Acknowledgments

Unit I Medical–Surgical Nursing Settings

Chapter 1 Caring for Medical-Surgical Patients

- Caring for Medical-Surgical Patients
- Roles of the LPN/LVN
- Employment Opportunities
- Ethical and Legal Practice
- Quality and Safety
- Health Care Today
- Financing of Health Care
- Providing Holistic Care
- Getting Ready for the NCLEX® Examination!

Chapter 2 Critical Thinking and the Nursing Process

- Critical Thinking and Clinical Judgment
- Applying LPN/LVN Standards in Medical-Surgical Nursing
- Interdisciplinary (Collaborative) Care Plans
- Get Ready for the NCLEX® Examination!

Unit II Medical–Surgical Patient Care Problems

Chapter 3 Fluids, Electrolytes, Acid-Base Balance, and Intravenous Therapy

- Distribution and Regulation of Body Fluids
- Fluid Imbalances
- Osmolality
- Electrolytes
- Acid-Base System
- Acid-Base Imbalances
- Intravenous Fluid Therapy
- Community Care
- Get Ready for the NCLEX® Examination!

Chapter 4 Care of Preoperative and Intraoperative Surgical Patients

- Surgery
- Technological Advances in Surgery
- Autologous Blood for Transfusion
- Bloodless Surgery
- The Surgical Team
- The Surgical Suite
- Anesthesia
- Potential Intraoperative Complications

Get Ready for the NCLEX® Examination!

Chapter 5 Care of Postoperative Surgical Patients

Immediate Postoperative Care

Discharge Planning

Community Care

Get Ready for the NCLEX® Examination!

Chapter 6 Infection Prevention and Control

The Infectious Process and Disease

The Body's Defense Against Infection

Infection Prevention and Control

Health Care–Associated Infections

Sepsis and Septic Shock

Community Care

Get Ready for the NCLEX® Examination!

Chapter 7 Care of Patients With Pain

Theories of Pain

Classification of Pain

Perception of Pain

Acute versus Chronic Pain

Management of Pain

Community Care

Get Ready for the NCLEX® Examination!

Chapter 8 Care of Patients With Cancer

The Impact of Cancer

Physiology of Cancer

Classification of Tumors

Metastasis

Causative Factors

Contributing Factors

Measures to Prevent Cancer

Detection of Cancer

Common Therapies, Problems, and Nursing Care

Evaluating the Effectiveness of Medical Treatment

Common Problems Related to Cancer or Cancer Treatment

Care for a Dying Cancer Patient

Get Ready for the NCLEX® Examination!

Chapter 9 Chronic Illness and Rehabilitation

Chronic Illness

Rehabilitation

Home Care

Get Ready for the NCLEX® Examination!

Unit III Immune System

Chapter 10 The Immune and Lymphatic Systems

Anatomy and Physiology of the Immune and Lymphatic Systems

Protective Mechanisms of the Immune and Lymphatic Systems

Immune and Lymphatic System Disorders

Common Problems Related to the Immune and Lymphatic Systems

Get Ready for the NCLEX® Examination!

Chapter 11 Care of Patients With Immune and Lymphatic Disorders

Immune Function and Dysfunction

Immune Deficiency Disorders

Therapeutic Immunosuppression

Human Immunodeficiency Virus and Acquired Immunodeficiency Syndrome

Human Immunodeficiency Virus Risk in Patients Older than 50 Years

Community Education and Care

Autoimmune Disorders

Disorders of the Lymphatic System

Disorders of Inappropriate Immune Response

Get Ready for the NCLEX® Examination!

Unit IV Respiratory System

Chapter 12 The Respiratory System

Overview of Anatomy and Physiology of the Respiratory System

Causes of Respiratory Disorders

Respiratory Disorders

Common Respiratory Patient Care Problems

Get Ready for the NCLEX® Examination!

Chapter 13 Care of Patients With Disorders of the Upper Respiratory System

Disorders of the Nose and Sinuses

Obstruction and Trauma

Community Care

Get Ready for the NCLEX® Examination!

Chapter 14 Care of Patients With Disorders of the Lower Respiratory System

Respiratory Infectious Diseases

Restrictive Pulmonary Disorders
Obstructive Pulmonary Disorders
Pulmonary Vascular Disorders
Chest Injuries
Lung Disorders
Common Therapeutic Measures
Community Care
Get Ready for the NCLEX® Examination!

Unit V Hematologic System

Chapter 15 The Hematologic System

Overview of Anatomy and Physiology of the Hematologic System
Causes of Hematologic Disorders
Prevention of Hematologic Disorders
Diagnostic Tests and Procedures
Common Problems Related to Disorders of the Hematologic System
Get Ready for the NCLEX® Examination!

Chapter 16 Care of Patients With Hematologic Disorders

Disorders of the Hematologic System
Therapies Frequently Used in the Management of Hematologic Disorders
Community Care
Get Ready for the NCLEX® Examination!

Unit VI Cardiovascular System

Chapter 17 The Cardiovascular System

Overview of Anatomy and Physiology of the Cardiovascular System
Cardiovascular Disease
Common Problems of Patients With Cardiovascular Disorders
Get Ready for the NCLEX® Examination!

Chapter 18 Care of Patients With Hypertension and Peripheral Vascular Disease

Hypertension
Arteriosclerosis and Atherosclerosis
Peripheral Vascular Disease
Venous Disorders
Community Care
Get Ready for the NCLEX® Examination!

Chapter 19 Care of Patients With Cardiac Disorders

Disorders of the Heart

Inflammatory and Infectious Diseases of the Heart
Cardiac Valve Disorders
Common Therapies and Their Nursing Implications
Community Care
Get Ready for the NCLEX® Examination!

Chapter 20 Care of Patients With Coronary Artery Disease and Cardiac Surgery

Coronary Artery Disease
Surgical and Nonsurgical Treatment Options
Community Care
Get Ready for the NCLEX® Examination!

UNIT VII Neurologic System

Chapter 21 The Neurologic System*

Anatomy and Physiology of the Neurologic System
Causative Factors Involved in Neurologic Disorders
Prevention of Neurologic Disorders
Evaluation of Neurologic Status
Common Neurologic Patient Care Problems
Get Ready for the NCLEX® Examination!

Chapter 22 Care of Patients With Head and Spinal Cord Injuries

Traumatic Brain (Head) Injuries
Increased Intracranial Pressure
Injuries of the Spine and Spinal Cord
Back Pain and Ruptured Intervertebral Disk ("Slipped Disk")
Get Ready for the NCLEX® Examination!

Chapter 23 Care of Patients With Brain Disorders

Seizure Disorders and Epilepsy
Transient Ischemic Attack
Cerebrovascular Accident (Stroke, Brain Attack)
Brain Tumor
Infectious and Inflammatory Disorders of the Nervous System
Headaches
Cranial Nerve Disorders
Get Ready for the NCLEX® Examination!

Chapter 24 Care of Patients With Peripheral Nerve and Degenerative Neurologic Disorders

Parkinson Disease
Multiple Sclerosis
Alzheimer Disease

Amyotrophic Lateral Sclerosis
Guillain-Barré Syndrome
Poliomyelitis and Postpolio Syndrome
Huntington Disease
Myasthenia Gravis
Restless Leg Syndrome
Community Care
Get Ready for the NCLEX® Examination!

Unit VIII Sensory System

Chapter 25 The Sensory System: Eye and Ear

Anatomy and Physiology of the Eye
The Eye
Community Care
Anatomy and Physiology of the Ear
The Ear
Community Care
Get Ready for the NCLEX® Examination!

Chapter 26 Care of Patients With Disorders of the Eyes and Ears

Common Disorders of the Eye
Nursing Care of Patients Having Eye Surgery
Community Care
Common Disorders of the Ear
Nursing Care of Patients Having Ear Surgery
Community Care
Get Ready for the NCLEX® Examination!

Unit IX Gastrointestinal System

Chapter 27 The Gastrointestinal System

Anatomy and Physiology of the Gastrointestinal System
The Gastrointestinal System
Get Ready for the NCLEX® Examination!

Chapter 28 Care of Patients With Disorders of the Upper Gastrointestinal System

Eating Disorders
Upper Gastrointestinal Disorders
Common Therapies for Disorders of the Gastrointestinal System
Get Ready for the NCLEX® Examination!

Chapter 29 Care of Patients With Disorders of the Lower Gastrointestinal System

[Disorders of the Abdomen and Bowel](#)

[Ostomy Surgery and Care](#)

[Anorectal Disorders](#)

[Community Care](#)

[Get Ready for the NCLEX® Examination!](#)

Chapter 30 Care of Patients With Disorders of the Gallbladder, Liver, and Pancreas

[Disorders of the Gallbladder](#)

[Disorders of the Liver](#)

[Disorders of the Pancreas](#)

[Community Care](#)

[Get Ready for the NCLEX® Examination!](#)

Unit X Musculoskeletal System

Chapter 31 The Musculoskeletal System

[Anatomy and Physiology of the Musculoskeletal System](#)

[Musculoskeletal Disorders](#)

[Get Ready for the NCLEX® Examination!](#)

Chapter 32 Care of Patients With Musculoskeletal and Connective Tissue Disorders

[Connective Tissue Disorders](#)

[Inflammatory Disorders of the Musculoskeletal System](#)

[Community Care](#)

[Get Ready for the NCLEX® Examination!](#)

Unit XI Urinary System

Chapter 33 The Urinary System

[Anatomy and Physiology of the Urologic System](#)

[The Urologic System](#)

[Common Urologic Problems](#)

[Get Ready for the NCLEX® Examination!](#)

Chapter 34 Care of Patients With Disorders of the Urinary System

[Inflammatory Disorders of the Urinary Tract](#)

[Obstructions of the Urinary Tract](#)

[Urologic System Trauma](#)

[Urologic System Cancers](#)

[Renal Failure](#)

[Community Care](#)

[Get Ready for the NCLEX® Examination!](#)

Unit XII Endocrine System

Chapter 35 The Endocrine System

Anatomy and Physiology of the Endocrine System

The Endocrine System

Community Care

Get Ready for the NCLEX® Examination!

Chapter 36 Care of Patients With Pituitary, Thyroid, Parathyroid, and Adrenal Disorders

Disorders of the Pituitary Gland

Disorders of the Thyroid Gland

Disorders of the Parathyroid Glands

Disorders of the Adrenal Glands

Community Care

Get Ready for the NCLEX® Examination!

Chapter 37 Care of Patients With Diabetes and Hypoglycemia

Diabetes Mellitus and Hypoglycemia

Community Care

Get Ready for the NCLEX® Examination!

Unit XIII Reproductive System

Chapter 38 Care of Women With Reproductive Disorders

Anatomy and Physiology of the Female Reproductive System

Women's Health Care

Disorders of the Female Reproductive Tract

Cancer of the Reproductive Tract

Disorders of the Breast

Home Care

Community Care

Get Ready for the NCLEX® Examination

Chapter 39 Care of Men With Reproductive Disorders

Anatomy and Physiology of the Male Reproductive System

The Male Reproductive System

Disorders of the Male Reproductive System

Community Care

Get Ready for the NCLEX® Examination!

Chapter 40 Care of Patients With Sexually Transmitted Infections

Common Infections of the Female Reproductive Tract

Risk Factors for Transmission of Sexually Transmitted Infections

Transmission of Sexually Transmitted Infections

Community Care

Get Ready for the NCLEX® Examination!

Unit XIV Integumentary System

Chapter 41 The Integumentary System

Anatomy and Physiology of the Integumentary System

The Integumentary System

Get Ready for the NCLEX® Examination!

Chapter 42 Care of Patients With Integumentary Disorders and Burns

Inflammatory Infections

Bacterial Infections

Viral Infections

Fungal Infections

Parasitic Infections

Noninfectious Disorders of Skin

Community Care

Get Ready for the NCLEX® Examination!

Unit XV Emergency and Disaster Management

Chapter 43 Care of Patients During Disasters, Bioterrorism Attacks, and Pandemic Infections

Disaster Preparedness and Response

Preparing for Chemical, Nuclear, or Biologic Disasters

Get Ready for the NCLEX® Examination!

Chapter 44 Care of Patients With Emergencies, Trauma, and Shock

Prevention of Accidents

First Aid and Good Samaritan Laws

Psychological and Social Emergencies

Emergency Care

Metabolic Emergencies

Injuries Caused by Extreme Heat and Cold

Poisoning

Bites and Stings

Choking Emergencies

Cardiopulmonary Resuscitation

Shock

Get Ready for the NCLEX® Examination!

Unit XVI Mental Health Nursing of the Adult

Chapter 45 Care of Patients With Anxiety, Mood, and Eating Disorders

Anxiety and Anxiety Disorders

[Mood Disorders](#)
[Suicidal Patients](#)
[Eating Disorders](#)
[Community Care](#)
[Get Ready for the NCLEX® Examination!](#)

[Chapter 46 Care of Patients With Substance Abuse Disorders](#)

[Substance and Alcohol Abuse](#)
[Disorders Associated with Substance Abuse](#)
[Community Care](#)
[Get Ready for the NCLEX® Examination!](#)

[Chapter 47 Care of Patients With Cognitive Disorders](#)

[Overview of Cognitive Disorders](#)
[Community Care](#)
[Get Ready for the NCLEX® Examination!](#)

[Chapter 48 Care of Patients With Thought and Personality Disorders](#)

[Overview of Thought Disorders](#)
[Overview of Personality Disorders](#)
[Community Care](#)
[Get Ready for the NCLEX® Examination!](#)

[Appendix A Most Common Laboratory Test Values](#)

Skills with Skill Performance Checklists

- 3-1 Starting the Primary Intravenous Infusion
- 3-2 Adding a New Solution to the Intravenous Infusion
- 3-3 Administering Intravenous Piggyback Medication
- 3-4 Adding Medication to an Intravenous Solution
- 3-5 Administering Medication via Saline or PRN Lock
- 3-6 Administering Medication With a Volume-Controlled Set
- 3-7 Administering an IV Bolus Medication (IV Push)
- 3-8 Discontinuing an Intravenous Infusion or PRN Lock
- 3-9 Administering Blood Products
- 13-1 Endotracheal and Tracheostomy Suctioning
- 13-2 Providing Tracheostomy Care
- 15-1 Phlebotomy and Obtaining Blood Samples With a Vacutainer System
- 28-1 Administering a Nasogastric, Duodenal, or Percutaneous Endoscopic Gastrostomy Tube Feeding
- 37-1 Combining Insulins
- 38-1 Assisting With a Pelvic Examination and Pap Test (Smear)

Nursing Care Plans

Chapter 18

Care of the Patient With a Venous Stasis Ulcer

Chapter 29

Care of the Patient With an Ostomy

Chapter 34

Care of the Patient With Renal Lithiasis

Chapter 45

Care of the Patient With Anxiety

Care of the Patient With Depression

Care of the Patient With Anorexia Nervosa

Chapter 48

Care of the Patient With Borderline Personality Disorder

Patient Teaching

In addition to those in the textbook, the following Patient Teaching guidelines are available on Evolve.

Chapter 11

Infection Control in the Home of the Person Who Is HIV Positive

Chapter 12

Guidelines for Effective Deep Breathing and Coughing

Chapter 14

Oxygen Use in the Home

Self-Care Measures for Tuberculosis

Chapter 16

Precautions for the Patient With a Low Platelet Count (Thrombocytopenia)

Precautions for Preventing Infection for the Patient With a Low White Blood Cell Count

Chapter 21

Preparation for an EEG (Electroencephalogram)

Chapter 22

Care After Sustaining a Concussion

Chapter 23

Dysphagia

Chapter 25

Instilling Eye Drops

Chapter 28

Healing a Peptic Ulcer

Chapter 29

Preventing Intestinal Blockage Related to Ileostomy

Chapter 33

Hygiene Practices to Prevent Urinary Tract Infections

Video Clips

Chapter 10

- Palpating Lymph Nodes in the Arms
- Palpating Lymph Nodes in the Head and Neck
- Palpating the Inguinal Lymph Nodes

Chapter 12

- Following the Percussion and Auscultation Sequence

Chapter 17

- Auscultating S₁ and S₂
- Identifying Sites for Heart Auscultation

Chapter 18

- Assessing Arterial Pulses

Chapter 21

- Assessing Cranial Nerves VII and IX
- Chapter 25**
- Assessing the Pupillary Response to Light
- Assessing the Six Cardinal Fields of Gaze
- Inspecting the Auditory Canal and Tympanic Membrane

Chapter 27

- Auscultating the Abdomen

Chapter 31

- Examining the Legs and Knees 2
- Observing Gait and Posture

Chapter 38

- Following Patterns for Breast Palpation
- Inspecting the Breasts in Different Positions

Chapter 41

- Assessing a Mole

About the Text

Medical-Surgical Nursing: Concepts & Practice is written specifically for the LPN/LVN student who must be educated to work within a variety of settings, including hospitals, long-term care facilities, rehabilitation institutes, ambulatory clinics, psychiatric agencies, physicians' offices, and home care agencies. All of the most common adult medical-surgical disorders are covered, but particular attention is devoted to disorders most prevalent in our society. Special consideration is given to the elderly population, those with chronic illnesses, and others in long-term care settings.

This text builds on—but does not repeat—the concepts and skills presented in a fundamentals of nursing course. Many states are expanding LPN/LVN scope of practice, via certification, to include administration of intravenous (IV) fluids and medications, but others do not. Information on IV therapy is included within this text so that schools in states where such certification is possible will have the necessary educational materials.

With the expanding and changing role of the LPN/LVN there is an even greater need for **critical thinking** and the development of **clinical judgment**. These crucial skills are stressed throughout the clinical chapters and again in the Study Guide.  **Evidence-based practice** is designated with a special icon so students come to understand that the foundation of nursing care is in research. Although evidence-based practice research within the nursing community is still developing, medical evidence-based research—on which nurses often base patient  teaching—is abundant. **Best practices** are highlighted throughout the narrative with an icon to emphasize cutting-edge information related to interventions.

The **nursing process** and its application to nursing care is an organizing principle throughout, and patients' needs are presented as the focus of nursing care. There is an emphasis on practical **assessment—including data collection**—to determine problems, monitor for the onset of complications, and evaluate the effectiveness of care. Data collection from the geriatric patient requires greater ability to elicit pertinent information from the patient and family, and the achievement of this skill is a major focus in this text. The text emphasizes the role of LPN/LVNs in data collection to assist the RN in choosing appropriate **nursing diagnoses** or formulating problem statements for each patient. Many health care agencies are not using NANDA-I nursing diagnoses and are utilizing problem statements instead. Agencies that use a collaborative care plan do not use nursing diagnoses at all. The NCLEX-PN® Examination no longer uses NANDA-I nursing diagnoses. For these reasons, this text provides problem statements and the option of choosing NANDA-I nursing diagnoses from the NANDA-I list on the inside back cover. The nursing care plans provide both the problem statement and a NANDA-I nursing diagnosis to accommodate programs that require nursing diagnoses on student care plans.

Planning holistic care must include consideration of the patient's cultural background and its impact on perception of health, illness, and health practices. **Implementation of nursing actions** is the heart of patient care and LPN/LVN practice. Nursing actions presented are specific, comprehensive, and organized by common care problems to decrease repetition of information within a chapter. This helps the student master concepts rather than memorize facts. Further interventions are discussed with each disorder as appropriate, and **safe practice** is emphasized throughout the text. Additional focal points are using **expected outcomes** and **evaluating** nursing care to ensure that those outcomes and goals have been met.

Patient teaching for health promotion and self-care is a basic function of the LPN/LVN. Each clinical chapter points out ways in which nurses can teach the public how to prevent many of the problems discussed. Self-care guidelines for the major disorders are presented, and relevant *Healthy People 2020* objectives have been identified and are incorporated on the Evolve website.

LPN/LVN nurse practice acts do not encompass **delegation** as a function. With a few exceptions, only RNs can delegate, although in many situations LPN/LVNs can **assign** tasks. Collaboration with other health care workers and the use of basic management skills to provide coordinated, cost-effective patient care is essential. In this text we particularly speak to the LPN/LVN management role in working with nursing assistants and assigning tasks appropriately.

Pedagogical Features

Special pedagogical features throughout the text help you teach your students to understand the chapter content and apply it in practice:

- The text has been thoroughly updated with the new **NCLEX-PN® Test Plan** in mind.
- Competencies identified through the **Quality and Safety Education for Nurses (QSEN) initiative**—and the associated knowledge, skills, and attitudes (KSAs)—have been integrated into the content and were a continual focus during the writing of this text and its ancillaries.
- The Joint Commission's **National Patient Safety Goals** are highlighted to help students integrate safety measures and quality controls into their practice, and **Safety Alerts** remind students of specific safety concerns.
- The Joint Commission's **National Quality Core Measures** and the Institute for Healthcare Improvement's (IHI) **bundles** are described as additional measures for providing safe, effective, and quality care.
- The purpose of **Healthy People 2020** as a nationwide health improvement agenda is explained, and goals related to specific patient problems are available on the Evolve site for students. Other **Health Promotion** boxes throughout the text also emphasize the importance of health promotion, disease prevention, and reduction of health care costs.
- **Evidence-based practice** is designated with a special icon so that the student will see the thrust of nursing toward a foundation based in research.
- **Overview of Anatomy and Physiology** at the beginning of each system introduction chapter provides basic information for understanding the body system and its disorders. Normal physiologic changes associated with aging are presented for each body system.
- **The Nursing Process** provides a consistent framework for the disorders chapters.
- Separate **Theory** and **Clinical Practice objectives** highlight the chapter's main learning goals.
- **Concept Maps** found in disorders chapters are designed to help students visualize difficult material and to illustrate how a disorder's multiple symptoms, treatments, and side effects relate to each other.
- End-of-chapter **Review Questions for the NCLEX® Examination** include **multiple choice** and **alternate-format questions**, and an extensive set of Interactive Review questions for the NCLEX® Examination are located on the Evolve website for students.
- The easily understandable **writing style** is aimed at gaining and retaining student attention to reading assignments.
- The term “patient” is used rather than “client” because that is what is still used in hospitals. “Resident” is used for those in long-term care facilities.
- The use of “he” and “she” for patient, physician, and nurse varies from chapter to chapter to emphasize the diversity among these populations.
- An **English-as-a-Second Language (ESL) consultant** reviewed each chapter to make the text more user-friendly and understandable for the student with limited proficiency in English. A section in each chapter of the *Study Guide* has been designed to assist this student to more easily master the chapter content and to enhance English skills.
- **Bolded text** throughout the narrative emphasizes key concepts and practice.

Organization of the Text

Unit I addresses medical-surgical nursing settings, nursing roles and issues, health care trends, assignment considerations, the nursing process, measures related to safe and effective care, and critical thinking. **Unit II** covers all the key medical-surgical nursing topics, including fluids and electrolytes, surgical patient care, infections, pain, cancer, palliative care, and a separate chapter on chronic illness, rehabilitation, and the interdisciplinary health care team. **Units III through XIV** cover all the body systems and their most common disorders, each unit beginning with a system overview, followed by specific disorders chapters. **Unit XV** addresses emergency and disaster management—including bioterrorism—as well as trauma and shock. **Unit XVI** is entirely devoted to mental health nursing and includes information on anxiety and mood disorders, eating disorders, cognitive disorders, thought and personality disorders, and substance abuse.

Content covering legal and ethical issues, nutrition considerations, care of the older adult, communication, cultural diversity, complementary and alternative therapies, patient teaching, home care, health promotion, and assignment and delegation have been integrated as appropriate rather than including individual chapters on these subjects. End-of-life issues and palliative care are presented at the end of [Chapter 8: Care of Patients With Cancer](#). **Chronic illness and rehabilitation care** are growing areas, and [Chapter 9](#) addresses the differences in care approaches and nursing care for these individuals as well as the interaction of the interdisciplinary health care team. **The care of patients with HIV/AIDS has been condensed and combined** into [Chapter 11: Care of Patients With Immune and Lymphatic Disorders](#), and the chapters that cover cardiac content (17 through 20) have been rearranged and augmented. [Chapters 45 through 48](#) have been updated using DSM-5 criteria. In [Chapter 45](#) an entire section has been added on PTSD, its assessment and treatment. The section on suicide assessment and prevention has been expanded.

LPN Threads

The third edition of *Medical-Surgical Nursing: Concepts & Practice* shares some features and design elements with other Elsevier LPN/LVN textbooks. The purpose of these *LPN Threads* is to make it easier for students and instructors to use the variety of books required by the relatively brief and demanding LPN/LVN curriculum. The following features are included in the *LPN Threads*.

- A **reading level evaluation** is performed on every manuscript chapter during the book's development to increase the consistency among chapters and ensure the text is easy to understand.
- The **full-color design, cover, photos, and illustrations** are visually appealing and pedagogically useful.
- **Objectives** (numbered) begin each chapter and provide a framework for content and are especially important in providing the structure for the TEACH Lesson Plans for the textbook.
- **Key Terms** with phonetic pronunciations and page number references are listed at the beginning of each chapter. Key terms appear in color in the chapter and are defined briefly, with full definitions in the **Glossary**. The goal is to help the student reader with limited proficiency in English to develop a greater command of the pronunciation of scientific and nonscientific English terminology.
- A wide variety of **special features** relate to critical thinking, clinical practice, health promotion, safety, patient teaching, complementary and alternative therapies, communication, home health care, delegation and assignment, and more. Refer to the To the Student section of this introduction on pp. xvi to xvii for descriptions.
- **Critical Thinking Questions** presented at the end of each chapter and with Nursing Care Plans give students opportunities to practice critical thinking and clinical decision-making skills with realistic patient scenarios. Answers are provided in the Student Resources section on the Evolve website.
- **Key Points** at the end of each chapter correlate to the objectives and serve as a useful chapter review.
- A full suite of **Instructor Resources** is available, including TEACH Lesson Plans and PowerPoint Slides, Test Bank, Image Collection, Open-Book Quizzes, and Answer Keys.
- In addition to consistent content, design, and support resources, these textbooks benefit from the advice and input of the **Elsevier LPN/LVN Advisory Board** (see p. xii)
- Teaching and Learning Package

For the Instructor

The comprehensive and free Evolve Instructor Resources with TEACH Instructor Resource include the following:

- **Test Bank** with approximately 1400 multiple-choice and alternate-format questions with correct answer, rationale, textbook page reference, topic, step of the nursing process, objective, cognitive level, and NCLEX® category of client needs
- **TEACH Instructor Resource** with Lesson Plans and PowerPoint Slides with Audience Response System Questions that correlate each text and ancillary component
- **Image Collection** that contains all the illustrations and photographs in the textbook
- **Open-Book Quizzes** for each chapter that you can administer during class for pre- or post-lecture evaluation or as take-home assignments
- **Answer Keys** for Open-Book Quizzes and the *Study Guide*
- **Suggestions for Working with English as a Second Language (ESL) Students**

For the Student

The Evolve Student Resources include the following assets:

- **Animations** depicting anatomy, physiology, and pathophysiology
- **Answers and Rationales** for in-text Review Questions for the NCLEX® Examination
- **Answer Guidelines** for Critical Thinking Questions and Think Critically boxes
- **Audio Clips** of heart and lung sounds
- **Audio Glossary** with pronunciations in English and Spanish
- **Bibliography and Suggested Readings**
- **Additional Content** including Skills, Skill Performance Checklists, Patient Teaching guidelines, Nursing Care Plans, and more
- **Calculators** for determining body mass index (BMI), body surface area, fluid deficit, Glasgow coma score, IV dosages, and conversion of units
- **Clinical References**, including forms, checklists, tools, and relevant *Healthy People 2020* goals for specific patient problems
- **Fluids and Electrolytes Tutorial**
- **Helpful Phrases for Communicating in Spanish**
- **Interactive Review Questions for the NCLEX® Examination**
- **Supplemental Image Collection**
- **Video clips** of patient assessment

The *Study Guide* (sold separately) is a valuable supplement to help students understand and apply the textbook content. There is an emphasis on **priority setting and decision making** throughout the chapters. Varied question and activity types provide students with learning tools for reinforcement and exploration of text material. Terminology, Short Answer, multiple choice and alternate-format Review Questions for the NCLEX® Examination, Critical Thinking Activities, and a special section called *Steps Toward Better Communication*—written by an ESL specialist—appear in most chapters. Other activity types include Completion, Identification, Review of Structure and Function, Priority Setting, and Application of Nursing Process. The Study Guide review questions, and an Answer Key is provided for instructors on the Evolve website.

To the Student

Reading and Review Tools

- **Objectives** introduce the chapter topics.
- **Key Terms** are listed with page number references, and difficult medical, nursing, or scientific terms are accompanied by simple phonetic pronunciations. Key terms are considered essential to understanding chapter content and are defined within the chapter. Key terms are in color the first time they appear in the narrative and are briefly defined in the text, with complete definitions in the [Glossary](#).
- Each chapter ends with a *Get Ready for the NCLEX® Examination!* section that includes (1) **Key Points** that reiterate the chapter objectives and serve as a useful review of concepts; (2) a list of **Additional Resources** including the Study Guide, Evolve Resources, and Online Resources; (3) an extensive set of **Review Questions for the NCLEX® Examination** with answers located in Appendix D and Answers and Rationales on Evolve; and (4) **Critical Thinking Questions** with Answer Guidelines located on Evolve.
- **Reader References** in the back of the text cite evidence-based information and provide resources for enhancing knowledge. An expanded **Bibliography** and **Suggested Readings** are available on Evolve.

Chapter Features

Assignment Considerations address situations in which the RN delegates tasks to the LPN/LVN or when the LPN/LVN assigns tasks to nurse assistants as allowed by each state's nurse practice act.

Think Critically boxes encourage students to synthesize information and apply concepts beyond the scope of the chapter.

Home Care Considerations focus on post-discharge adaptations of medical-surgical nursing care to the home environment.

Elder Care Points address the unique medical-surgical care issues that affect older adults and provide suggestions for assessment (data collection) and particular interventions for the long-term and home care patient.

Focused Assessment boxes are located in each body system overview chapter and include history taking and psychosocial assessment, physical assessment, and guidance on how to collect data/information for specific disorders.

Clinical Cues provide guidance and advice related to the application of nursing care.

Nursing Care Plans, developed around specific case studies, include nursing diagnoses with an emphasis on patient goals and outcomes and questions to promote **critical thinking**. Additional nursing care plans are available on the Evolve site.

Safety Alerts emphasize the importance of maintaining safety in patient care to protect patients, family, health care providers, and the public from accidents, spread of disease, and medication-related issues.

Health Promotion boxes emphasize healthy lifestyle choices, preventive behaviors, and screening tests.

Medication tables provide quick access to information about medications commonly used in medical-surgical nursing care.

Cultural Considerations explore select specific cultural preferences and how to address the needs of a culturally diverse patient and family.

Nutrition Considerations related to nursing care for specific disorders address the need for holistic care.

Patient Teaching boxes include step-by-step instructions and self-care guidelines.

Communication boxes provide guidance in therapeutic communication skills in realistic patient care situations.

Legal and Ethical Considerations present pertinent information about the legal issues and ethical dilemmas that may face the practicing nurse.

Complementary and Alternative Therapies boxes contain information on how nontraditional treatments for medical-surgical conditions may be used to complement traditional treatment.

Bonus Content, Clinical References, and other materials available on **Evolve** are referenced with icons in the margins where related text appears.

Animations depicting anatomy, physiology, and pathophysiology available on Evolve are referenced with icons in the margins where applicable.

Video clips of patient assessment available on Evolve are referenced with icons in the margins where applicable.

Evidence-Based Practice icons highlight current references to research in nursing and medical practice.

Best Practice icons highlight current information related to interventions.

Acknowledgments

We appreciate the help of our contributor Trena Rich. Thanks also go to the reviewers whose comments helped us to refine and clarify content as needed.

Thanks to the following people for their hard work and dedication to prepare a great ancillary package with the textbook. Thanks to Mark Matusiak for revising the Open Book Quizzes and to Courtney Moore for updating the Test Bank. Thank you to Jennifer Ponto for updating the accompanying Virtual Clinical Excursions. We thank all previous ancillary writers for their contributions to earlier editions: Larry Manalo, Kim Cooper, and Kelly Gosnell.

We also thank Thomas Sadowski who did a phenomenal job with the ESL review and suggestions in previous editions of this work. He evaluated every chapter in the text and Study Guide and provided recommendations for making information more understandable for the ESL students.

Thanks to Southwestern Washington Medical Center for allowing us to photograph within their facility. Their patients, staff, and administration are so willing to help with whatever they can for the education of nursing students. Jack Sanders is a talented, creative, professional photographer whose beautiful photos are seen throughout this book. Ginger Navarro was a wonderful and efficient photo coordinator and her help was invaluable.

Thanks to Nancy O'Brien, Senior Content Strategist, and Laura Goodrich and Heather Rippetoe, Content Development Specialists, at Elsevier who have brought this project to fruition. Their dedication and friendship have kept the project on track. Mary Stueck, Senior Project Manager, makes the production process pleasurable. Her sense of humor always gets us through the tough parts and lightens the days. Mary is extremely good at her job. The updated design of the book, which follows the Threads design of other Elsevier LPN/LVN texts, was provided by Renée Duenow. Brittany Clements, Marketing Manager, has applied creative ideas to promote the book among students and instructors.

Teaching nursing has been one of the most exciting and gratifying phases of our lives. We hope this textbook and its ancillaries make your job as an instructor easier and class preparation more time-efficient. May your students find excitement and joy in learning and applying the information you impart in the clinical setting.

UNIT I

Medical–Surgical Nursing Settings

OUTLINE

Chapter 1 Caring for Medical-Surgical Patients

Chapter 2 Critical Thinking and the Nursing Process

CHAPTER 1

Roles of the LPN/LVN

Today you have an exciting, evolving role as an LPN/LVN. Roles include caregiver, educator, collaborator, **advocate**, leader, and delegator. As a caregiver, you perform treatments, give medications, and provide care to meet patients' basic needs. You gather data to assist in planning and evaluating care. You assist patients with exercise and help them to obtain sufficient rest, all while keeping their environment neat, clean, and orderly. Therapeutic communication and **active listening** (listening with concentration and focused energy) are incorporated into your care. You give objective and thorough end-of-shift reports and document objectively about the care given and the status of patients.

Clinical Cues

If a patient declines morning care (bath, brushing teeth, etc.), you can be flexible and fit it in elsewhere in your day, as time allows. Leaving care to be performed by the next shift is not acceptable practice, because it burdens the oncoming staff. Listen to the patient's reasons for not wanting care. If it appears that care really is being refused for that complete day, talk with the staff nurse or charge nurse about it. Although the patient does have the right to refuse care, many times if the benefits of care are explained, you can gain the patient's cooperation. Conferring with more experienced team members can help a new nurse determine when the routine can be altered in the patient's best interests.

As an educator you provide health teaching to patients and their significant others to maintain wellness or promote healing. An important aspect of nursing care is to show patients and families how to care for themselves or care for loved ones to prevent complications, restore health, and prevent further illness. You teach basic hygiene and nutrition to promote good health. Examples of teaching include reinforcing what the registered nurse or **provider** advises regarding scheduled diagnostic tests, upcoming surgery, how to treat a wound, or how to change a dressing, while addressing the patient's questions and concerns. Other teaching activities concern how to take prescribed medication, what side effects to report, and the self-care activities and lifestyle changes required to promote rehabilitation and independence. You contribute to the discharge plan by reinforcing discharge instructions and providing information to patients about community resources and self-help groups.

Think Critically

How could you reinforce dietary teaching for a patient newly diagnosed with diabetes?

As a collaborator, you interact with other members of the health care team to provide the patient with an integrated, comprehensive plan of care ([Figure 1-1](#)). You work closely with the RNs and nursing assistants to ensure that all aspects of the patients' basic needs are met. When you share information with the team members, the team can best use the expertise and experience of the various members. You assist in recognizing when a patient is experiencing complications and intervene to maintain patient safety. You assist with the discharge plan and deliver discharge instructions and teaching.

