

#### HEROIN WITHDRAWAL

- Low birth weight
- Small for gestational age (SGA)
- Manifestations of neonatal abstinence syndrome
- Increased risk of sudden infant death syndrome (SIDS)

#### METHADONE WITHDRAWAL

##### **Manifestations of neonatal abstinence syndrome:**

Increased incidence of seizures, sleep pattern disturbances, stillbirth, SIDS, higher birth weights (compared to with heroin exposure)

#### MARIJUANA WITHDRAWAL

- Preterm birth, intrauterine growth restriction
- Long-term effects, such as deficits in attention, cognition, memory, and motor skills

**AMPHETAMINE WITHDRAWAL:** Preterm or SGA, drowsiness, jitteriness, sleep pattern disturbances, respiratory distress, frequent infections, poor weight gain, emotional disturbances, delayed growth and development

**ALCOHOL WITHDRAWAL:** Jitteriness, irritability, increased tone and reflex responses, seizures

#### FETAL ALCOHOL SYNDROME

- Facial anomalies: small eyes, flat midface, smooth philtrum, thin upper lip, eyes with a wide-spaced appearance, epicanthal folds, strabismus, ptosis, poor suck, small teeth, cleft lip or palate
- Many vital organ anomalies, such as heart defects, including atrial and ventricular septal defects, tetralogy of Fallot, patent ductus arteriosus
- Developmental delays and neurologic abnormalities
- Prenatal and postnatal growth delays
- Sleep disturbances

**TOBACCO:** Prematurity, low birth weight, increased risk for SIDS, increased risk for bronchitis, pneumonia, and developmental delays

#### LABORATORY TESTS

Blood tests should be done to differentiate between neonatal drug withdrawal and central nervous system disorders.

- CBC
- Blood glucose
- Thyroid-stimulating hormone, thyroxine, triiodothyronine
- Drug screen of urine or meconium to reveal the substance used by the parent
- Hair analysis

#### DIAGNOSTIC PROCEDURES

Chest x-ray for FAS to rule out congenital heart defects

### PATIENT-CENTERED CARE

#### NURSING CARE

Nursing care for maternal substance use and neonatal effects or withdrawal include the following in addition to normal newborn care.

- Perform ongoing assessment of the newborn using the neonatal abstinence scoring system assessment, as prescribed.
- Elicit and assess the newborn's reflexes.
- Monitor the newborn's ability to feed and digest intake. Offer small frequent feedings.
- Swaddle the newborn with legs flexed.
- Offer non-nutritive sucking.
- Monitor the newborn's fluids and electrolytes with skin turgor, mucous membranes, fontanels, daily weights, and I&O.
- Reduce environmental stimuli (decrease lights, lower noise level).

#### MEDICATIONS

Based on withdrawal manifestations

##### **Morphine sulfate**

CLASSIFICATION: Opioid

##### **Phenobarbital**

CLASSIFICATION: Anticonvulsant

**INTENDED EFFECT:** Decrease CNS irritability and control seizures for newborns who have alcohol or opioid withdrawal

#### NURSING ACTIONS

- Assess IV site frequently.
- Check for any medication incompatibilities.
- Decrease environmental stimuli.
- Cluster cares to minimize stimulation.
- Swaddle the newborn to reduce self-stimulation and protect the skin from abrasions.
- Monitor and maintain fluids and electrolytes.
- Administer frequent, small feedings of high-calorie formula; can require gavage feedings.
- Elevate the newborn's head during and following feedings, and burp the newborn to reduce vomiting and aspiration. **Qs**
- Try various nipples to compensate for a poor suck reflex.
- Have suction available to reduce the risk for aspiration.
- For newborns who are withdrawing from cocaine, avoid eye contact and use vertical rocking and a pacifier.
- Prevent infection.
- Initiate a consult with child protective services.
- Consult lactation services to evaluate whether breastfeeding is desired or contraindicated to avoid passing narcotics in breast milk. Methadone is not contraindicated during breastfeeding.

#### CLIENT EDUCATION

- Utilize a drug and/or alcohol treatment center.
- Understand the importance of SIDS prevention activities due to the increased rate in newborns of parents who used methadone.

### *Hypoglycemia*

The newborn's source of glucose stops when the umbilical cord is clamped. If newborns have other physiological stress, they can experience hypoglycemia due to inadequate gluconeogenesis or increased use of glycogen stores.

- An initial drop in blood glucose after birth is a common occurrence due to the cessation of the maternal supply of glucose. Healthy term newborns can compensate for this change by utilizing their glycogen stores to mobilize free fatty acids and ketones to provide energy.
  - Healthy term newborns can tolerate a decrease in glucose levels to as low as 30 mg/dL within the first 2 hours after birth.
- Newborns who are at risk for inadequate glycogen stores to compensate for this physiological change should have their glucose levels closely monitored after birth.
  - This includes newborns who are preterm, small or large for gestational age, newborns of diabetic clients, and any who display manifestations of hypoglycemia or experienced difficulty transitioning to extra-uterine life.
- Interventions to raise blood glucose levels are usually indicated when glucose levels fall below 40 to 45 mg/dL.
- Untreated hypoglycemia can result in seizures and neurologic injury.

### ASSESSMENT

#### RISK FACTORS

- Maternal diabetes mellitus
- Preterm infant
- LGA or SGA
- Stress at birth (cold stress, asphyxia)

## EXPECTED FINDINGS

### PHYSICAL ASSESSMENT FINDINGS

- Poor feeding
- Jitteriness/tremors
- Hypothermia
- Weak cry
- Lethargy
- Flaccid muscle tone
- Seizures/coma
- Irregular respirations
- Cyanosis
- Apnea

### LABORATORY TESTS

Obtain a laboratory specimen to verify a bedside blood glucose level of less than 40 to 45 mg/dL, dependent upon facility protocol.

## PATIENT-CENTERED CARE

### NURSING CARE

- Perform blood glucose monitoring by heel stick for all newborns who are identified as being at-risk or displaying manifestations of hypoglycemia.
- Initiate early feedings, within the first hour of life, if the newborn is clinically stable.
  - Newborns who are unstable or unable to feed can require intravenous glucose infusions to maintain blood glucose levels.
- Continue to monitor blood glucose levels and feed every 2 to 3 hr for at least the first 24 hr of life, dependent on facility protocol.
- Skin-to-skin contact will promote breastfeeding and thermoregulation to stabilize blood sugar levels.