Quality and Safety

The Institute of Medicine (IOM) in *Health Professions Education: A Bridge to Quality* (2003) identified the following five competencies:

1. Provide patient-centered care.
2. Collaborate with the interdisciplinary health care team.
3. Implement evidence-based practice.
4. Use quality improvement in patient care.
5. Use informatics in patient care.

A study noted in the *Journal of Patient Safety* states “between 210,000 and 440,000 patients in the hospital suffer some type of preventable harm that contributes to their death” (James, 2013). The Quality and Safety Education for Nurses (QSEN) initiative added *safety* as a separate competency to the IOM set. Specific knowledge, skills, and attitudes have been identified to assist with the development of the competencies incorporated into nursing curriculum.

Patient-centered care means that the patient is a full partner in decisions about his care. Compassionate and coordinated care should be planned and delivered with respect and consideration for the patient's preferences, values, and needs. Collaboration with the interdisciplinary (ID) team requires open communication, mutual respect, and shared decision making. An important member of the ID team is the care manager, who may be a designated nurse or a social worker within the hospital. The case manager strives to work with the ID team to provide quality and cost-effective services and resources so that positive patient outcomes are achieved.

Evidence-Based Practice (EBP)

Evidence-based practice uses the best current evidence from research findings to make decisions about patient care. Evidence data are drawn from quality-improvement practices, management initiatives such as those from The Joint Commission (TJC), and professional organization standards. There are five steps in the process of developing evidence-based practice standards. The implementation of evidence-based practice must consider the patient's unique circumstances and preferences. Nurses must continually seek scientific evidence that supports best patient outcomes.

Quality Improvement

Nurses use data from completed interventions to monitor the outcomes of the care delivered by various processes and then use the resulting data to design methods of quality improvement. Each accredited health care agency has a continuous quality improvement (CQI) program in place that sets standards for care ([Figure 1-3](#)). These standards are based on standards for nursing practice set by the American Nurses Association, the AHA, and TJC. Nursing units have a CQI committee to do periodic audits of charts to determine whether standards of care are being upheld and to what extent compliance is occurring. The goal is to find discrepancies and continually improve the safety and quality of patient care systems ([QSEN Institute, 2014](#)). Medical-surgical nurses are expected to do the following:

- Identify indicators to monitor the quality and effectiveness of care delivered.
- Gather and evaluate data to monitor the effectiveness of care.
- Recommend ways to improve care.
- Implement activities to improve care.

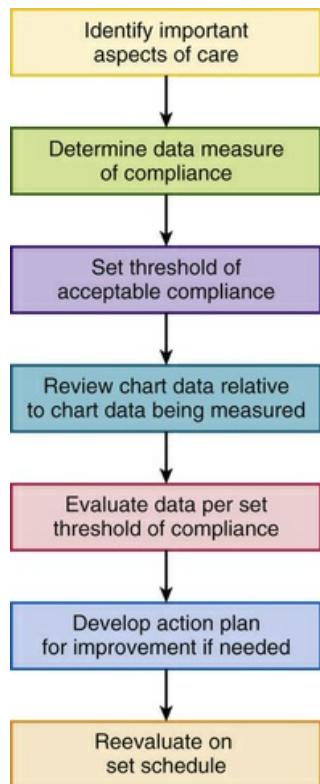

FIGURE 1-3 Continuous quality improvement process.

Informatics

Using information and technology to communicate, manage knowledge, prevent or mitigate error, and support decision making comprises informatics (QSEN Institute, 2014). The key components of informatics are communication, documentation, electronic data access, and data use. The electronic medical record (EMR), or electronic health record (EHR), is at the heart of informatics. The EMR is central to documenting nursing and interdisciplinary care and patient health data.

Central hospital or agency computers store all data and connect to the Internet to allow searches for information on disease processes, medications, diagnostic tests, current care guidelines, and evidence-based practice research. Mobile devices are now common among health care professionals for data access and team communication through text or e-mail. Many health professionals carry tablets or smart phones to access data and to communicate with other team members.

Safety

Every nurse should consider safety during every patient interaction. Patients are vulnerable to injury when they are ill or incapacitated in the hospital. The NCSBN has identified areas in which nursing practice can improve safety. Clear communication of patient data and clinical assessments is one area. Using SBAR (Situation, Background, Assessment, and Recommendation) technique when communicating with other members of the team is one way to promote clarity and safety.

Be attentive to the National Patient Safety Goals (see Table 1-1). It is vitally important that you prepare medications in a quiet atmosphere and use the “Six Rights of Medication Administration” and nursing responsibilities when administering medications to patients. You must know the purpose, action, side effects, and nursing implications of each medication to be given. Evaluation of the medication’s effect is often given insufficient attention. Always check orders carefully before performing a procedure. To ensure patient safety as well as your own, rigorously adhere to infection control guidelines at all times and use proper equipment and methods to lift and turn patients to avoid injuries. Always check electrical equipment before use. Report unsafe practices and self-report errors to promote a safer environment. Follow core measures that are in place to prevent infection to promote better patient outcomes.

Health Care Today

Biomedicine

Biomedicine is the dominant health system in the United States and focuses on symptoms. The goal of biomedicine is to find the cause of disease and to eliminate or correct the problem. However, many Americans use methods that focus on the whole body—and not exclusively on symptoms—when treating disease. Holistic medicine, or **holistic care**, incorporates a variety of measures and techniques to treat the whole person.

Complementary and Alternative Medicine

Complementary (used in conjunction with biomedical treatments) **and alternative** (substituted for biomedical medicine) **medicine (CAM)** focuses on assisting the body's own healing powers and restoring body balance. The National Center for Complementary and Alternative Medicine (NCCAM) of the National Institutes of Health (NIH) researches and evaluates the effectiveness and safety of CAM therapies. Natural medicines often have not undergone scientific studies to determine correct doses, side effects, or risk of interactions with other medicines or foods. Patients need to be reminded that all herbals and supplements need to be included when they are asked for a list of drugs taken.

Healthy People 2020

Healthy People 2020 is a health promotion and disease prevention initiative by the U.S. Department of Health and Human Services aimed at improving the health of people in the United States by promoting longer, healthier lives. The four overarching goals are as follows:

1. Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.
2. Achieve health equity, eliminate disparities, and improve the health of all groups.
3. Create social and physical environments that promote good health for all.
4. Promote quality of life, healthy development, and healthy behaviors across all life stages.

Individuals, groups, and organizations must work together to incorporate the goals of *Healthy People 2020* into current programs, education, special events, publications, and meetings. Every LPN/LVN has the responsibility to educate patients about healthy lifestyles and to work with their communities through education for health promotion. You can also model healthier lifestyles for your patients by not smoking, maintaining healthy eating habits, and exercising.

Financing of Health Care

Health Insurance: The Affordable Care Act, Medicare, and Medicaid

It is helpful to understand a little about payment methods, because it is important to keep **cost containment** in mind when delivering nursing care. Health insurance, like any type of insurance, spreads risk among a group of insured individuals. The young and the healthy generally do not have claims for as many health care services as older adults. When the fee structure is equivalent for all, the young and healthy subsidize (support) the sick and older people covered by the insurance provider. The Affordable Care Act (ACA) is based on this assumption. The effect of those who choose to remain uninsured or who are underinsured on the health care system remains to be seen. Many younger people may choose to pay the lower-cost fine rather than pay for insurance.

The traditional method of financing health care services, **fee-for-service**, involves direct reimbursement by an insurance company to a provider (a licensed health care person such as a physician, dentist, or nurse practitioner) whose health care services are covered by a health insurance plan. To improve coverage of costs, insurance providers charge a **deductible** (the yearly amount an insured person must spend out-of-pocket for health care services **before** the insurance provider will begin to pay for services), a **copayment** (the amount an insured person must pay at the time of an office visit, for a prescription, or for hospital service), and **coinsurance** (once a deductible is met, the percentage of the total bill paid by the insured person). The insurance company subtracts the amount the patient must pay from the total bill, and then pays the remainder to the provider.

The intention of the ACA, also known as Obama-care, is to provide insurance for everyone so they can obtain the necessary care to achieve the *Healthy People 2020* goals (**Box 1-3**). The ACA mandates began implementation by enabling children younger than 26 years of age to continue to be included on their parents' health care policies and by making it illegal for insurance companies to deny coverage to people with preexisting conditions, who previously were unable to obtain health insurance. Various parts of the ACA will be implemented over the coming years. Health care exchanges have been formed to provide coverage for all people who do not have access to health insurance. A large percentage of covered individuals will receive a subsidy for their insurance premiums from the government because their income is below a certain level. There are many controversial aspects to the ACA, and the cost is under great debate. As time goes on and it becomes more clear what works and what needs to be altered within the 1300-page law, expect to see changes.

Box 1-3

Major Goals of the Affordable Care Act

- Ensure affordable, quality health coverage for all Americans.
- Improve patient safety and quality of care.
- Invest in prevention of illness and promotion of wellness for Americans.
- Guarantee a choice of health care providers and health insurance plans.
- Prevent a cap on lifetime insurance limits.
- Require large employers to provide insurance for employees.

Medicare is a federal public insurance program that helps to partially finance health care for everyone older than 65 years (and their spouses), who have at least a 10-year (40 quarters) record in Medicare-covered employment, and who are citizens or permanent residents of the United States. Coverage is also given to people younger than 65 years who have end-stage renal disease or are

permanently and totally disabled. Those eligible because of age or disability are entitled, by law, to the benefits of Medicare programs. In November 2003, Congress passed the Medicare Prescription Drug, Improvement, and Modernization Act, which is the largest expansion of Medicare since it was enacted in 1965 (**Box 1-4**). The ACA contains a long list of reform provisions to contain Medicare costs. Medicare A covers hospital and durable medical equipment expenses. Part B of Medicare covers out-of-hospital expenses. Medicare Part C involves **managed care** providers. Part D is the Medicare drug program that covers a portion of prescription expenses. There are monthly premiums for Parts B, C, and D, as well as deductibles and copay amounts. Many patients with Medicare purchase a private supplemental health insurance policy to help pay for expenses not paid by Medicare.

Box 1-4

Basic Components of Medicare

Medicare Part A

- Is available without cost to those eligible for the program.
- Helps pay for inpatient hospital care, including drugs, supplies, laboratory tests, radiology, and the intensive care unit.
- Covers 20 days after hospitalization at a skilled nursing facility care for rehabilitation services, home health care services under certain conditions, and hospice care.
- Does not pay for nursing home custodial services (e.g., patients only needing help with activities of daily living or feeding), private rooms, telephones, or televisions provided by hospitals or skilled nursing facilities.

Medicare Part B

- Is similar to a major medical insurance plan and is funded by monthly premiums based on income.
- Requires a deductible and pays 80% of most covered charges. The remaining 20% of charges are the responsibility of the patient.
- Helps pay for medically necessary providers' services; outpatient hospital services (including emergency department visits); ambulance transportation; diagnostic tests, including laboratory services and mammography and Pap smear screenings; and physical therapy, occupational therapy, and speech therapy in a hospital outpatient department or Medicare-certified rehabilitation agency.
- Does not pay for most prescription drugs, routine physicals, services not related to treatment of illness or injury, dental care, dentures, cosmetic surgery, routine foot care, hearing aids, eye examinations, or glasses.

Medicare Part C

- Refers to Medicare Advantage plans, such as HMOs or regional PPOs.
- Provides Part A, B, and D benefits to people who elect this type of coverage instead of the original fee-for-service program.

Medicare Part D

- Refers to the outpatient prescription drug benefit.
- Is available to all Medicare enrollees in the original fee-for-service program for an additional monthly fee.

The **Medicaid** program, which is funded jointly by the federal and state governments, provides medical assistance for eligible families and individuals with low incomes and few resources. Each state establishes its own program services and requirements, including eligibility. Proportionally, Medicaid is the second largest item in state budgets (Box 1-5). The program is meant to cover the population of people considered under the Federal Poverty Line (FPL). Some states have elected an option under the ACA to expand Medicaid to 138% of the FPL. Many people just above the FPL are working families who do not have insurance. This population is the “working poor” and is who the ACA aims to address. The ACA has contributed to considerable expansion of the Medicaid programs, which will increase the states' expense in future years.

Box 1-5

The Medicaid Program

- Medicaid is the second largest item in state budgets and covers more than 50 million low-income children and individuals, many in working families.
- Medicaid is the largest source of health insurance for children in the United States. The Children's Health Insurance Program (CHIP) supplements Medicaid in some states by providing coverage for children from lower-income families who do not qualify for Medicaid.
- Medicaid is the primary source of health and long-term care coverage for low-income individuals with disabilities or chronic illnesses and those who need mental health services and substance abuse treatment.
- Medicaid covers services that Medicare does not cover for low-income Medicare beneficiaries, including long-term care and vision and dental care. Medicare beneficiaries who are also enrolled in Medicaid are known as *dual eligibles*.

Cost Containment

The driving force today in all health care facilities is cost containment (holding costs to within fixed limits, while remaining competitive in the health care marketplace). Health care agencies are interested in improving their agency's “bottom line” with business principles that reduce waste and inefficiency. Consumers would like the cost of health care to be reduced while high-quality care and service are maintained. Service, quality, and cost control are attributes of health care that need to be understood and considered in all clinical situations (Box 1-6).

Box 1-6

LPN/LVN Role in Containing Health Care Costs in the Work Setting

1. Charge out all supplies and equipment used in each patient's care; discontinue charges for equipment as soon as use has ended.
2. Follow facility policy for documenting all patient care for reimbursement.
3. Organize patient care for effective and efficient use of time. It is less expensive to do something right the first time.
4. Implement nursing care to help prevent complications and catch signs of complications.

The federal government was the first group to try to stop the skyrocketing cost of health care. In 1983 the Health Care Financing Administration (now the Centers for Medicare and Medicaid Services [CMS]) adopted a system called **diagnosis-related groups (DRGs)**, or illness groups. This system pays hospitals a flat rate for Medicare services, and hospitals know in advance how much

they will be reimbursed by this **prospective payment system (PPS)**. Under the DRG system, the fee the government will pay for hospitalization depends on the DRG category (illness). Hospitals receive a flat fee for each patient's DRG category, **regardless of length of stay in the hospital**; thus hospitals have an incentive to treat patients and discharge them as quickly as possible. If the hospital keeps the patient longer than the government's fee will cover, and the patient cannot be reclassified in the DRG system, the hospital must absorb the difference in costs. However, if the acute care facility can treat the patient for less than the guaranteed reimbursement amount, **the facility can keep the difference in payment as profit**. Because Medicare patients, like all patients, are discharged sooner from hospitals than they were in the past, extended care units or skilled care facilities and home care are commonly used to continue convalescence. With the goal of improving quality of care and saving millions of taxpayer dollars each year, Medicare will not cover specific *preventable* conditions of hospitalized patients ([Box 1-7](#)).

Think Critically

Should Medicare pay for new, expensive technological procedures developed to treat common medical problems of older adults? Should cost-effectiveness enter the picture for treating Medicare patients? Explain the reasoning behind your answer.

Box 1-7

Health Care–Associated Conditions Not Paid for by Medicare or Medicaid

The conditions listed are those that are acquired during hospitalization and are considered preventable.

- Foreign object left in the patient after surgery
- Air embolism
- Blood incompatibility
- Stages III and IV pressure ulcers
- Falls and trauma (fractures, dislocations, intracranial injuries, crushing injuries, burns, electrical shocks)
- Poor glycemic control (diabetic ketoacidosis, nonketotic hyperosmolar coma, hypoglycemic coma, secondary diabetes with ketoacidosis, secondary diabetes with hyperosmolarity)
- Catheter-related urinary tract infection
- Vascular catheter–associated infection
- Surgical site infection after coronary artery bypass graft, particularly mediastinitis (infection in the chest), or after bariatric surgery, gastroenterostomy, laparoscopic gastric restrictive surgery, or orthopedic procedures
- Deep vein thrombosis or pulmonary embolism after total knee replacement or hip replacement
- Surgical site infection after cardiac implantable electronic device insertion
- Iatrogenic pneumothorax with venous catheterization

Data from Centers for Medicare Services (CMS): Medicare program: General information, 2014. Retrieved from <http://www.cms.gov/Medicare/Medicare-General-Information/MedicareGenInfo/index.html>.

Another measure aimed at cost containment is **capitation**, an alternative for fee-for-service payment. It involves a set monthly fee charged by the provider of health care services for each

member of the insurance group for a specific set of health care services. If services cost more than the monthly fee, the provider absorbs the cost of those services. At the end of the year, if any money is left over from the unused portions of monthly fees, the health care provider keeps this remainder as a profit.

Managed care is a type of group health insurance developed to provide quality health care with cost and care use controls. This is accomplished by paying providers to care for groups of patients for a set capitation fee and by limiting services. Medical necessity and the appropriateness of health care services are monitored by a use review system. Types of managed care systems include **health maintenance organizations (HMOs)** and **preferred provider organizations (PPOs)**. This option is used by both Medicare and private insurance companies.

Providing Holistic Care

Holistic nursing care involves being aware of and attending to the physiologic, psychological, social, cultural, and spiritual needs of patients. Data for many of these needs can be collected, and interventions carried out, while care and treatments are administered. Assisting with bathing, feeding, ambulating, and other physical care provides an opportunity to find out about dimensions of the patient's life beyond physical problems. Use time with the patient constructively. Data gathering guidelines are presented in [Chapter 2](#).

Promoting a Therapeutic Nurse-Patient Relationship

The focus of the nurse-patient relationship is on the patient's problems and needs. The relationship is therapeutic, because it provides the patient with the help needed for healing or for a return to wellness. In comparison, a social relationship lacks goals, exists primarily for pleasure, and meets the needs of each person in the relationship. You need to maintain a therapeutic relationship when working with patients and avoid using patient contact to meet personal needs (e.g., the need to be liked, for friendship, or for approval). Develop awareness of your own personal needs and separate them from the patient's needs. A therapeutic nurse-patient relationship ends when the patient has completed treatment or therapy.

A patient who is physically ill is also affected emotionally by the illness or injury. It is not unusual for patients to display behavior that is not their usual manner. Patients' emotional needs and the resulting behaviors are usually temporary and related to the stresses of illness. Occasionally, patient behavior is related to underlying disorders that will benefit from a psychiatric consultation or treatment (see [Chapters 45 through 48](#)). Even patients whose primary illness is physical rather than psychological can sometimes express emotional discomfort through **dependent** (inability or unwillingness to do tasks for oneself), withdrawn, hostile, or manipulative behavior. They may act in ways that are confusing and are uncomfortable for a nurse who is not prepared to act therapeutically.

It is easier to deal with patients' behaviors if their responses to particular situations are understood. Your task is to recognize that patients' behavior results from their current situation. Appropriate nursing responses require kindness, understanding, and sometimes firmness. People may become childlike and fearful when they are ill, or act as if they are unaffected by their illness. Patients appreciate having someone available to guide them through their ordeal in a therapeutic manner.

Think Critically

When assigned to a patient recuperating from major surgery who is displaying very dependent behavior, how can you help to promote a return to independence?

Inability to assume personal responsibilities can be a source of worry for patients and may interfere with a positive outcome after illness or surgery. Some patients are caring for aging parents; are grandparents who play an active, daily role in caring for grandchildren; or are single parents with young children. If a patient lives alone, pet care may be a concern. Patients who are employed might have used available sick leave, may not have health insurance, or may carry a high insurance deductible that is a concern. Patients enrolled in an educational program might be concerned about having to drop a course or leave a program because of time lost to hospitalization, diagnostic tests, or restrictions such as not being able to drive. Conversing with these patients in a therapeutic manner may help them identify their concerns and begin problem solving.

Think Critically

What effect would your admission today for an emergency appendectomy have on your life? How could you resolve your concerns? Who could help you in this situation?

Establishing Trust

To develop a therapeutic relationship, trust needs to be established between the patient and nurse. In today's health care system, time with patients is limited and each patient contact must be efficiently used. Knock before entering the room, give your name, identify yourself as a nursing student or LPN/LVN student, and give the reason for your visit. Explain how long you will be on duty, inform the patient when to expect meals to arrive and the approximate time providers may visit, and so on. Explain what care will be given on the shift and when it will be offered. Many older patients are not accustomed to the informality of having strangers address them by their given (first) name. Clarify how the patient would like to be addressed. Put the patient at ease with a pleasant, unhurried approach.

Using Empathy

An important part of the nurse-patient relationship is the nurse's ability to demonstrate empathy. No one can know or feel what another experiences. **Empathy** involves accurately perceiving the patient's feelings and understanding their meanings, even though the nurse cannot experience the same emotional effect of these feelings, and displaying appreciation for what the other person is feeling.

An empathetic nurse conveys the interpretation of the patient's feelings back to the patient, for validation of accuracy. In this way, the patient's feelings are valued and accepted as legitimate. An example of an empathetic statement by the nurse is, "You appear to be upset about your surgery tomorrow." In contrast, sympathy involves entering into feelings with patients and is displayed by showing sorrow and pity. An example of a sympathetic statement by the nurse is, "You poor thing. I had that surgery." Patients judge their health care experiences by the nature of the help they receive.

Using Therapeutic Communication

Communicate at the level of the patient's understanding. Active listening helps the patient express needs and feelings. Ask patients what they think and actively listen to their answers, concerns, and fears by rephrasing the message when the patient is finished to verify that you understand. Avoid judging the message or the patient. Make sure the patient's and your verbal and nonverbal communication are congruent. Avoid forming a response while the patient is speaking. Answer all of the patient's questions, when possible. Admit when you do not know the answer to a question, and find out and deliver the answer as soon as possible. The focus needs to be the physical and mental well-being of patients. Thank the patient for cooperation and attention as appropriate.

Maintaining Patients' Self-Esteem

A major problem for patients of any age during illness or debilitation is the loss of self-esteem. Avoid referring to a patient by the illness or diagnosis; instead refer to the patient by name. Identify the strengths of patients and find a way to support those strengths and thereby sustain their self-esteem. Allowing patients to perform what self-care they can manage and praising them for any effort with activities of daily living or rehabilitation exercises helps rebuild self-esteem. Nurses and providers are especially important in providing encouragement.

Think Critically

Have you observed a patient being treated in a less than respectful manner? How did it make you feel? How would you have treated the patient to preserve or build self-esteem?

Ensuring Pain Control

Many nursing actions help to decrease patient stress, but pain control is an especially important action. Anticipate patients' pain control needs before they are expressed—for example, administer prescribed pain medication before painful procedures. After surgery, regularly assess for pain and medicate as needed per orders. Patients with chronic disease often need regular medication for pain relief. Assess the need for further pain medication before the next dose is due and determine whether the medication is effective. If the pain medicine is not doing its job, approach the provider and ask for an order change. Use adjunctive measures for pain control such as distraction. Provide whatever comfort measures you can, such as a straightened bed or a massage for added relief.

Touch can be reassuring, calming, and encouraging to patients. In this era of threats of sexual harassment, some nurses may be afraid to touch patients. Ask if touch is okay or touch an arm or a hand and watch the patient's reaction to see if this gesture is acceptable. Be aware of cultural taboos about being touched. Touch that is therapeutic can range anywhere from a friendly touch on the shoulder to massage or exercise of joints. Touch has been shown to effectively help manage pain in patients experiencing illness or disease.

Older Adult Care Points

- Treat older adults with respect. Do not assume a mental impairment is present unless one is stated by the health care provider in the chart. Speak at a normal volume, with a medium to low pitch, and enunciate clearly.
- Be certain glasses and/or hearing aids are in place before beginning an interaction.
- Display patience and plan extra time, because it might take older adults longer to accomplish usual tasks or to formulate answers to questions.
- Give information slowly, and ask for feedback to evaluate understanding. Supply printed material when possible.
- Have the patient answer questions rather than allowing other family members or friends to answer.
- Include the older adult in decision making and care planning.

Meeting Cultural Needs

Health care must accommodate patients of many cultural backgrounds. Patients may think and behave differently because of social class, religion, ethnic background, minority group status, marital status, or sexual preference. Avoid making judgments about people who are culturally different from you. You should be open-minded and **nonjudgmental**, take differences at face value, accept people as they are, and give high-quality care. **Transcultural nursing** is recognizing cultural diversity and delivering nursing care that is sensitive to the particular needs of the patient and family. To do this you must develop cultural competence through knowledge of various cultures and by being sensitive to issues and preferences related to culture, race, gender, sexual orientation, social class, and economic situation. Cultural competence requires examining your own values, attitudes, beliefs, and prejudices; keeping an open mind; and attempting to look at the world through the perspectives of diverse cultures.

Think Critically

Can you give examples of judgmental behaviors you observed in staff members during your clinical rotation?

The philosophy of **individual worth** is the belief in the uniqueness and value of each human being. Nurses need to realize that individuals have the right to live according to personal beliefs and values **as long as those beliefs and values do not interfere with the rights of others and are within the law**. Applying information to all individuals in a group can lead to assumptions, which are called **stereotypes**. A stereotype is a generic simplification used to describe all members of a group, without exception. Stereotyping is an element of profiling and provides an expectation that all individuals in a group will act in a particular way in a given situation. Profiling ignores individual differences. Members of any group or culture may not wholly observe the values and practices of their culture. Information about cultural groups can help explain—but cannot predict—individual behavior.

Cultural Considerations

Examples of Cultural Preferences

- People from the Philippines may be shy and feel awkward in unfamiliar surroundings. They may give little direct eye contact. A family member should be allowed at the bedside at all times. The patient may be reluctant to venture out of the room to ambulate.
- Many Cambodians believe that the soul resides in the head, and it is inappropriate to touch their heads without permission. Ask before touching the head when changing head dressings or administering eyedrops.
- Hmong from Southeast Asia prefer their own relatives as interpreters and may not trust a hospital-employed interpreter. The interpreter should be of the same sex as the patient, as neither Hmong men nor women may discuss or admit to intimate problems to an interpreter of the opposite sex.

When disease strikes, people may blame pathogens (germs), spirits, or an imbalance in the body. Some cultural groups have folk medicine rituals or special procedures to address maladies (e.g., rubbing the skin with the edge of a coin to release the toxins causing illness). Some groups have special individuals who are charged with curing disease (provider, herbalist, shaman, or curandero). Some groups believe that special foods, food combinations ("cold" foods for "hot" illness), or herbs (Echinacea, feverfew) can prevent or cure illnesses. Others see no relationship between the diet and health. Some patients consider the prevention of illness as an attempt to control the future; they may wonder about the necessity to see a health care provider for preventive care (e.g., immunizations). Different beliefs of patients need to be respected.

Meeting Spiritual Needs

Spirituality incorporates the beliefs and values that provide strength and hope, awareness of self (including inner strengths), and understanding of life's meaning and purpose. Patients have a spiritual self with spiritual needs and may use spiritual practices to meet those needs. Examples of personal spiritual practices may include gardening, reading inspirational books, listening to music, meditating, praying, communing with nature, practicing breathing techniques, volunteering, expressing gratitude, and counting blessings.

Spirituality and *religion* are related terms but they do not have the same meaning. Religion attempts to formalize and ritualize spiritual beliefs. Some patients fulfill spiritual needs by belonging to a religious denomination. Concrete symbols, such as books, pictures, icons, herb packets, beads, statues, jewelry, and other objects, can affirm patients' connection with their belief in a higher power. The value of patients' rituals and religious practices is determined by their faith and is not subject to scientific evidence. Spirituality, on the other hand, does not necessarily include religion.

Crisis situations often surface in acute health care situations. Patients' beliefs and values can profoundly affect their response to these crises, attitude toward treatment, and rate of recovery. The need for spiritual care for patients and families may be intensified by hospitalization, pain experiences, chronic or incurable disease, terminal illness, or the death of a loved one. The pastoral care team allies with nurses in providing spiritual care for patients. Follow agency policy for arranging visits of patients' clergy or spiritual advisors, when such visits are desired, and provide private time for spiritual or religious practices.

Getting Ready for the NCLEX® Examination!

Key Points

- Medical-surgical nursing is a vast nursing specialty that involves several roles for LPN/LVNs.
- Qualities and skills needed by LPN/LVNs for medical-surgical nursing include upholding clinical practice standards, providing safe patient care, teaching patients, communicating effectively, working as a collaborative member of the health care team, advocating for the patient, and displaying leadership.
- Assignment involves allocating tasks to unlicensed personnel—when those tasks are within their job descriptions.
- Delegation involves designating to unlicensed personnel duties that are in the job description of the LPN/LVN, are within the boundaries of the NPA, and are advisable considering the patient situation.
- The most common site of employment for LPN/LVNs as a charge nurse is a nursing home or long-term care facility.
- Each state's NPA defines what the LPN/LVN legally can and cannot do in practice, including delegating from the position of charge nurse. LPN/LVNs use evidence-based practice, quality improvement measures, informatics, and safety practices to enhance the quality and safety of nursing care.
- Health care today includes biomedicine, complementary and alternative medicine practices, and the *Healthy People 2020* initiative.
- The ACA, Medicare, and Medicaid are examples of government-sponsored health insurance in the United States.
- To help curb rising health care costs, the federal government adopted the payment system of DRGs as part of Medicare.
- In another measure to cut costs, preventable hospital-acquired problems will not be reimbursed by Medicare.
- Holistic care includes awareness of the physical, psychological, social, cultural, and spiritual needs of patients when planning and delivering care.

Review Questions for the NCLEX® Examination

1. Which of the following is within the role of the LPN/LVN? (*Select all that apply.*)

1. Admitting a patient on a medical-surgical unit.
2. Changing a dressing on a postoperative patient.

3. Assessing a patient whose condition has deteriorated.
4. Collaborating with the physical therapist on how to motivate the patient to ambulate.
5. Advocating for a patient with a physician when prescribed pain medication is insufficient.
6. Teaching the patient about the side effects of a new medication.

NCLEX Client Need: Safe and Effective Care Environment; Coordinated Care

2. What should be the *first* thing considered before delegating a specific task? (*Priority setting.*)

1. Know whether the task is within the scope of practice of the LPN/LVN.
2. Be aware of the nursing assistant's competency and experience.
3. Seek approval from the facility administration.
4. Determine the stability of the patient's condition.
5. Provide adequate explanation and oversight of the task.

NCLEX Client Need: Safe and Effective Care Environment: Coordinated Care, Concepts of Management and Supervision

3. In caring for patients with pressure ulcers, which task would be most appropriate to assign to the nursing assistant?

1. Providing assistance in making dietary choices, including fluids
2. Participating in determining the appropriate type of wound care
3. Repositioning the patient every 2 hours
4. Describing the condition of the wound and any drainage

NCLEX Client Need: Safe and Effective Care Environment: Coordinated Care, Concepts of Management and Supervision

4. The LPN/LVN in the hospital practices under the state's Nurse Practice Act, the Standards of Practice, and the _____. (*Fill in the blank.*)

NCLEX Client Need: Safe and Effective Care Environment: Legal Responsibilities

5. QSEN prepares the nurse to: (*Select all that apply.*)

1. carry out nursing tasks efficiently for a group of patients.
2. consider safety factors at all times when delivering care.
3. apply evidence-based practice to the care of patients.
4. use informatics to collaborate and communicate with the health care team.
5. note ways that quality of care might be improved.
6. assign tasks to UAP on the team in a timely manner.

NCLEX Client Need: Safe and Effective Care Environment

6. In the process of developing evidence-based practice, after developing and asking a clinical question, the next step is to:

1. apply valid, relevant evidence in practice.
2. use data to improve safety.
3. evaluate outcomes based on evidence.
4. search for and collect sources of evidence.

NCLEX Client Need: Safe and Effective Care Environment: Performance Improvement

7. One way nurses apply National Patient Safety Goals to patients is to:

1. report signs of infection in a patient's wound immediately.
2. use two ways to identify patients each time before administering a medication.
3. educate patients about the purpose and side effects of each medication.
4. use lift equipment to get patients out of bed and into a chair.

NCLEX Client Need: Physiologic Integrity: Reduction of Risk Potential

8. The reason that Medicare will not pay for care for a deep vein thrombosis on a patient in the

hospital after knee replacement is:

1. the patient was considered at risk for this problem.
2. the deep vein thrombosis is considered preventable.
3. Medicare is working hard to lower costs of the program.
4. the patient's private insurance will cover the costs.

NCLEX Client Need: Safe and Effective Care Environment: Coordinated care, Performance Improvement

9. Which statement, made by a LPN/LVN during a patient interaction, indicates a therapeutic response?

1. "I am sorry for your loss. I just lost my mother last year."
2. "Try putting on some ointment before dressing the wound."
3. "Are you saying that your cast is uncomfortable? Tell me more about your discomfort."
4. "I understand. I do not like surgery either."

NCLEX Client Need: Mental Health Concepts: Therapeutic Communication

10. The nurse finds a confused patient with a history of falls attempting to get out of bed. To maintain the patient's self-esteem and safety, the nurse's intervention should be to:

1. apply physical restraints to keep the patient in bed.
2. administer sedatives per doctor's order.
3. install a bed alarm to notify staff.
4. ascertain what the patient is searching for.

NCLEX Client Need: Safety and Infection Control: Restraints and Safety Devices

Critical Thinking Questions

Scenario A

Rosa, a student, is about to graduate as an LPN/LVN. She wants to begin searching for a job within her community. In looking at local advertisements, she notices that some are for RNs and some for LPN/LVNs.

1. What type of employment and duties require an RN rather than a new LPN/LVN?
2. When seeking employment in a long-term care facility or a rehabilitation facility, what type of positions might be available for LPN/LVNs?
3. What is the overall requirement for an LPN/LVN no matter where she or he works?

Scenario B

Hector Pulido, age 75, who has pneumonia, was surprised at the aloofness of the admission clerk as she “entered” him into the electronic system during his first hospital experience. Two personnel who assisted him to his assigned room called him “Hector.” Neither introduced themselves or indicated the role they played in his admission. While he was wearing a patient gown that did not fit his large frame and waiting for a nurse to interview him, people kept coming into his room without knocking. One asked his wife if he drank coffee or tea with his meals. That night, the sound of televisions, the click and beep of machines, and staff talking in the halls prevented him from getting a good night’s sleep.

1. List the things that went wrong with Mr. Pulido's admission-day experience.
2. Describe how you would have made his admission day a better experience.
3. Explain the reasons for the things you chose to do differently.

Scenario C

The United States federal government is faced with budget problems resulting in large deficits and the need to reduce spending. Congress suggests reducing spending by making cuts in the Medicare and Medicaid programs. The congressional representative for your district asks for your opinion and your rationale in response to each of the following questions:

1. Should Medicare pay the cost of coronary bypass surgery for an active 85-year-old person?
2. Should Medicaid pay for care in an extended care facility for an 88-year-old person who has had a stroke and is long-term comatose?
3. Should Medicare or Medicaid pay for lifestyle prescription drugs (e.g., Viagra) for men eligible for these programs?

CHAPTER 2

Critical Thinking and the Nursing Process

Objectives

Theory

1. Illustrate how critical thinking affects clinical judgment.
2. Explain what characteristics are necessary to think critically.
3. Correlate how problem solving and decision making are a part of critical thinking.
4. Discuss the LPN/LVN standards for medical-surgical nursing practice.
5. Explain three fundamental beliefs about human life as the basis for nursing process.
6. Distinguish how critical thinking, clinical reasoning, and clinical judgment are applied to the nursing process.

Clinical Practice

7. Identify factors that influence critical thinking during patient care.
8. Provide a clinical example of how nursing process is used in the care of medical-surgical patients.
9. Demonstrate each of the following techniques of physical examination: inspection and observation, olfaction, auscultation, and percussion.
10. Include the patient in formulation of the nursing care plan.
11. Use clinical reasoning to prioritize care for a specific patient.
12. Prepare a prioritized list for beginning-of-shift assessment for a specific patient.