## *Respiratory distress syndrome, asphyxia, and meconium aspiration*

- RDS occurs as a result of surfactant deficiency in the lungs and is characterized by poor gas exchange and ventilatory failure.
- Surfactant is a phospholipid that assists in alveoli expansion. Surfactant keeps alveoli from collapsing and allows gas exchange to occur.
- Atelectasis (collapsing of a portion of lung) increases the work of breathing. As a result, respiratory acidosis and hypoxemia can develop.
- Birth weight alone is not an indicator of fetal lung maturity.
- Complications from RDS are related to oxygen therapy and mechanical ventilation.
  - Pneumothorax
  - Pneumomediastinum
  - Retinopathy of prematurity
  - Bronchopulmonary dysplasia
  - Infection
  - Intraventricular hemorrhage

## ASSESSMENT

### RISK FACTORS

- Preterm gestation
- Perinatal asphyxia (meconium staining, cord prolapse, nuchal cord)
- Maternal diabetes mellitus
- Premature rupture of membranes
- Maternal use of barbiturates or narcotics close to birth
- Maternal hypotension
- Cesarean birth without labor
- Hydrops fetalis (massive edema of the fetus caused by hyperbilirubinemia)
- Maternal bleeding during the third trimester
- Hypovolemia
- Genetics: white males

### EXPECTED FINDINGS

#### PHYSICAL ASSESSMENT FINDINGS

- Tachypnea (respiratory rate greater than 60/min)
- Nasal flaring
- Expiratory grunting
- Retractions
- Labored breathing with prolonged expiration
- Fine crackles on auscultation
- Cyanosis
- Unresponsiveness, flaccidity, and apnea with decreased breath sounds (manifestations of worsened RDS)

### LABORATORY TESTS

- ABGs
- Complete blood count with differential
- Culture and sensitivity of the blood, urine, and cerebrospinal fluid
- Blood glucose

### DIAGNOSTIC PROCEDURES

Chest x-ray

## PATIENT-CENTERED CARE

### NURSING CARE

- Suction the newborn's mouth, trachea, and nose as needed.
- Maintain thermoregulation.
- Provide mouth and skin care.
- Correct respiratory acidosis with ventilatory support.
- Correct metabolic acidosis by administering sodium bicarbonate.
- Maintain adequate oxygenation, prevent lactic acidosis, and avoid the toxic effects of oxygen.
- Monitor pulse oximetry.
- Provide parenteral nutrition as prescribed.
- Monitor laboratory results, I&O, and weight to evaluate hydration status.
- Decrease stimuli.

## MEDICATIONS

### *Beractant, calfactant, lucinactant*

CLASSIFICATION: Lung surfactant

INTENDED EFFECT: Restores surfactant and improves respiratory compliance for newborns who are premature and have RDS

#### NURSING ACTIONS

- Perform a respiratory assessment including ABGs, respiratory rhythm, and rate and skin color before and after administration of agent.
- Provide suction to the newborn prior to administration of the medication.
- Assess endotracheal tube placement.
- Avoid suctioning of the endotracheal tube for 1 hr after administration of the medication.

Factors that can accelerate lung maturation in the fetus while in utero include increased gestational age, intrauterine stress, exogenous steroid use, and ruptured membranes.

## *Preterm newborn*

- A preterm newborn's birth occurs after 20 weeks of gestation and before completion of 37 weeks of gestation.
- A late preterm newborn's birth occurs from 34 to 36 ½ weeks of gestation.
- Preterm newborns are at risk for a variety of complications due to immature organ systems. The degree of complications depends on gestational age. There is a decreased risk for complications the closer the newborn is to 40 weeks of gestation.
  - Goals include meeting the newborn's growth and development needs, and anticipating and managing associated complications (RDS, sepsis).
  - The main priority in treating newborns who are preterm is supporting the cardiac and respiratory systems as needed. Most newborns who are preterm are cared for in a neonatal intensive care unit (NICU). Meticulous care and observation in the NICU is necessary until the newborn can receive oral feedings, maintain body temperature, and weighs approximately 2 kg (4.4 lb).

## COMPLICATIONS

**Respiratory distress syndrome:** Decreased surfactant in the alveoli occurs, regardless of a newborn's birth weight

**Bronchopulmonary dysplasia (BPD):** Causes the lungs to become stiff and noncompliant, requiring a newborn to receive mechanical ventilation and oxygen. BPD is also commonly caused by mechanical ventilation. It is sometimes difficult to remove the newborn from ventilation and oxygen after initial placement.

**Aspiration:** A result of a newborn who is premature not having an intact gag reflex or the ability to effectively suck or swallow

**Apnea of prematurity:** A result of immature neurological and chemical mechanisms

**Intraventricular hemorrhage:** Bleeding in or around the ventricles of the brain

**Retinopathy of prematurity:** Disease caused by abnormal growth of retinal blood vessels and is a complication associated with oxygen administration to the newborn; can cause mild to severe eye and vision problems

**Patent ductus arteriosus:** Occurs when the ductus arteriosus reopens after birth due to neonatal hypoxia, or when the ductus arteriosus does not close after birth

**Necrotizing enterocolitis:** An inflammatory disease of the gastrointestinal mucosa due to ischemia. It results in necrosis and perforation of the bowel. (Short-gut syndrome can be the result secondary to removal of most or part of the small intestine due to necrosis.)

**Additional complications:** Infection, hyperbilirubinemia, anemia, hypoglycemia, and delayed growth and development

## ASSESSMENT

### RISK FACTORS

- Maternal gestational hypertension
- Multiple pregnancies that are closely spaced
- Adolescent pregnancy
- Lack of prenatal care
- Maternal substance use, smoking
- Previous history of preterm delivery
- Abnormalities of the uterus
- Cervical incompetence
- Placenta previa
- Preterm labor
- Preterm premature rupture of membranes

### EXPECTED FINDINGS

#### PHYSICAL ASSESSMENT FINDINGS

- Ballard assessment showing a physical and neurological assessment totaling less than 37 weeks of gestation
- Periodic breathing consisting of 5- to 10-second respiratory pauses, followed by 10- to 15-second compensatory rapid respirations
- Manifestations of increased respiratory effort and/or respiratory distress including nasal flaring or retractions of the chest wall during inspirations, expiratory grunting, and tachypnea
- Apnea: a pause in respirations 20 seconds or greater
- Low birth weight
- Minimal subcutaneous fat deposits
- Head that is large in comparison with the body, and small fontanels
- Wrinkled features with abundance of lanugo covering back, forearms, forehead, and sides of face, and few or no creases on soles of feet
- Skull and rib cage that feel soft
- Eyes closed if the newborn is born at 22 to 24 weeks of gestation

- Weak grasp reflex
- Inability to coordinate suck and swallow; weak or absent gag, suck, and cough reflex; weak swallow
- Hypotonic muscles, decreased level of activity, and a weak cry for more than 24 hr
- Lethargy, tachycardia, and poor weight gain

## LABORATORY TESTS

- CBC showing decreased Hgb and Hct as a result of slow production of RBCs
- Urinalysis and specific gravity
- Increased PT and aPTT time with an increased tendency to bleed
- Serum glucose
- Calcium
- Bilirubin
- ABGs