KEY TERMS

- auscultation** (ăw-skūl-TĀ-shūn, p. 20)
- clinical judgment** (KLĪN-ĕ-kāl JŪJ-měnt, p. 15)
- congruent** (kōn-GRŪ-ĕnt, p. 20)
- critical thinking** (p. 15)
- data collection** (DĀ-tă, p. 17)
- evaluation** (ih-văl-ū-Ā-shūn, p. 26)
- expected outcomes** (p. 25)
- focused assessment** (p. 21)
- goals** (p. 25)
- implementation** (ĭm-plī-měn-TĀ-shūn, p. 17)
- inspection** (p. 20)
- interdisciplinary (collaborative) care plans** (kō-LĂB-ĕr-ă-tīv plănz, p. 26)
- NANDA-I** (NĂN-dă-Ī, p. 23)

nursing diagnosis (p. 23)
nursing interventions (p. 25)
nursing process (p. 17)
objective data (öb-JĚK-tív DĀ-tă, p. 18)
observation (p. 20)
olfaction (öl-FÄK-shün, p. 20)
palpation (päl-PĀ-shün, p. 20)
percussion (pěr-KŪ-shün, p. 21)
planning (p. 17)
priority setting (p. 23)
subjective data (süb-JĚK-tív DĀ-tă, p. 18)

Critical Thinking and Clinical Judgment

Critical thinking is a method for solving problems. It is directed, purposeful mental activity by which you evaluate ideas, construct plans, and determine desired outcomes. *Reasoning* is a synonym used for critical thinking. In nursing practice, critical thinking incorporates the scientific method and uses clinical reasoning to make reliable observations and to draw sound conclusions from obtained data. Developing critical thinking skills is a lifelong process and improves over time with experience. **Clinical judgment** is the result of critical thinking applied to clinical situations.

Critical thinking applied to clinical judgment in practical/vocational nursing can be described as being the following:

- Purposeful, informed, and outcome focused (results oriented), requiring careful identification of patient problems, issues, and risks, and making accurate decisions about what is happening, what needs to be done, and what the priorities are for patient care
- Driven by patient, family, and community health care needs
- Based on principles of nursing process (Box 2-1) and the scientific method

Box 2-1

Characteristics of the Critical Thinker

- Maintains an open mind and a questioning attitude
- Recognizes his own biases and limitations
- Is persistent in seeking solutions
- Separates relevant information from irrelevant information
- Recognizes inconsistencies in data gathered
- Identifies missing information
- Considers all possibilities
- Assumes an empathetic attitude
- Uses an organized and systematic approach to problems
- Verifies accuracy and reliability of data
- Considers all possible solutions before making a decision
- Admits what he does not know
- Reasons logically
- Strives for excellence and improvement
- Draws valid conclusions from the evidence or data
- Sets priorities and makes carefully considered decisions
- Is flexible, realistic, creative, humble, honest, curious, and insightful
- Focused on using both logic and intuition and based on knowledge, skills, and the professional experience of the LPN/LVN
- Guided by standards and ethical codes of the following organizations:

- National Association of Practical Nurse Education and Service, Inc. (NAPNES) *Standards of Practice for Licensed Practical/Vocational Nurses* (see Appendix on *evolve*) and *Code of Ethics*
- National Federation of Licensed Practical Nurses, Inc. (NFLPN) *Nursing Practice Standards for the Licensed Practical/Vocational Nurse* (see Appendix on *evolve*) and *The Code for Licensed Practical/Vocational Nurses*
- Interested in strategies that make the most of human potential (e.g., using individual strengths) and compensating for problems created by human nature (e.g., overcoming the powerful influence of personal beliefs, values, and prejudices)
- Committed to constantly reevaluating, self-correcting, and striving to improve (e.g., practicing skills, learning new skills, attending classes and workshops, and reading nursing journals) (Alfaro-Lefevre, 2013; [Hill and Howlett, 2013](#))

Think Critically

Can you list three examples in which you might use critical thinking in the classroom?

Critical thinking is most effective when the brain is purposefully engaged—for example, attentively listening to a report at the beginning of the shift and thinking about how you will apply the information you have gained. Observe the critical thinking activities that take place among the nurses during the report as they collaborate in solving a patient-related problem. Observe the same elements later in the shift as nurses make decisions about patient care issues or about when to notify the provider of a problem or a need for a change of orders. Consider the following when receiving a report:

- What will I be expected to do for my assigned patients?
- What are the priorities of nursing care for each patient?
- What areas need further clarification?
- What procedures can be done independently, and which require supervision?

Examine your thinking and the thinking of others, and apply the knowledge to patient care. Critical thinking is based on science and scientific principles and includes the following:

- Collecting data in an organized way
- Verifying data
- Looking for gaps in information
- Analyzing the data

As a nurse, you must access, understand, recall, and use information as the basis for critical thinking in the clinical area. A sound knowledge base is essential to critical thinking, and that base will grow throughout your nursing education. Critical thinking allows the nurse to apply learned knowledge and principles to different patient care situations.

Factors That Influence Critical Thinking and Nursing Care

Attitude

A major factor in learning to apply critical thinking is attitude. The critical thinker is humble and recognizes that he does not have all the answers; he also recognizes that his perceptions may be clouded by personal values and beliefs. The critical thinker makes an effort to consider evidence that is presented objectively.

Communication Skills

The critical thinker communicates effectively both orally and in writing. He reflects on thoughts before speaking and presents information in a clear, concise manner. The critical thinker listens attentively. When documenting, he clearly conveys to other health team members what was planned, the patient's reaction to any care offered or provided, and whether expected outcomes were met (Box 2-2).

Box 2-2

Actual Examples of Student Charting (Unclear Communication)

- Vaginal packing out. Dr. Heffle in.
- Dr. Jones in. Had large, formed brown stool.
- On the second day the knee was better, and on the third day it disappeared.
- She is numb from the toes down.
- Patient was alert and nonresponsive.

It is helpful to identify a nurse who is skilled at thinking critically and who can communicate clearly both verbally and through charting. This person can serve as a mentor to you as you learn to apply critical thinking and knowledge. The most effective mentor will be one who coaches by asking questions, rather than someone who merely provides answers.

Many other factors influence your critical thinking, such as your personality, age or maturity, prejudices and biases, past experience, and situational factors such as anxiety, stress, and fatigue.

Think Critically

When listening to the report on a patient, what constitutes attentive listening? How does critical thinking help you obtain all the data you need to care for the patient?

Problem Solving and Decision Making

The ability to problem solve and make decisions is integral to critical thinking. Incorporating scientific knowledge and research into nursing requires a consistent, logical method to solve problems. Using the scientific method, one first defines the problem, then gathers information, analyzes the information, and develops solutions (Box 2-3). Next a decision is made about which solution to use; then **implementation** of the solution occurs. Evidence-based research findings are considered when choosing actions to implement the solution.

Box 2-3

Steps in the Problem-Solving Process

1. Define the problem clearly.
2. Consider all possible alternatives as solutions to the problem.
3. Consider the possible outcomes, both positive and negative, for each alternative.
4. Predict the likelihood of each outcome occurring.
5. Choose the alternative with the best chance of success and least chance of undesirable outcomes.

Adapted from deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4. St. Louis, 2014, Mosby.

Integrating Critical Thinking and the Nursing Process

Critical thinking, clinical reasoning, and clinical judgment are integral to the nursing process. It is essential to know the boundaries of the role of the LPN/LVN in your state. If in doubt about the role of the LPN/LVN in the nursing process, direct your questions to your state's board of nursing. According to NCSBN research, all U.S. states and territories identify a scope of practice for either LPNs or LVNs. However, the scope of practice allowed varies widely. Most LPN/LVN scopes of practice stipulate a directed role under the supervision of an RN, but scopes of practice differ in the areas of care **planning**, assessment, intravenous therapy, teaching, and delegation from state to state ([Hill and Howlett, 2013](#)).

The NCSBN has clearly defined the LPN/LVN role in the nursing process. What does your state's NPA indicate about the role of the LPN/LVN?

Think Critically

What questions do you have regarding clarification of the Nurse Practice Act?

Nursing process is the language of nursing. It is an orderly way to assess a patient's response to current health status and to plan, implement, and evaluate the patient's response to nursing care. It is a way to communicate to all nursing personnel what is to be done and who is to do it, during all shifts. Nursing process provides a way to make changes in patient care if progress is not being made. The nursing process builds on a patient's strengths and creates a partnership between the nurse and patient whenever possible. The goal of the nursing process is to alleviate, minimize, or prevent real or potential health problems[®] ([Box 2-4](#)).

Box 2-4

Four Phases of the Nursing Process for LPN/LVNs

1. **Data Collection:** Assist the RN by systematically gathering and reviewing information about the patient and communicating it to appropriate members of the health care team.
2. **Planning:** Assist the RN in the development of expected outcomes and interventions for a patient's plan of care.
3. **Implementation:** Provide planned nursing care to accomplish expected outcomes.
4. **Evaluation:** Compare actual outcomes of nursing care to expected outcomes and assist with updating the nursing care plan.

Applying LPN/LVN Standards in Medical-Surgical Nursing

The five basic steps of the nursing process are (1) assessment (data collection), (2) nursing diagnosis, (3) planning, (4) implementation, and (5) evaluation. The LPN/LVN assists the RN with steps 1, 3, 4, and 5. The RN is responsible for formulating the problem statements in step 2 from the assessment data obtained from all sources.

Assessment (Data Collection)

The purpose of **data collection** is to have a relevant database from which patient problems and potential problems may be identified. Data collection provides the basis for developing a problem list, from which problem statements or nursing diagnoses will be developed. The RN is responsible for the initial admission assessment, but the LPN/LVN may be asked to assist with parts of it. The LPN/LVN is responsible for ongoing assessment for assigned patients.

The LPN/LVN acts in a more independent role when participating in data collection (assessment) and during the implementation phase of the nursing process. LPN/LVNs systematically gather and review data about the patient and communicate their findings to appropriate members of the health care team. A complete database includes a thorough health history®, physical assessment, psychosocial assessment, and cultural and spiritual assessments. Many sources are used to compile a complete database for the patient. Most health care facilities use a standardized form for the **admission assessment**. Both **subjective data** (data that the patient gives that cannot be seen or felt by another, such as pain) and **objective data** (data that can be verified by sight, smell, touch, or sound) are included.

If there is an immediate life-threatening problem, determine immediately what action must be taken and if additional expertise is needed to deal with the problem. Once the patient's physical condition is stabilized, a formal care plan can be developed (*Nursing Care Plan 2-1*).

* Nursing Care Plan 2-1

Care of the Patient With Imbalanced Nutrition

Scenario

Mr. Nielson, age 82, was admitted because of continued loss of weight and weakness. He is a frail-looking man who walks slowly and with hesitation. The patient has experienced loss of appetite, loss of weight, and loss of energy since his right lung lobectomy 3 years ago.

Problem Statement/Nursing Diagnosis

Altered nutrition/*Imbalanced nutrition: less than body requirements, related to loss of appetite and weakness and weight loss*

Supporting Assessment Data

Objective: Height 5'9", weight 128 lb, loss of 35 lb

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will eat 1500 calories of soft diet and drink 2000 mL of liquids each 24-hr period.	Serve six small meals at 8 A.M., 10 A.M., noon, 2 P.M., 4 P.M., and 6 P.M.	Small, attractively arranged soft diet of favorite foods will entice patient to eat without feeling too full.	By day 2, patient will be able to consume 1000 calories in a 24-hr period.
	Assist patient to chair using minimal assistance.	Sitting up encourages proper digestion.	Sitting up for all meals.
	Encourage self-feeding. Assist only if needed. Assess preferred diet.	Encourages independence. Patients eat more when presented with food they prefer.	Feeding self. Prefers chicken, mashed potatoes, gravy, creamed peas, and lemon pie.
	Set up tray for easy reach.	Preserves strength and helps patient overcome weakness.	Trays set up. Continue plan.
By day 4, patient will be able to remove lids and cut most of meat.	Open packages and milk carton. Remove lids. Cut meat.	Helps conserve energy.	Continue plan.
By day 2, patient will drink 1000 mL during 24-hr period.	Offer 240 mL of liquids at 6 A.M., 9 A.M., 11 A.M., 3 P.M., 5 P.M., 7 P.M., and 9 P.M. Vary choices with apple juice, orange juice, lemon-lime drink, tea, ice cream, water, and gelatin. Record time, amount, and liquids taken.	A variety of favorite liquids in small amounts, alternating between meals, will be easier to consume. Verifies amount of liquid consumed.	Intake: 500 mL this shift.
Patient will verbalize increased energy and spend more time awake during the day.	Collect data on amount of hours patient is awake and the length and number of naps.	Provides objective data as a baseline.	Patient states that he feels more energetic and will decrease the length of morning and afternoon nap times to 30 min each.

Critical Thinking Questions

1. What practical methods can you use to entice the patient to eat, without actually feeding him?
2. What are measures that you can use to encourage activity, without tiring the patient excessively?

Sources of Information for the Database

Admission forms, history, and physical.

An admission form generally⁸ accompanies a patient to the unit. The admission form covers basic information such as the patient's name, reason for admission, and other important information. If the patient has been hospitalized in the past, previous records may be sent to the unit. The medical diagnosis will guide you in collecting assessment data and in identifying patient problems. Check to see if results of preliminary laboratory work, radiographs, or other test results are included. If available, read the current information before entering the patient's room; knowing current information will enhance your critical thinking and observation skills during your initial patient contact (and will keep you from repeating obvious questions).

Think Critically

How many sources can you identify that would provide information for a nursing database on a patient who has been admitted to a long-term care facility?

Interview.

Ask patients what they think is their major problem or "chief complaint." Other questions concern the present level of pain, when the last bowel movement occurred, problems with urination or appetite, difficulty sleeping, and whether patients have any additional concerns or complaints. The patient is the primary source of current information and knows more about the problem than anyone else.

Focused Assessment

General Interview Guide

Social Assessment

- Are you married?
- Who lives with you?
- What kind of work do you do?
- Are you a member of a church or belong to any organizations?
- Do you have health insurance?
- How are things at home if you are not there while in the hospital?
- Are there any medical problems that are common in your family?
- Have you had previous surgeries or serious injuries?
- In your life now, who is helpful to you?
- What prescription drugs do you take? What over-the-counter medicines or supplements?
- Do you smoke? How much?

- Do you drink alcohol? How often do you drink and how much?
- Are you allergic to any drugs? Foods? Other substances?
- What do you like to eat? Describe yesterday's meals and snacks.

Physical Assessment

- Why were you admitted here?
- What health problems do you have?
- Do you routinely see doctors? If so, for what?

Review of Systems (Ask questions regarding the following)

Head and Neck

Frequent headaches; dizziness, ringing of the ears, hearing problems; visual problems, glaucoma, cataracts, glasses or contact lenses; surgery of the brain, eyes, or ears; frequent colds; nasal allergies; sinus infections; frequent sore throats; hoarseness; trouble swallowing; swollen glands; mouth sores; date of last dental examination; history of thyroid problems; use of a hearing aid; difficulty sleeping; napping

Chest

Male and female: Cough, sputum production; asthma, wheezing, frequent bronchitis; history of pneumonia; tuberculosis, exposure to tuberculosis; exposure to occupational respiratory hazards; palpitations, chest pain; shortness of breath; history of heart problems, murmurs, hypertension; anemia; surgery

Female: Frequency of breast examinations; date of last mammogram; nipple discharge; breast lumps

Abdomen (Gastrointestinal Tract)

Indigestion; pain; nausea; vomiting; excessive thirst or hunger; frequency of bowel movements; change in bowel movements; rectal bleeding; black or tarry stools; constipation; diarrhea; excessive gas; hemorrhoids; history of gallbladder or liver problems

Genitourinary (Inquire With Cultural Sensitivity)

Male and female: Problems with urination; up at night to urinate; dribbling of urine; history of urinary tract infection; stones

Female: Sexual activity; sexual problems; menstrual cycle and any problems; last menstrual period; bleeding between periods or after menopause; vaginal discharge; date of last Pap smear; history of sexually transmitted infections or vaginal disorders

Male: Sexual activity; genital problems; penile discharge; history of sexually transmitted infections; sexual problems

Extremities and Musculoskeletal System

Joint pain or stiffness; back problems; muscle pain; limited range of motion; vascular problems in legs or arms; easy bruising; skin lesions; history of phlebitis; thrombophlebitis; gout, osteoarthritis, rheumatoid arthritis, fractures, injury

Psychological Assessment

- Are you experiencing anxiety? Depression?
- Do you have unusual memory problems?
- Do you have difficulty thinking?
- Are you ever confused?

If for some reason the patient is incapacitated, secondary sources of information are useful (e.g.,

spouse, significant other, relative, friend, or patient advocate). The secondary source can also help verify information that was provided by the patient. **Box 2-5** provides suggestions for interviewing. The remainder of the admission form is filled out and includes the status of advance directives, assessments for fall risk, pain level, pressure ulcer risk, nutrition requirements, and ability to perform activities of daily living. Psychosocial, cultural, and spiritual assessment data are gathered as well.

Older Adult Care Points

Plan extra time for an interview with a patient who is older. An older person who is ill may think and speak more slowly than expected, may have a hearing loss, and often has a longer health history to relate than does a younger person.

Box 2-5

Interview Suggestions

- Introduce yourself to the patient by name and as an LPN/LVN student.
- Be respectful.
- A patient is entitled to be addressed by her surname. Do so, unless the patient asks you to address her differently.
- Pull up a chair so that the patient can see you at her eye level and can hear you clearly.
- Speak slowly and clearly.
- Ask your questions without dropping your voice at the end of the sentence. Be alert to any hearing difficulty the patient may have.
- Give time for the patient to respond.
- Attempt to resolve incongruence between body language and responses.
- Ask for clarification if you are unsure what the patient means by a particular statement or response.
- Summarize for the patient what you think you heard during the interview.
- Ask the patient for any corrections or additions.

After obtaining a list of current medications from the patient or transferring facility, a medication reconciliation form to identify[®] and prevent **polypharmacy** (multiple drugs prescribed for the same condition by different providers) is filled out. Medication reconciliation also reduces the risk of medication order errors and adverse interactions between drugs. Patient allergies and medications—prescription, over-the-counter, and herbal preparations and supplements—are included on the form, which is reviewed by both the provider and the pharmacist. Patients need to know that the information gathered will be recorded and used in planning their care.

Physical assessment.

Physical data collection usually begins with measuring the patient's blood pressure, pulse, respiration, temperature, weight, and height. **Accuracy is essential.** Data collection correlates current readings with the baseline data, with trends of past readings, with the patient's current clinical status, and with any medical care that has been provided. Such data yield significant information about the patient's condition and response to medication and other treatments. Complete assessments are performed daily.

Inspection and observation.

Inspection (looking) and **observation** (looking and noting) are important aspects of nursing assessment. Use your eyes to pick up clues about the patient's physical and mental condition. Note the patient's facial expression, posture, grimaces, movements, and whether answers are **congruent** (match the feeling tone of what is said verbally). Inspect the hair, skin, nails, and oral mucous membranes for data about hydration and dental hygiene. Observe the patient's state of personal care. Is the hair combed, and are the nails clean and reasonably trimmed? Is there anything in the room that gives evidence of support systems, family, or friends?

Olfaction.

Olfaction (smelling) can provide data about a patient's personal hygiene, as well as clues to possible illness. The sweet, fruity odor of acetone can be indicative of diabetic acidosis. The smell of newly mown clover can be present with hepatic coma. The smell of alcohol indicates the patient has been drinking. Sometimes patients with acute alcoholism may smell like aftershave, mouthwash, vanilla, Sterno, or other substances that contain a high percentage of alcohol. Foul or metallic mouth odors usually indicate poor oral hygiene or periodontal disease. Odor from the nose may be indicative of chronic sinusitis with postnasal drip or an obstruction in the nasal passages.

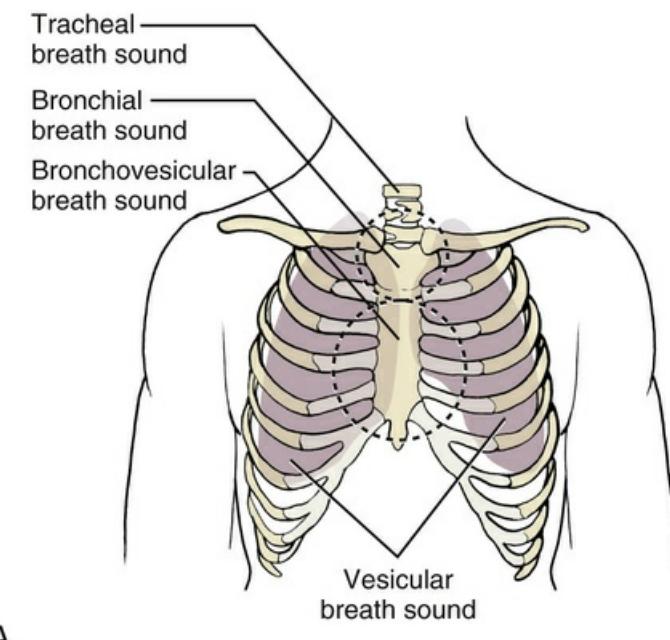

Patients who have anemia, an endocrine problem, or a central nervous system abnormality may be trying to cover up unpleasant body odor with bath powder or heavy perfume. An unpleasant genital odor may indicate an infection, poor hygiene, or insufficient fluid intake (commonly found in female patients in long-term care facilities). Without additional attention, body areas that are unattended may become reddened, irritated, and sometimes infected.

Palpation.

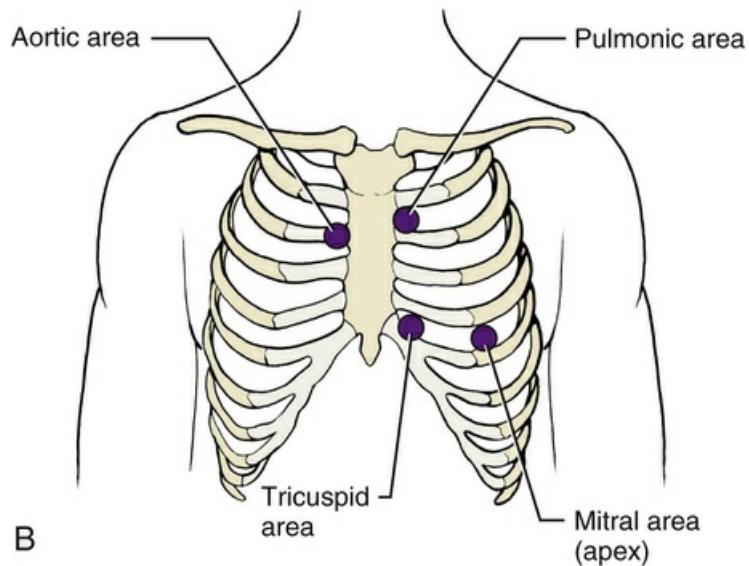

Palpate (touch) the patient's skin to determine whether it feels healthy or is coarse, dry, swollen, cold, or clammy. Dryness may be related to dehydration, and swelling may indicate edema (fluid in the tissues). If you depress the skin with your fingers and your touch leaves pitting (indentation) on the skin, edema is present. Measure and record the depth of pitting and the length of time the tissue remains indented. **Palpation** of the skin can provide additional information. Cold extremities may indicate poor circulation. Hot tissue may be the result of localized inflammation, and you will want to examine the area more carefully. Use your fingertips, not your thumb, to palpate the pulses. Use the flat of the hand to palpate the abdomen to determine whether it is soft or hard and whether there are any tender areas. Palpate the breasts for abnormal growths. Premenopausal women may have masses in their breasts, making it difficult to determine which lumps are significant (this is a good time to ask assistance from your instructor, the staff RN, or the clinical nurse specialist).

Auscultation.

Auscultation (listening) is an important skill in gathering data. Listen to the sounds of the patient's breathing—with a stethoscope and without a stethoscope. You may hear wheezing from constricted bronchi or stridor caused by a partial airway obstruction. Listening to the quality of a patient's cough will determine whether it is dry or moist. With the stethoscope, the sounds are amplified and you can auscultate normal, abnormal, or adventitious breath sounds ([Figure 2-1](#)). Listen to the apical pulse at the apex of the heart and on the abdomen for bowel sounds; listen carefully in each quadrant ([Figure 2-2](#)).

A

B

FIGURE 2-1 A, Place the stethoscope on the bare skin at these locations to hear the lung sounds. B, Place the stethoscope at the apex of the heart (56th intercostal space) to listen to the apical pulse.

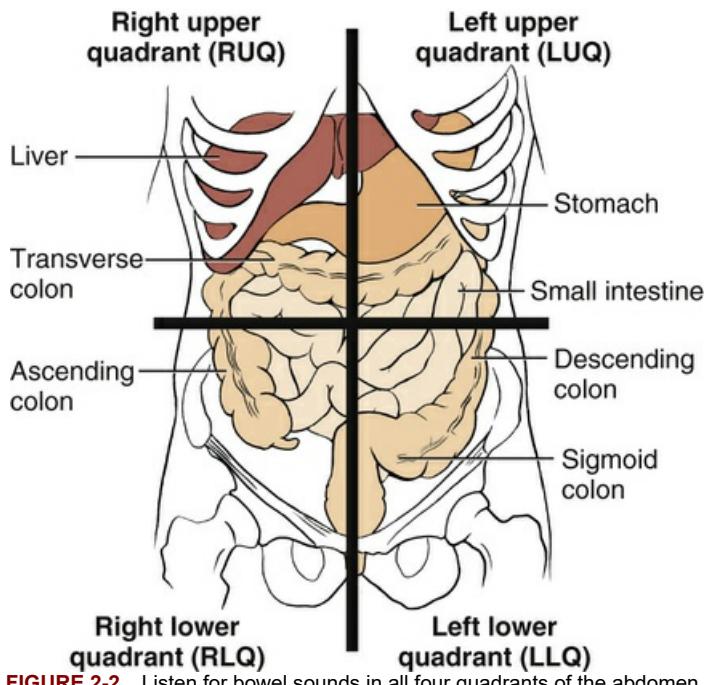

FIGURE 2-2 Listen for bowel sounds in all four quadrants of the abdomen.

Percussion.

Percussion consists of using light, quick tapping on different surfaces of the body to tell the size, location, and density of different organs, especially in the chest, abdomen, and kidney areas. Percussion of the abdomen will reveal areas of excessive gas in the bowel.

Daily Focused Assessment (Data Collection)

A daily **focused assessment**, usually performed at the beginning of the shift, is directed to areas in which the patient is experiencing health problems. This assessment augments the admission assessment of the patient and is based on the identified problems, data from the report, and medical diagnoses and treatment. Many hospitals have standardized assessment forms for collecting head-to-toe data on the patient. Information from reviewing the patient's chart and care plan is used to identify areas in which focused assessment data should be collected. Ask for a demonstration of an appropriate head-to-toe assessment.

Focused Assessment

Beginning-of-Shift Assessment

Physical Review*

- Assess the patient's level of consciousness (LOC), including the patient's ability to respond quickly and appropriately and orientation to person, place, and time. Refer to the Glasgow Coma Scale in [Chapter 21](#) for patients with neurologic problems.
- Check the patient's ability to think (mentate) by asking questions within the client's capacity (e.g., Who is the president?).
- Observe the skin color and texture and degree of moisture.
- Note the appearance of the eyes.
- Measure the vital signs (temperature, pulse, respiration, and blood pressure). Note the rhythm and strength of the pulse, rhythm and depth of respiration, and respiratory effort.

- Ask the patient to describe any pain. Determine the location, severity, quality, and precipitating and alleviating factors.
- Auscultate the chest using the stethoscope. Listen for breath sounds, noting normal, abnormal, and adventitious breath sounds. Listen at the apex of the heart, checking for regularity of rhythm. Auscultate the apical pulse for 60 seconds to count the rate and note the rhythm of the heartbeat. It is difficult for a new nurse to pick up extra heart sounds, but you can determine whether there is an increase or decrease in the heart rate.
- Assess the skin turgor (elasticity) by gently lifting the skin on the upper chest with your thumb and forefinger and observing the speed with which it snaps back when you let go.
- Observe the contour of the abdomen (e.g., flat, round, distended).
- When the patient is in a supine position or low Fowler's position, auscultate bowel sounds in all four quadrants.
- Gently palpate the abdomen with the palm side of the fingers, noting whether the abdomen is soft or firm. Also ask the patient whether she experiences any pain or discomfort, indicating areas of tenderness. Inquire about appetite and weight changes.
- Assess the patient's bowel and bladder status. Note the time of patient's last bowel movement (from the chart or by asking the patient) and whether or not flatus is being passed. Review the intake and output (I&O) for the past 24 hours. Observe and palpate the pubic area to assess bladder distention, especially if there is a discrepancy between the current and previous I&O. If the patient has an indwelling catheter, observe the characteristics of the urine in the drainage tube and the rate of drainage.
- Ask the patient to move each extremity. Observe the ability to actively move the joints through the range of motion and the coordination of the movements. If the patient is unable to actively move any joints, assist the patient with passive motion and note the degree of flexibility. Ask the patient to move extremities against resistance, to determine extremity strength. The nurse can also determine the patient's level of cooperation and ability to follow directions during the exercises.
- Compare the peripheral pulses bilaterally.
- Note the presence of any edema.

Tubes and Equipment Status

- Intravenous catheter:** Condition of site; fluid in progress, rate, additives; time next fluid is to be hung
- Nasogastric tube:** Suction setting; amount and character of drainage; patency of tube; security of tube
- Urinary catheter:** Character and quantity of drainage; tubing not positioned underneath patient
- Dressings:** Location; drains in place; wound suction devices; amount and character of wound drainage
- Pulse oximeter:** Intact probe; readings
- Patient-controlled analgesia pump:** Properly functioning; correct medication infusing; amount of solution remaining
- Traction:** Correct weight; body alignment; weights hanging free
- Equipment:** Applied properly; functioning as ordered

*The physical review may include a head-to-toe assessment based on the patient's needs.

Chart Review

The face sheet of the chart provides demographic data such as address, marital status, insurance coverage, age, date of birth, occupation, significant others, and emergency contact information. The provider's history, physical examination, progress notes, and results of diagnostic tests give an overview of the patient's total health status and provide a summary of current health problems and progress toward resolving them. Allergy information should be identified as part of the admission information and displayed prominently on the front of the chart and at other locations as required by the facility's policies and procedures. The current provider's orders provide a clue as to the plan for that day (tests or treatments).

The medication profile sheets or medication administration record (MAR) list the routine and as-needed (PRN) medications and provide documentation of medication administration. Consultation sheets or nursing documentation include narrative notes and flow sheets that describe care provided to the patient and the patient's response to that care. Reviewing the nursing documentation provides a comprehensive picture of the patient's needs and will assist in preparing for beginning patient care.

Older Adult Care Points

You walk into your patient's room and find that Mr. Nethers, age 72, has been restrained because he pulled out his oxygen tube, IV line, and urinary catheter earlier in the morning. He has also attempted to get out of bed several times. Yesterday he was alert and had a lucid conversation with you. Mr. Nethers had surgery yesterday after you left the unit to go to class, and you see in the documentation that he has been receiving codeine for pain. You recall when you looked up medications that codeine could have a severe behavioral side effect, especially for an older patient. You inform the medication nurse of your observations and ask that the provider be consulted before giving additional doses.

Diagnostic Test Results

Review laboratory and test data to identify general concerns and to confirm assessment findings. Particularly note test data related to the patient's problems that indicate improvement or a complication.

Other Resources

Course textbooks are a primary resource; other texts, journal articles, and the Internet can provide a wealth of information. Handheld devices with downloaded electronic books (e.g., medical-surgical, drug, and laboratory texts) provide instant access to clinical resources. Because there is no control over information placed on the Internet, resources should be evaluated carefully. Your instructor, pharmacists, dietitians, social workers, occupational therapists, physical therapists, physicians, and other specialists can provide valuable information about specific aspects of the patient. Work to gain a comprehensive picture of the patient's situation, diagnoses, medications, and potential actions for care.

Analysis and Nursing Diagnosis

The LPN/LVN reports data collection findings to the RN and assists in verifying, categorizing, and grouping the collected data in a logical order. The LPN/LVN also assists in analyzing the data to determine significant relationships among data, patient needs, and problems. A **prioritized** list of patient problems is developed. The focus is on actual and potential patient problems that can be addressed with independent nursing interventions. From the analysis, the RN chooses problem statements or uses nursing diagnoses from the current list from **NANDA-I** (see the inside back cover). Many facilities do not use NANDA-I nursing diagnoses. They use problem statements on care plans or they use interdisciplinary care plans with medical diagnosis listed.

Nursing care is based on the **priority** of patient problems. High-priority problems are dealt with first, and lower priority problems are dealt with as time permits. The problem statements or

nursing diagnoses are based on all of the available patient data, including—but not limited to—the nursing assessment (subjective and objective) data, diagnostic test data, and the medical diagnosis. Placing a problem statement/nursing diagnosis in the care plan means that the nurse is accepting accountability for accuracy of the statement. Permitting a problem to continue without designating a problem statement can lead to patient harm (Alfaro-Lefevre, 2013).

Think Critically

What is important in choosing the correct problem statement for a care plan? How would you determine that a problem statement/nursing diagnosis on a facility care plan is appropriate for the patient?

It is important to differentiate between a problem statement or **nursing diagnosis** and a medical diagnosis. The provider is concerned with health problems that can be treated with surgery, medications, and other forms of therapy provided or prescribed by the provider. Problem statements/nursing diagnoses identify the patient's response to an illness or a health condition. Nursing practice addresses physical, psychological, social, cultural, and spiritual comfort and well-being; the prevention of complications; and patient education. Nursing care focuses on preventing, minimizing, and alleviating specific health problems. Although the provider is responsible for managing medical problems, the nurse often uses clues from the medical diagnosis to identify patient problems and to develop accurate nursing problem statements/diagnoses.

When using NANDA-I diagnoses, NANDA-I-approved stems are based on an analysis of available data. These approved stems label the patient problems that can be independently treated using nursing interventions. Other components of a NANDA-I nursing diagnosis make statements specific to the patient's situation, and direct the planning and implementation phases of the nursing process. A complete NANDA-I nursing diagnosis includes the problem (NANDA-I stem), the etiology (related causes of the problem), and the signs and symptoms (evidence of the problem).

The etiology component describes the known or suspected cause or causes of a problem (e.g., a patient's ineffective breathing patterns could be related to etiologies of reduced lung capacity, anxiety, or pain). The signs and symptoms of the problem describe the subjective and objective evidence of the problem (i.e., the diagnosis is supported [evidenced] by the assessment data). To follow our example, a patient's ineffective breathing pattern might be evidenced by a statement of shortness of breath, or by the observation of dyspnea (difficulty breathing), changes in respiratory rate or rhythm, or decreased oxygen saturation levels. The following NANDA-I diagnosis statement might be derived from the data: *Ineffective Breathing Pattern related to abdominal incision pain as evidenced by shallow respirations and low pulse oximeter readings (89% to 92%)*. The problem statement “Altered breathing pattern” may be used instead of a nursing diagnosis.

Actual problems are problems that the patient currently exhibits, and documentation should include all three components of the diagnosis statement (problem, etiology, signs and symptoms). Sometimes the patient does not currently exhibit evidence of actual problems, but the data demonstrate that a problem could occur—these situations describe potential problems. NANDA-I potential problem statements begin with the phrase “risk for” and include the NANDA-I stem and the etiology. An example of a potential problem is: *Risk for Deficient Fluid Volume related to vomiting and diarrhea*. In this example, the patient is not currently showing signs of dehydration, but is at risk because of the fluid loss associated with vomiting and diarrhea. A problem statement could be “Potential fluid deficit.” By identifying potential problems, the nurse is alerted to take preventive measures, rather than wait for a problem to materialize before taking action. Most facilities do not use NANDA-I nursing diagnoses, but the LPN/LVN may be expected to be familiar with the NANDA-I list of nursing diagnoses.

Setting Priorities of Care

Priority setting is a method of handling problems and tasks according to the importance (priority) of the patient's problems. Maslow's hierarchy of needs is one way to prioritize patient problems and nursing care (Figure 2-3). Other factors to consider are safety and involvement of the patient (see Chapter 1). Problem statements/nursing diagnoses are listed on the care plan in order of priority. The need to sustain life, such as an airway and breathing, must be attended to immediately, even before a formal care plan is developed. All possible patient problems might not be included in the

initial plan. As problem statements/nursing diagnoses are dealt with successfully, they are modified or discontinued. Other problems are added to the plan as they arise.

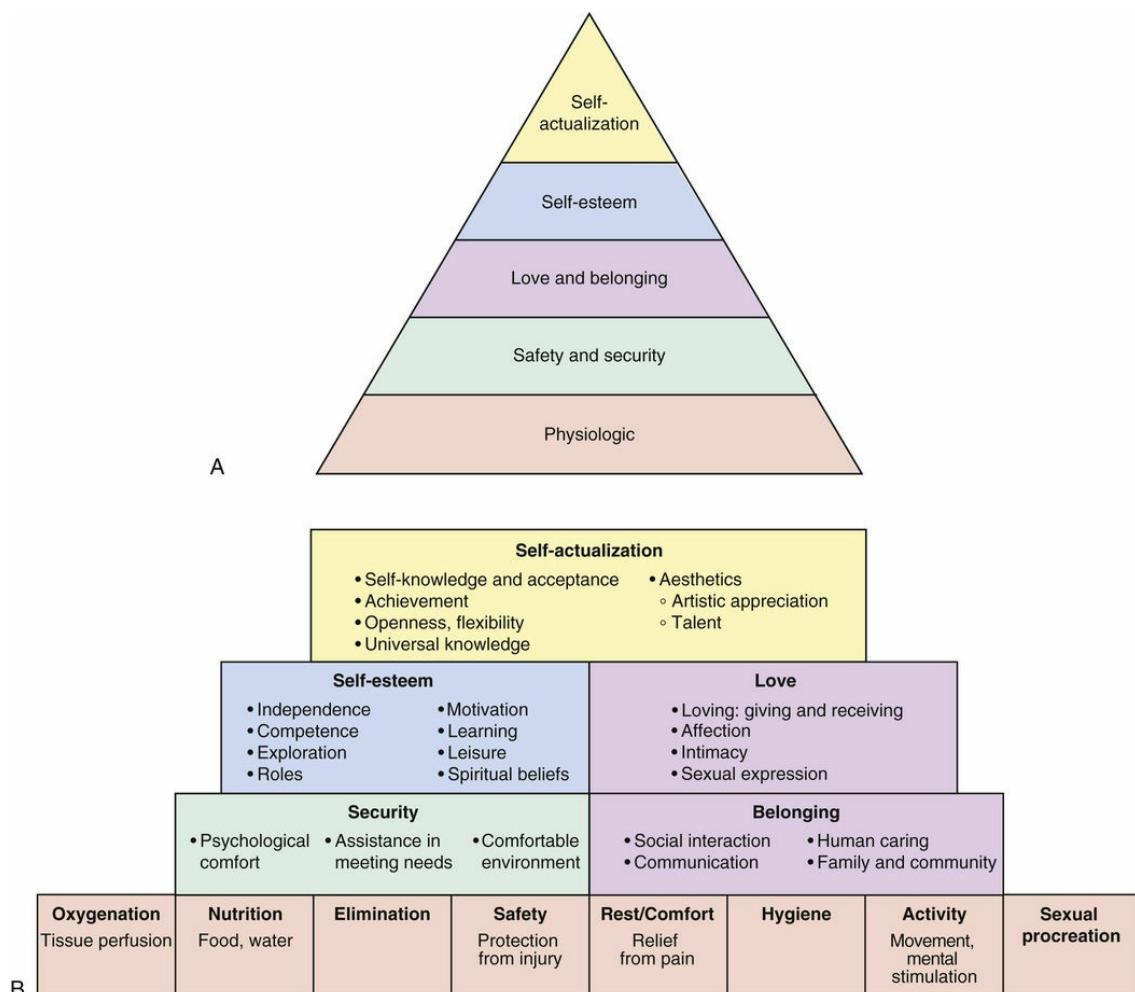

FIGURE 2-3 A, Maslow's hierarchy of needs. B, Evolving hierarchy of needs adapted by nursing to help determine priorities of care. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4. St. Louis, 2014, Elsevier.)

Planning

LPN/LVN standards of care indicate that the LPN/LVN will use the nursing process in planning nursing care and will assist the RN in the identification of health goals, outcomes, and interventions for a patient's plan of care. For a care plan to be effective, the patient should be involved in determining which problems are most important. Data regarding what the patient is willing and able to do to improve the situation and what education is needed are also gathered for the care plan. Sometimes, something that you might consider minor is very important to the patient.

Goals and Expected Outcomes

All goals or expected outcomes, set together by the patient and the nurse, must be patient-centered, be realistically achievable, be measurable, and include a time frame within which they will be met. Goals and expected outcomes relate to (1) restoring health when there is a health problem and (2) promoting health when the patient's resources can and should be directed at regaining or maintaining health. For example, the patient is eager to learn how to live with the diagnosis of diabetes. The patient needs to be instructed about the illness, how to monitor the glucose level, what action is needed to stabilize the glucose level, how to administer insulin or oral medication,

how to maintain a supportive diet, what kinds and what frequency of exercise are appropriate, how to prevent infections, and when to seek additional medical help.

Goals state a general intent about what the patient will achieve. **Expected outcomes** describe a specific result expected at a certain point in time. The terms are used interchangeably in some agencies, although the American Nurses Association prefers the term *outcome* to describe what the patient, not the nurse, will do. An outcome is written as “*The patient will....*” Patient input is important to establish motivation to accomplish the outcome. Outcome statements are derived from the signs and symptoms included in the problem statements. The word *patient* is used as the subject of the statement. The outcome statements are written with a subject, an action verb, conditions or modifiers, and the criterion (standard) for desired performance. Expected outcomes should include the following:

- Patient activity that can be observed, or patient knowledge that can be assessed. Consider how “the patient will select [*action verb—can be measured or observed*] low-sodium foods from a list” provides a better indicator of knowledge than “the patient will understand [*passive verb*] a low-sodium diet.”
- A description of how the patient's behavior will be measured, including the accuracy and quality of performance, and the time frame within which the objective is to be met.

Nursing Interventions

Nursing interventions are nursing actions and patient activities chosen to achieve the goals and expected outcomes. Evidence-based practice research is considered to locate best practices for the type of interventions that are appropriate for each problem statement/nursing diagnosis. Independent nursing interventions can be initiated and implemented without a provider's order. Dependent actions are ordered by the provider. Chosen interventions are listed on the nursing care plan.

Prioritizing Delivery of Care

Prioritizing care is the most important step in planning competent, timely patient care. Prioritizing of care includes when to give medications, measure vital signs, monitor blood glucose, change dressings, check IVs, and so on. Prioritizing also includes identifying which tasks are urgent and which tasks can wait. An urgent task would be medication administration on schedule, whereas a nonurgent task would be ambulating the patient.

Nursing students often have only one or two patients assigned to them for clinical care. After graduation, the norm is four to six patients. During low staffing, expect the number of assigned patients to increase. Once you receive your assignments:

- Review the patient's chart, computer printout, or whichever system is used for patient information.
- Look up required drug information for each routine and PRN drug listed, including IV solutions and additives.
- List focused assessments you will make and data you will collect, both at intervals and before you go off duty.
- List procedures that will be performed and a list of equipment for each.
- Attend report and make additional notes, and question what you do not understand.
- Make rounds on all your assigned patients (unless a bedside report was given). Seeing the patient alerts you to changes that need immediate attention.
- Consider a plan for your shift, including when the patient might be out of the unit for a test, when medications are due, when meals are served, when physicians usually make rounds, what time physical therapy or respiratory therapy might be working with the patient, treatments that are ordered, and when a spouse might arrive to visit. Consider when patient teaching might be worked in and when you might chart and revise the care plan if needed.

Priority setting is a skill that must be developed to work efficiently and safely. During prioritizing, it should become apparent if there is a need to assign some tasks to others.

Implementation

LPN/LVN standards require providing care within the scope of practice to accomplish established goals. Standardized care plans are frequently found on medical-surgical units and include generic nursing care for commonly encountered patient problems. The standardized plan is not individualized for a specific patient. However, problems and/or interventions can be added or deleted if they are not appropriate for the patient. An individualized plan of care is more thorough, because it is developed for a specific patient.

Distinguish which activities to carry out, and which activities the patient must learn to do to gain independence. Sometimes when you are exceptionally busy, it seems faster to do an activity for the patient—for example, feeding a patient who needs to learn to feed herself. The interventions listed in the care plan should indicate that the caregiver is to sit beside the patient and encourage her verbally, as needed. In this way the patient will gain independence by eventually feeding herself.

Staff Communication Regarding Care

Communication among staff members occurs in numerous ways throughout the day. Sometimes staff communication must be immediate to communicate urgent and relevant data that were discovered during an assessment of the patient. Urgent data are usually communicated verbally and may require immediate action. Use the SBAR format for communicating information (**Situation, Background, Assessment, Recommendation**).

Charting occurs on nurses' notes, treatment flow sheets, MARs, and activity flow sheets. Nurses also might chart on common charting forms with other health care providers. Health care facilities are moving to electronic documentation and records management. An electronic health record (EHR) is a computerized comprehensive record of a patient's history and care across all facilities and admissions (deWit and O'Neill, 2014). For the sake of security, health care providers use passwords to obtain information from the record or to record new information.

Think critically about what needs to be documented and be succinct in recording the information. Follow agency policy for the method of documentation to be used (e.g., problem-oriented record, focus charting, or charting by exception).

Legal and Ethical Considerations

Privacy and Protected Health Information

Other clinicians such as the dietitian, respiratory therapist, and social worker contribute documentation to the patient's chart. Information provided by these clinicians completes the comprehensive picture of the patient. You must keep all information you gather private.

Any protected health information from a patient's chart must be carefully guarded to avoid violating the confidentiality component of the Health Insurance Portability and Accountability Act (HIPAA). Information that is retained by a student for educational purposes must be devoid of identifying information. Student preparation paperwork that contains protected health information must be destroyed before leaving the facility according to the policies and procedures of the facility.

Report is conducted at the change of shifts according to facility protocol to ensure continuity of care for the patients. On some medical-surgical units, all the staff members listen to report on all of the patients, the advantage of which is that all of the nurses and nursing assistants are aware of the needs of every patient. Other units use an individualized report system in which a nurse receives report on assigned patients only. Walking rounds are another method for change-of-shift report in which nurses go to patients' rooms and the departing nurse and patient describe what happened during the previous shift. They discuss what the departing nurse and patient see as priorities for the next shift. It is more time-consuming than other methods, but walking rounds provide a sense of partnering for the patient, and the arriving nurse has an opportunity to see and hear the patient before beginning care. It is especially helpful and saves time if the arriving nurse has the computer care plan in hand during report.

Think Critically

How will you use the patients' care plans to effectively receive and give report? What are the items

to which you will pay greatest attention, or that you will emphasize?

Evaluation

The LPN/LVN standards require comparison of **actual** outcomes of patient care to the **expected** outcomes. This comparison is known as **evaluation**. Evaluation begins as soon as a nursing plan is implemented. To make the comparisons needed for evaluation, collect data with every patient contact, think critically about how the patient is progressing in response to nursing actions, and determine whether there is a way to improve care. Daily evaluation is part of the natural flow of nursing process, regardless of the time frame established for patient outcomes. The collected and documented data demonstrate a patient's progress toward meeting the expected outcomes. If the data show a lack of progress toward meeting the expected outcomes with planned interventions, the interventions should be reviewed and revised.

Interdisciplinary (Collaborative) Care Plans

Interdisciplinary (collaborative) care plans require input from all health team members involved in patient care. The collaborative care plan is developed using the interdisciplinary focus of each professional (e.g., nurse, social worker, occupational therapist, recreational therapist). A separate care plan for each profession is considered repetitious. The focus of interdisciplinary planning is on patient problems rather than on nursing diagnoses, making the language used in the plan common to all professions. Interdisciplinary care plans have the following characteristics:

- The patient's medical diagnosis is used, rather than a problem statement or nursing diagnosis.
- Observations (data collected) are shared among all providers involved in the care of the patient.
- A problem list is developed and prioritized. The patient's statement of problems that led to admission is considered. **Priority is given to lifesaving or physiologic needs.**
- A shared care plan is created, identifying specific and shared responsibilities for all professions represented.
- The plan is discussed with the patient (when possible) or patient advocate. The team plays a supportive role during implementation of the plan.
- Documentation of progress is usually on a common form or computer record to allow easy access for all team members involved with the patient.
- Evaluation is ongoing, with periodic in-depth evaluation by the team on agreed-on dates. Interventions are deleted, added, and changed as needed.

Get Ready for the NCLEX® Examination!

Key Points

- Critical thinking generates new ideas and judges the worth of those ideas. Critical thinking prompts the LPN/LVN to ask what could be improved and what measures would prevent further harm to the patient.
- Clinical judgment is a proactive reasoning skill that uses critical thinking in the clinical area to determine the appropriate actions to take in specific situations.
- Factors that influence critical thinking and the decisions about nursing care include our culture, personal motivation, attitude, and verbal and written communication ability.
- Nursing process is an advanced problem-solving method used to collect and analyze data to plan, implement, and evaluate patient care in an orderly way.
- Goals and expected outcomes are patient centered and describe what the patient will achieve.
- Receiving a patient assignment and preparing a preliminary care plan before beginning patient care is considered safe practice for student nurses.
- Techniques of physical examination used by the LPN/LVN include inspection and observation, olfaction, palpation, percussion, and auscultation. Nurses need to be aware of common laboratory and other diagnostic tests and their relationship to common illness. Laboratory and diagnostic tests also provide a way to track the effectiveness of treatments and the emergence of side effects of medications.
- Staff communication takes place both verbally and by charting. Urgent communication is done verbally, and as soon as possible.
- Interdisciplinary (collaborative) care plans are used in health facilities where one plan for all disciplines works best.

Review Questions for the NCLEX® Examination

1. Which critical thinking skill is important to apply when formulating a nursing care plan?
 1. Having the nursing assistant help with assessment.
 2. Reading the history and physical in the chart.
 3. Analyzing the data to determine appropriate nursing diagnoses.
 4. Including the patient in formulating the care plan.

NCLEX Client Need: Integrated Processes: Clinical Problem-Solving Process

2. Critical thinking is useful to the nursing process because it:

1. can provide a better outcome for the patient.
2. simplifies the planning process for the nurse.
3. allows the patient to have input to the plan.
4. directly communicates the plan to others.

NCLEX Client Need: Integrated Processes: Clinical Problem-Solving Process

3. The assessment technique of percussion is used by the nurse to:

1. determine whether lung sounds are normal.
2. assess for air in the intestine.
3. check for abdominal rigidity.
4. assess the degree of abdominal pain.

NCLEX Client Need: Physiologic Adaptation: Alterations in Body Systems

4. Assessing a patient's sleep patterns should include which aspect(s)? (*Select all that apply.*)

1. Family history of sleep disorders
2. Rituals associated with sleep
3. Feelings of restfulness
4. Diet choices
5. Urinary habits

NCLEX Client Need: Integrated Processes: Clinical Problem-Solving Process

5. When caring for an older woman who developed a 5-cm pressure ulcer on her sacrum because of being immobilized and incontinent, an appropriate expected outcome for the problem of altered skin integrity would be:

1. "Patient will be able to ambulate to the bathroom with minimal assistance."

2. "Turning and repositioning schedules will be provided for the staff."
3. "Patient will demonstrate a decrease in size of the ulcer within 1 week."
4. "Family will be able to provide protein-rich foods during the hospital stay."

NCLEX Client Need: Integrated Processes: Clinical Problem-Solving Process

6. Assessing a risk for falls would be considered a high priority for a patient with a problem of:
 1. Altered skin integrity due to repair of umbilical hernia
 2. Altered mobility due to knee arthritis
 3. Altered nutrition due to weight of 265 lb
 4. Altered self-care due to extreme weakness

NCLEX Client Need: Physiologic Integrity: Alterations in Body Systems

7. The nurse is collecting data from an older patient with a history of fractures who has just had gallbladder surgery. Along with a focused assessment, the nurse should include:
 1. determining orientation to person, place, and time.
 2. auscultating for a heart murmur.
 3. checking pulse oximetry.
 4. testing passive and active range of motion.

NCLEX Client Need: Physiologic Integrity: Alterations in Body Systems

8. When evaluating patient understanding regarding the use of an incentive spirometer, which statement confirms a need for more teaching?
 1. "I will inhale as deeply as possible each time I use the spirometer."
 2. "I need to slightly tilt the incentive spirometer to reduce effort."
 3. "To monitor progress, I will record the top volume achieved."

4. "I need to seal my lips around the mouthpiece."

NCLEX Client Need: Integrated Processes: Teaching and learning

9. Using critical thinking, choose the nursing actions that should be implemented when addressing the needs of an older patient with the problem diagnosis of *Altered nutrition due to poor dentition?* (*Select all that apply.*)

1. Encourage more fluid intake if not contraindicated by the medical condition.
2. Inspect the oral cavity and the condition of mucous membranes and teeth.
3. Assist with swallowing.
4. Initiate speech therapy and a dietitian consult.
5. Monitor daily caloric intake and weekly weights.
6. Provide mouth care three times a day.

NCLEX Client Need: Integrated Processes: Clinical Problem-Solving Process

10. When evaluating for side effects of the action of "administer anticoagulant," which patient statement(s) would strongly correlate with a side effect problem? (*Select all that apply.*)

1. "I have noticed some blood streaking in my bowel movements."
2. "I have been embarrassed by frequent, uncontrollable gassiness."
3. "My urine has been cloudy with an odd aroma."
4. "I readily bruise whenever I bump into anything."
5. "I notice some blood when I floss my teeth."

NCLEX Client Need: Physiologic Integrity: Pharmacological Therapies/Expected Actions/Outcomes

Critical Thinking Questions

Scenario A

Review the section on Critical Thinking and Clinical Judgment. Consider how the critical thinking points discussed have helped you learn clinical judgment.

1. Describe an example from personal experience explaining how you used critical thinking and

clinical judgment in a situation involving a patient, a patient's family member, or a friend.

2. Is there more you could have done, or could it have been done in a better way?
3. Did your action prevent harm to the person?

Scenario B

Mr. Nash is 68 years old and describes himself as a tough guy. He is currently on bed rest with his right leg in traction. He fell from his roof while adjusting the satellite dish. His main theme is, "What do I have to do to get out of here?" Although grumpy, Mr. Nash's positive attribute is that he will do whatever will get him released from the hospital. "I've got to smell my own air and I want my evening beer!" Problem statement in his chart is *Altered mobility due to right leg in traction*.

1. Write an example of a patient-centered expected outcome for Mr. Nash that is realistic, time referenced, and measurable.
2. Plan nursing interventions to meet the expected outcome you have written.

Scenario C

Because no jobs are currently available in the medical-surgical unit at the local hospital, you have applied at the mental health facility. You know that your medical-surgical observation skills will be useful in data collection (assessment). The mental health facility uses interdisciplinary care plans.

1. Explain the major differences in a nursing process–focused plan and an interdisciplinary plan.
2. What is the responsibility of each medical specialist for developing and carrying out the interdisciplinary plan?

Scenario D

You are assigned to a mixed medical-surgical nursing unit for your student assignment. You have arrived half an hour early (at 6:30 A.M.) to begin preparation for patient care on the medical-surgical unit at the local hospital. Your assignment involves the following four patients:

Patient 1: Scheduled for abdominal surgery at 10 A.M.; arrives during report and says she was held up in traffic

Patient 2: Newly diagnosed with diabetes, requiring blood glucose readings before each meal with a sliding scale diabetic teaching

Patient 3: Total knee replacement 2 days ago; is scheduled for physical therapy (PT) at 10 A.M.

Patient 4: Has pneumonia; admitted during the night; oxygen at 4 L/min via nasal cannula; has an oxygen saturation monitor

1. Which tasks are priorities?
2. How soon before surgery should the preoperative preparation start?
3. What time is glucose monitoring performed, and does the patient receive insulin based on the glucose reading?
4. When are IVs assessed?
5. What is required for preparation for PT?
6. Which patients need a full assessment and which need a focused assessment?
7. Does Patient 3 require a dressing change and, if so, when?

UNIT II

Medical–Surgical Patient Care Problems

OUTLINE

- Chapter 3 Fluids, Electrolytes, Acid-Base Balance, and Intravenous Therapy
- Chapter 4 Care of Preoperative and Intraoperative Surgical Patients
- Chapter 5 Care of Postoperative Surgical Patients
- Chapter 6 Infection Prevention and Control
- Chapter 7 Care of Patients With Pain
- Chapter 8 Care of Patients With Cancer
- Chapter 9 Chronic Illness and Rehabilitation

CHAPTER 3

Fluids, Electrolytes, Acid-Base Balance, and Intravenous Therapy

Objectives

Theory

1. Explain the various functions fluid performs in the body.
2. Describe the body's mechanisms for fluid regulation.
3. Review three ways in which body fluids are continually being distributed among the body's fluid compartments.
4. Distinguish the signs and symptoms of various electrolyte imbalances.
5. Discuss why older adults have more problems with fluid and electrolyte imbalances.
6. Describe the disorders that cause specific fluid and electrolyte imbalances.
7. Compare the major causes of acid-base imbalances.
8. Apply interventions to correct an acid-base imbalance.
9. Discuss the steps in managing an intravenous infusion.
10. Explain the measures used to prevent the complications of intravenous therapy.
11. Identify intravenous fluids that are isotonic and when they are used.
12. Interpret the principles of intravenous therapy.

Clinical Practice

13. Assess patients for signs of dehydration.
14. Correctly assess for and identify edema and signs of overhydration.
15. Apply knowledge of normal laboratory values to recognize electrolyte imbalances.
16. Perform interventions to correct an electrolyte imbalance.
17. Determine whether a patient has an acid-base imbalance.
18. Execute measures to prevent the complications of intravenous therapy.
19. Compare interventions for the care of a patient receiving total parenteral nutrition with those for a patient undergoing intravenous therapy.

KEY TERMS

acidosis (äh-si-DÖ-sis, p. 39)
active transport (ÄK-tiv, p. 32)
aldosterone (äl-DÖS-tér-ön, p. 30)
alkalosis (äl-kä-LÖ-sis, p. 43)
anions (ÄN-ī-önz, p. 39)
antidiuretic hormone (ADH) (än-ti-dī-ū-RĚT-ik HÖR-mōn, p. 30)
ascites (äh-SI-tēz, p. 39)
atrial natriuretic peptide (ANP) (p. 30)
carpopedal spasm (späzm, p. 43)
cations (KÄT-ī-önz, p. 39)
dehydration (dē-hī-DRÄ-shün, p. 33)
diffusion (dī-FÜ-zhün, p. 31)
edema (ěh-DĒ-mă, p. 37)
electrolytes (ěh-LĚK-trō-līts, p. 32)
extracellular (ěks-trä-SËL-ū-lär, p. 30)
filtration (fil-TRÄ-shün, p. 32)
hydrostatic pressure (hī-drō-STÄ-tik PRĚ-shür, p. 32)
hypercalcemia (hī-pěr-käl-SË-mē-ăh, p. 43)
hyperchloremia (hī-pěr-klör-Ē-mē-ăh, p. 44)
hyperkalemia (hī-pěr-kä-LĒ-mē-ăh, p. 43)
hypermagnesemia (hī-pěr-mäg-në-SË-mē-ăh, p. 44)
hypernatremia (hī-pěr-nä-TRĒ-mē-ăh, p. 39)
hyperphosphatemia (hī-pěr-fös-fä-TĒ-mē-ăh, p. 44)
hypertonic (hī-pěr-TÖN-ik, p. 32)
hyperventilation (hī-pěr-věn-ti-LÄ-shün, p. 48)
hypovolemia (hī-pěr-vō-LĒ-mē-ăh, p. 37)
hypocalcemia (hī-pō-käl-SË-mē-ăh, p. 43)
hypochloremia (hī-pō-klör-Ē-mē-ăh, p. 44)
hypodermoclysis (hī-pō-děrm-ök-LÍ-sis, p. 54)
hypokalemia (hī-pō-kä-LĒ-mē-ăh, p. 42)
hypomagnesemia (hī-pō-mäg-në-SË-mē-ăh, p. 44)
hyponatremia (hī-pō-nä-TRĒ-mē-ăh, p. 39)
hypophosphatemia (hī-pō-fös-fäw-TĒ-mē-ăh, p. 44)
hypotonic (hī-pō-TÖN-ik, p. 32)
hypovolemia (hī-pō-vō-LĒ-mē-ăh, p. 38)
hypoxemia (hī-pök-SË-mē-ăh, p. 48)
insensible (in-sen(t)-sē-bēl, p. 32)
interstitial (in-těr-STISH-äl, p. 31)
intracellular (in-trä-SËL-ū-lär, p. 30)
intravascular (in-trä-VÄS-cü-lär, p. 32)
ions (ī-önz, p. 32)
isotonic (ī-sō-TÖN-ik, p. 32)
ketoacidosis (kē-tō-ă-si-DÖ-sis, p. 47)
osmolality (öz-mō-LÄ-li-tē, p. 39)
osmosis (öz-MÖ-sis, p. 32)
stridor (STRĪ-dör, p. 48)
tetany (TĚT-ă-nē, p. 43)
transcellular (träns-SË-lü-lär, Box 3-1 p. 31)
turgor (TÜR-gör, p. 33)

More than half of the human body's weight is water. Throughout life there is a gradual decline in the amount of body water. An infant's body is approximately 77% water, and an older adult's body is about 45% water. Women's bodies have less water than men's. **The older adult and the very young are more likely to experience severe consequences with even minor changes in their fluid**

balance. Fatty tissue does not contain as much water as other tissues; thus the greater the amount of fat in the body, the less the percentage of body water. Maintaining a healthy weight is important in regulating the body's percentage of water. Keeping body fluids within a normal range is especially necessary, because for every cell of every organ, life processes take place within fluid. The nutrients needed for life, reproduction, and the normal functioning of a cell must be dissolved or suspended in water, and the largest part of each cell is fluid. For all of the cell's life processes to take place, there must be a continuous exchange of water, glucose, oxygen, nutrients, electrolytes, and waste products. Water in the body has four main functions:

1. Be a vehicle for the transportation of substances to and from the cells
2. Aid heat regulation by providing perspiration, which evaporates and cools the body
3. Assist in maintenance of hydrogen (H^+) balance in the body
4. Serve as a medium for the enzymatic action of digestion

[Table 3-1](#) shows sources of water and avenues of a body's water loss.

Table 3-1
Sources of Water and Avenues of Water Loss

SOURCE	24 HOURS (AVERAGE INTAKE)	AVENUE OF LOSS	AMOUNT OF LOSS (AVERAGE OUTPUT)
Oral fluids	1500 mL	Urine	1500 mL
Food	800 mL	Perspiration	400 mL
Metabolism	200 mL	Feces	200 mL
Total	2500 mL	Expired air	400 mL

Modified from deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.

Distribution and Regulation of Body Fluids

Pathophysiology

Body fluids are continually in motion, moving in and out of the blood and lymph vessels, through the spaces surrounding the cells, and through the bodies of the cells themselves. Fluid within the cell is considered to be in one compartment (**intracellular**) and fluid outside the cell in another (**extracellular**) (Figure 3-1). The three types of extracellular fluid (ECF) and body fluid distribution are shown in Box 3-1. Excretion of the body's fluid is mainly achieved through the kidney. Control of fluid balance is managed by:

- **Osmoreceptors** in the hypothalamus sense the internal environment and promote the intake of fluid (thirst mechanism) when needed.
- **Antidiuretic hormone (ADH)**, released by the posterior pituitary, controls how much fluid leaves the body in the urine and causes reabsorption of water from the kidney tubules.
- **Aldosterone** and **atrial natriuretic peptide (ANP)** regulate the reabsorption of water and sodium ions from the kidney tubules.
- Baroreceptors in the carotid sinus and aortic arch detect pressure changes that indicate an increase or decrease in blood volume and stimulate the sympathetic or parasympathetic nervous system to return the pressure to normal.

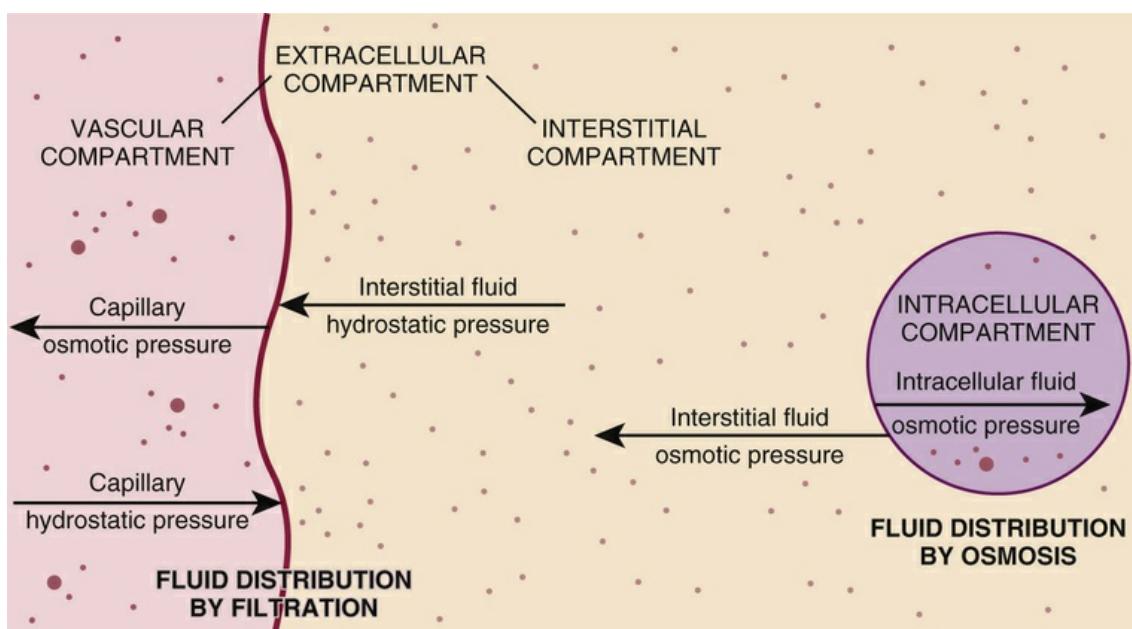

FIGURE 3-1 Factors that influence body fluid distribution.

Box 3-1

Body Fluid Distribution

Extracellular Fluid (Outside of Cells)

- Approximately one third of total body water
- Transports water, nutrients, oxygen, waste, etc., to and from the cells
- Regulated by renal, metabolic, and neurologic factors

- High in sodium (Na^+) content

Intravascular Fluid

- Fluid within the blood vessels
- Consists of plasma and fluid within blood cells
- Contains large amounts of protein and electrolytes

Interstitial Fluid

- Fluid in the spaces surrounding the cells
- High in Na^+ content

Transcellular Fluid

- Includes aqueous humor; saliva; cerebrospinal, pleural, peritoneal, synovial, and pericardial fluids; gastrointestinal secretions; and fluid in the urinary system and lymphatics

Intracellular Fluid (Within Cells)

- About two thirds of total body fluid
- Fluid contained within the cell walls; most cell walls are permeable to water
- High in potassium (K^+) content

Modified from deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.

Pain, nausea, and stress can also cause the release of ADH by the pituitary. When the ECF volume is low, or when sodium concentration is elevated, the adrenal cortex releases aldosterone, which causes reabsorption of sodium from the renal tubules. The **renin-angiotensin-aldosterone system** regulates the release of aldosterone. Renin is released when there is decreased blood flow to the kidney. Baroreceptors in the atrium of the heart detect fluid overload and stimulate the myocardium to release ANP. ANP helps protect the body from fluid overload by increasing sodium excretion. Where sodium goes, water follows.

To be normally distributed within the body, water and the substances suspended or dissolved in water must move from compartment to compartment. As blood flows through the capillaries, fluid and solutes can move into the **interstitial** spaces, where the cells of the body can exchange nutrients and wastes. Several processes accomplish the movement of fluids, electrolytes, nutrients, and waste products back and forth across the cell membranes ([Figure 3-2](#)).

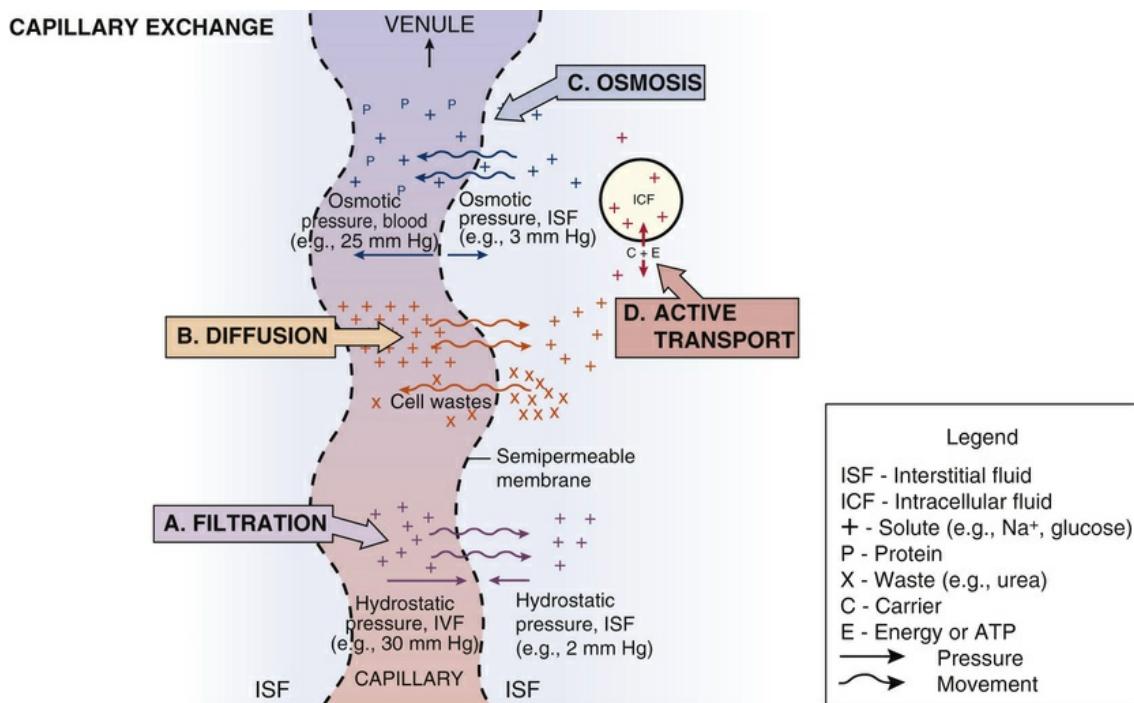

FIGURE 3-2 Movement of water and electrolytes between compartments. (From Gould BE: *Pathophysiology for health professions*, ed. 4, Philadelphia, 2011, Saunders.)

Movement of Fluid and Electrolytes

Passive Transport

Diffusion.