## DIAGNOSTIC PROCEDURES

- Chest x-ray
- Head ultrasounds
- Echocardiography
- Eye exams

## PATIENT-CENTERED CARE

### NURSING CARE

- Perform rapid initial assessment.
- Perform resuscitative measures if needed.
- Monitor the newborn's vital signs.
- Assess the newborn's ability to consume and digest nutrients. Before feeding by breast or nipple, the newborn must have an intact gag reflex and be able to suck and swallow to prevent aspiration.
- Monitor I&O and daily weight.
- Monitor the newborn for bleeding from puncture sites and the gastrointestinal tract.
- Ensure and maintain thermoregulation in a newborn who is preterm by using a radiant heat warmer.
  - Manifestations of hypothermia: Apnea, cyanosis, hypoglycemia, feeding intolerance, lethargy, irritability, bradycardia
- Administer respiratory support measures, such as surfactant and/or oxygen administration.
- Administer parenteral or enteral nutrition and fluids as prescribed (most preterm newborns who are less than 34 weeks of gestation will receive fluids either by IV and/or gavage feedings). Provide for nonnutritive sucking, such as using a pacifier while gavage feeding.
- Minimize the newborn's stimulation. Cluster nursing care. Touch the newborn very smoothly and lightly. Keep lighting dim and noise levels reduced.
- Position the newborn in neutral flexion with the extremities close to the body to conserve body heat. Prone and side-lying positions are preferred to supine with body containment using blanket rolls and swaddling, but only in the nursery under monitored supervision.

- Perform a skin assessment tool daily to minimize risk of skin breakdown.
- Encourage skin-to-skin contact (Kangaroo care) whenever possible to reduce preterm infant stress.
- Protect the newborn against infection by enforcing hand hygiene and gowning procedures.
  - Equipment should not be shared with other newborns.
  - **Evidence of infection:** Temperature instability, lethargy, irritability, cyanosis, bradycardia or tachycardia, apnea or tachypnea, feeding intolerance, glucose instability
- Observe the newborn for findings of dehydration or overhydration (resulting from IV nutrition and fluid administration).
  - **Dehydration**
    - Urine output less than 1 mL/kg/hr
    - Urine-specific gravity greater than 1.015
    - Weight loss
    - Dry mucous membranes
    - Absent skin turgor
    - Depressed fontanel
  - **Overhydration**
    - Urine output greater than 3 mL/kg/hr
    - Urine-specific gravity less than 1.001
    - Edema
    - Increased weight gain
    - Crackles in lungs
    - Intake greater than output

## CLIENT EDUCATION

Remain informed about and engaged in the care of the preterm newborn.

## *Small for gestational age newborn*

- SGA describes a newborn whose birth weight is at or below the 10th percentile and who has intrauterine growth restriction.
- Common complications of newborns who are SGA are perinatal asphyxia, meconium aspiration, hypoglycemia, polycythemia, and instability of body temperature.

## ASSESSMENT

### RISK FACTORS

- Congenital or chromosomal anomalies
- Maternal infections, disease, or malnutrition
- Gestational hypertension and/or diabetes
- Maternal smoking, drug, or alcohol use
- Multiple gestations
- Placental factors (small placenta, placenta previa, decreased placental perfusion)
- Fetal congenital infections (rubella, toxoplasmosis)

## EXPECTED FINDINGS

### PHYSICAL ASSESSMENT FINDINGS

- Weight below 10th percentile
- Normal skull, but reduced body dimensions
- Hair is sparse on scalp
- Wide skull sutures from inadequate bone growth
- Dry, loose skin
- Decreased subcutaneous fat
- Decreased muscle mass, particularly over the cheeks and buttocks
- Thin, dry, yellow, and dull umbilical cord rather than gray, glistening, and moist
- Drawn abdomen rather than well-rounded
- Respiratory distress and hypoxia
- Wide-eyed and alert, which is attributed to prolonged fetal hypoxia
- Hypotonia
- Evidence of meconium aspiration
- Hypoglycemia
- Acrocyanosis

## LABORATORY TESTS

- Blood glucose for hypoglycemia.
- CBC will show polycythemia resulting from fetal hypoxia and intrauterine stress.
- ABGs can be prescribed due to chronic hypoxia in utero due to placental insufficiency.

## DIAGNOSTIC PROCEDURES

Chest x-ray to rule out meconium aspiration syndrome

## PATIENT-CENTERED CARE

### NURSING CARE

- Support respiratory efforts, and suction the newborn as necessary to maintain an open airway. **Qs**
- Provide a neutral thermal environment for the newborn (isolette or radiant heat warmer) to prevent cold stress.
- Initiate early feedings. (A newborn who is SGA will require feedings that are more frequent.)
- Administer parenteral nutrition if necessary.
- Maintain adequate hydration.
- Conserve the newborn's energy level.
- Prevent skin breakdown.
- Protect the newborn from infection.
- Provide support to the newborn's parents and extended family

## CLIENT EDUCATION

Participate in caring for the newborn. Anticipate home care needs.

## *Large for gestational age (macrosomic) newborn*

- LGA occurs in neonates who weigh above the 90th percentile or more than 4,000 g (8.8 lb).
- Neonates who are LGA can be preterm, postmature, or full-term.
- Newborns who are macrosomic are at risk for birth injuries (shoulder dystocia, clavicle fracture or a cesarean birth, asphyxia, hypoglycemia, polycythemia and Erb-Duchenne paralysis due to birth trauma).
- Uncontrolled hyperglycemia during pregnancy (leading risk factor for LGA) can lead to congenital defects with the most common being congenital heart defects, tracheoesophageal fistula (TEF), and CNS anomalies.

## ASSESSMENT

### RISK FACTORS

- Newborns who are postmature
- Maternal diabetes mellitus during pregnancy (high glucose levels stimulate continued insulin production by the fetus)
- Genetic factors
- Maternal obesity
- Multiparity

## EXPECTED FINDINGS

### PHYSICAL ASSESSMENT FINDINGS

- Weight above 90th percentile (4,000 g)
- Large head
- Plump and full-faced ( cushingoid appearance) from increased subcutaneous fat
- Manifestations of hypoxia including tachypnea, retractions, cyanosis, nasal flaring, and grunting
- Birth trauma (fractures, shoulder dystocia, intracranial hemorrhage, CNS injury)
- Sluggishness, hypotonic muscles, and hypoactivity
- Tremors from hypocalcemia
- Hypoglycemia
- Respiratory distress from immature lungs or meconium aspiration

**Findings of increased intracranial pressure:** dilated pupils, vomiting, bulging fontanelles, high-pitched cry

## LABORATORY TESTS

- Blood glucose levels to monitor closely for hypoglycemia
- ABGs can be prescribed due to chronic hypoxia in utero secondary to placental insufficiency.
- CBC shows polycythemia (Hct greater than 65%) from in utero hypoxia.
- Hyperbilirubinemia resulting from polycythemia as excessive RBCs break down after birth.
- Hypocalcemia can result in response to a long and difficult birth.