Diffusion is the process by which substances move across the membrane until they are evenly distributed in the available space. As the plasma moves along a capillary, large amounts of fluid filter through pores in the capillary walls. The fluid moves into and out of the capillaries by filtering through the permeable capillary wall or cell membrane walls. A capillary hydrostatic pressure inside the capillary pushes against its membrane. **When the solution on one side of the membrane is more concentrated than the solution on the other side of the membrane, the particles in the more concentrated solution travel through the membrane to the less concentrated side in an attempt to equalize the concentration of the two solutions.** Diffusion is possible because of kinetic motion, which diffuses the molecules in the intracellular fluid (ICF) and the plasma. The molecules literally bounce off one another, mixing and stirring the body fluids.

Diffusion is a spontaneous mixing and moving that allows the exchange of molecules, **ions** (electrically charged particles), cellular nutrients, wastes, and other substances dissolved or suspended in body water. The direction of water flow depends on which side of the membrane has the greatest concentration of solutes. Substances will move from a high to a low concentration until the concentration on both sides of the membrane is equal. This is called *movement down a concentration gradient*. **Glucose, oxygen, carbon dioxide, water, and other small ions and molecules move by diffusion, which is a process of equalization.**

Diffusion may occur by movement along an electrical gradient as well. The attraction between particles of opposite charge and the repellent action between particles of like charge create an electrical gradient. Many intracellular proteins have a negative charge that tends to attract the positively charged sodium and potassium ions from the ECF.

Osmosis.

Osmosis is the movement of pure solvent (liquid) across a membrane. **Water moves by osmosis.** When there are differences in concentration of fluids in the various compartments, osmotic pressure (what holds fluid in the vascular space) will move water from the area of lesser concentration of solutes to the area of greater concentration until the solutions in the compartments are of equal

concentration. The process takes place via a **semipermeable membrane**—a membrane that allows some substances to pass through but prevents the passage of other substances. **Fluid moves between the interstitial and intracellular and between the interstitial and intravascular compartments by osmosis.**

When living cells are surrounded by a solution that has the same concentration of particles, the water concentration of the ICF and the ECF will be equal. Such a solution is termed **isotonic** (of equal solute concentration). If cells are surrounded by a solution that has a greater concentration of solute than the cells, the water in the cells will move to the more concentrated solution, and the cells will dehydrate and shrink. The solution is **hypertonic** (of greater concentration) in relation to the cells. If the cells are surrounded by a solution that has less solute than the cells, the solution is **hypotonic** (of less concentration) in relation to the cells. The particles within the cells exert osmotic pressure and draw water inward through the semipermeable membrane. The cells swell from the extra fluid (overhydrate). These concepts are important to the administration of IV fluids (see discussion later in this chapter). Solutions are classified as isotonic, hypertonic, or hypotonic according to their concentration of **electrolytes** and other solutes.

Think Critically

Can you describe to a classmate the difference between osmosis and diffusion?

Filtration.

Filtration is the movement of water and solutes through a semipermeable membrane as a result of a pushing force on one side of the membrane. The pumping action of the heart creates **hydrostatic pressure** (pressure exerted by fluid) within the capillaries. Hydrostatic pressure causes fluid to press outward on the vessel. Water and electrolytes move through the capillary wall to the interstitial fluid. Filtration occurs in the kidney, where waste substances and excess water are eliminated.

Active Transport

In contrast to diffusion, osmosis, and filtration, **active transport** requires cellular energy, which can move molecules into cells regardless of their electrical charge or the concentrations already in the cell. **Active transport may move substances from an area of lower concentration to an area of higher concentration.** The energy source for the process is adenosine triphosphate (ATP). ATP is produced during the complex metabolic processes in the body's cells. Enzyme reactions metabolize carbon chains of sugars, fatty acids, and amino acids, yielding carbon dioxide, water, and high-energy phosphate bonds. **Amino acids, glucose, iron, hydrogen, sodium, potassium, and calcium are moved through the cell membrane by active transport.** The “sodium pump” is the mechanism by which sodium and potassium are moved into or out of the cell via active transport.

Fluid Imbalances

Pathophysiology

Healthy people maintain fluid balance by drinking sufficient fluids and eating a balanced diet each day. Solid foods contain up to 85% water, and water is also produced in the body as a by-product of metabolism. **The healthy kidney balances the amount of substances entering and leaving the blood, helping to maintain normal concentrations of fluid and electrolytes.** Illness affects fluid balance in many ways. The patient may be unable to ingest food or liquids, there may be a problem with absorption from the intestinal tract, or there may be a kidney impairment that affects excretion or reabsorption of water and electrolytes. Any disease that affects circulation (e.g., heart failure) will ultimately affect the distribution and composition of body fluids. Extra fluid is lost when the metabolic rate is accelerated, such as occurs in fever, thyroid crisis, burns, severe trauma, and states of extreme stress. Perspiration can account for a fluid loss of up to 2 L/hr in an adult. For every degree of fever on the Celsius scale, an **insensible** (unaware of) water loss of 10% may occur. Perspiration and water lost in respiration are insensible losses. When the weather is hot and dry, water loss from the body is greater. Patients on mechanical ventilators, those with rapid respirations, and those with severe diarrhea or excessive amounts of fistula drainage also lose greater quantities of water. **Any seriously ill patient is at risk for a fluid and electrolyte imbalance.**

A fluid imbalance exists when there is an excess (too much) or a deficit (too little) of water in the body. When this occurs, there will be an accompanying imbalance in the substances dissolved in body water. When considering sodium imbalances, **it is important to remember that water follows sodium in the body, through osmosis.** The sodium concentration causes an osmotic pull, and water will go to where the sodium concentration is highest.

Think Critically

Can you give an example of active transport taking place within the body?

Deficient Fluid Volume

Patients at risk for deficient fluid volume are those who are unable to take in sufficient quantities of fluid because of impaired swallowing, extreme weakness, disorientation or coma, or the unavailability of water, and patients who lose excessive amounts of fluid through prolonged vomiting, diarrhea, hemorrhage, diaphoresis (sweating), excessive wound drainage, or diuretic therapy.

When a fluid deficit occurs, water moves from the cells into the interstitial and intravascular spaces. This movement of water out of the cells causes **dehydration** of the cells. Dehydration is treated by administering fluid orally, intravenously, or through feeding or gastrectomy tubes. For patients who will be unable to take in fluids or food on their own for an extended period, a feeding tube must be placed or total parenteral nutrition (TPN) started (see [Chapter 29](#)). Signs and symptoms of dehydration are presented in [Box 3-2](#). **Turgor** (degree of elasticity) is checked by gently pinching up the skin over the abdomen, forearm, sternum, forehead, clavicle, or thigh ([Figure 3-3](#)). In a person with normal fluid balance, the pinched skin will immediately fall back to normal when released. If a fluid deficit is present, the skin may remain elevated or tented for several seconds. However, because pinching the skin to measure fluid deficit also measures skin elasticity, this test is not a valid indicator of fluid status in older adults, whose skin is often inelastic and routinely tents when pinched. In infants, dehydration is evident by sunken fontanelles.

Clinical Cues

The most accurate measure of fluid gain or loss for any age group is weight change. A weight gain or loss of 2.2 lb (1 kg) in 24 hours indicates a gain or loss of 1 L of fluid.

Older Adult Care Points

Fluid volume deficit is a common problem in older adults. There is an age-related decline in total body water and a decrease in thirst sensation and taste that causes older adults to become dehydrated more easily. If urinary incontinence is a problem, the person becomes reluctant to drink extra fluids. Thirst is a late sign of dehydration in older adults.

Box 3-2

Signs and Symptoms of Dehydration and Overhydration

Signs and Symptoms of Dehydration

- Thirst
- Poor skin turgor
- Weight loss
- Weakness
- Complaints of dizziness
- Postural hypotension
- Decreased urine production
- Dark, concentrated urine
- Dry, cracked lips and tongue
- Dry mucous membranes
- Sunken, soft eyeballs
- Thick saliva
- Dry, scaly skin
- Flat neck veins when lying down
- Rapid, weak, thready pulse
- Elevated temperature $\geq 100.6^{\circ}$ F (38.1° C)
- Increased hematocrit
- High urine specific gravity with low volume

Signs and Symptoms of Overhydration

- Weight gain
- Slow, bounding pulse
- Elevated blood pressure
- Firm subcutaneous tissues
- Possibly edema
- Possibly crackles in lungs on auscultation

- Lethargy, possibly seizures
- Possibly visible neck veins when lying down
- Decreased serum sodium
- Decreased hematocrit from hemodilution
- Low urine specific gravity with high volume

FIGURE 3-3 Testing tissue turgor. (From Jarvis C: *Physical examination and health assessment*, ed. 4, Philadelphia, 2004, Saunders.)

Many older adults rely on laxatives and enemas to clear the bowel. This practice can cause fluid volume deficit along with sodium and potassium loss. **Fluid volume deficit contributes to constipation and orthostatic hypotension with related dizziness and falls and makes the person more susceptible to infection.**

A furrowed, dry tongue that is not the result of drug therapy indicates a fluid deficit. If the person has fever, this adds to the fluid loss. Because of the fluid and accompanying electrolyte losses, the person may become confused. Offering the patient small amounts of liquid and electrolyte solution frequently—if fluid can be kept down—helps prevent additional problems.

Clinical Cues

Measure the blood pressure and pulse in the lying, sitting, and standing positions. A systolic blood pressure drop of 20 mm Hg accompanied by a pulse rate increase of 10 beats per minute (bpm) at 1 minute after the position change suggests a fluid volume deficit. This is termed *orthostatic* or *postural hypotension*.

Nursing Management

Provide an adequate fluid intake for those who are unable to do this for themselves. Include the patient's preferences for liquids on the plan of care. The patient should receive fruit juices, bouillon, and any other nutritious liquid tolerated ([Nursing Care Plan 3-1](#)).

Nursing Care Plan 3-1

Care of the Patient With Deficient Fluid Volume

Scenario

Mrs. Cabot, age 78, is admitted to the hospital after 3 days of vomiting and diarrhea. She is confused, disoriented, dehydrated, and very weak.

Problem Statement/Nursing Diagnosis

Fluid volume deficit/*Deficient Fluid Volume related to fluid loss and inability to take in sufficient fluids*

Supporting Assessment Data

Subjective: Hx of vomiting and diarrhea for 3 days; unable to keep anything in stomach. Had eaten food at a church picnic on a hot day.

Objective: Furrowed tongue, tenting of skin on sternum, thick saliva, and dry mucous membranes; 3-lb weight loss from normal. Urine sp. gr. 1.030; scant urine; temp. 101.4° F (40° C).

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation*
Diarrhea and vomiting will stop within 24 hr.	Medicate with antiemetic as ordered.	Antiemetic should stop vomiting.	IM injection of Hydroxyzine given Z-track as ordered. Has not vomited in last hour.
Patient will be able to eat normally before discharge.	Initiate IV therapy as ordered.	IV therapy will replenish fluids and electrolytes in the body.	IV fluids infusing. Site clean, dry without redness.
Fluid balance will be reestablished within 72 hr.	Monitor IV site and fluid every hour.		
	Initiate I&O recording.	I&O record provides data to determine degree of fluid imbalance.	Two liquid stools. Continue plan.
	Keep patient clean and dry.		
	Reduce odors in room to decrease nausea.	Odors contribute to nausea.	No odor in room.
	Provide assistance to bathroom as needed.	Assistance helps prevent falls in weak patients.	Assistance provided ×4.
	Protect perianal skin with ointment as ordered.	A barrier cream or ointment will protect the perianal skin from excoriation from diarrhea.	Perianal skin slightly reddened.
	When vomiting stops, administer medication for diarrhea as ordered.	Medication will slow or stop the diarrhea.	Took diphenoxylate/atropine tab with a sip of Gatorade.
	When able to take PO fluids, offer sips of electrolyte solution, and progress to a clear liquid diet.	Small sips of fluid are easier to keep in the stomach. Electrolyte solution replenishes low electrolytes.	Taking sips of a sports drink designed to replenish carbohydrates and electrolytes.
	Offer mouth care after vomiting and at least q2hr.	Mouth care promotes comfort and reduces nausea.	Mouth care provided.
	Monitor mucous membrane status and skin turgor.	Provides data about rehydration status.	Mucous membranes more moist.
	Weigh daily.		
	Monitor electrolyte values.	Provides data about electrolyte imbalances.	Laboratory results not back yet. Continue plan.

*Evaluation data must be documented in the medical record.

Critical Thinking Questions

1. What would be other concerns that should be addressed in her care plan?
2. What do you think is the cause of her confusion and disorientation?

Key: Hx, history; I&O, intake and output; IM, intramuscular; IV, intravenous; PO, oral; sp. gr., specific gravity; temp., temperature.

A common cause of excessive fluid loss is abnormally rapid excretion of intestinal fluids, such as occurs from vomiting and diarrhea.

Assignment Considerations

Increasing Fluid Intake

If a nursing assistant or unlicensed assistive personnel (UAP) is available to assist, **assign** the task of increasing fluid intake to that person. Work out a timed plan to help the patient with regular, periodic intake of fluids by mouth. Ask that the patient drink 4 oz of fluid every hour. Advise of any safety precautions regarding difficulty swallowing or need for assistance.

Think Critically

Why is it important to the body's function to administer fluid and electrolytes during a fever?

Nausea and Vomiting

Nausea is a feeling of discomfort or an unpleasant sensation vaguely felt in the epigastrium and abdomen. It is a symptom of illness and is often accompanied by vomiting. Nausea is experienced when nerve endings in the stomach and other parts of the body are irritated. Irritated nerve endings in the stomach send messages to the part of the brain that controls the vomiting reflex; however, nerve cells in other parts of the body can trigger the same response. Pain can trigger the nausea-

vomiting mechanism. Nausea and vomiting are automatic responses of the involuntary autonomic nervous system to unpleasant stimuli.

■ Complementary and Alternative Therapies

Preventing Nausea

Sea bands (acupressure wristbands) are very helpful to many people who suffer from nausea and vomiting. They are available at most drugstores. Ginger tea and ginger ale are another alternative therapy that has proven helpful, as are small pieces of ginger candy.

Nausea and vomiting may occur from gastrointestinal irritation from foods, viruses, radiation of the mucosa, and some drugs and other chemicals. Certain types of anesthetics may trigger nausea, as may pregnancy.

■ Safety Alert

Prolonged Vomiting

Prolonged vomiting can lead to sodium and potassium deficits and metabolic alkalosis because of the loss of electrolytes and stomach acids.

The patient may complain of nausea or feeling “sick to my stomach,” of queasiness, abdominal pain, epigastric discomfort or burning, and vomiting. The patient may also exhibit pallor; mild diaphoresis; cold, clammy skin; or excessive salivation and may attempt to remain quiet and motionless. **If vomiting occurs, the vomitus should be observed for odor, color, contents (e.g., undigested food), and amount.** Noting and recording vomiting patterns, conditions that trigger vomiting, and quality of nausea as described by the patient can be helpful in planning treatment.

Medical treatment for nausea consists of administering one of the antiemetic drugs (Table 3-2). Antihistamines, sedatives and hypnotics, anticholinergics, phenothiazines, and other drugs are used to control nausea and vomiting. The patient is given nothing by mouth (kept NPO) until vomiting has stopped; afterward, the patient is allowed clear liquids, progressing slowly to a regular diet. Sips of carbonated drinks at first are usually tolerated well.

■ Table 3-2

Drugs Commonly Prescribed to Treat Vomiting and Diarrhea

CLASSIFICATION	ACTION	NURSING IMPLICATIONS	PATIENT TEACHING
Antiemetics			
Hydroxyzine (Vistaril, Atarax) Promethazine (Phenergan)	Antihistamine-antiemetic used to stop nausea and vomiting Depresses the central nervous system (CNS)	Give by Z-track injection. Never give IV (except promethazine) or subcutaneously. Monitor vital signs. Check compatibility before mixing with other drugs. Monitor for dizziness and hypotension. Observe for urinary retention.	Avoid concurrent alcohol ingestion or other CNS depressants. Avoid activities that require alertness. Raise patient slowly to prevent dizziness. Avoid prolonged sunlight.
Prochlorperazine maleate (Compazine)	Blocks chemoreceptor trigger zone, which in turn acts on vomiting center Stops nausea and vomiting	Monitor vital signs and for respiratory depression, especially in older adults. Check compatibilities before mixing with other drugs. Watch for seizures, muscle stiffness, and other negative reactions.	Avoid hazardous activities; avoid alcohol and other CNS depressants. Avoid urine may be pink to reddish brown. Avoid the sun or use sunscreen and protective clothing. Report bleeding, rash, bruising, blurred vision, or clay-colored stools.
Ondansetron (Zofran)	Blocks serotonin peripherally, centrally, and in the small intestine	Monitor for extrapyramidal signs (shuffling gait, tremors, grimacing, rigidity). Observe for rash or bronchospasm.	Report diarrhea, constipation, rash, change in respiration, or discomfort at IV insertion site.
Metoclopramide (Reglan, Metozolv)	Decreases reflux, stimulates stomach emptying, and raises threshold of chemoreceptor trigger zone	Monitor for extrapyramidal symptoms with IV administration. Assess for rash. Monitor renal function, blood pressure, and heart rate.	Report involuntary eye, facial, or limb movements. Avoid alcohol.
Antidiarrheals			
Diphenoxylate atropine (Lomotil)	Slows intestinal motility. Slows or stops diarrhea.	Assess bowel pattern and monitor for constipation. Discontinue if not effective after 2 days of treatment.	Do not use alcohol or CNS depressants. Do not exceed the prescribed dosage. May be habit forming. Avoid hazardous activities.
Loperamide HCl (Imodium)	Works on intestinal muscles to decrease peristalsis; reduces volume and increases stool bulk Slows or stops diarrhea	Monitor stools and for electrolyte imbalances. Monitor for dehydration. Discontinue if not effective after 2 days of treatment.	Drowsiness may occur; do not operate machinery. Do not take other over-the-counter preparations.
Kaolin-pectin (Kaopectate)	Decreases gastric motility and water content of stool; acts as absorbent and demulcent	Monitor bowel pattern. Monitor for dehydration and electrolyte imbalances.	Do not exceed recommended dosage. Shake suspension well. Take other medications 2 hr before or after administration.

Bismuth subsalicylate (Pepto-Bismol)	Inhibits prostaglandin synthesis responsible for gastrointestinal hypermotility; stimulates absorption of fluid and electrolytes Prevents or stops diarrhea	Monitor bowel pattern. Do not give to children younger than 3 yr.	Shake liquid before using. The tongue may darken and stools may turn black. Do not take other salicylates along with this medication. Stop taking if diarrhea has not stopped in 2 days.
Camphorated opium tincture (paregoric)	Opiate that acts to decrease intestinal motility	Controlled substance. Addictive with long-term use. Monitor bowel function. May cause nausea and vomiting.	Do not exceed prescribed dosage. Causes CNS depression; do not operate machinery.

Nursing Management

Have the patient lie down and turn his head to one side, or have the patient sit and lower his head between his legs so that vomitus is not aspirated into the respiratory tract. Hold an emesis basin close to the side of the face. Use a cool, damp washcloth to wipe the patient's face and the back of the neck. Have the patient breathe through the mouth. Provide mouth care after the episode. Sucking on ice chips helps reduce nausea in some patients. A quiet, cool, odor-free environment helps calm nausea. If nausea and vomiting persist, observe for dehydration.

Older Adult Care Points

Older patients must be rehydrated cautiously. Any patient who has a cardiac problem is at risk for fluid overload from IV infusions. If a liter of fluid infuses too fast, it can cause the patient to go into heart failure. **If an IV infusion falls behind, do not make up for lost time by infusing fluid at a rate faster than ordered.**

Diarrhea

Diarrhea is defined as the rapid movement of fecal matter through the intestine. Frequent, watery bowel movements, abdominal cramping, and general weakness characterize diarrhea. Diarrheic watery stools often contain mucus and are blood streaked. It is the consistency rather than the number of stools per day that is the hallmark of diarrhea. In some cases the number can be as high as 15 to 20 liquid stools. If the condition is chronic, the patient can suffer from dehydration, malnutrition, and anemia. During diarrhea, patients absorb nutrients poorly and lose water and electrolytes. These electrolytic substances—especially the potassium needed by the body to prevent alkalosis—are lost in large amounts by patients with diarrhea.

Most diarrhea is related to local irritation of the intestinal mucosa, especially irritation caused by infectious agents, such as *Salmonella*, *Clostridium difficile*, and *Escherichia coli*; by gastrointestinal irritation; and by chemicals. Chronic and prolonged diarrhea is typical of such disorders as ulcerative colitis, irritable bowel syndrome, allergies, lactose intolerance, and nontropical sprue. Recently gluten intolerance has been recognized to cause gastrointestinal disorders, and sensitivity to gluten includes alternate bouts of diarrhea and constipation in its list of symptoms. Obstruction to the flow of intestinal contents, such as from a tumor or a fecal impaction, also can produce diarrhea. Considerable potassium and sodium are lost during diarrhea.

To rest the intestines and stomach of a patient with acute diarrhea, limit the intake of foods. Once oral feedings are allowed, begin clear liquids and progress to bland liquids and then solid foods of increased calories and high-protein, high-carbohydrate content. Give rehydrating solutions containing glucose and electrolytes first. **Avoid iced fluids, carbonated drinks, whole milk, roughage, raw fruits, and highly seasoned foods.**

Medications prescribed for diarrhea depend on the cause of the disorder and the length of time the condition has been present (see Table 3-2). Mild cases usually respond well to kaolin and bismuth preparations (e.g., Kaopectate), which coat the intestinal tract and make the stools firmer. Bismuth subsalicylate (e.g., Pepto-Bismol) is the recommended treatment for “traveler’s diarrhea”; when given in advance of travel, bismuth subsalicylate may prevent this type of diarrhea. Diarrhea caused by infections may be treated with drugs that are specific for the causative organism. Depending on the organism responsible, it is sometimes advisable to allow the toxins to be eliminated naturally from the body, so drugs may not be given initially. Bowel sounds are likely to be gurgling and tinkling sounds that come in waves and are hyperactive. Note and record the bowel sounds and number of stools during the shift and the characteristics of each stool and any associated pain.

Think Critically

If a patient has food poisoning and suffers from vomiting and diarrhea, what type of fluid and electrolyte imbalance may the patient develop?

Nursing Management

Nursing measures for diarrhea aim to provide physical and mental rest, prevent unnecessary loss of water and nutrients, protect the rectal mucosa, and eventually replace lost fluids. Diarrhea can be associated with nervous tension and anxiety. The patient often is embarrassed by the condition and inconvenienced by frequent trips to the bathroom or the need to request a bedpan. This emotional stress only serves to make the condition worse. Help break the vicious cycle by maintaining a calm and dignified manner, accepting and understanding the patient's behavior, and providing privacy and a restful environment for the patient.

Think Critically

How would you assess a patient with diarrhea for signs of dehydration?

Excess Fluid Volume

An excessive amount of **body water** usually occurs first in the extracellular compartment, because this is where water enters and leaves the body. When people become ill, they may receive more water than they excrete, which can happen if they receive IV fluid too quickly, are given tap water enemas, or are persuaded to drink more fluids than they can eliminate. These situations lead to fluid volume excess, and the patient is likely to develop **water intoxication**.

Impaired elimination, such as occurs in renal failure, is a major cause of fluid volume excess (see Box 3-2). An objective measure of water excess and circulatory overload is the hematocrit. The hematocrit measures the percentage of red blood cells in a volume of whole blood. When fluid volume excess occurs, **hypervolemia** (excessive blood volume) may also occur. Hypervolemia elevates blood pressure.

Clinical Cues

Normal hematocrit values range from 35 to 54 mL of red blood cells per 100 mL of whole blood, depending on age and sex. If there is an excess of water, the proportion of red blood cells to milliliters of blood will be lower, and the hematocrit will be below the normal values because of dilution by the water.

Urine concentration provides another clue to the fluid status. Urine concentration is commonly measured by specific gravity and compared with the specific gravity of distilled water, which is 1.000. Urine contains urea, electrolytes, and other substances, so its specific gravity will exceed 1.000 and ranges between 1.003 and 1.030. The average range is 1.010 to 1.025.

Edema

Edema is associated with the retention of water, sodium, and chloride and is defined as an accumulation of freely moving interstitial fluid (fluid surrounding cells). Look for puffy eyelids and swollen hands. Edema also can occur in body cavities, as in the peritoneal cavity (ascites) and the cranial cavity. The accumulation of body fluids can affect almost all of the tissue spaces (**generalized edema**). Alternatively, fluid accumulation can affect a limited area (**localized edema**). Generalized edema occurs when the body's mechanisms for eliminating excess sodium fail. Edema becomes life-threatening when accumulated fluids overload the circulatory system, as in congestive heart failure, and when fluids accumulate in the lungs, as in pulmonary edema.

Four general causes of edema are (1) an increase in capillary hydrostatic pressure, (2) a loss of plasma proteins, (3) obstruction of lymphatic circulation, and (4) an increase in capillary permeability.

Increased hydrostatic pressure causes pulmonary edema. A loss of plasma proteins decreases osmotic pressure in the vascular system, causing fluid to leak from the vessels, leading to edema. A

tumor or infection can damage a lymph node, or lymph nodes may be removed during cancer surgery. When lymph nodes are removed during mastectomy surgery, lymph may accumulate in the tissues, resulting in **lymphedema**.

When an inflammatory response or infection occurs, histamine and other chemical mediators are released from the cells involved in the tissue injury. These chemicals cause increased capillary permeability, and more fluid moves into the interstitial spaces. Proteins leak into the interstitial spaces also, decreasing the osmotic pressure in the capillaries. Protein in the interstitial spaces holds fluid there rather than moving that fluid back into the capillaries. When fluid shifts from the vascular space (from the plasma) to the interstitial space, dehydration and **hypovolemia** (too little blood volume) can occur. The occurrence of the shift of fluid is termed *third spacing* and may occur with extensive trauma, burns, peritonitis, intestinal obstruction, nephrosis, sepsis, or cirrhosis of the liver in which there is an increase in capillary hydrostatic pressure or increased capillary membrane permeability.

Think Critically

What characteristics would you expect to find in a urine specimen from a patient who is dehydrated? How would it differ from a urine specimen from a patient who has a fluid volume excess?

Localized edema often occurs with inflammation. Localized edema usually is nonpitting, does not come and go, and is characterized by tight, shiny skin that is stretched over a hard and red area. Causes of localized edema include trauma, allergies, burns, obstruction of lymph flow, and liver failure.

Dependent edema is noted in the feet, ankles, and lower legs, or in the sacral region of patients confined to the bed or chair. Dependent edema is an effect of gravity and therefore can be somewhat relieved by elevating the affected body part 18 inches (or above heart level, when possible) and by repositioning the patient frequently. Pitting edema is common in patients with dependent edema. The name is derived from the fact that pressing a fingertip against the swollen tissue can create a pit or depression. **To check for pitting edema, press your thumb into the patient's skin at a bony prominence, such as the tibia or malleolus, and hold for 5 seconds.** If the depression, or "pit," remains for a while after the pressure is released, the patient has pitting edema. Assessing the severity and progress of pitting edema in the feet and ankles (pedal edema) can be done more accurately by rating the findings and comparing assessments from one shift to another (Figure 3-4).

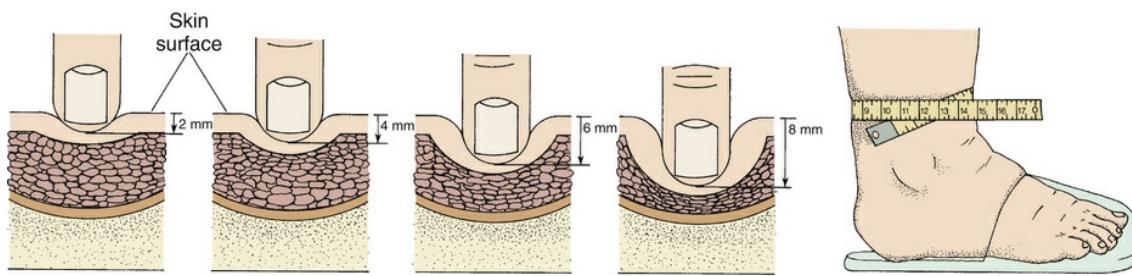

FIGURE 3-4 Measuring pedal edema.

The scale used for rating pedal edema is:

1+ Mild pitting—slight indentation with no perceptible swelling of the leg
2+ Moderate pitting—indentation subsides quickly, foot is perceived as mildly swollen
3+ Deep pitting—indentation remains for a short time and leg looks swollen
4+ Very deep pitting—indentation lasts a long time and leg is very swollen

Treatment.

Treatment of a fluid imbalance involves correcting the underlying cause and assisting the body to rebalance fluid content. For conditions of edema, fluid may be restricted or diuretic drugs may be administered to facilitate excretion of the excess fluid. A diuretic is a drug that prompts the kidneys

to increase the excretion of fluid. Bed rest may be ordered to facilitate fluid excretion, because the kidneys function best when the body is supine.

A low-sodium diet is initiated. Elastic stockings or sequential compression devices are ordered for foot and leg edema. Intake and output (I&O) recording is requested.

Think Critically

Can you describe the assessments you would make to determine whether your 68-year-old patient is experiencing edema?

Home Care

It is important to teach patients with a fluid deficit and their family how to measure fluid I&O and how to keep a log of the amounts. The patient should be encouraged to take small amounts of liquid every hour while awake. If the patient has been vomiting, it is better to let carbonated beverages go flat before drinking them, to decrease stomach distention.

If an older adult has been vomiting considerably for several hours or has had constant diarrhea without fluid intake, a visit to the emergency department is necessary so that IV fluids can be given to prevent serious dehydration.

A patient with fluid excess should be weighed daily and a chart kept. The patient and family should be taught how to assess edema and to record findings. If edema is worsening or weight is increasing, the provider should be notified.

Osmolality

Nonelectrolyte solutes include protein, urea, glucose, creatinine, and bilirubin. Along with the electrolytes, these solutes contribute to the **osmolality** (concentration of the solution determined by the number of solutes in it) of the body fluid. Osmolality controls water movement and the body fluid distribution in the intracellular and extracellular compartments. Potassium maintains the osmolality of the ICF. Sodium controls the osmolality of the ECF. Normal osmolality of body fluids is 280 to 294 milliosmoles per kilogram (mOsm/kg).

Think Critically

Why should you watch for signs of fluid imbalance in any patient who has a serious infection or who has suffered considerable physical trauma?

Electrolytes

Some molecules, when placed in solution, undergo a separation of their atoms into electrically charged ions. These molecules are called **electrolytes** because their atomic particles are capable of conducting an electrical current. The molecules of electrolytes break up into atomic particles that are either negatively charged (**anions**) or positively charged (**cations**). For example, when sodium chloride (table salt) is dissolved in body water, its molecules separate into sodium ions, which are positively charged (Na^+), and chloride ions, which are negatively charged (Cl^-).

Because electrolytes are electrically charged, they are chemically active. This chemical activity allows for the creation of an electrical impulse across the cell membrane, making possible the transmission of nerve impulses, contraction of muscles, and excretion of hormones and other substances from glandular cells. Thus electrolytes are essential to the normal functioning of the body.

Electrolyte Imbalances

Electrolytes have many functions in the body. To determine whether there is an electrolyte imbalance, you must know the normal range for each electrolyte (Table 3-3). Many disorders can cause a shift in electrolytes and thus an imbalance—with too much or too little of an electrolyte circulating in the bloodstream or inside the cells of the body.

Table 3-3
Normal Ranges and Functions of Major Electrolytes

ELECTROLYTE	NORMAL RANGE	SI* UNITS	FUNCTION
Sodium (Na^+)	135-145 mEq/L	135-145 mmol/L	Major cation of the extracellular fluid Major role in regulation of water balance Regulates extracellular fluid volume through osmotic pressure Water follows sodium concentration in the body Essential to the transmission of nerve impulses and helps maintain neuromuscular irritability Important in controlling contractility of the heart Helps maintain acid-base balance Aids in maintenance of electroneutrality
Potassium (K^+)	3.5-5.0 mEq/L	3.5-5.0 mmol/L	Major intracellular cation Important to nerve transmission and muscle contraction Helps maintain normal heart rhythm Helps maintain plasma acid-base balance
Calcium (Ca^{2+})	8.4-10.6 mg/dL	2.10-2.65 mmol/L	Involved in formation of bone and teeth Necessary for blood coagulation Essential for normal nerve and muscle activity
Magnesium (Mg^{2+})	1.3-2.1 mg/dL	0.65-1.05 mmol/L	Necessary for building bones and teeth Necessary for nerve transmission and involved in muscle contraction Plays an important role in many metabolic reactions, where it acts as a cofactor to cellular enzymes
Phosphate (PO_4^{3-})	3.0-4.5 mg/dL	1.0-1.5 mmol/L	Necessary for formation of adenosine triphosphate (ATP) Cofactor in carbohydrate, protein, and lipid metabolism Activates B-complex vitamins
Chloride (Cl^-)	96-106 mEq/L	96-106 mmol/L	Helps maintain acid-base balance Important to formation of hydrochloric acid for secretion to the stomach Aids in maintaining plasma electroneutrality
Bicarbonate (HCO_3^-)	22-26 mEq/L	23-29 mmol/L	A buffer that neutralizes excess acids in the body Helps regulate acid-base balance

*International System of Units.

Modified from deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.

Sodium Imbalances

Hyponatremia.

Hyponatremia, a deficit of sodium in the blood (Na^+ less than 135 mEq/L), is the most common electrolyte imbalance. Hyponatremia can occur from either a sodium loss, an inadequate intake of dietary sodium, or an excess of water. Decreased secretion of aldosterone results in sodium loss. Congestive heart failure, liver disease with **ascites** (abnormal accumulation of fluid within the peritoneal cavity), and chronic renal failure result in excessive water retention—without concurrent sodium retention—and this results in hypervolemia combined with hyponatremia. Decreased osmotic pressure in the extracellular compartment may cause a fluid shift into the cells. A decrease in blood pressure may occur. The average intake of sodium is 4 to 5 g/day. If there is a problem with water balance, sodium may be restricted in the diet. The consequence of hyponatremia is impaired nerve conduction. Table 3-4 presents the signs and symptoms, risk factors, and nursing interventions for hyponatremia.

Table 3-4
Electrolyte Imbalances and Nursing Interventions

SERUM VALUE	SIGNS AND SYMPTOMS	CAUSES AND RISK FACTORS	NURSING INTERVENTIONS
Sodium (Normal Range: 135-145 mEq/L)			
Hyponatremia <135 mEq/L	Central nervous system and neuromuscular changes resulting from failure of swollen cells to transmit electrical impulses Fatigue, lethargy, headache, mental confusion, altered level of consciousness, anxiety, coma, anorexia, nausea, vomiting, muscle cramps, seizures, decreased sensation, and decreased blood pressure (BP)	Inadequate sodium intake, as in patients on low-sodium diets Excessive intake or retention of water (kidney failure and heart failure) Loss of bile, which is rich in sodium, as a result of fistulas, drainage, gastrointestinal surgery, nausea and vomiting, and suction Loss of sodium through burn wounds Administration of intravenous (IV) fluids that do not contain electrolytes	Restrict water intake as ordered for patients with congestive heart failure, kidney failure, and inadequate antidiuretic hormone production. Liberalize a low-sodium diet. Closely monitor patient receiving IV solutions to correct hyponatremia. Replace water loss with fluids containing sodium.
Hypernatremia >145 mEq/L	Dry mucous membranes, taut skin turgor, intense thirst, flushed skin, oliguria, and possibly elevated temperature Weakness, lethargy, irritability, twitching, seizures, coma, intracranial bleeding	High-sodium diet, inadequate water intake as in a comatose, mentally confused, or debilitated patient Excessive sweating, diarrhea, failure of kidney to reabsorb water from urine Administration of high-protein, hyperosmotic tube feedings and osmotic diuretics	Encourage increased fluid intake. Measure intake and output (I&O). Give water between tube feedings. Restrict sodium intake. Monitor temperature.
Potassium (Normal Range: 3.5-5.0 mEq/L)			
Hypokalemia <3.5 mEq/L	Abdominal pain, paralytic ileus, gaseous distention of intestines Cardiac dysrhythmias, muscle weakness, decreased reflexes, paralysis, urinary retention, increased urinary pH, lethargy, confusion, electrocardiogram (ECG) changes	Inadequate intake of potassium-rich foods Loss of potassium in urine when kidneys do not reabsorb the mineral Loss of potassium from intestinal tract as a result of diarrhea or vomiting, drainage from fistulas, or overuse of gastric suction Improper use of diuretics	Instruct patients (especially those taking diuretics) about foods high in potassium content; encourage intake. Observe closely for signs of digitalis toxicity in patients taking this drug. Teach patients to watch for signs of hypokalemia. Administer potassium chloride supplement as ordered. Monitor I&O and cardiac rhythm.
Hyperkalemia >5.0 mEq/L	Muscle weakness, fatigue, hypotension, nausea, paresthesias, paralysis, cardiac dysrhythmias, ECG changes	Kidney failure, decreased kidney function Intestinal obstruction that prevents elimination of potassium in the feces Addison disease, digitalis toxicity, uncontrolled diabetes mellitus, insulin deficit, crushing injuries, and burns Overuse of potassium-containing salt substitute, or overuse of potassium-sparing diuretic	Decrease intake of foods high in potassium. Increase fluid intake to enhance urinary excretion of potassium; provide adequate carbohydrate intake to prevent use of body proteins for energy. Carefully administer proper dose of insulin to diabetic patients. Instruct patient in proper use of salt substitutes containing potassium.
Calcium (Normal Range: 8.4-10.6 mg/dL)			
Hypocalcemia <8.4 mg/dL	Paresthesias, abdominal cramps, weak pulse, decreased BP, seizures, muscle spasms, tetany, hand spasm, positive Chvostek sign, positive Troussseau sign, cardiac dysrhythmia, wheezing, dyspnea, difficulty swallowing, colic, cardiac failure, excessive blood transfusions	Metastatic cancer Inadequate dietary intake of calcium and vitamin D Impaired absorption of calcium from intestinal tract, as in diarrhea, sprue, or overuse of laxatives and enemas containing phosphates (phosphorus tends to be more readily absorbed from the intestinal tract than calcium and suppresses calcium retention in the body) Hyposecretion of parathyroid hormone (the parathyroid regulates calcium and phosphorus levels)	Encourage adults to consume sufficient calcium from cheese, broccoli, shrimp, and other dietary sources. Have 10% calcium gluconate solution at bedside of patient having thyroidectomy in case of surgical damage to the parathyroid glands. Give all oral medicines containing calcium 30 min before meals to facilitate absorption.
Hypercalcemia >10.6 mg/dL	Anorexia, nausea, abdominal pain, constipation, muscle weakness, oliguria, confusion Renal calculi, pathologic fractures, dysrhythmias, cardiac arrest	Excess intake of calcium, as in patient taking antacids indiscriminately Excess intake of vitamin D Conditions that cause movement of calcium out of bones and into extracellular fluid (e.g., bone tumor, multiple fractures) Tumors of the lung, stomach, and kidney and multiple myeloma Immobility and osteoporosis	Administer diuretics as prescribed to increase urinary output and calcium excretion. Monitor I&O; encourage high fluid intake (3000-4000 mL/day).
Magnesium (Normal Range: 1.3-2.1 mEq/L)			
Hypomagnesemia <1.3 mEq/L	Insomnia, hyperactive reflexes, leg and foot cramps, twitching, tremors Seizures, cardiac dysrhythmias, positive Chvostek sign, positive Troussseau sign, vertigo, hypocalcemia, hypokalemia	Chronic malnutrition, chronic diarrhea Bowel resection with ileostomy or colostomy Chronic alcoholism Thiazide diuretic use Prolonged gastric suction Acute pancreatitis Biliary or intestinal fistula Osmotic diuretic therapy Diabetic ketoacidosis	Provide diet counseling to help at-risk patients increase their level of magnesium (e.g., milk and cereals). Monitor IV infusions of magnesium closely. Monitor I&O.
Hypermagnesemia >2.1 mEq/L	Hypotension, sweating and flushing, nausea and vomiting Muscle weakness, paralysis, respiratory depression Cardiac dysrhythmias	Overuse of antacids and cathartics containing magnesium Aspiration of sea water, as in near-drowning Chronic kidney failure	Teach patients to avoid abuse of laxatives and antacids; instruct patients with renal problems to avoid over-the-counter drugs that contain magnesium. Encourage fluid intake to increase urinary excretion of magnesium if not contraindicated. Monitor I&O. Administer diuretics as ordered.
Phosphate (Normal Range: 3.0-4.5 mg/dL)			
Hypophosphatemia	Confusion, seizures, numbness, weakness, possible coma Chronic state: rickets and osteomalacia	Vitamin D deficiency or hyperparathyroidism Use of aluminum-containing antacids	Assess for vitamin D deficiency, hyperparathyroidism, or overuse of aluminum-containing antacids.
Hyperphosphatemia	Anorexia, nausea, vomiting	Renal insufficiency	Assess for restlessness, confusion, chest pain, and cyanosis. Monitor respirations. Check all electrolyte levels.

Modified from deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.

Hypernatremia.

Hypernatremia occurs when the sodium level rises above 145 mEq/L. Water loss from fever, respiratory infection, or watery diarrhea is the usual cause. The body tries to correct the situation by conserving water through reabsorption in the renal tubules. Another cause of hypernatremia is the

excessive administration of sodium bicarbonate for the treatment of **acidosis** (excess acid or depletion of alkaline substances in the blood and body tissues). Good tissue turgor and firm subcutaneous tissues can be observed during hypernatremia. Hypernatremia causes an osmotic shift of fluid from the cells to the interstitial spaces, causing a cellular dehydration and interruption of normal cell processes. **Sodium intake is restricted for patients with hypernatremia** (see [Table 3-4](#)).

■ Nutrition Considerations

Foods High in Sodium*

- | | |
|---|---|
| <ul style="list-style-type: none">• Buttermilk• Canned meats or fish• Canned soups• Canned vegetables• Casserole and pasta mixes• Catsup• Cheese (all kinds)• Delicatessen meats• Dried fruits• Dried soup mixes• Foods containing monosodium glutamate (MSG)• Frozen vegetables with sauces• Gravy mixes | <ul style="list-style-type: none">• Ham• Hot dogs• Olives• Pickles• Prepared mustard• Preserved meats• Processed foods• Salted nuts• Salted popcorn• Salted snack foods• Softened water• Soy sauce• Tomato or vegetable juice |
|---|---|

* Check all packaged food labels for sodium content.

Potassium Imbalances

Hypokalemia.

Hypokalemia occurs when the potassium level falls below 3.5 mEq/L and has a variety of causes. Hypokalemia can cause serious problems. See [Table 3-4](#) for risk factors, signs and symptoms, and interventions for hypokalemia.

It is important to teach patients taking diuretics that are not potassium sparing to increase potassium in the diet, take potassium supplements as prescribed, and watch for signs of hypokalemia.

Severe hypokalemia (K^+ less than 2.5 mEq/L) may cause cardiac arrest. Extra potassium must be given to help correct an imbalance.

■ Nutrition Considerations

Common Foods High in Potassium

- | | |
|--|---|
| <ul style="list-style-type: none">• Apricots• Avocado• Baked potato with skin (small)• Banana (1 med)• Cantaloupe ($\frac{1}{4}$ med)• Dates, chopped• Figs• Honeydew melon ($\frac{1}{4}$ med)• Mango | <ul style="list-style-type: none">• Orange juice• Orange (1 med)• Pinto beans ($\frac{1}{2}$ cup)• Prune juice ($\frac{1}{2}$ cup)• Prunes• Raisins, seedless• Spinach• Tomatoes• Winter squash |
|--|---|

■ Safety Alert

Intravenous Potassium

Urine output must be at least 30 mL/hr before intravenous (IV) potassium is administered. Intravenous potassium must always be diluted before administration and is never given as a “push” (rapid, undiluted) injection.

Hyperkalemia.

Hyperkalemia occurs when the serum potassium level rises above 5.0 mEq/L. The mechanical disruption of cell membranes causes a shift of potassium from the ICF to the ECF. This shift happens when extensive tissue damage occurs from burns or crush injuries. **Hyperkalemia can cause life-threatening cardiac dysrhythmia.**

Calcium Imbalances

Hypocalcemia.

Hypocalcemia occurs when the calcium level drops below 8.4 mg/dL. Hypocalcemia results from disorders in which there is a shift of calcium into the bone. Removal or injury of the parathyroid glands during thyroidectomy causes parathyroid hormone deficiency and consequent hypocalcemia. Conditions that cause **alkalosis** (excess of alkaline or decrease of acid substances in the blood and body fluids) may cause hypocalcemia. Hypocalcemia in renal failure results from retention of phosphate ions, which causes a loss of calcium ions. In addition, during renal failure, vitamin D is not activated, causing the loss of absorption of calcium from the intestinal tract.

- Calcium ions are needed for a variety of metabolic processes and enzyme reactions, including for blood clotting. Calcium deficit upsets the stability of nerve membranes, causing abnormalities in nerve conduction and muscle contractions. **Carpopedal spasm** (also called Trousseau sign), hyperactive reflexes, Chvostek sign, and **tetany** (skeletal muscle spasm in which the muscles are in sustained contraction and causing spasm) may occur. Laryngospasm may occur if the deficit is severe (see [Table 3-4](#)).
- Check for Trousseau and Chvostek signs when calcium or magnesium deficit are a possibility. To test for Trousseau sign, place a blood pressure cuff on the arm, inflate above systolic pressure, and hold for 3 minutes; if a spasm of the hand occurs, the reaction is positive ([Figure 3-5](#)). Tapping the facial nerve about an inch in front of the earlobe assesses Chvostek sign. A unilateral twitching of the face is a positive response ([Figure 3-6](#)). Test deep tendon reflexes by tapping a partially stretched muscle tendon with a percussion hammer. The extent of the reflex is scored from 0 to 4+, with 0 representing no response, 2+ a normal response, and 4+ a hyperactive response.

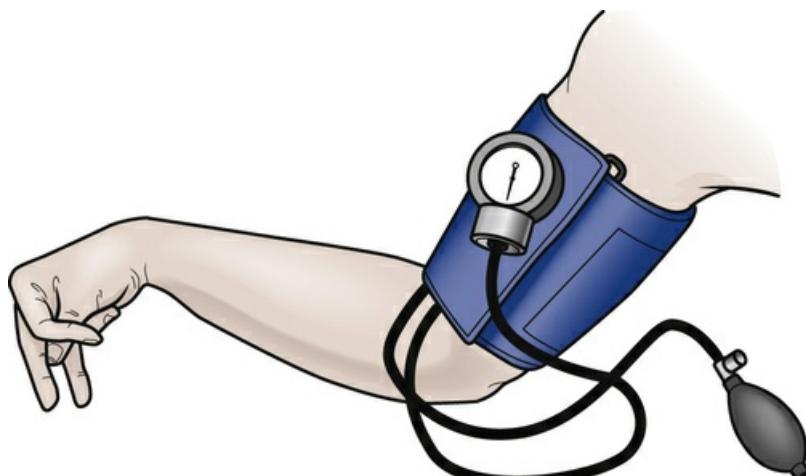

FIGURE 3-5 Palmar flexion (carpopedal spasm) indicating positive Trousseau sign in hypocalcemia. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Critical thinking for collaborative care*, ed. 6, Philadelphia, 2010, Saunders.)

FIGURE 3-6 Facial muscle response indicating positive Chvostek sign in hypocalcemia. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Critical thinking for collaborative care*, ed. 6, Philadelphia, 2010, Saunders.)

Hypercalcemia.

Hypercalcemia occurs when the serum calcium level is above 10.6 mg/dL. This can occur during periods of lengthy immobilization, when calcium is mobilized from the bone, or when an excess of calcium or vitamin D is taken into the body. See [Table 3-4](#) for signs and symptoms, risk factors, and interventions. Administer diuretics to increase calcium excretion, and encourage high fluid intake.

Magnesium Imbalances

Hypomagnesemia.

Hypomagnesemia occurs when the serum level drops below 1.3 mEq/L and usually is present when hypokalemia and hypocalcemia occur. Magnesium is important in deoxyribonucleic acid (DNA) and protein synthesis and in many enzyme reactions. Magnesium imbalances are rare but can be caused by a variety of factors (see [Table 3-4](#)).

Hypermagnesemia.

Hypermagnesemia is present when the serum level is above 2.1 mEq/L. It can occur in the presence of renal failure or from overuse of magnesium-containing antacids and cathartics. Hypermagnesemia is rare.

Anion Imbalances

Because of electroneutrality, imbalances of chloride, phosphate, and bicarbonate accompany cation imbalances. **Hypochloremia** (a chloride level below 95 mEq/L) is associated with hyponatremia. Hypochloremia can also occur with severe vomiting and is seen as a compensatory decrease in acid-base disorders. **Hyperchloremia** (a chloride level above 103 mEq/L) that coincides with hypernatremia is a form of metabolic acidosis. **Hypophosphatemia** occurs when the phosphate level falls below 3.0 mg/dL. Hypophosphatemia may result from use of aluminum-containing antacids that bind phosphate, vitamin D deficiency, or hyperparathyroidism. **Hyperphosphatemia** (a level above 4.5 mg/dL) commonly occurs in renal failure. See [Table 3-4](#) for signs and symptoms of phosphate imbalance.

Acid-Base System

Physiology

It is crucial to maintain acid-base balance, because cell enzymes function within a very narrow pH range (7.35 to 7.45). To understand the concept of acid-base balance and how it is maintained in the body fluids, you should be familiar with some basic facts about biochemistry and the terms commonly used in discussions of hydrogen ion concentration (Box 3-3).

Box 3-3

Some Chemistry Facts Related to Acid-Base Balance

- An **acid** is a substance capable of giving up a hydrogen ion during chemical exchange.
- A **base** is a substance capable of accepting a hydrogen ion.
- Acids react with bases to form water and a salt.
- A reaction of an acid and a base to form water and a salt is a *neutralization reaction* because *both the acid and the base are neutralized*.
- Acids react with carbonates and bicarbonates to form carbon dioxide gas.
- The term *pH* refers to the concentration of hydrogen (H) in a solution. The “p” represents a **negative logarithm**, which is an inverse proportion. This means that **the higher the concentration of hydrogen ions in a solution, the lower the pH**. A higher pH indicates the opposite, that is, a lower concentration of hydrogen ions.
- A chemically neutral solution has a pH of 7.0.
- **The pH of the body's fluids is normally somewhat alkaline (between 7.35 and 7.45).**
- A pH below 7.25 or above 7.55 is considered life-threatening.
- A pH below 6.8 (**acidosis**) or above 7.8 (**alkalosis**) usually is fatal.
- A blood pH of 7.4 indicates a ratio of 1 part carbonic acid to 20 parts bicarbonate (base).
- Acidosis is the result of either a loss of base or an accumulation of acid.

Nutrients in the blood diffuse into the cells, where various metabolic processes take place. Metabolic wastes, including acids, from those cellular processes diffuse back from the cells to the blood. The following three mechanisms control or try to rebalance pH:

- Buffer pairs—groups of chemicals that absorb excess acids or excess bases—circulating in the blood respond to pH changes quickly. The bicarbonate–carbonic acid buffer system is responsible for more than half of the buffering. Three other buffer systems in the body include the phosphate, hemoglobin, and protein systems.
- The respiratory system alters breathing rate and depth. Because carbon dioxide dissolves in the blood and combines with water to form carbonic acid, retaining or blowing off carbon dioxide helps retain or eliminate acids from the body.
- The kidneys change the excretion rate of acids and the production and absorption of bicarbonate ion. The kidneys are slow to compensate but are the most effective compensating mechanism (Figure 3-7).

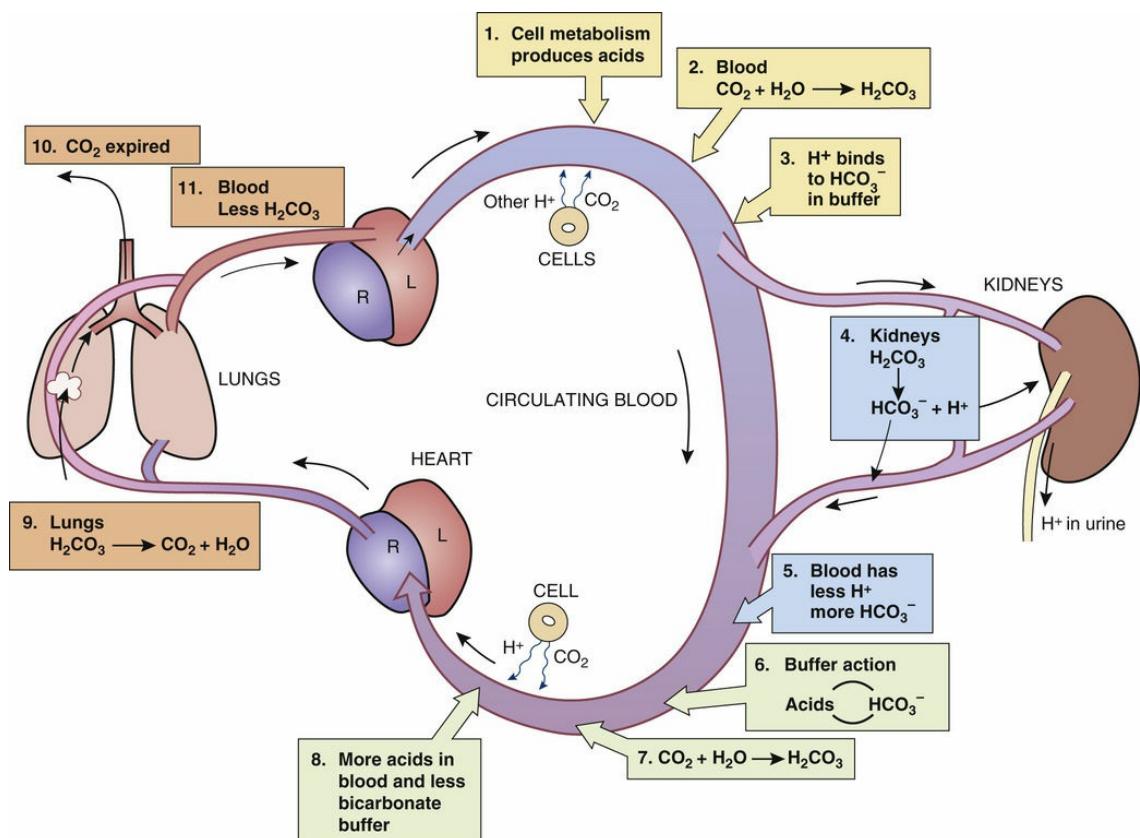

FIGURE 3-7 Regulation of acid-base balance by chemical buffers, respiratory system, and renal system. (From deWit SC: *Fundamental concepts and skills for nursing*, ed. 2, Philadelphia, 2005, Saunders.)

The bicarbonate–carbonic acid buffer system links an acid (carbon dioxide) with water and a base (bicarbonate ion). A buffer is a substance that increases the amount of acid or alkali in the solution to produce a unit change in pH. The balance of the bicarbonate ions and carbonic acid ions is controlled by the respiratory system and by the kidneys. The carbon dioxide produced by cell metabolism diffuses into the blood. There carbon dioxide reacts with water and forms carbonic acid. The carbonic acid dissociates (separates) to form hydrogen ions and bicarbonate ions, as needed. The process can be reversed in the lungs, freeing up carbon dioxide so it can be expired along with water, thereby reducing the total acid in the body.

Enzymes in the kidney promote the formation of hydrogen ions, which are excreted in the urine while the bicarbonate ions are returned to the blood. The kidneys, through the influence of aldosterone, can exchange hydrogen ions for sodium ions. Acids can be removed in the kidney by combining them with ammonia and other basic chemicals. Urine pH can vary from 4.5 to 8.0 as kidney compensation occurs.

Acid-Base Imbalances

Pathophysiology

Most of the body's metabolic activities produce carbon dioxide gas, which moves from the tissues into the blood, where it combines with water to form carbonic acid ($\text{CO}_2 + \text{H}_2\text{O} = \text{H}_2\text{CO}_3$). The body deals with this constant manufacture of acid in a number of ways so that the correct ratio of carbonic acid to bicarbonate can be maintained and an alkaline environment provided for normal cellular activities. If the ratio is not maintained, the acid-base balance is upset. The pH will either fall below the normal range and acidosis will occur, or pH will rise above normal range and alkalosis will be present. As long as the ratio of carbonic acid to bicarbonate is maintained at 1 : 20, the pH remains within normal limits. In a respiratory imbalance, the lungs retain or "blow off" (excrete) carbon dioxide (CO_2). In **hypoventilation**, the lungs do not eliminate enough CO_2 , and CO_2 remains in the body, unites with water, and forms carbonic acid. The opposite is **hyperventilation**, in which too much CO_2 may be blown off.

The kidneys are the principal organs of control in maintaining a normal pH during metabolic activities because they either reabsorb or excrete bicarbonate. If they eliminate too much bicarbonate, acidosis will develop. Conversely, if they fail to eliminate enough bicarbonate and allow it to be reabsorbed into the bloodstream, alkalosis will develop.

In the presence of respiratory acidosis, the kidneys will retain and manufacture more bicarbonate than normal so it is available to neutralize the excess acid. However, this is a slow process that takes from a few hours to several days. In the presence of respiratory alkalosis, the kidneys will increase their excretion of bicarbonate. In response to metabolic acidosis, the patient will involuntarily hyperventilate to remove CO_2 so it is not available to produce carbonic acid. If metabolic alkalosis develops, the patient will hypoventilate to retain the supply of carbon dioxide.

The foregoing information on acid-base balance, hydrogen ion concentration, and the carbon dioxide–bicarbonate ratio does not represent an in-depth explanation. Many complex chemical activities are involved in maintaining an internal environment that must be slightly alkaline for normal body function.

Because acidosis and alkalosis are common to a great variety of medical and surgical illnesses and conditions, the chapters on specific illnesses will address associated problems of acid-base imbalance.

The four types of acid-base imbalances are shown in **Table 3-5**. To determine whether an acid-base imbalance exists, the pH, PaCO_2 , and HCO_3^- are measured by arterial blood gas analysis. Imbalances may be acute or chronic. **An initial change in carbon dioxide is nearly always the result of a respiratory disorder. Metabolic disorders show an initial change in bicarbonate ions.** Three control mechanisms continually work together to maintain acid-base balance: the respiratory system, the kidneys, and the bicarbonate buffer system. When an imbalance occurs, the lungs and kidneys try to **compensate** by working to bring the pH back toward normal limits.

Table 3-5
The Four Acid-Base Imbalances

IMBALANCE	CAUSES	BLOOD GAS VALUES
Respiratory acidosis	Slow, shallow respirations	pH < 7.35
	Respiratory congestion or obstruction	$\text{PaCO}_2 > 45 \text{ mm Hg}$
Metabolic acidosis	Shock (poor circulation)	pH < 7.35
	Diabetic ketoacidosis	$\text{HCO}_3^- < 22 \text{ mEq/L}$
	Renal failure	
	Diarrhea	
Respiratory alkalosis	Hyperventilation	pH > 7.45
		$\text{PaCO}_2 > 35 \text{ mm Hg}$
Metabolic alkalosis	Vomiting	pH > 7.45
	Excessive antacid intake	$\text{HCO}_3^- > 26 \text{ mEq/L}$
	Hypokalemia	

From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.

Arterial Blood Gas Analysis

Studies of the percentages of gases (oxygen and carbon dioxide) in the blood and the hydrogen ion concentration (pH) are useful in assessing the status of both respiratory and metabolic acid-base imbalances. Blood gas studies are valuable indicators of a patient's progress toward recovery, or lack of it. Blood gas analyses reflect the ability of the lungs to exchange oxygen and carbon dioxide, the effectiveness of the kidneys in balancing retention and elimination of bicarbonate, and the effectiveness of the heart as a pump. The results of analyses of arterial blood gases (ABGs) are reported as follows:

- **Pao₂:** Partial pressure (P) exerted by oxygen (O₂) in the arterial blood (a). The normal value is 80 to 100 mm Hg; it indicates the amount of oxygen carried in the blood.
- **Paco₂:** Partial pressure of carbon dioxide in the arterial blood. The normal value is 35 to 45 mm Hg; it indicates the amount of carbon dioxide in the blood.
- **pH:** An expression of the extent to which the blood is alkaline or acid. The normal value is 7.35 to 7.45.
- **SaO₂** (also abbreviated **O₂ Sat.**): Percentage of available hemoglobin that is saturated (Sa) with oxygen, that is, the ratio of the amount of oxygen that is combined with hemoglobin to the total amount of oxygen the hemoglobin can carry. The normal value is 94% to 100%.
- **HCO₃⁻:** The level of plasma bicarbonate; an indicator of the metabolic acid-base status. The normal value is 22 to 26 mEq/L.
- **Base excess or deficit:** Indicates the amount of blood buffer present. Alkalosis is present when this value is abnormally high. Abnormally low values indicate acidosis. Alkalosis is measured in "+" or "-" values.

Respiratory Acidosis

An increase in carbon dioxide levels occurs in a variety of disorders. It is seen in the following conditions:

- Acute problems such as airway obstruction, pneumonia, asthma, chest injuries, or pulmonary edema
- Chronic obstructive pulmonary disease (COPD), such as emphysema
- With opiate use that depresses the respiratory rate

Think Critically

What could you do to help prevent respiratory acidosis in a home care patient who has pneumonia?

A patient with COPD is most likely to develop acute acidosis when an infection of the respiratory tract further impairs breathing capacity and the removal of carbon dioxide. Signs and symptoms of respiratory acidosis include complaints of increasing difficulty in breathing, a history of respiratory obstruction (acute or chronic), dyspnea, weakness, dizziness, restlessness, sleepiness, and change in mental alertness.

The treatment for respiratory acidosis is establishment or maintenance of an airway. A tracheostomy or the insertion of an endotracheal tube may be necessary. Oxygen administration may be needed, and the assistance of a mechanical ventilator may be required. Conservative treatment is by postural drainage, deep-breathing exercises, bronchodilators, and antibiotics if indicated. Care must be taken when administering certain drugs that depress the respiratory center, including narcotics, hypnotics, and tranquilizers.

The patient must be watched closely for respiratory and cardiac arrest. Should either occur, it will be necessary to maintain respiration and circulation artificially through cardiopulmonary resuscitation.

Clinical Cues

In patients with COPD, the respiratory drive mechanism is altered, and oxygen can act as a respiratory depressant. Oxygen should be administered with great care to these patients (no more

than 2 to 3 L/min) because it can cause respiratory arrest.

If a patient's history is unknown, oxygen is begun at a rate of 2 to 3 L/min until it is determined that a higher flow rate can be tolerated.

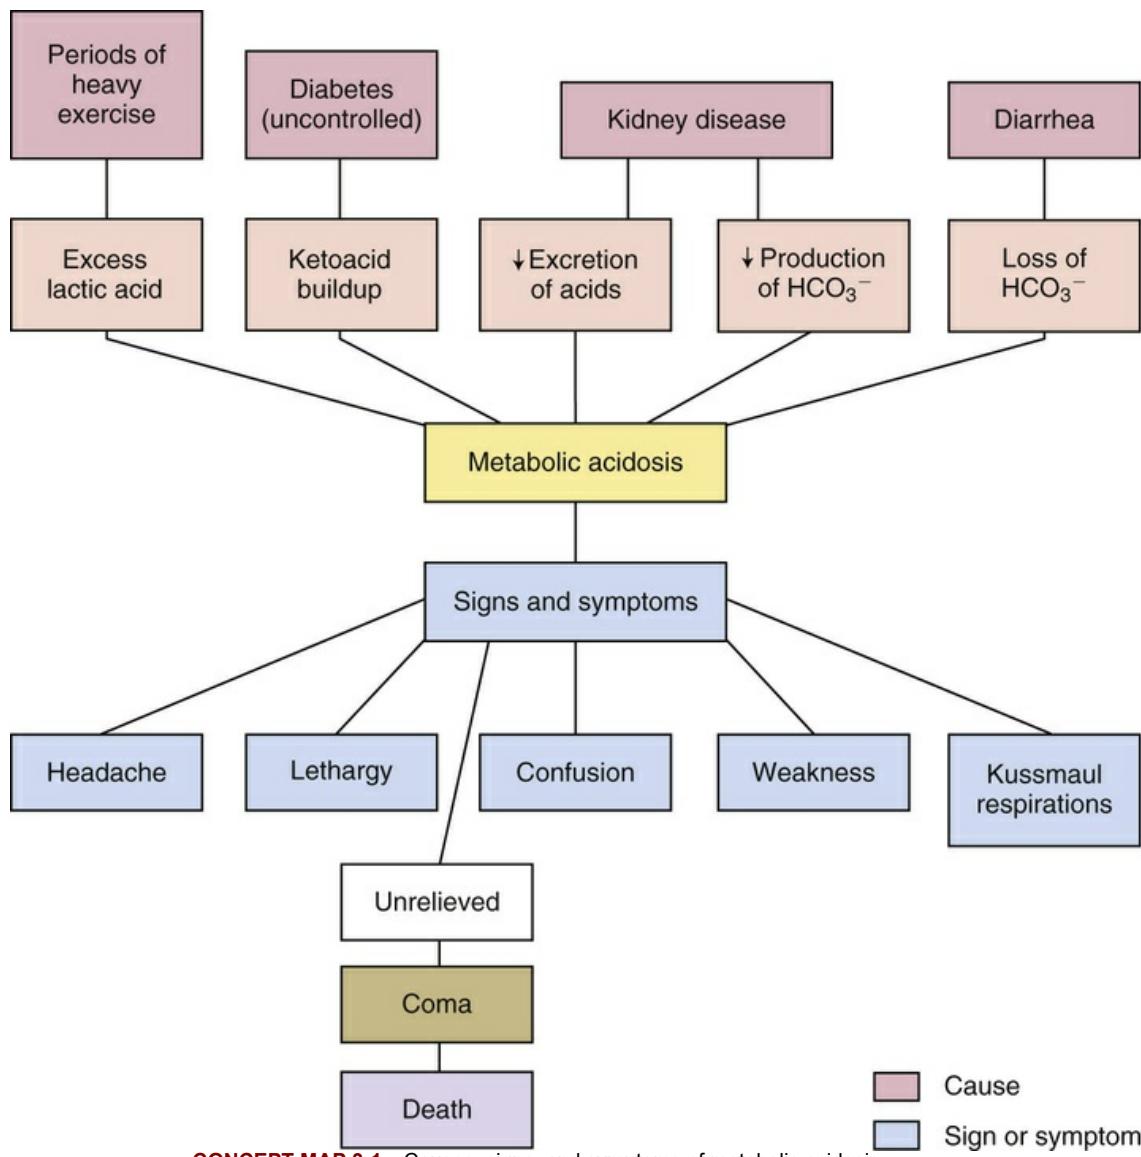

Metabolic Acidosis

An excessive loss of bicarbonate ions or an increased production or retention of hydrogen ions leads to metabolic acidosis. The main causes of metabolic acidosis include:

- Excessive loss of bicarbonate ions from diarrhea
- Renal failure
- Diabetic ketoacidosis
- Hyperkalemia

In diabetes mellitus, insulin insufficiency leads to excessive burning of fats, and the end product is fatty acids. When more energy than usual is expended, as in athletic competition, lactic acid builds up in the body as oxygenation of tissue falls. In kidney disease there is decreased excretion of acids and decreased production of bicarbonate. The increased buildup of acids causes metabolic acidosis.

The symptoms of metabolic acidosis include weakness, lethargy, headache, and confusion ([Concept Map 3-1](#)). If the acidosis is not relieved, these symptoms progress to stupor, unconsciousness, coma, and death. The breath of the patient may have a fruity odor from the ketone bodies ([ketacidosis](#)). Vomiting and diarrhea may occur and aggravate the metabolic imbalance because of the loss of fluids and electrolytes, which are essential to restoring the acid-base balance. When compensatory mechanisms are working to correct metabolic acidosis, the patient may have deep, rapid breathing (Kussmaul respirations) and may secrete urine with a low pH.

Treatment of metabolic acidosis is aimed at the underlying cause. Insulin is administered if the patient is in diabetic ketoacidosis. Dialysis may be necessary to correct the problem in a patient with kidney failure. **Immediate treatment of severe metabolic acidosis requires administration of IV bicarbonate or lactate.**

Respiratory Alkalosis

Alkalosis is less common than acidosis. **Hyperventilation** (a rapid respiratory rate) results in respiratory alkalosis. Hyperventilation is usually caused by:

- Anxiety
- High fever
- An overdose of aspirin

Patients hyperventilate for a variety of reasons, including **hypoxemia** (insufficient oxygen, which triggers an automatic increase in respiration), reactions to certain drugs, pain, and panic. The overzealous use of mechanical ventilation also can cause hyperventilation, when too much CO₂ is blown off. Head injuries may also lead to hyperventilation. **Symptoms of respiratory alkalosis include deep, rapid breathing, tingling of the fingers, pallor around the mouth, dizziness, and spasms of the muscles of the hands.**

Treatment for hyperventilation addresses the underlying disorder. The person may breathe

through a re-breather mask temporarily, mixing the excessively exhaled carbon dioxide with oxygen so that carbon dioxide is reinhaled. If the underlying cause of respiratory alkalosis is panic, treatment is aimed at preventing further hyperventilation and helping the patient reestablish a normal level of carbon dioxide in the blood. Sedatives may be given to calm the patient. To aid in the retention of carbon dioxide, the patient may be instructed to hold the breath, or to breathe into a paper sack and re-breathe the carbon dioxide just exhaled. This recycling of carbon dioxide can eventually restore normal carbonic acid levels in the blood.

Metabolic Alkalosis

Metabolic alkalosis follows a loss of hydrochloric acid from the stomach. Causes include the following:

- Vomiting
- Extensive gastrointestinal suction
- Hypokalemia
- Excessive use of antacids with bicarbonate

Hypokalemia causes metabolic alkalosis, because the kidney retains K^+ while excreting H^+ .

Other causes include drainage from intestinal fistula; diuresis resulting from potent diuretics that increase potassium loss in the urine; and steroid therapy, which causes retention of sodium and chloride and loss of potassium and hydrogen.

Symptoms of metabolic alkalosis include such neurologic signs as irritability, disorientation, lethargy, muscle twitching, tingling and numbness of the fingers, and convulsions and respiratory manifestations such as slow, shallow respirations; decreased chest movements; and cyanosis. In addition, there may be symptoms of potassium and calcium depletion. If alkalosis progresses, tetany will occur, with resulting seizures and coma. Tetany is characterized by severe muscle cramps, carpopedal spasms, laryngeal spasms, and **stridor** (a shrill, harsh sound on inspiration).

Treatment is directed at correcting the underlying cause and attempting to restore the body fluids to a less alkaline state. Fluids and electrolytes are replaced orally and parenterally as needed. Emergency measures include the administration of an acidifying solution, such as ammonium chloride. [Figure 3-8](#) compares the causes, physiologic effects, and compensatory mechanisms for acidosis and alkalosis.

Think Critically

Can you identify the type of imbalance that might result from (1) rapid respiratory rate, (2) out-of-control diabetes, (3) renal failure, and (4) eating antacids for a nervous stomach?