## DIAGNOSTIC PROCEDURES

Chest x-ray to rule out meconium aspiration syndrome

## PATIENT-CENTERED CARE

### NURSING CARE

#### *Prior to delivery*

- Prepare the client for a possible vacuum-assisted or cesarean birth.
- Prepare to place the client in McRoberts position (lithotomy position with legs flexed to chest to maximize pelvic outlet).
- Prepare to apply suprapubic pressure to aid in the delivery of the anterior shoulder, which is located inferior to the maternal symphysis pubis.
- Assess the newborn for birth trauma (broken clavicle, Erb-Duchenne paralysis).

#### *For a newborn who is LGA following delivery*

- Obtain blood glucose level within the first hour of life.
- Initiate early feedings or IV therapy to maintain glucose levels within the expected reference range.
- Identify and treat any birth injuries.

### *Postmature infant*

- A newborn who is postmature is born after the completion of 42 weeks of gestation. Postmaturity of the infant can be associated with either of the following.
  - **Dysmaturity from placental degeneration and uteroplacental insufficiency** (placenta functions effectively for approximately 40 weeks) resulting in chronic fetal hypoxia and fetal distress in utero. The fetal response is polycythemia, meconium aspiration, and/or neonatal respiratory problems. Perinatal mortality is higher when a postmature placenta fails to meet increased oxygen demands of the fetus during labor.
  - **Continued growth of the fetus in utero** because the placenta continues to function effectively and the newborn becomes LGA at birth. This leads to a difficult delivery, cephalopelvic disproportion, as well as high insulin reserves and insufficient glucose reserves at birth. The neonatal response can be birth trauma, perinatal asphyxia, a clavicle fracture, seizures, hypoglycemia, and/or temperature instability (cold stress).
- A newborn who is postmature can be either SGA or LGA depending on how well the placenta functions during the last weeks of pregnancy.
- Newborns who are postmature have an increased risk for aspirating the meconium passed by the fetus in utero.
- Persistent pulmonary hypertension (persistent fetal circulation) is a complication that can result from meconium aspiration. There is an interference in the transition from fetal to neonatal circulation, and the ductus arteriosus (connecting the main pulmonary artery and the aorta) and foramen ovale (shunt between the right and left atria) remain open, and fetal pathways of blood flow continue.

## ASSESSMENT

### RISK FACTORS

In most cases, the cause of a pregnancy that extends beyond 40 weeks of gestation is unknown, but there is a higher incidence in first pregnancies and in clients who have had a previous postmature pregnancy.

### EXPECTED FINDINGS

#### PHYSICAL ASSESSMENT FINDINGS

- Wasted appearance, thin with loose skin, having lost some of the subcutaneous fat
- Peeling, cracked, and dry skin; leathery from decreased protection of vernix and amniotic fluid
- Long, thin body
- Meconium staining of fingernails and umbilical cord
- Hair and nails can be long
- Alertness similar to a 2-week-old newborn
- Difficulty establishing respirations secondary to meconium aspiration
- Hypoglycemia due to insufficient stores of glycogen
- Clinical findings of cold stress
- Neurological manifestations that become apparent with the development of fine motor skills
- Macrosomia

### LABORATORY TESTS

- Blood glucose levels to monitor for hypoglycemia
- ABGs secondary to chronic hypoxia in utero due to placental insufficiency
- CBC to show polycythemia from decreased oxygenation in utero
- Hct elevated from polycythemia and dehydration

### DIAGNOSTIC PROCEDURES

- Cesarean birth
- Chest x-ray to rule out meconium aspiration syndrome

## PATIENT-CENTERED CARE

### NURSING CARE

- Monitor vital signs.
- Administer and monitor IV fluids.
- Moisturize the skin with a petrolatum-based ointment
- Use mechanical ventilation if necessary.
- Administer oxygen as prescribed.
- Prepare and/or assist with exchange transfusion if hematocrit is high.
- Provide thermoregulation in an isolette to avoid cold stress.
- Provide early feedings to avoid hypoglycemia.
- Identify and treat any birth injuries.

## Tracheoesophageal fistula

TEF is a gastrointestinal anomaly that can occur independently or together with an EA. TEF alone can include a variety of abnormal connections between the esophagus and trachea. TEF and EA combined include a blind esophagus pouch and/or abnormal connection between the esophagus and trachea. The presence of a TEF places the infant at risk for aspiration and respiratory complications.

### **HEALTH PROMOTION AND DISEASE PREVENTION**

TEF can be detected and diagnosed during a prenatal ultrasound.

### **ASSESSMENT**

#### **RISK FACTORS**

- History of polyhydramnios
- Cardiac anomaly
- Cleft lip/palate
- Neural tube defects

#### **EXPECTED FINDINGS**

- Depends on specific defect present
- Excessive oral secretions
- Drooling
- Feeding intolerance (gagging, coughing during feeding, spitting up, gastric distention)
- Respiratory distress and cyanosis

#### **DIAGNOSTIC PROCEDURES**

Prenatal ultrasound

### **PATIENT-CENTERED CARE**

Maintain thermoregulation, electrolyte balance and acid-base balance

#### **NURSING CARE**

- Position supine with head of bed elevated.
- Orogastric tube to low-continuous suction.
- Monitor for signs of respiratory distress. *Qs*

**!** Do not feed any infant who has excessive oral secretions with respiratory distress until a provider is consulted.

#### **MEDICATIONS**

- Antireflux medications
- Antacids

#### **THERAPEUTIC PROCEDURES**

Surgical intervention to correct specific defect

### **COMPLICATIONS**

- Respiratory distress
- Depends upon other anomalies present

## Newborn infection, sepsis (*sepsis neonatorum*)

- Infection can be contracted by the newborn before, during, or after delivery. Newborns are more susceptible to micro-organisms due to their limited immunity and inability to localize infection. The infection can spread rapidly into the bloodstream.
- Newborn sepsis is the presence of micro-organisms or their toxins in the blood or tissues of the newborn during the first month after birth. Manifestations of sepsis are subtle and can resemble other diseases; the nurse often notices them during routine care of the newborn.
- Organisms frequently responsible for newborn infections include *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Escherichia coli*, *Haemophilus influenzae*, and *streptococcus beta-hemolytic*, Group B.
- Prevention of infection and newborn sepsis starts perinatally with maternal screening for infections, prophylactic interventions, and the use of sterile and aseptic techniques during delivery. Prophylactic antibiotic treatment of the eyes of all newborns and appropriate umbilical cord care also help to prevent newborn infection and sepsis.