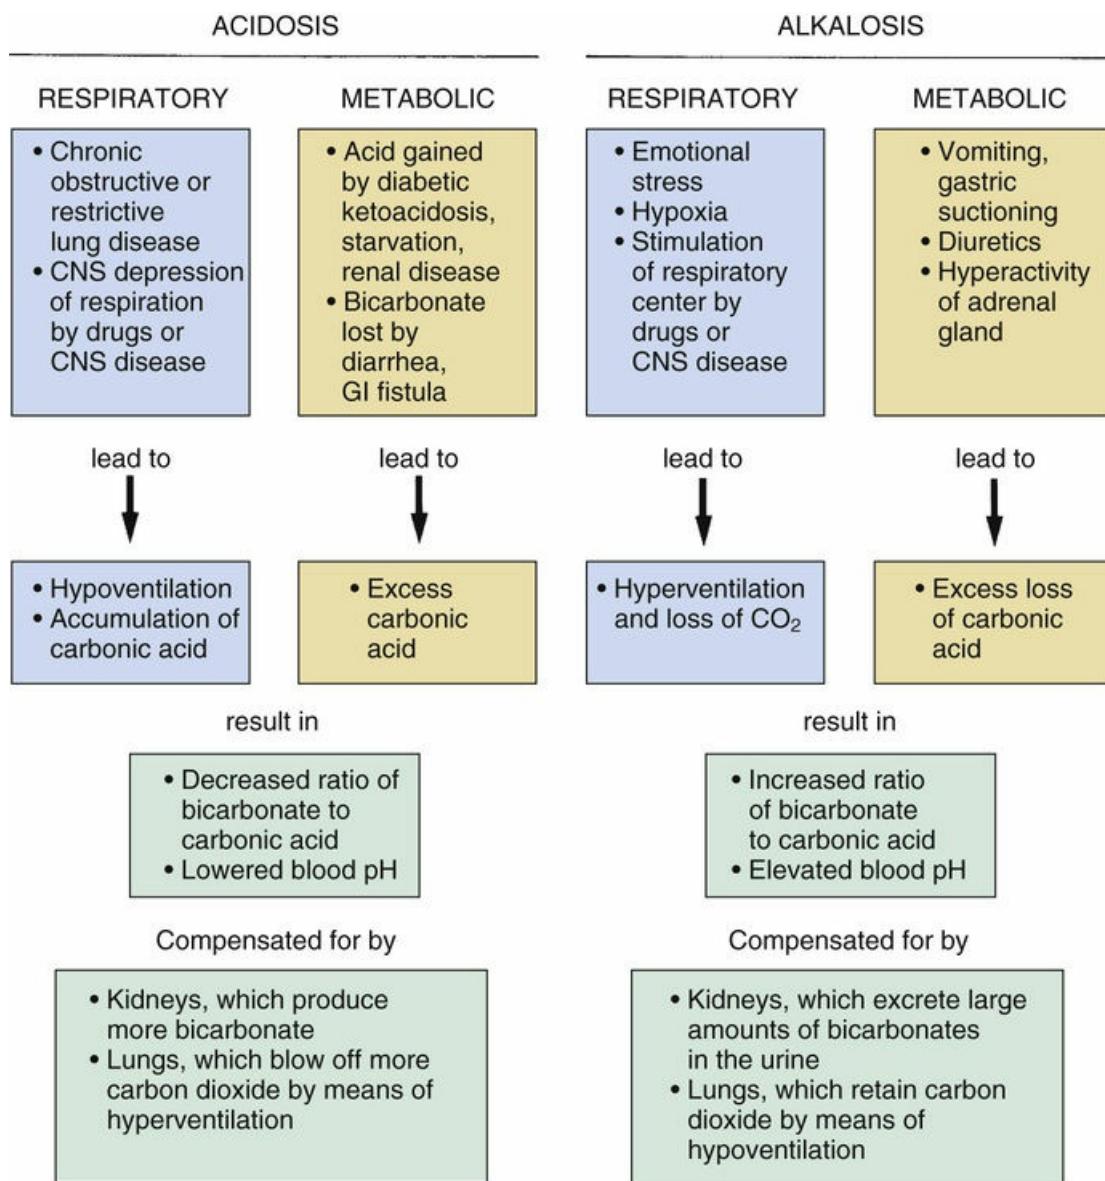

FIGURE 3-8 Comparison of causes, physiologic effects, and compensatory mechanisms for acidosis and alkalosis. CNS, Central nervous system; GI, gastrointestinal. (From deWit SC: *Fundamental concepts and skills for nursing*, ed. 2, Philadelphia, 2005, Saunders.)

Home Care

For the home care patient, teach about the requirements for fluid intake or restriction. Monitor adherence to sodium restriction by periodically checking the patient's food intake. Obtain feedback to be certain the patient understands the instructions. Collaborate with the patient on the plan of care to obtain patient compliance.

When acid-base imbalance occurs, control of the underlying disorder is a priority. Blood gases are monitored, and oxygen and electrolytes are administered as needed. Nursing measures to improve pulmonary function are instituted as appropriate.

Think Critically

What measures could assist a patient who is in metabolic acidosis to restore acid-base balance?

Intravenous Fluid Therapy

Administering fluids through the veins is the most common means by which water, electrolytes, nutrients, and some drugs may be given when oral intake is not possible or must be supplemented. Intravenous therapy is often used when a fluid deficit is present or when there are electrolyte imbalances. Intravenous fluids may also be used to help reestablish acid-base balance. Medications are administered in an IV solution when rapid action is required. TPN is used for administering nutrients to patients with gastrointestinal problems who cannot take in nutrients in any other way.

Some terms related to the concentration of an IV fluid and its effect on cells include:

- **Isotonic:** A solution that has the same osmotic pressure as ICF. Body cells can be bathed in an isotonic solution without net flow of water across the cell membrane.
- **Hypotonic:** A solution that has a lower osmotic pressure (is less concentrated) than that of body fluids. Cells bathed in a hypotonic solution will swell as water passes from the less-concentrated solution across the cell membrane and into the cell. **Note: Sterile distilled water is hypotonic and is never added to an IV solution.**
- **Hypertonic:** A solution that has a higher osmotic pressure than that of body fluids. Cells bathed in a hypertonic solution will shrink as water passes out of the cell into the fluid surrounding it.

An example of an isotonic solution is 0.9% normal saline. Hypotonic solutions are those with less than 5% glucose or with anions less than 150 mEq/L. Fluids commonly used in IV therapy are presented in **Table 3-6**.

Table 3-6
Commonly Prescribed IV Solutions

SOLUTION	TONICITY	mOsm/kg	GLUCOSE (g/L)	INDICATIONS AND CONSIDERATIONS
Dextrose in Water				
5%	Isotonic	278	50	Provides free water necessary for renal excretion of solutes Used to replace water losses and treat hyponatremia Provides 170 calories/L Does not provide any electrolytes
10%	Hypertonic	556	100	Provides free water only, no electrolytes Provides 340 calories/L
Saline				
0.45%	Hypotonic	154	0	Provides free water in addition to Na^+ and Cl^- Used to replace hypotonic fluid losses Used as maintenance solution, although it does not replace daily losses of other electrolytes Provides no calories
0.9%	Isotonic	308	0	Used to expand intravascular volume and replace extracellular fluid losses Only solution that may be administered with blood products Contains Na^+ and Cl^- in excess of plasma levels Does not provide free water, calories, other electrolytes May cause intravascular overload or hyperchloremic acidosis
3.0%	Hypertonic	1026	0	Used to treat symptomatic hyponatremia Must be administered slowly and with extreme caution because it may cause dangerous intravascular volume overload and pulmonary edema
Dextrose in Saline				
5% in 0.225%	Isotonic	355	50	Provides Na^+ , Cl^- , and free water Used to replace hypotonic losses and treat hyponatremia Provides 170 calories/L
5% in 0.45%	Hypertonic	432	50	Same as 0.45% NaCl except provides 170 calories/L
5% in 0.9%	Hypertonic	586	50	Same as 0.45% NaCl except provides 170 calories/L
Multiple Electrolyte Solutions				
Ringer's solution	Isotonic	309	0	Similar in composition to plasma except that it has excess Cl^- , no Mg^{2+} , and no HCO_3^- Does not provide free water or calories Used to expand the intravascular volume and replace extracellular fluid losses
Lactated Ringer's (Hartmann's) solution	Isotonic	274	0	Similar in composition to normal plasma except does not contain Mg^{2+} Used to treat losses from burns and lower gastrointestinal tract May be used to treat mild metabolic acidosis but should not be used to treat lactic acidosis Does not provide free water or calories

Modified from Lewis SM, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2014, Mosby.

Blood-related fluids that are given IV include whole blood; packed cells from which the plasma has been removed, leaving only the red blood cells; and plasma. Whole blood is sometimes given to replace blood that has been lost through hemorrhage. Packed cells may be administered to patients with anemia or some other blood disorder, or to patients who cannot tolerate a large volume of fluid very well, such as those with renal disease or heart failure. Plasma is given to increase blood volume (as in shock), to provide protein, and to treat disorders of coagulation.

In the treatment of shock, **plasma expanders** are administered to increase the volume of plasma. Examples of plasma expanders are low-molecular-weight dextran, albumin, Hespan, and Plasmanate. Blood disorders and blood product administration are further presented in [Chapter 16](#).

Nursing Responsibilities in Administering Intravenous Fluids

Responsibility for the safe and effective administration of IV fluids rests with every member of the nursing staff.

Legal and Ethical Considerations

Intravenous Therapy Guidelines

Check your state's nurse practice act to determine what aspects of IV therapy, if any, your state will allow the LPN/LVN to perform. With the continuation of the nursing shortage, a few states have expanded their LPN/LVN practice act to allow licensed LPN/LVNs to perform a variety of IV therapy functions. Other states are considering expanding their practice acts accordingly.

As with any therapeutic measure, IV therapy is not without its hazards to the patient. Many complications can be avoided through careful handling of equipment and meticulous monitoring of the patient's reaction to the fluids being administered. Maintaining sterility is paramount.

Safety Alert

Intravenous Line Connection Safety

When connecting an IV solution or disconnecting a line, always trace the line to where it connects to the patient to make certain that it is an IV line and connects to an IV device. Many mistakes have been made when IV fluids have been connected to the wrong device.

The four goals of nursing care for a patient receiving an IV infusion are to (1) prevent infection, (2) minimize physical injury to the veins and surrounding tissues, (3) administer the correct fluid at the prescribed time and at a safe rate of flow, and (4) observe the patient's reaction to the fluid and medications being administered ([Box 3-4](#)).

Box 3-4

The Six Rights Applied to Intravenous Therapy

Be sure you have:

1. The right solution with or without additives as ordered; the correct solution to follow what has been infusing
2. The right dose (amount) of solution and additive as ordered
3. The right route (peripheral intravenous [IV], peripherally inserted central catheter [PICC], central line, port)
4. The right time (to infuse)
5. The right patient as identified with two identifiers
6. The right documentation

Additionally:

- Teach the patient the reason for administration of the fluid and/or drug and signs and symptoms of problems to report to you.
- Check for drug and latex allergies.
- Be aware of potential interactions with IV medications or irrigating solutions.

- Maintain sterility of all solutions, tubing, and connections.

All equipment and fluids used for IV therapy must be sterile and safe for administration. **Before any plastic bag or bottle of solution is added to an IV set, it must be checked for leaks and possible contamination.**

Safety Alert

Intravenous Solution Safety

A plastic bag of solution may be squeezed to check for leaks. Any solution that is discolored or has small particles, a white cloud, or film in it should not be used. If there is no vacuum in a bottle when it is opened, the solution may be contaminated. Gently invert the bag or bottle and hold it up to the light so you can see if there are any particles floating in it.

When a new bottle of fluid or additional medication is added to an IV infusion already in progress, strict surgical asepsis must be observed because there is a danger of introducing bacteria into the patient's blood system. Because of the danger of incompatibility, it is essential to check each drug and each solution to be certain they can be mixed. Your pharmacist is a good resource to consult. **Always wash your hands just before handling IV fluids and equipment. The port on the IV tubing into which the administration set of a piggyback medication is to be attached must be carefully and thoroughly wiped with a fresh alcohol swab, scrubbing thoroughly for 15 seconds, before the tubing is attached to the container.**

There should be a clear occlusive (airtight) dressing over the IV insertion site. The edges of the dressing should adhere to the skin on all sides. Tubing should be secured so that accidental pulling on the tubing will not affect the IV cannula. Dressings are changed according to agency protocol, but usually are changed at least every 72 hours. If a dressing becomes loose, soiled, or contaminated, it should be removed and a new dressing applied ([Box 3-5](#)). Label tubing and dressing with the date.

Box 3-5

Intravenous Therapy Guidelines

- **Keep intravenous (IV) fluid sterile.** Make sure that everything coming in contact with the solution is sterile, including the inside surface of the cannula hub and all connecting points between the bag and drip chamber and between the tubing and the needle.
- **Protect the cannula site from contamination to prevent possible infection.** An airtight, transparent dressing is used over the cannula site.
- **Keep tubing free of air.** Clear tubing of air before connecting to the cannula. Do not allow the current bag to run dry before changing to the next one.
- **Hang fluids at the correct height.** Fluids flow through the tubing by the force of gravity. If there is negative pressure in the IV line, blood will flow back into the tubing. Keep the bag of fluid sufficiently above the level of the cannula site to maintain flow, but avoid having it too high because this significantly increases the effect of gravity.
- **Carefully regulate the rate of flow.** If the IV infusion is behind schedule, do not open up the clamp and run in a large amount of fluid at one time to catch up. Rather, recalculate either (1) the span of time for the infusion or (2) the rate of drops per minute for the fluid to run at the ordered rate.
- **Track intake and output when a patient is receiving IV fluids or blood.** Keep accurate intake and output records and compare intake with output over 24 hours.

- **The solution to run in first should be hung the highest.** When a second bag is attached piggyback to a primary IV line, lower the primary bag without clamping the tubing so it will begin to flow when the piggyback has run in. Attach the piggyback beneath the roller clamp on the primary tubing.
- **Assess the site frequently for signs of complications.** Infiltration, swelling at the IV site, irritation of the vein, formation of a clot stopping the flow, or systemic reaction should be identified quickly. Signs of infiltration are pain or discomfort at the site caused by dislodgement of the needle or puncture of the vein. Vital signs should be taken several times a day to detect early signs of infection or adverse reaction.

Go to Evolve for step-by-step Skills related to IV therapy.

The site of venipuncture should be watched closely for signs of inflammation. Redness, swelling, and heat in the area should be reported, because they are possible signs of phlebitis. Chills and elevated body temperature may indicate a bacterial infection. **Table 3-7** presents the potential complications of IV therapy.

Table 3-7
Complications of Intravenous Therapy and Nursing Interventions

COMPLICATION	SIGNS AND SYMPTOMS	NURSING INTERVENTIONS
Local		
Infiltration	Arm swollen, tender, cool to touch; IV catheter may or may not have blood return	Remove IV catheter and restart IV infusion in the other extremity.
Extravasation	Pain at insertion site, tender and cool to touch, IV flow slows, edema, burning, pale, fluid leaking around catheter Tissue sloughing may occur in 1-4 wk	Stop infusion immediately. If drug is involved, aspirate from short cannula. Then remove the IV catheter after injecting an antidote through the IV catheter if one is available, and restart in the other extremity. Apply cold compresses if not contraindicated. Photograph site. Monitor site for 24 hr. Provide written instructions for patient and family.
Phlebitis	Vein hard with skin red, swollen, tender, warm Blood return present IV infusion may or may not be sluggish	Remove IV catheter, document; apply warm, moist pack to the IV site. Restart IV infusion in other extremity. Monitor frequently.
Thrombophlebitis	Site red, tender, warm IV infusion sluggish	Never irrigate the IV catheter; remove the IV catheter, notify the provider, restart IV infusion in opposite extremity. Apply cool compresses initially, followed by warm compresses.
IV site skin infection	Site hot, red, painful but not hard or swollen IV infusion sluggish	Remove IV catheter, restart in opposite extremity, change entire administration system. Clean site with alcohol. Apply warm compresses. May send tip of catheter for culture.
Venous spasm	Slowing of infusion rate Cramping or pain at or above the insertion site Numbness in the area Inability to withdraw peripherally inserted central catheter (PICC) or midline catheter	Slow infusion rate and apply warm compresses. Do not apply tension to catheter or forcibly remove it. Encourage consumption of warm liquids. Keep extremity covered and dry.
Nerve damage	Tingling, "pins and needles" feeling, or numbness at or below the catheter insertion site	Immediately stop the cannula insertion if patient complains of severe pain. If sensations do not go away once the catheter is secured, remove the catheter.
Catheter embolus	Decrease in blood pressure (BP); pain along vein; weak, rapid pulse; cyanosis of nail beds; loss of consciousness	Remove IV catheter and inspect, place a tourniquet high on limb of IV site, notify provider, obtain x-ray, prepare for surgery to remove pieces.
Systemic		
Infection	Fever, chills, general malaise	Change the infusion system, notify the provider, obtain cultures as ordered.
Severe shock	Light-headedness or dizziness, flushed face, irregular pulse, decreased BP, loss of consciousness, cardiac arrest	Stop the infusion, notify the provider, monitor vital signs frequently. Run dextrose 5% in water at a keep-vein-open rate.
Circulatory overload	Shortness of breath, tachypnea, increased BP, moist cough, crackles, puffiness around eyes and dependent edema	Elevate head of the bed, keep patient warm, assess for edema, slow the infusion rate; notify the provider. Administer oxygen and diuretic as ordered.

When an IV infusion is discontinued, the tubing is clamped, all tape is removed, and the needle or catheter is gently, but quickly, withdrawn using *Standard Precautions* (see Chapter 6). Check to be sure the catheter has been completely removed and the tip is intact. A dry, sterile gauze is held on the site with enough pressure to control the leakage of blood and avoid the formation of a hematoma. If possible, raise the patient's limb for a minute or two to drain blood from the site of insertion and help prevent leakage of blood from the punctured vein.

A safety goal of The Joint Commission requires that at least two patient identifiers (neither identifier being the patient's room number) must be used whenever IV fluid is administered. You should check the patient's armband with the medication administration record for the correct name and the correct agency identification number, and then ask the patient to state his name.

Safety Alert

Six Rights for Intravenous Therapy

The IV administration of fluids requires the same safety precautions as any other medication. Follow the Six Rights and the additional rules for drug administration (see [Box 3-4](#)). The label must be read and compared with the order or the MAR three times to ensure that the correct solution is being given to the correct patient. The patient's ID band must be checked each time a solution is administered. Use two patient identifiers before administration.

Calculating and Regulating the Rate of Flow

Rate of flow is an important factor in safe and effective IV therapy. Intravenous setups should be checked once every hour, to be certain that the fluid is running correctly and that there are no problems. When possible, use an IV pump that is set for the specific rate of flow to administer IV fluids. Intravenous pumps, although not infallible, keep IV fluids flowing at the desired rate and act as safeguards should a problem arise. **Even when an IV pump is used, you must check to see that it is delivering the solution accurately, as prescribed.** Principles that affect the rate of flow for IV infusions **not** administered by a pump are as follows:

- The higher the container is placed above the level of the patient's heart, the faster the rate of flow, because gravity affects flow.
- The fuller the container, the faster the rate of flow.
- The more viscous (thicker) the fluid, the slower the flow; for example, packed red cells will flow more slowly than 5% dextrose in water.
- The larger the diameter of the needle and tubing, the faster the flow.
- The higher the pressure within the vein, the slower the flow. As an infusion progresses and the veins become fuller, the IV solution may drip more slowly.
- Fluid will pass through a straight tube faster than through one that is coiled or hanging below the level of the cannula.

There usually is a chart available to determine the number of drops that should be given per minute to administer a given amount of fluid in a specified time. The IV tubing package will contain information about the number of drops the set will deliver per milliliter. If a chart is not available, calculate the number of drops per minute to be infused. To check the rate of flow, you must know how many drops should pass through the drip chamber in **1 minute**.

Once the number of drops per minute has been set and the IV infusion is flowing, the IV setup must be checked at 30- to 60-minute intervals to be sure that it continues to flow at the prescribed rate. As explained in the list of principles that affect the rate of flow, a number of factors can speed up or slow down the infusion.

Older Adult Care Points

Older people and those with either renal or cardiac conditions cannot tolerate rapid administration of fluids. Check IV infusions for these patients every 30 minutes.

If the IV infusion slows down and has not been checked and readjusted for some time, **no attempt should be made to "catch up"** by speeding up the rate of flow beyond that ordered. This can lead to circulatory overload and a volume excess that may produce pulmonary edema in susceptible people. [Table 3-8](#) presents points to check when an IV solution will not run at the prescribed rate.

Clinical Cues

Whenever a patient who is receiving an IV infusion is out of bed, recheck the drop rate once he is back in bed. The fluid drop rate often changes when the patient is up and moving around.

Think Critically

How would you calculate the rate of flow for an order for "1000 mL of D₅W (dextrose 5% in water) over 8 hours" using a drip set that delivers 15 drops (gtt)/mL? How would the rate differ if the drip set delivers 20 gtt/mL? How would you calculate the flow rate for an order for "250 mL NS [normal

saline] at 50 mL/hour" using a microdrip set (60 gtt/mL)?

Table 3-8

Troubleshooting Intravenous Infusion Flow

CHECK	RATIONALE
Height of infusion container	Patient may have changed position. The container should be at least 36 inches above the heart.
System vent	The air vent, required for infusing with glass bottles, may be absent or occluded, which will prevent the flow.
Position of tubing	Tubing may be kinked, obstructing flow. Tubing may be hanging below the bed, interfering with the gravity flow.
Position of the extremity where the site is located	Flexion of the extremity may have compressed the vein, slowing the flow.
Any possible obstruction to flow	A protective device on the limb may be too tight. Tape may be compressing the circumference of the extremity.
When filter was changed	The filter may be occluded.
Position of the cannula within the vessel	The cannula may be lying against the vessel wall, obstructing flow. Slightly turning the cannula to reposition the tip may cure the problem.
If other measures have not opened the line, attempt to aspirate blood from the cannula	A small clot may be obstructing the cannula. Aspiration may withdraw the clot.

Intravenous Intake

The total amount of IV fluid infused during the shift is calculated at the end of the shift. For example, if the beginning count is 350 mL (in the container at the beginning of the shift), and the 350 mL is infused during the shift, then (during the same shift) a new solution of 1000 mL is added and some additional infusion takes place, we calculate as follows:

	COUNT	INFUSED
Count at beginning of shift	350 mL	
New solution added at 11:30	1000 mL	350 mL
Count left at end of shift	525 mL	475 mL
Total amount of IV intake for shift		825 mL

■ Safety Alert

No Margin for Error

Intravenous therapy may become such a commonplace procedure to nurses that they are tempted to be complacent about it. However, it should never be thought of as a routine procedure that requires little attention. Any fluid or medication that enters a vein has an immediate effect. There is no margin for error in its administration.

Flushing As-Needed Locks or Central Intravenous Lines

Flushing the catheter or line prevents contact and reactions between the fluid that was last infused and incompatible drugs. Flushing the catheter or line maintains patency of the lumen. Either normal saline alone or normal saline followed by a heparin solution is used.

Before using a PRN lock, flush the catheter according to agency policy to determine patency (openness) of the lumen and to flush out any heparinized solution. The procedure will depend on the type of valved catheter or positive fluid-displacement needleless device in place. When flushing the catheter, apply slow, gentle pressure to the syringe plunger. **If you feel any resistance, stop the procedure immediately.** Proceeding may force a clot into the venous circulation that will become an embolus that could cause severe damage to the patient. Aspirate for a brisk blood return from the catheter lumen, and then flush the blood from the catheter with the flush solution. Depending on the length of the catheter that is in place, 3 to 10 mL of normal saline is used.

■ Safety Alert

Flushing Intravenous Catheters

Do not use more than 30 mL of bacteriostatic normal saline within a 24-hour period to flush the catheter. Always use single-dose vials or syringes of solution for flushing. **Do not use a multiple-dose vial for this purpose, because it may be contaminated and could cause infection.**

PRN locks and catheters should be flushed immediately after use or whenever an IV piggyback medication infusion is completed. Delay in disconnecting the intermittent infusion administration

set and flushing the lock could allow blood backflow into the catheter lumen, because the infusion pressure drops lower than the venous pressure when the infusion is complete. In such a case, a clot can form, occluding the lumen. **Be aware of when an intermittent infusion should be completed, and at the appropriate time be at the bedside prepared to remove the piggyback infusion set and to flush the PRN lock.**

Clinical Cues

When heparinized saline is required to keep the lumen of a catheter patent, use a volume of the solution that is equal to twice the volume of the catheter lumen with the extension set or connectors added on. This will usually be between 5 and 10 mL; check your facility's policy.

Providing Central Line Care

If a gauze dressing is in place, provide site care every 24 to 48 hours per agency protocol. Transparent dressings require site care every 3 to 7 days. Every central line dressing should be examined once each shift, and the dressing should be changed if it is soiled. Central line dressing change and site care are sterile procedures. O'Grady et al (2002) developed guidelines for preventing catheter-related infections. The old  dressing is removed using gloves. A Central Line Bundle (series of interventions) has been developed by the Institute for Healthcare Improvement (IHI) to prevent infection from central lines. It has five components: optimal site selection, chlorhexidine skin antisepsis, hand hygiene, maximal barrier precautions, and daily review of line necessity with prompt removal if it is not needed (IHI, 2013).

Blood drawing.

 Drawing blood from a central line is not recommended unless venipuncture is not advisable. If a blood draw is performed, use strict aseptic technique. It is preferable to use needleless connectors and vacuum tubes, rather than a needle and syringe or vacuum tube with needle.

Subcutaneous infusion.

Subcutaneous infusion is often used in home care or during hospice palliative care. Subcutaneous therapy is useful when the patient cannot tolerate oral medications, when injections are too painful, or when vascular access is too difficult to obtain. Pain management is the primary use, although several other types of drugs are infused in this manner.

Hypodermoclysis (the slow infusion of isotonic fluid into subcutaneous tissue) may be used for small volumes of fluid. Generally, the front and sides of the thighs, the hips, the area under the clavicle, and the upper abdomen are usual sites for hypodermoclysis. A butterfly needle or a special subcutaneous infusion device is used to provide access for the hypodermoclysis fluid.

Epidural infusion.

Epidural infusion is used to administer medication for pain control or for anesthesia (see Chapter 7).

Partial or total parenteral nutrition.

Many patients with fluid and electrolyte imbalances are nutritionally depleted. Partial parenteral nutrition (PPN) is given when a patient cannot maintain an adequate nutritional status with oral intake. PPN is given through a large peripheral vein in the arm. If sufficient nutrition cannot be delivered by oral intake and PPN, or by enteral feedings, TPN is begun. Figure 3-9 shows placement of a peripherally inserted central catheter and of a central venous catheter.

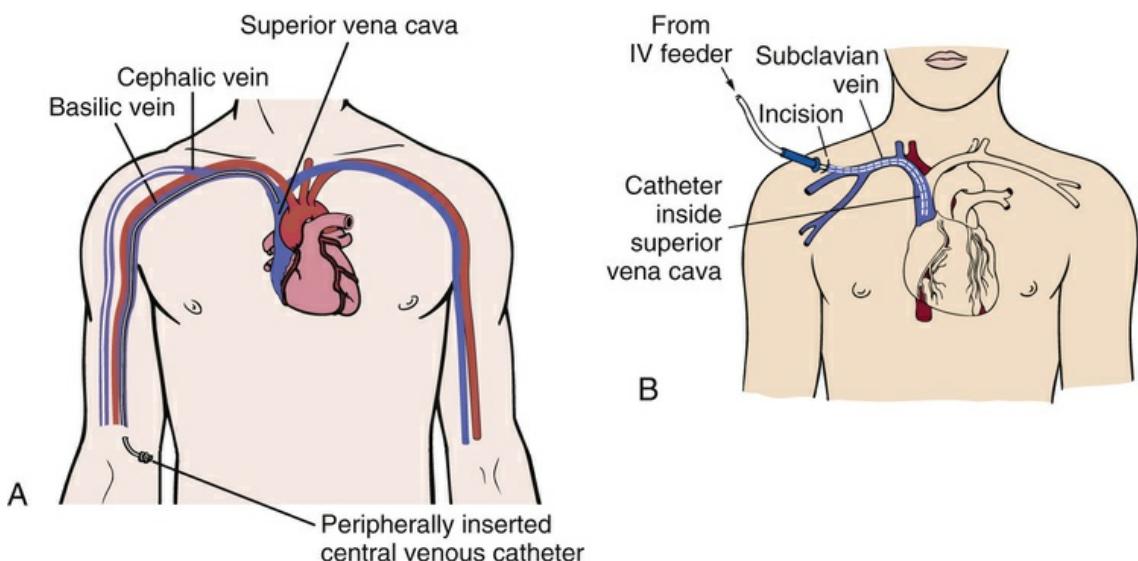

FIGURE 3-9 A, Placement of a peripherally inserted central catheter (PICC) through the antecubital fossa. B, Placement of a central venous catheter inserted into the subclavian vein. IV, Intravenous. (A, from Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 7, St. Louis, 2007, Mosby. B, from Elkin MK, Perry AG, Potter AG: *Nursing interventions and clinical skills*, ed. 3, St. Louis, 2004, Mosby.)

TPN solution is made up of a nitrogen (protein) source, hypertonic dextrose, and supplementary vitamins and minerals. The solution is hypertonic and contains 1 calorie/mL or 1000 calories/L. Some solutions also contain lipids. Because of its degree of concentration, TPN solution must be infused through a central vein, usually the subclavian, where the high rate of blood flow quickly dilutes it. The Hickman, Broviac, and Groshong catheters are the most commonly used central line catheters, and they can be used for long-term therapy. TPN solution is administered with a pump or an infusion controller device so that the flow rate is constant.

Safety Alert

Total Parenteral Nutrition Safety Precaution

The flow rate for TPN solution is never changed to “catch up” on the amount of fluid that should have been infused if the flow has slowed for some reason. The hypertonic solution can draw fluid into the vascular system, causing fluid overload.

TPN solutions and catheters must be handled with strict asepsis, because the solution is an ideal medium for bacterial growth. The TPN solution is mixed in the pharmacy under sterile conditions. However, infection is a major complication of TPN. There are many complications of TPN in addition to infection, including glucose intolerance, electrolyte imbalance, phlebitis, allergic reaction, and fluid overload. The port through which TPN is administered should not be used for any other solution. When beginning TPN, start the flow rate slowly at about 60 to 80 mL/hr, then gradually increase in increments of 25 mL/hr, until reaching the maintenance rate. This allows the body to adjust to the glucose load. During TPN carefully monitor the patient. Perform blood glucose determinations frequently during the stabilization period, which is usually the first week. If the patient's body has difficulty with glucose tolerance, insulin may be ordered and added to the TPN solution. At the end of therapy, taper down the flow rate for 1 to 2 hours before stopping the fluid, to allow the body to adjust.

PPN is used for patients in whom central venous access is not possible or who need IV nutritional support for only 7 to 10 days. A solution of less concentration is given to these patients because the solution does not flow into a vessel with a large blood flow, which would dilute it. **Box 3-6** summarizes the principles for administering TPN.

Box 3-6

Principles for Administration of Total Parenteral Nutrition

- Placement of a central venous catheter must be verified by x-ray before beginning the infusion of the total parenteral nutrition (TPN) solution.
- Use an infusion pump to administer TPN solution; start the infusion slowly at first and increase to the desired rate over a 24-hour period.
- If the solution is administered cyclically (e.g., at night only), taper to the desired flow over 1 to 2 hours and taper flow down for 1 to 2 hours before completion.
- Check the amount actually infusing every 30 to 60 minutes; do not rely solely on the pump functioning accurately.
- Before administering other solutions or drugs through another lumen of the central line, check compatibility with the TPN solution.
- Monitor continuously for signs of complications such as glucose intolerance, infection, fluid volume excess, phlebitis, and sepsis.
- Record the intake and output accurately.
- Never speed up the solution flow rate beyond that ordered, even if it falls behind for some reason.

Free-flow protection must be used on all general-use and patient-controlled analgesia infusion pumps. Alarms should be tested regularly, be activated with appropriate settings, and be sufficiently audible at all times when an infusion pump is in use. Although important for any IV infusion, an alarm system is vitally important when TPN is being administered.

Focused Assessment

Data Collection for Problems of Fluid, Electrolyte, and Acid-Base Imbalance

Assess the following:

Current Illness

Head

- Alertness, orientation, dizziness, signs of confusion, irritability, restlessness
- Appearance of eyes and eyelids
- Condition of oral mucous membranes, tongue, thickness of saliva

Skin and Extremities

- Color, moisture, temperature, areas of discoloration
- Turgor
- Tightness of rings
- Evidence and degree of edema
- Strength of handgrip
- Cramping of muscles
- Reflexes

- Chvostek sign

- Trousseau sign

Laboratory and Diagnostic Tests

- Hematocrit changes
- Urine amount, color, odor, and specific gravity
- Electrolyte values
- Blood gas values
- Electrocardiogram T-wave changes

Vital Signs

- Blood pressure changes
- Pulse rate, rhythm, and character
- Temperature
- Respirations
- Change in weight

Lungs

- Breath sounds (any crackles?)

Intake and Output

Known Disease Conditions

Medications

❖Nursing Management

■ Assessment (Data Collection)

First, assess the patient for **risk** of fluid, electrolyte, or acid-base imbalance, then assess for actual signs and symptoms of fluid, electrolyte, and acid-base imbalance. Question the patient about subjective signs and symptoms.

▣ Older Adult Care Points

Remember that checking for tenting is not an accurate way to assess dehydration in older adults, because their skin loses elasticity with aging and will tent with normal hydration. It is better to check for dry mucous membranes, concentrated urine, and other signs and symptoms in these patients.

■ Nursing Diagnosis

Analyze the assessment data, identify problem areas, and choose problem statements/nursing diagnoses. Common problem statements for patients with fluid, electrolyte, or acid-base imbalances include:

- Fluid volume deficit
- Fluid volume excess
- Potential for electrolyte imbalance
- Altered tissue perfusion

- Altered cardiac output
- Altered gas exchange
- Altered breathing pattern

Other problem statements may be appropriate as a result of the fluid, electrolyte, or acid-base imbalance or may be related to the cause of the imbalance, for example, diarrhea. Specific NANDA-I diagnoses may be chosen from the NANDA-I list (see inside back cover).

■ Planning

The goal is to restore the patient's fluid, electrolyte, or acid-base balance. Write the individual, expected outcomes. Expected outcomes might be one or more of the following:

- Patient will exhibit normal skin turgor.
- Patient's weight will stabilize at normal baseline.
- Intake and output will be balanced.
- Blood gases will return to normal.
- Breath sounds will be clear to auscultation.
- There will be no evidence of edema.
- Electrolyte values will be within normal limits.
- Patient will not experience complications of IV therapy.

See [Nursing Care Plan 3-1](#) for examples of expected outcomes with nursing interventions.

■ Implementation

When patients are unable to take in sufficient fluids on their own, work with the provider to provide adequate fluid and electrolytes. If patients can swallow and retain fluid, assist patients to frequently take small amounts of fluid. Establish a plan for assisting with both hot and cold liquid consumption. With conscientious care, the need for IV feeding can be avoided. It is helpful to assess what the patient prefers. In addition to water, offer the patient fruit juices, bouillon, ice pops, soft drinks, or gelatin.

? Think Critically

What type of fluid and electrolyte imbalance is a patient likely to have who has gastroenteritis and is suffering from both vomiting and diarrhea?

A patient with fluid volume excess may have an order for fluid restriction. This means that the patient may take in only a certain amount of fluid over a 24-hour period. Work out a schedule of fluid intake so that liquids are spaced evenly and the patient does not receive all the allotted liquids in a short time. A typical schedule would be day, 600 mL; evening, 400 mL; night, 200 mL. If not prohibited, sugarless hard candies and chewing gum can help relieve thirst. Frequent oral care is essential.

Diuretics may be prescribed, particularly if there is a potential for congestive heart failure or pulmonary edema. For patients at such risk, daily weight and electrolyte status must be monitored, along with I&O.