### **ASSESSMENT**

#### **RISK FACTORS**

- Premature rupture of membranes
- Prolonged labor
- Toxoplasmosis, rubella, cytomegalovirus, and herpes (TORCH)
- Chorioamnionitis
- Preterm birth
- Low birth weight
- Maternal substance use
- Maternal urinary tract infection
- Meconium aspiration
- HIV transmitted from the parent to the newborn perinatally through the placenta and postnatally through the breast milk

#### **EXPECTED FINDINGS**

##### **PHYSICAL ASSESSMENT FINDINGS**

- Temperature instability
- Suspicious drainage (eyes, umbilical stump)
- Poor feeding pattern (weak suck, decreased intake)
- Vomiting and diarrhea
- Hypoglycemia, hyperglycemia
- Abdominal distention
- Apnea, retractions, grunting, nasal flaring
- Decreased oxygen saturation

- Color changes (pallor, jaundice, petechiae)
- Tachycardia or bradycardia
- Tachypnea
- Low blood pressure
- Irritability and seizure activity
- Poor muscle tone and lethargy

## LABORATORY TESTS

- CBC with differential, C-reactive protein
- Blood, urine, and cerebrospinal fluid cultures and sensitivities
- Chemical profile to show a fluid and electrolyte imbalance

## PATIENT-CENTERED CARE

### NURSING CARE

- Assess infection risks. (Review maternal health record.)
- Monitor for clinical findings of opportunistic infection.
- Monitor vital signs continuously.
- Monitor I&O and daily weight.
- Monitor fluid and electrolyte status.
- Monitor the newborn's visitors for infection.
- Obtain specimens (blood, urine, stool) to assist in identifying the causative organism.
- Initiate and maintain IV therapy as prescribed to administer electrolyte replacements, fluids, and medications
- Isolation precautions as indicated.
- Administer medications as prescribed (antibiotics, antivirals, or antifungals).
- Initiate and maintain respiratory support as needed.
- Assess IV site for evidence of infection.
- Provide newborn care to maintain temperature.
- Clean and sterilize all equipment to be used.
- Provide emotional support to the family.

### CLIENT EDUCATION

#### DISCHARGE INSTRUCTIONS

- Understand and adhere to infection control.
  - Use clean bottles and nipples for each feeding.
  - Discard any unused formula.
  - Perform proper hand hygiene.
- Promote adequate rest for newborn, and decrease physical stimulation.

## Birth trauma or injury

Birth injury occurs during childbirth resulting in physical injury to a newborn. Most injuries are minor and resolve rapidly. Other injuries can require some intervention. A few are serious enough to be fatal.

#### TYPES OF BIRTH INJURIES

- **Skull:** Linear fracture, depressed fracture
- **Scalp:** Caput succedaneum, hemorrhage
- **Intracranial:** Epidural or subdural hematoma, contusions
- **Spinal cord:** Spinal cord transaction or injury, vertebral artery injury
- **Plexus:** Brachial plexus injury, Klumpke's palsy
- **Cranial and peripheral nerve:** Radial nerve palsy, diaphragmatic paralysis

## ASSESSMENT

### RISK FACTORS

- Maternal age: younger than 16 or older than 35
- Fetal macrosomia
- Abnormal or difficult presentations
- Prolonged labor
- Precipitous labor
- Oligohydramnios
- Cephalopelvic disproportion
- Multifetal gestation
- Congenital abnormalities
- Internal FHR monitoring
- Forceps or vacuum extraction
- External version
- Cesarean birth

### EXPECTED FINDINGS

#### PHYSICAL ASSESSMENT FINDINGS

- Irritability, seizures within the first 72 hr, and decreased level of consciousness are manifestations of a subarachnoid hemorrhage.
- Facial flattening and unresponsiveness to grimace that accompanies crying or stimulation, as well as eyes remaining open, are findings to assess for facial paralysis.
- A weak or hoarse cry is characteristic of laryngeal nerve palsy from excessive traction on the neck.
- Flaccid muscle tone can signal joint dislocations and separation during birth.
- Flaccid muscle tone of the extremities suggests nerve–plexus injuries or long bone fractures.
- Limited motion of an arm, crepitus over a clavicle, and absence of the Moro reflex on the affected side are manifestations of clavicular fractures.
- A flaccid arm with the elbow extended and the hand rotated inward, absence of the Moro reflex on the affected side, sensory loss over the lateral aspect of the arm, and intact grasp reflex are manifestations of Erb–Duchenne paralysis (brachial palsy).
- Localized discoloration, ecchymosis, petechiae, and edema over the presenting part are seen with soft-tissue injuries.

## DIAGNOSTIC PROCEDURES

Birth injuries are normally diagnosed by a CT scan, x-ray of suspected area of fracture, or neurological exam to determine paralysis of nerves.

## PATIENT-CENTERED CARE

### NURSING CARE

- Review maternal history for factors that can predispose the newborn to injuries.
- Review Apgar scoring that might indicate a possibility of birth injury.
- Perform frequent head-to-toe physical assessments.
- Obtain vital signs and temperature.
- Promote parent-newborn interaction as much as possible.
- Administer treatment to the newborn based on the injury and according to the provider's prescriptions.

### CLIENT EDUCATION

#### DISCHARGE INSTRUCTIONS

- Understand the injury and management of the injury.
- Perform parent-newborn bonding.

## *Hyperbilirubinemia*

Hyperbilirubinemia is an elevation of serum bilirubin levels resulting in jaundice. Jaundice normally appears on the head (especially the sclera and mucous membranes), and then progresses down the thorax, abdomen, and extremities.

**Jaundice** can be physiologic or pathologic.

- **Physiologic jaundice** is considered benign (resulting from normal newborn physiology of increased bilirubin production due to the shortened lifespan and breakdown of fetal RBCs and liver immaturity). The newborn who has physiological jaundice exhibits an increase in unconjugated bilirubin levels 72 to 120 hr after birth, with a rapid decline to 3 mg/dL 5 to 10 days after birth.
- **Pathologic jaundice** is a result of an underlying disease. Pathologic jaundice appears before 24 hr of age or is persistent after day 14. In the term newborn, bilirubin levels increase more than 0.5 mg/dL/hr, peaks at greater than 12.9 mg/dL, or is associated with anemia and hepatosplenomegaly. Pathologic jaundice is usually caused by a blood group incompatibility or an infection, but can be the result of RBC disorders.

**Acute bilirubin encephalopathy** is when the bilirubin is deposited in the brain. This occurs once all of the binding sites for the bilirubin are used within the body, resulting in necrosis of neurons. Bilirubin levels higher than 25 mg/dL place the newborn at risk. This can result in permanent damage including dystonia and athetosis, upward gaze, hearing loss, and cognitive impairments.

**Kernicterus** is an irreversible, chronic result of bilirubin toxicity. The newborn demonstrates many of the same manifestations of bilirubin encephalopathy with hypotonia, severe cognitive impairments, and spastic quadriplegia.

## ASSESSMENT

### RISK FACTORS

- Increased RBC production or breakdown
- Rh or ABO incompatibility
- Decreased liver function
- Maternal ingestion of diazepam, salicylates, or sulfonamides close to birth
- Maternal diabetes
- Oxytocin during labor
- Neonatal hyperthyroidism
- Ecchymosis or hemangioma
- Cephalohematomas
- Prematurity

### EXPECTED FINDINGS

#### PHYSICAL ASSESSMENT FINDINGS

- Yellowish tint to skin, sclera, and mucous membranes.
- To verify jaundice, press the newborn's skin on the cheek or abdomen lightly with one finger. Then, release pressure, and observe the newborn's skin color for yellowish tint as the skin is blanched.
- Note the time of jaundice onset.
- Assess the underlying cause by reviewing the maternal prenatal, family, and newborn history.
- Hypoxia, hypothermia, hypoglycemia, and metabolic acidosis can occur as a result of hyperbilirubinemia and can increase the risk of brain damage.

### LABORATORY TESTS

- An elevated serum bilirubin level can occur (direct and indirect bilirubin). Monitor the newborn's bilirubin levels every 4 hr until the level returns to normal. **Qs**
- Assess maternal and newborn blood type to determine whether there is ABO incompatibility. This occurs if the newborn has blood type A or B, and the parent is type O.
- Review Hgb and Hct.
- A direct Coombs' test reveals the presence of antibody-coated (sensitized) Rh-positive RBCs in the newborn.
- Check electrolyte levels for dehydration from phototherapy.

## DIAGNOSTIC PROCEDURES

Transcutaneous bilirubin level is a noninvasive method to measure a newborn's bilirubin level.

## PATIENT-CENTERED CARE

### NURSING CARE

- Observe the skin and mucous membranes for jaundice.
- Monitor vital signs.
- Set up phototherapy if prescribed.
  - Maintain an eye mask over the newborn's eyes for protection of corneas and retinas.
  - Keep the newborn undressed. For a male newborn, a surgical mask should be placed (like a bikini) over the genitalia to prevent possible testicular damage from heat and light waves. Be sure to remove the metal strip from the mask to prevent burning.
  - Avoid applying lotions or ointments to the skin because they absorb heat and can cause burns.
  - Remove the newborn from phototherapy every 4 hr, and unmask the newborn's eyes, checking for inflammation or injury.
  - Reposition the newborn every 2 hr to expose all of the body surfaces to the phototherapy lights and prevent pressure sores.
  - Check the lamp energy with a photometer per facility protocol.
  - Turn off the phototherapy lights before drawing blood for testing.
- Observe the newborn for effects of phototherapy.
  - Bronze discoloration: not a serious complication
  - Maculopapular skin rash: not a serious complication
  - Development of pressure areas
  - Dehydration: poor skin turgor, dry mucous membranes, decreased urinary output
  - Elevated temperature
- Encourage the parents to hold and interact with the newborn when phototherapy lights are off.
- Monitor elimination and daily weights, watching for evidence of dehydration.
- Check the newborn's axillary temperature every 4 hr during phototherapy because temperature can become elevated.
- Feed the newborn early and frequently, every 3 to 4 hr. This will promote bilirubin excretion in the stools.
- Encourage continued breastfeeding of the newborn. Supplementation with formula can be prescribed.
- Maintain adequate fluid intake to prevent dehydration.
- Reassure the parents that most newborns experience some degree of jaundice.
- Explain hyperbilirubinemia, its causes, diagnostic tests, and treatment to parents.
- Explain that the newborn's stool contains some bile that will be loose and green.
- Administer an exchange transfusion for newborns who are at risk for kernicterus.

### THERAPEUTIC PROCEDURES

**Phototherapy:** The newborn's bilirubin should start to decrease within 4 to 6 hr after starting treatment.

## CLIENT EDUCATION

### DISCHARGE INSTRUCTIONS

- Remember and adhere to the newborn's plan of care.
- Infants who have low to moderate risk of hyperbilirubinemia should receive follow up care within two days. Infants at higher risk should be seen within 24 hr.

### Congenital anomalies

Newborns can be born with congenital anomalies involving all systems. Anomalies are often diagnosed prenatally. A nurse should provide emotional support to the parents whose newborn is facing procedures or surgeries to correct the defects.

When congenital anomalies are present at birth, they can involve any of the body systems. Major anomalies causing serious problems include the following.

- **Congenital heart disease (CHD):** Atrial septal defects, ventricular septal defects, coarctation of the aorta, tetralogy of Fallot, transposition of the great vessels, stenosis, atresia of valves
- **Neurological defects:** Neural tube defects, hydrocephalus, anencephaly, encephalocele, meningocele, myelomeningocele
- **Gastrointestinal problems:** Cleft lip/palate, diaphragmatic hernia, imperforate anus, tracheoesophageal fistula/esophageal atresia (EA), duodenal atresia, omphalocele, gastroschisis, umbilical hernia, intestinal obstruction
- **Musculoskeletal deformities:** Clubfoot, polydactyly, developmental dysplasia of the hip
- **Genitourinary deformities:** Hypospadias, epispadias, exstrophy of the bladder, ambiguous genitalia
- **Metabolic disorders:** Phenylketonuria, galactosemia, hypothyroidism
- **Chromosomal abnormalities**

Congenital anomalies are generally identified soon after birth by Apgar scoring and a brief assessment indicating the need for further investigation. Once identified, congenital anomalies are treated in a pediatric setting.

- **Cleft lip/palate:** Failure of the lip or hard or soft palate to fuse
- **Tracheoesophageal atresia:** Failure of the esophagus to connect to the stomach
- **Phenylketonuria (PKU):** Inability to metabolize the amino acid phenylalanine
- **Galactosemia:** Inability to metabolize galactose into glucose
- **Hypothyroidism:** Slow metabolism caused by maternal iodine deficiency or maternal antithyroid medications during pregnancy
- **Neurologic anomalies (spina bifida):** A neural tube defect in which the vertebral arch fails to close
- **Hydrocephalus:** Excessive spinal fluid accumulation in the ventricles of the brain
- **Patent ductus arteriosus:** A noncyanotic heart defect in which the ductus arteriosus connecting the pulmonary artery and the aorta fails to close after birth

- **Tetralogy of Fallot:** Cyanotic heart defect characterized by a ventricular septal defect, the aorta positioned over the ventricular septal defect, stenosis of the pulmonary valve, and hypertrophy of the right ventricle
- **Down syndrome:** Trisomy 21, which is the most common trisomic abnormality with 47 chromosomes in each cell

## ASSESSMENT

### RISK FACTORS

#### GENETIC AND/OR ENVIRONMENTAL FACTORS

- Maternal age greater than 40 years
- Chromosome abnormalities, such as Down syndrome
- Viral infections, such as rubella
- Excessive body heat exposure during the first trimester (neural tube defects)
- Medications and substance use during pregnancy
- Maternal obesity
- Radiation exposure
- Maternal metabolic disorders (phenylketonuria, diabetes mellitus)
- Poor maternal nutrition such as folic acid deficiency (neural tube defects)
- Newborns who are preterm
- Newborns who are SGA
- Oligohydramnios or polyhydramnios

### EXPECTED FINDINGS

Monitor the newborn for evidence of congenital anomalies.

**Cleft lip/palate:** Opening in the lip or palate

**Tracheoesophageal atresia:** Excessive mucous secretions and drooling, periodic cyanotic episodes and choking, abdominal distention after birth, immediate regurgitation after birth

**Duodenal atresia:** Abdominal distention, bilious vomiting, failure to pass meconium in the first 24 hr

**PKU:** Can result in cognitive impairment if untreated; not evident at birth, but will be identified with neonatal screening

**Galactosemia:** Can result in failure to thrive, cataracts, jaundice, cirrhosis of the liver, sepsis, and cognitive impairment if untreated; this will not be evident at birth, but will be identified with neonatal screening

**Hypothyroidism:** Can result in hypothermia, poor feeding, lethargy, jaundice, and cretinism if untreated; not evident at birth, but can be identified at 6 weeks by manifestations of bradycardia, abdominal distention, coarse dry hair, and thick dry skin, which can progress to delayed CNS development

**Neurologic anomalies (spina bifida):** Protrusion of the meninges and/or spinal cord

**Hydrocephalus:** Enlarged head and bulging fontanels; sun-setting sign is common in which the whites of the eyes are visible above the iris

**Patent ductus arteriosus:** Murmurs, abnormal heart rate or rhythm, breathlessness, and fatigue while feeding

**Tetralogy of Fallot:** Respiratory difficulties, cyanosis, tachycardia, tachypnea, and diaphoresis

**Down syndrome:** Oblique palpebral fissures or upward slant of eyes, epicanthal folds, flat facial profile with a depressed nasal bridge and a small nose, protruding tongue, small low-set ears, short broad hands with a fifth finger that has one flexion crease instead of two, a deep crease across the center of the palm (frequently referred to as a simian crease), hyperflexibility, hypotonic muscles

### NURSING ASSESSMENT

- Newborn's ability to take in adequate nourishment
- Newborn's ability to eliminate waste products
- Vital signs and axillary temperature
- Newborn-parental bonding, observing the parent's response to the diagnosis of a congenital defect, and encouraging the parents to verbalize concerns 

### DIAGNOSTIC AND THERAPEUTIC PROCEDURES

- Prenatal screening for congenital anomalies can be done by ultrasound and multiple-marker screening (triple and quad screen).
- Confirmation of a diagnosis depends on the anomaly.
- Prenatal diagnosis or confirmation of congenital anomalies is often made by amniocentesis, chorionic villi sampling, or ultrasound.
- Pulse oximetry readings for CHD.
- Routine testing of newborns for metabolic disorders (inborn errors of metabolism):
  - A Guthrie test for PKU is done to show elevations of phenylalanine in the blood and urine. It is not reliable until the newborn has ingested sufficient amounts of protein.
  - Monitor blood and urine levels of galactose (galactosemia).
  - Measure thyroxine (hypothyroidism).
  - Cytologic studies (karyotyping of chromosomes), such as a buccal smear, uses cells scraped from the mucosa from inside the newborn's mouth.

## PATIENT-CENTERED CARE

### NURSING CARE

Nursing interventions for congenital anomalies are dependent upon the type and extent of the anomaly.

- Establish and maintain adequate respiratory status.
- Establish and maintain extrauterine circulation.
- Establish and maintain adequate thermoregulation.
- Administer medications as prescribed, such as thyroid replacement for hypothyroidism.
- Educate the parents regarding preoperative and postoperative treatment procedures.
- Encourage the parents to hold, touch, and talk to the newborn.
- Ensure that parents provide consistent care to the newborn.
- Provide parents with information about parent groups or support systems.

#### *Neurologic anomalies (spina bifida)*

- Protect the membrane with a sterile covering and plastic to prevent drying.
- Observe for leakage of cerebrospinal fluid.
- Handle the newborn gently by positioning them prone to prevent trauma.
- Prevent infection by keeping the area free from contamination by urine and feces.
- Measure the circumference of the newborn's head to identify hydrocephalus.
- Assess the newborn for increased intracranial pressure.

#### *Hydrocephalus*

- Frequently reposition the newborn's head to prevent sores.
- Measure the newborn's head circumference daily.
- Assess for manifestations of increased intracranial pressure (vomiting, shrill cry).

#### *Patent ductus arteriosus*

Educate the parents about surgical treatment.

#### *Tetralogy of Fallot*

- Conserve the newborn's energy to reduce the workload on the heart.
- Administer gavage feedings, or give oral feedings with a specialized nipple.
- Elevate the newborn's head and shoulders to improve respirations and reduce the cardiac workload.
- Prevent infection.
- Place the newborn in a knee-chest position during respiratory distress.

### *Cleft lip/palate*

- Encourage expression of parental concerns, grief, and fears.
- Monitor the newborn's weight daily while hospitalized.
- Monitor for manifestations of dehydration.
- Encourage parental attachment.
- Suction nose and mouth gently with bulb syringe as needed to clear airway.
- Position infant facilitate drainage of sections.
- Educate parents on feeding requirements of infants.

## NUTRITION

Provide adequate nutrition.

**Cleft lip/palate:** Determine the most effective nipple for feeding. Can use specialized bottles, cups, or syringes to feed the infant. Infants who have cleft lip can achieve breastfeeding with changes in positioning. Feed the newborn in the upright position to decrease aspiration risk. Feed the newborn slowly, and burp them frequently so that they do not swallow air. Cleanse the mouth with water after feedings.

**Tracheoesophageal atresia:** Withhold feedings until esophageal patency is determined. Elevate the head of the newborn's crib to prevent gastric juice reflux. Supervise the first feeding to observe for this anomaly.

**Duodenal atresia:** Withhold feedings until surgical repair is done and the newborn has begun to pass stools. Administer IV fluids as prescribed. Monitor for jaundice.

**PKU:** Specialized synthetic formula in which phenylalanine is removed or reduced. The parent should restrict meat, dairy products, diet drinks (artificial sweeteners), and protein during pregnancy. Aspartame must be avoided.

**Galactosemia:** Give the newborn a soy-based formula because galactose is present in milk. Eliminate lactose and galactose in the newborn's diet. Breastfeeding is also contraindicated.

## Application Exercises

1. A nurse is caring for a client who is at 42 weeks gestation and in labor. The client asks the nurse what to expect because the baby is postmature. Which of the following statements should the nurse make?

  - A. "Your baby will have excess body fat."
  - B. "Your baby will have flat areola without breast buds."
  - C. "Your baby's heels will easily move to his ears."
  - D. "Your baby's skin will have a leathery appearance."
  
2. A nurse is caring for an infant who has a high bilirubin level and is receiving phototherapy. Which of the following is the priority finding in the newborn?

  - A. Conjunctivitis
  - B. Bronze skin discoloration
  - C. Sunken fontanel
  - D. Maculopapular skin rash
  
3. A nurse is called to the birthing room to assist with the assessment of a newborn who was born at 32 weeks of gestation. The newborn's birth weight is 1,100 g. Which of the following are expected findings in this newborn? (Select all that apply.)

  - A. Lanugo
  - B. Long nails
  - C. Weak grasp reflex
  - D. Translucent skin
  - E. Plump face
  
4. A nurse is caring for a newborn who is preterm and has respiratory distress syndrome. Which of the following should the nurse monitor to evaluate the newborn's condition following administration of synthetic surfactant?

  - A. Oxygen saturation
  - B. Body temperature
  - C. Serum bilirubin
  - D. Heart rate
  
5. A nurse is teaching a newly licensed nurse about neonatal abstinence syndrome. Which of the following statements by the newly licensed nurse indicate understanding of the teaching?

  - A. "The newborn will have decreased muscle tone."
  - B. "The newborn will have a continuous high-pitched cry."
  - C. "The newborn will sleep for 2 to 3 hours after a feeding."
  - D. "The newborn will have mild tremors when disturbed."

## Active Learning Scenario

A nurse educator is reviewing hyperbilirubinemia with a newly hired nurse. What should the nurse educator include in this review? Use the ATI Active Learning Template: System Disorder to complete this item.

**ALTERATION IN HEALTH (DIAGNOSIS):** Describe the difference between physiologic and pathologic jaundice, acute bilirubin encephalopathy, and kernicterus.

**DIAGNOSTIC PROCEDURES:** Describe the procedure that can be used to verify the presence of jaundice.

**NURSING CARE:** Describe care of the infant receiving phototherapy.

## Application Exercises Key

1. A. Excess body fat is seen in a newborn who is macrosomic.  
B. Flat areolas without breast buds are seen in a newborn who is preterm.  
C. Heels that are movable fully to the ears are seen in a newborn who is preterm.  
D. **CORRECT:** Leathery, cracked, and wrinkled skin is seen in a newborn who is postmature due to placental insufficiency.

NCLEX® Connection: Health Promotion and Maintenance, Ante/Intra/Postpartum and Newborn Care

2. A. Conjunctivitis is an important finding, but it is not the priority.  
B. Bronze skin discoloration is an important finding, but it is not the priority.  
C. **CORRECT:** Using the safety and risk reduction framework, sunken fontanelles is the priority finding. Infants receiving phototherapy are at risk for dehydration from loose stools due to increased bilirubin excretion.  
D. Maculopapular skin rash is an important finding, but it is not the priority.

NCLEX® Connection: Physiological Adaptation, Alterations in Body Systems

3. A. **CORRECT:** Characteristics of a preterm newborn include the presence of abundant lanugo.  
B. Long nails are a finding in a newborn who is postmature.  
C. **CORRECT:** A weak grasp reflex is characteristic of a preterm newborn.  
D. **CORRECT:** Skin that is thin, smooth, shiny, and translucent is a finding in a preterm newborn.  
E. A plump face would be observed in a newborn who is macrosomic.

NCLEX® Connection: Health Promotion and Maintenance, Health Screening

4. A. **CORRECT:** Surfactant stabilizes the alveoli and helps increase oxygen saturation.  
B. Surfactant administration has no direct effect on body temperature.  
C. Surfactant administration has no direct effect on bilirubin levels.  
D. Surfactant administration has no direct effect on heart rate.

NCLEX® Connection: Pharmacological and Parenteral Therapies, Expected Actions/Outcomes

5. A. Increased muscle tone is seen in a newborn who has neonatal abstinence syndrome.  
B. **CORRECT:** A continuous high-pitched cry is often an indication of CNS disturbances in a newborn who has neonatal abstinence syndrome.  
C. A newborn who has neonatal abstinence syndrome can have sleep pattern disturbances and would have difficulty sleeping for 2 to 3 hr after feeding.  
D. A newborn who has neonatal abstinence syndrome often has moderate to severe tremors when undisturbed. Most newborns exhibit mild tremors when disturbed.

NCLEX® Connection: Physiological Adaptation, Illness Management

## Active Learning Scenario Key

Using the ATI Active Learning Template: System Disorder

### ALTERATION IN HEALTH (DIAGNOSIS)

- Physiologic jaundice is considered benign (resulting from normal newborn physiology of increased bilirubin production due to the shortened lifespan and breakdown of fetal RBCs and liver immaturity). The newborn who has physiological jaundice exhibits an increase in unconjugated bilirubin levels 72 to 120 hr after birth, with a rapid decline to 3 mg/dL 5 to 10 days after birth.
- Pathologic jaundice is a result of an underlying disease. Pathologic jaundice appears before 24 hr of age or is persistent after day 14. In the term newborn, bilirubin levels increase more than 0.5 mg/dL/hr, peaks at greater than 12.9 mg/dL, or is associated with anemia and hepatosplenomegaly. Pathologic jaundice is usually caused by a blood group incompatibility or an infection, but can be the result of RBC disorders.
- Acute bilirubin encephalopathy is when the bilirubin is deposited in the brain. This occurs once all of the binding sites for the bilirubin are used within the body, resulting in necrosis of neurons. Bilirubin levels greater than 25 mg/dL place the newborn at risk for permanent damage, including dystonia, athetosis, upward gaze, hearing loss, and cognitive impairments.
- Kernicterus is an irreversible, chronic result of bilirubin toxicity. The newborn demonstrates many of the same manifestations of bilirubin encephalopathy with hypotonia, severe cognitive impairments, and spastic quadriplegia.

DIAGNOSTIC PROCEDURES: Press the newborn's skin on the cheek or abdomen lightly with one finger. Then release pressure, and observe for a yellowish tint to the skin as the skin is blanched.

### NURSING CARE

Maintain an eye mask over the newborn's eyes.

Keep the newborn undressed. Place a mask (like a bikini) over the genitalia of a male newborn.

Remove the newborn from phototherapy every 4 hr, and unmask the eyes.

Reposition the newborn every 2 hr to expose all body surfaces to the phototherapy lights and prevent pressure sores.

Check the lamp energy with a photometer following facility protocol.

Turn off the phototherapy lights before drawing blood for testing.

NCLEX® Connection: Physiological Adaptation, Alterations in Body Systems