Assignment Considerations

Obtaining a Daily Weight

When assigning the daily weighing of patients to a certified nursing assistant (CNA) or UAP, remind the person that weight should be measured before breakfast, with the patient in essentially the same amount of clothing as at the last measurement, and after voiding. The same scale should be used each day to ensure reliable data for comparison. Any gain of 2 lb or more over 2 days should be reported to you immediately.

Skin care is particularly important in preventing a breakdown over an edematous area. The

stretched skin is extremely fragile, has a decreased blood supply, and is no longer flexible. Keep bed linens dry and smooth and turn the patient frequently to relieve pressure over bony prominences. **Be very gentle in repositioning and turning the patient; to avoid friction on the skin, use a turning sheet. A break in edematous skin can quickly form a pressure ulcer.**

When acid-base imbalance occurs, institute control of the underlying disorder. Monitor blood gases, and administer oxygen and electrolytes as needed. Apply nursing measures to improve pulmonary function, as appropriate.

Think Critically

Your patient has a PaO_2 of 94, pH of 7.32, Paco_2 of 48, and HCO_3^- of 26. What type of acid-base imbalance does he have?

Evaluation

Every 24 hours, perform evaluations to determine whether nursing interventions are assisting the patient to meet expected outcomes. If the patient is not progressing toward achievement of the outcomes, problem-solve and think critically to determine why, then alter the plan of care appropriately. When a specific outcome is met, discontinue that portion of the plan.

Community Care

Nurses in long-term care facilities deal every day with the problems of delicate fluid balance in their older adult patients. These patients often are taking multiple drugs that can affect their fluid and electrolyte status. Diuretics in particular can upset fluid and electrolyte status. It is especially important that the long-term care and home care nurse be vigilant for the signs of hypokalemia (see [Table 3-4](#)). Potassium imbalances are particularly dangerous for heart patients. Hypokalemia alters the way digitalis is metabolized in the body and predisposes the patient to digitalis toxicity. Signs of digitalis toxicity are fatigue, anorexia, headache, blurred vision, yellow-green halos around lights, nausea, diarrhea, and cardiac dysrhythmias.

Clinical Cues

Any patient in a long-term care facility or at home who is taking digitalis and is experiencing nausea, vomiting, diarrhea, or fluid and electrolyte alterations should be questioned daily about symptoms of hypokalemia and digitalis toxicity.

Dehydration and hyponatremia from infection account for many of the hospital admissions of patients from long-term care facilities and home situations. It takes a caring, skillful nurse to see that long-term and home care patients take in enough fluids without interfering with their nutritional intake.

The home care nurse must collaborate with the infusion company nurse when the patient is receiving IV fluids at home or is on TPN. Clear instructions must be given to the patient and family regarding the IV therapy. An older adult patient who has a fluid volume excess from congestive heart failure may already have a diminished appetite. In this instance restricting sodium in the diet may do more harm than good. You, along with the provider, must make individual judgments about the patient's priority needs.

Patient Teaching

Home Care Intravenous Therapy

Call me when:

- Swelling, redness, or pain occurs at the IV site or along the vessel.
- The solution will not flow even after you have checked that the clamps are open.
- The solution leaks at the catheter site and you have checked to see that the tubing is firmly attached to the catheter.
- The patient's temperature rises above 100° F (38° C).

Telephone number _____

Get Ready for the NCLEX® Examination!

Key Points

- Fluid balance is essential, because the life processes of every cell take place within fluid.
- Infants and older adults are at greatest risk for fluid imbalance.
- Water has four main functions in the body.
- Body fluids are distributed in intracellular compartments and extracellular compartments.
- Control of fluid balance is managed by hormones and by the thirst mechanism.
- Fluids and solutes move within the body by diffusion, filtration, osmosis, and active transport.
- Tonicity refers to the amount of solutes in relation to the amount of fluid.
- Filtration occurs through a semipermeable membrane.
- Hydrostatic pressure causes filtration of fluid out of the intravascular system into the interstitial spaces.
- Water diffuses by osmosis.
- Diffusion moves water from the interstitial spaces into the cells.
- The kidney is a major factor in the regulation of fluid and electrolyte balance in the body.
- Fluid volume deficit may result from fluid losses or because of lack of fluid intake (see [Table 3-1](#)).
- A fluid deficit causes dehydration. Checking skin turgor is one way to assess for dehydration.
- Check the tongue and mucous membranes of older adults to assess for dehydration.
- Weight change is the most accurate measure of fluid gain or loss.
- Fluid deficit is a common problem in older adults.
- Electrolytes need to be replaced along with fluid when there has been a fluid deficit.
- Prolonged vomiting leads to sodium and potassium deficits and metabolic alkalosis.
- Position the vomiting patient so that aspiration of vomitus does not occur.
- Rehydrate the dehydrated older adult patient cautiously so that overhydration does not occur.
- Medications can be administered to help stop vomiting and diarrhea (see [Table 3-2](#)).
- Fluid volume excess leads to hypervolemia, edema, and possibly to pulmonary edema.
- Assessment will reveal elevated blood pressure and a full, bounding pulse.
- Edema may be localized or general; pitting edema may occur.
- Loss of plasma proteins may cause edema.
- When fluid shifts from the intravascular space to the interstitial spaces, hypovolemia may occur.
- With fluid excess, sensorium may be clouded.
- Edema may be treated with diuretic medications, a low-sodium diet, and elastic stockings or sequential compression devices.
- Electrolytes are responsible for the transmission of nerve impulses, contraction of muscles, and excretion of hormones (see [Table 3-4](#)).
- Urine output must be at least 30 mL/hr before IV potassium is given.
- Intravenous potassium is always diluted and never given as a bolus injection.
- Acid-base imbalances upset the normal function of the body's systems.
- The kidneys are the principal organ in controlling a normal pH; the lungs also assist.
- Too much carbonic acid in the body causes acidosis; too much bicarbonate in the body causes alkalosis.
- Changes in carbon dioxide are usually respiratory; changes in bicarbonate are usually metabolic.
- Diabetic ketoacidosis causes metabolic acidosis and can be life-threatening.
- Arterial blood gases are analyzed to determine whether there is an acid-base imbalance and what type of imbalance is present.
- Each acid-base imbalance has its own signs and symptoms and probable treatments.

- Every ill patient should be assessed for a fluid, electrolyte, and acid-base imbalance.
- Intravenous therapy can provide the patient with fluid, electrolytes, and nutrients.
- Intravenous fluids are isotonic, hypotonic, or hypertonic (see [Table 3-6](#)).
- Intravenous therapy must be administered in a strict aseptic manner.
- The “Six Rights” should be used when administering any IV fluid or drug (see [Box 3-4](#)).
- Monitoring for complications of IV therapy is a top priority (see [Table 3-7](#)).
- Rate of IV flow must be monitored closely; never rely solely on an IV pump.
- Older adults can become fluid overloaded very quickly.
- Subcutaneous infusion is mostly used for pain control.
- TPN is used when a patient cannot obtain adequate nutrition by other means.

Review Questions for the NCLEX® Examination

1. What should nurses monitor when a patient is receiving a diuretic regularly? (*Select all that apply.*)
 1. Skin turgor and integrity
 2. Daily weight
 3. Electrolyte status
 4. Mentation

NCLEX Client Need: Physiological Integrity

2. Which patient(s) can be considered at high risk for fluid and electrolyte imbalance? (*Select all that apply.*)
 1. A 45-year-old woman with thyroid crisis
 2. A 35-year-old trauma victim on a ventilator
 3. A 60-year-old woman with temperature of 99.6° F (37° C)
 4. A 70-year-old man on anticoagulant therapy

5. A 30-year-old woman complaining of persistent diarrhea

NCLEX Client Need: Health Promotion and Maintenance

3. An older adult man is admitted for severe disorientation, confusion, and general weakness. His spouse reports that he is not able to tolerate any food or fluids and has had several episodes of vomiting and diarrhea. Which imbalance is the patient most likely experiencing?

1. Hypokalemia
2. Metabolic acidosis
3. Hyponatremia
4. Respiratory alkalosis

NCLEX Client Need: Physiological Integrity

4. In planning care for a patient with congestive heart failure, you choose the problem statement: fluid volume excess due to altered cardiac output. The Problem statement would most likely be supported by which sign or symptom?

1. Temperature of 101.5° F (38.6° C)
2. Hematocrit 35%
3. Fine crackles in the lung sounds
4. Clear, yellow urine

NCLEX Client Need: Physiological Integrity

5. A patient who has congestive heart failure has a fluid excess with a weight gain of 1.5 pounds since yesterday and edematous ankles. Which provider's order has the highest priority?

1. Maintain accurate intake and output.
2. Monitor skin for signs of breakdown.
3. Administer furosemide 20 mg PO once daily.
4. Obtain daily weight.

NCLEX Client Need: Physiological Integrity

6. The new patient on the floor has been diagnosed with gastroenteritis. What would be the most

critical level to assess?

1. Blood glucose
2. Potassium
3. Calcium
4. Sodium

NCLEX Client Need: Physiological Integrity

7. You appropriately elicit a sign of hypocalcemia by:

1. tapping the face about 1 inch from the ear.
2. palpating a partially stretched tendon.
3. inspecting facial symmetry.
4. applying pressure on the radial pulse.

NCLEX Client Need: Physiological Integrity

8. At the beginning of the shift, there is 410 mL of fluid in the IV bag. A piggyback medication containing 150 mL is hung at 12:00 noon to run over 30 minutes. You hang a new bag of 1000 mL at 1:00 P.M. to run at 125 mL/hr. At the end of shift there is 250 mL left in the bag. The count for the total amount of fluid infused during your shift ending at 7:00 P.M. is:

1. 1260 mL
2. 1285 mL
3. 1560 mL
4. 1310 mL

NCLEX Client Need: Safe and Effective Care Environment

9. Which would be the most accurate way to assess for dehydration in an elderly patient?

1. Skin turgor
2. Urine output

3. Respirations

4. Thirst levels

NCLEX Client Need: Physiological Integrity

10. You respond to a patient complaining of pain, burning, and wetness over the peripheral IV site. On assessment, you find that the IV insertion site is tender and cool to touch. These are signs and symptoms of:

1. phlebitis.
2. infiltration.
3. infection.
4. venous spasm.

NCLEX Client Need: Safe and Effective Care Environment

Critical Thinking Questions

Scenario A

Mrs. Thompson, age 64, is admitted to the hospital for congestive heart failure. She is very edematous. She is slightly confused on admission, and although she is not on absolute bed rest, she tells you she is too weak to get out of bed.

1. What type of diet would you expect the provider to order for Mrs. Thompson? Why?
2. Why are daily weights ordered for Mrs. Thompson? Why are those data important?
3. Mrs. Thompson is on fluid restrictions. How would you schedule her fluid intake?

Scenario B

Mr. Mendez, age 76, is admitted with dehydration and diarrhea. He is confused and listless.

1. What parameters would you assess to see if his fluid balance is improving?
2. What electrolyte imbalances would you expect to find?
3. Why would you need to keep a close eye on the IV infusion that is ordered?
4. What acid-base imbalance is he likely to be experiencing?
5. What assessment data would tell you that Mr. Mendez's plan of care is working to rebalance his fluid and electrolytes?

CHAPTER 4

Care of Preoperative and Intraoperative Surgical Patients

Objectives

Theory

1. Discuss the advantages of current technological advances in surgery.
2. Explain the preparation of patients physically, emotionally, and psychosocially for surgical procedures.
3. Identify the types of patients most at risk for surgical complications, and state why each patient is at risk.
4. Plan and implement patient and family teaching to prevent postoperative complications.
5. Compare the roles of the scrub nurse and the circulating nurse.
6. Analyze the differences in the various types of anesthesia and list the advantages and disadvantages of each to the health care team and the patient.

Clinical Practice

7. Perform a thorough nursing assessment for a preoperative patient.
8. Teach a patient postoperative exercises during the preoperative period.
9. Prepare a patient for surgery using a preoperative checklist.
10. Document preoperative care and assessment data.
11. Observe during a patient's surgery.

KEY TERMS

- anesthesia** (ă-nĕs-THĒ-zē-ă, p. 75)
atelectasis (ă-tĕ-LĒK-tā-sĭs, p. 65)

thrombophlebitis (thrōm-bō-flē-BĪ-tĭs, p. 69)

Surgery

Surgery is performed for a variety of reasons (Table 4-1). For the patient, any type of surgery is a serious event. Knowing terminology specific to surgical procedures helps you envision the procedure so that you may better prepare patients for surgery and care for them afterward (Box 4-1). Surgery may be elective, urgent, or performed as an emergency.

Table 4-1
Selected Categories of Surgical Procedures

CATEGORY	DESCRIPTION	CONDITION OR SURGICAL PROCEDURE
Reasons for Surgery		
Diagnostic	Performed to determine the origin and cause of a disorder or the cell type for cancer	Breast biopsy Exploratory laparotomy Arthroscopy
Curative	Performed to resolve a health problem by repairing or removing the cause	Laparoscopic cholecystectomy Mastectomy Hysterectomy
Restorative	Performed to improve a patient's functional ability	Total knee replacement Finger reimplantation
Palliative	Performed to relieve symptoms of a disease process, but does not cure	Colostomy Nerve root resection Tumor debulking Ileostomy
Cosmetic	Performed primarily to alter or enhance personal appearance	Liposuction Revision of scars Rhinoplasty Blepharoplasty
Urgency of Surgery		
Elective	Planned for correction of a nonacute problem	Cataract removal Hernia repair Hemorrhoidectomy Total joint replacement
Urgent	Requires prompt intervention; may be life-threatening if treatment is delayed more than 24-48 hr	Intestinal obstruction Bladder obstruction Kidney or ureteral stones Bone fracture Eye injury Acute cholecystitis
Emergent	Requires immediate intervention to prevent life-threatening consequences	Gunshot or stab wound Severe bleeding Abdominal aortic aneurysm Compound fracture Appendectomy
Degree of Risk of Surgery		
Minor	Procedure without significant risk; often done with local anesthesia	Incision and drainage (I&D) Implantation of a venous access device (VAD) Muscle biopsy
Major	Procedure of greater risk, usually longer and more extensive than a minor procedure	Mitral valve replacement Pancreas transplant Lymph node dissection
Extent of Surgery		
Simple	Only the most overtly affected areas are involved in the surgery	Simple/partial mastectomy
Radical	Extensive surgery beyond the area obviously involved; is directed at finding a root cause	Radical prostatectomy Radical hysterectomy

From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Critical thinking for collaborative care*, ed. 7, Philadelphia, 2013, Saunders.

Box 4-1

Terminology Used for Surgical Procedures

Suffixes are often attached to a stem word to describe a surgical procedure. For example, *appendectomy* means cutting out the appendix.

-ectomy: Cutting out or off (colectomy: cutting out a part of the colon)

-lysis: Removal or destruction of (neurolysis: freeing a nerve from adhesions)

-oma: Tumor (excision of a fibroma: removal of a connective tissue tumor)

-ostomy: To furnish with an outlet (colostomy: creating an outlet for the colon from the body)

-otomy: Cutting into (thoracotomy: cutting into the chest cavity)

-plasty: Revision, molding, or repair of tissue (mammoplasty: revision of the breast)

-pexy: Fixation, anchoring in place (orchiopepxy: fixation of an undescended testicle in the scrotum)

In a hospital surgery may be performed as a same-day or outpatient procedure, or as an inpatient procedure. Many surgeries are done in a free-standing surgery center. Minor surgery is often performed in a provider's office; LPN/LVNs assist more with surgery in this setting. For any surgery, preparation is usually begun before admission. The patient undergoes diagnostic tests and is taught preoperative and postoperative care during the days just before the scheduled surgery. The ability to deliver and reinforce teaching for postoperative and home care is crucial to the well-being and quick recovery of patients.

Technological Advances in Surgery

Laparoscopic and endoscopic procedures have replaced many “open” surgeries (in which a large incision is necessary). Minimally invasive laparoscopic surgery (done through small openings in the abdomen) can be performed more quickly. This results in less trauma to tissue, less inflammatory response and therefore less pain, and a faster recovery. For example, laparoscopic cholecystectomy for gallbladder removal has reduced a patient's recovery time from 6 weeks to approximately 1 week. Endoscopic surgery (in which instruments are used to visualize interior structures of the body), operating microscopes, and lasers are commonplace in the surgical suite.

Medical **robotics** (design of computerized, mechanical instruments) provides a key to less invasive, less traumatic surgeries. A medical robot is operated from a nearby computer while the surgeon views magnified three-dimensional images of the surgical field on the computer's screen. The robot's tiny camera has multiple lenses that allow magnification up to 12 times that of normal vision. There are assistants and a second surgeon next to the patient, but the primary surgeon at the computer uses the robot to perform the surgery. Remote-controlled instruments are inserted through small incisions. An advantage of using the robot is that it has “rock-steady” hands, providing precision that is beyond human dexterity. Because only small incisions are needed, the patient has less pain postoperatively and requires less time to heal. With robotic surgical techniques, the patient experiences less scarring (because incisions are smaller), and the small surgical wounds heal faster. Surgeries can be transmitted via videoconferencing to locations around the world to enhance skill levels of surgeons everywhere.

Autologous Blood for Transfusion

Since the mid-1980s, patients undergoing elective surgery have had the option of banking their own blood before surgery, in case a transfusion is needed. The patient's blood is withdrawn at the blood bank several weeks before the surgery, prepared, and stored. The blood is prepared for **autologous** (related to self) transfusion. Cell savers can be used to collect and salvage blood during and after surgery, so the patient's own blood can be reinfused if the patient needs it. Access to autologous procedures has greatly decreased the anxiety of patients who fear infection with a blood-borne virus, such as human immunodeficiency virus (HIV) or hepatitis B or C.

Bloodless Surgery

Some patients opt for bloodless surgery to avoid completely the risk inherent in a blood transfusion. Bloodless surgery uses a combination of techniques to minimize blood loss and maximize blood volume and function. Epoetin alfa (Epogen, Procrit) may be given before surgery to stimulate red blood cell production, and hemostatic agents may be given before or during surgery to promote clotting (National Institutes of Health, 2012). During surgery, the surgeon may request induced hypotension or hypothermia to decrease oxygen demand.

Another bloodless surgical technique is hemodilution, in which several units of the patient's blood are removed and replaced with crystalloids or colloids to expand vascular volume. Hemodilution decreases blood viscosity, improves oxygen transport, and—if bleeding occurs during surgery—minimizes the loss of red blood cells.

Cultural Considerations

Jehovah's Witness Patients and Blood Transfusions

Followers of Jehovah's Witness will not accept a blood transfusion from another person because of their religious beliefs. They believe that there are eternal consequences from receiving blood not their own. In the past, this precluded them from having certain major surgeries. Now bloodless surgery is one option for them, because fluid expanders are available for them.

❖ Perioperative Nursing Management

Perioperative nursing refers to care of the patient before, during, and after surgery. The nurse plays a key role during the perioperative period.

■ Assessment (Data Collection)

Before surgery, the patient should be in the best possible physical condition. In emergencies, of course, physical condition cannot be controlled, but planned surgery may be postponed until the patient is physically able to withstand the stress of anesthesia and major surgery. To determine the patient's readiness for surgery, a thorough health assessment is conducted and risk factors are considered. In addition to the admission assessment data that are gathered when the patient is first admitted (see [Chapter 2](#)), the perioperative nurse gathers data specific to the surgical procedure and postoperative course. Thorough assessment facilitates planning of care during and after surgery.

Older Adult Care Points

Patients older than 75 years have surgical complication rates three times higher than those of younger adults. An older adult patient is less able to adjust and compensate for the stress of surgery, because physiologic reserves (cardiac, respiratory, renal) have already declined with age. Older adult patients are more likely to have impaired renal, hepatic, respiratory, and cardiac functions that alter their metabolism and excretion of drugs and anesthesia. The presence of chronic diseases causes vulnerability to fluid and electrolyte imbalances during and after surgery.

When assessing the presurgical patient, any significant deviations from normal range should be brought to the attention of the surgeon. For example, an elevated temperature might indicate an infection that would need to be brought under control before surgery.

Think Critically

If your 76-year-old patient seems confused the morning after her hip replacement, what would you check in her chart to see if there is an alteration?

Knowing the patient's usual blood pressure reading is necessary for comparison after surgery,

when postoperative shock is a concern. Height and weight are measured and charted before surgery so the anesthesiologist can accurately calculate anesthetic dosages. Allergies must be identified and noted on the front of the patient's chart and on an allergy bracelet worn on the patient's arm. This includes allergy to iodine prep solutions such as Betadine, although this solution is no longer commonly used.

Focused Assessment

Preoperative Data Collection

Health History and Psychosocial Assessment

- Have you previously had surgery? What was your experience?
- What is the reason for this surgery?
- How do you feel about having this surgery?
- What do you know about this surgery and the before and after care?
- What are your expectations of this surgery?
- Have you or any family members ever experienced any problems with surgery or anesthesia?
- Will this surgery create any problems in your usual roles or relationships?
- Do you have any chronic illnesses?
- Have you gained or lost considerable weight recently?
- Do you have any allergies to medications, iodine, shellfish, adhesive tape, or latex?
- What medications, over-the-counter preparations, vitamins, herbs, and supplements do you take?
- Do you smoke? How much and for how many years?
- What is your usual use of alcohol?
- When was your last bowel movement?
- Do you have any problems with urination?
- Do you currently have an upper respiratory tract infection?
- Do you have any musculoskeletal problems that need to be addressed during positioning for surgery?
- Do you have health insurance?
- What people will be able to help you during your recovery?
- Will you be able to cope with inconveniences during your recovery without additional help?
- How do you usually cope with pain?
- Are there any particular concerns or fears that you have regarding the surgery now?

Cultural Assessment

- What is your primary language?

- Do you have any cultural or spiritual practices that you would like to observe during this period of surgery and recovery?
- What are your cultural customs regarding privacy, blood transfusions, and disposal of body parts?

Spiritual Assessment

- Do you have spiritual or religious beliefs?
- Do you wish to talk with or see your spiritual or religious advisor?
- Is there any conflict between your value or belief system and this planned surgery?

Physical Assessment

- Measure height and weight.
- Measure vital signs.
- Auscultate the lungs and heart.
- Listen for bowel sounds.
- Check pulses and compare bilaterally.
- Gather basic neurologic data: level of consciousness, orientation to time, place, and person; ability to think, answer questions, and follow instructions.
- Assess skin status, integrity, moisture, and temperature.
- Assess for recent tattoos, piercings, and body jewelry.
- Assess for limitations in joint range of motion.
- Assess for muscle weakness.
- Assess for loose teeth, dentures, bridges, contact lenses, hearing aids, and other prostheses.

Laboratory and Diagnostic Test Data

- Verify that test results are in the chart.
- Note any abnormal findings.

Assessment for particular risk factors for surgical site infection includes preexisting infection or medical condition, nasal bacterial colonization, malnutrition, advancing age, diabetes mellitus, nicotine use, immunosuppression, and obesity.

Safety Alert

Latex Allergy

A patient who is allergic to latex is at high risk of exposure during surgery when unconscious and unable to monitor the environment. Contact and airborne precautions are necessary. The perioperative nurse must be constantly vigilant to keep anything with latex on it out of the patient's environment. Even rubber stoppers on medication bottles or intravenous (IV) supply containers can be a problem. The operating room must be prepared to be "latex free." A "latex-free" crash cart is kept at hand in case of emergency. ☺

Think Critically

Why would a localized infection be a contraindication for surgery in some instances?

It is particularly important to know if a patient is taking a corticosteroid, which can delay wound healing, alter fluid and electrolyte balance, and affect several metabolic functions in the body—factors that increase surgical risk. Patients should be questioned about medicines and eyedrops that may contain a corticosteroid. Corticosteroids should be tapered slowly before surgery, but never stopped abruptly. Vitamin E, aspirin and other nonsteroidal anti-inflammatory drugs (NSAIDs), and anticoagulants have a continuing effect on blood clotting for several days; these supplements and medicines are usually discontinued 7 to 14 days before surgery.

Complementary and Alternative Therapies

Herbals and Supplements

Most anesthesiologists will ask patients to discontinue taking herbal supplements 2 to 3 weeks before surgery, because many herbal supplements interact with anesthetic agents or interfere with blood clotting. If doing without a supplement is not possible, the herbal supplement container should be brought to the anesthesiologist. Black cohosh, St. John's wort, feverfew, valerian, goldenseal, licorice, and kava can have interactions with other medications and anesthetics and should be stopped 2 to 3 weeks before surgery. Ginger, feverfew, garlic, ginseng, and ginkgo biloba all can have adverse effects on clotting mechanisms. It is best to stop all herbals several days before surgery. After surgery, the patient should ask the health care provider when each herb can be restarted.

Nutritional status and body weight are significant factors in healing and repair of the surgical site. Obesity presents problems for such routine procedures as venipuncture and intubation for general anesthesia, and **obesity causes prolonged uptake of anesthetic drugs**.

The operating room personnel are notified if the patient has a hearing impairment, is essentially blind when glasses are not in place, or has a **prosthesis** (artificial body part).

The news that surgery is needed usually comes as an emotional shock to patients and their families. Surgery causes changes in the routine of their lives that could result in personal and financial burdens on patients and their families. Surgery will alter the lives of some patients permanently, and possibly may leave them physically impaired. Others might expect to be greatly helped by the surgical procedure. In any event, there will be fears and misgivings about the prospect of undergoing anesthesia and surgery.

Cultural Considerations

Beliefs Regarding Surgery

Cultural beliefs and values regarding surgery must be taken into consideration. If the patient does not speak the same language as the surgical team, an interpreter should be enlisted to assist with communication. If a female patient's culture has strict rules for female attire, she needs assurance of sufficient privacy and protection of modesty to allay any fears she might have. Such issues and interventions must be conveyed to the surgical team. If there are certain cultural taboos regarding an aspect of the surgery, the surgical team needs to know them and plan a way to achieve a good outcome without violating such taboos. It is especially important to know whether the patient will accept a blood transfusion.

Older Adult Care Points

Older patients who are experiencing serious depression are at high risk for complications of surgery, because their motivation for recovery often is very low.

Determine whether the patient will have adequate help at home when discharged from the hospital. Many older people live alone, and although self-sufficient before surgery, may have difficulty preparing meals, bathing, or performing wound care while recovering from surgery.

Some people are concerned about whether they will “wake up” or survive the anesthesia and surgical procedure. Some patients have a strong spiritual belief that helps them cope independently with sickness, suffering, and death. Others may need help in finding the spiritual support they need. Still others do not want to discuss this particular facet of their lives. Allow time with clergy or a spiritual advisor before the surgical procedure according to the patient's desire.

Cultural Considerations

Financial Burden

With the Affordable Care Act, individuals who formerly would forego insurance may now have it. Deductibles and copays may still present a problem for those with modest income. If the primary income earner in the household will be unable to work for an extended period, financial hardship may occur.

Laboratory and Diagnostic Test Data

Box 4-2 lists the tests most frequently required before surgery. A chest radiograph is usually obtained, and an electrocardiogram is ordered for many patients older than 40 years. If the patient has lung disease, pulmonary function tests may be ordered. If the laboratory reports indicate any abnormal values, surgery may be postponed. Most surgeons prefer to delay surgery if a patient's hemoglobin level is below 10 g/dL.

Think Critically

Why would anemia make a patient a poor surgical candidate?

Box 4-2

Commonly Ordered Preoperative Laboratory Tests

- Complete blood count (CBC)
- Urinalysis (UA)
- Blood glucose*
- Electrolytes
- Prothrombin time (PT)
- Partial thromboplastin time (PTT)
- Blood type and crossmatch
- Liver function tests (AST, ALT, bilirubin)*
- Renal function tests (BUN, creatinine)*
- Beta-human chorionic gonadotropin†

ALT, Alanine aminotransferase; *AST*, aspartate aminotransferase; *BUN*, blood urea nitrogen.

*May be ordered as part of a metabolic panel or sequential multiple assay (SMA)-6 or SMA-12.

†To check for pregnancy in women of childbearing age.

Surgery puts a strain on the cardiovascular, renal, and respiratory systems. Liver function is important because the liver is involved in synthesizing clotting factors, producing albumin, and metabolizing and detoxifying drugs. Although requesting preoperative diagnostic tests is the responsibility of the provider, you will need to explain to the patient why these tests have been ordered.

Surgical Risk Factors

Carefully assess the patient before surgery for risk of complications (Table 4-2). Infants and older adults are at higher risk for complications of surgery due to either immature body systems or a decline in function of various body systems. Maintaining core body temperature is one concern when caring for these patients. Although smoking is a risk factor, research has shown that quitting smoking and alcohol intake 3 to 8 weeks before surgery will reduce the incidence of serious postoperative complications (Doheny, 2012).  Smoking is not allowed within the hospital.

Think Critically

What points would you make when explaining how smoking is harmful to the surgery patient?

Table 4-2
Surgical Risk Factors

FACTOR	KEY POINTS
Diabetes mellitus and other chronic diseases	Stress of surgery may cause swings in blood glucose levels that are difficult to control. Patients may receive intravenous insulin during and after surgery. Wound healing tends to be delayed in patients with diabetes, making the risk of dehiscence (wound separation) greater. The incidence of infection in surgical wounds is also higher. Liver and kidney disease makes it more difficult to metabolize and eliminate anesthesia and waste products.
Advanced age with inactivity	Healing is slower in older adults. The risk of disuse syndrome, hypostatic pneumonia , (inflammation and consolidation in the lungs), and thrombus formation is higher in inactive older adults.
Very young person	Infants have difficulty with temperature control and in maintaining normal circulatory blood volume; they are at risk of dehydration.
Malnutrition	Inadequate nutritional stores lead to poor wound healing and skin breakdown.
Dehydration	Reduced circulating volume reduces kidney perfusion and predisposes the patient to a reduced urine output and thrombus formation. Dehydration also alters electrolyte values. A dehydrated patient is more at risk for problems with pressure areas during surgery.
Obesity	An extremely heavy patient does not breathe as deeply and is at risk of hypostatic pneumonia. Excessive fatty tissue also is a factor in poor wound healing.
Cardiovascular problems	Patients with hypertension, left ventricular hypertrophy, cardiac dysrhythmias, or a history of congestive heart failure are at a higher risk for myocardial infarction from the stresses of surgery and anesthesia.
Peripheral vascular disease	Poor circulation in the extremities predisposes the patient to possible thrombus formation and pressure sores on the lower legs and feet. Anti-embolism stockings or devices are generally prescribed for use during and after surgery.
Liver disease	Interferes with normal blood clotting; liver cannot properly detoxify anesthetics and other drugs.
Respiratory disease	Inhaled anesthetics may irritate the respiratory mucosa, creating more secretions. With immobility there is greater probability of accumulated secretions and inflammation of the lungs and bronchial tree. Impaired oxygen–carbon dioxide exchange may cause acid-base imbalance.
Substance abuse or alcohol dependence	May alter reaction to anesthetic agents. Alcohol dependence may cause withdrawal symptoms if the use of alcohol is discontinued abruptly.
Smoking	Causes increased lung secretions from anesthesia and predisposes the patient to atelectasis (collapsed alveoli) and pneumonia postoperatively. Smokers are more prone to thrombus formation.
Regular use of certain drugs	Aspirin, nonsteroidal anti-inflammatory drugs, and anticoagulants make the patient more prone to excessive bleeding. Corticosteroids reduce the body's response to infection and delay the healing process.
Excessive fear	Stimulates the sympathetic nervous system and causes the release of hormones, causing swings in the body's chemistry and vital signs. Increased muscle tension makes surgery more difficult. Physical manifestations of fear can interfere with achieving the desired state of anesthesia.

Adapted from deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.

Learning Needs

General information should be provided to the surgical patient about what will happen immediately before, during, and after surgery, as well as specific preventive measures (see Implementation). If members of the family or supportive friends are expected to assist the patient during the postoperative period, they need to be instructed during teaching sessions.

Patient and Family Teaching

General Preoperative Teaching

Whenever possible one or more family members should be included in teaching sessions. All surgical patients should receive information related to:

- **Preoperative procedures:** Enemas, skin preparation, care of belongings, restriction of food and liquid intake, and administration of bedtime sedatives and preoperative medication; time to come to the hospital
- **Technical information:** Anticipated surgical procedure; location of incisions; dressings, tubes,

drains, catheters, or other equipment that is expected

- **Day of surgery:** Time surgery is scheduled, time to arrive at the hospital or time patient is to leave her room, probable length of procedure, effects of preoperative medications, where family will wait, when and where family can see the patient after surgery, pain control, and postoperative routine
- **Postanesthesia care unit (PACU):** General environment (noise, lights, equipment), frequent taking of vital signs, pulse oximetry, and administration of oxygen
- **Surgical intensive care unit (SICU)** (if patient is to go there from PACU): Location of the unit, expected length of stay, and visiting privileges

■ Nursing Diagnosis

The LPN/LVN assists in gathering data so that based on the total assessment data, the RN can formulate problem statements in the preoperative stage that include both actual and potential problems. Common preoperative problem statements include:

- Anxiety due to the surgical experience and outcome
- Fear due to the potential for death, effects of impending surgery, or loss of control due to anesthesia
- Potential for grief due to impending loss of a body function or body part
- Insufficient knowledge of preoperative and postoperative routines
- Insomnia due to stress or unfamiliar environment
- Limited coping ability due to lack of problem-solving skills or adequate support
- Altered role performance due to inability to perform job duties or to care for children during hospitalization

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover). Each problem is supported by data obtained during the nursing assessment.

■ Planning

Specific expected outcomes will be written for each problem ([Nursing Care Plan 4-1](#)). However, there are general **nursing goals** for all preoperative patients. The expectation is that the patient will be:

- Prepared for surgery physically and emotionally
- Able to demonstrate deep breathing, coughing, and leg exercises
- Able to verbalize understanding of the procedure and the expectations for the postoperative period
- Able to maintain fluid and electrolyte balance throughout the perioperative period

[Nursing Care Plan 4-1](#)

Care of a Patient Scheduled for a Simple Mastectomy

Scenario

Mrs. Talbot, a married 38-year-old woman and the mother of two children ages 16 and 14 years, is scheduled for a simple mastectomy as treatment for a localized malignant tumor that was detected by self-examination of her breasts.

Problem Statement/Nursing Diagnosis

Fear of diagnosis/*Fear related to cancer, disfigurement, and possible death*

Supporting Assessment Data

Subjective: Grandmother died of breast cancer.

Objective: Malignant tumor by biopsy, crying at intervals; states is worried about husband's reaction to the loss of the breast

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will discuss fears openly by day 2.	Establish rapport and trust.	Establishing trust helps patient express fears and concerns.	Spent time with patient answering questions.
Patient will look at incisional area before discharge.	Encourage her to discuss fears with nurse and family.	Expressing fears decreases anxiety.	
Patient will identify spiritual support before discharge.	Encourage her to think of cancer as a challenge.	A positive perspective empowers the patient.	
Patient will talk about having cancer by postoperative day 2.	Help her to identify specific fears and deal with each one separately.	Identifying fears decreases the fear of the unknown. Dispelling fear and anxiety makes learning easier.	Stated is afraid of chemotherapy. Is now using the word "cancer" when discussing her surgery.
			Discussed ways to meet the challenges of chemotherapy.
	Teach relaxation exercises to decrease anxiety.	Relaxation exercises help decrease anxiety.	Expressed willingness to learn a relaxation exercise.
			Tried relaxation exercises twice.
Patient will join support group for cancer patients after discharge.	Advise of community resources available to her.		Expressed appreciation for information about a support group.
Patient will use community resources after discharge.			

Problem Statement/Nursing Diagnosis

Insufficient knowledge/Readiness for Enhanced Knowledge about preoperative routine and postoperative care

Supporting Assessment Data

Subjective: States, "I've never had surgery before. What will I need to do?"

Objective: Puzzled expression on face

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will verbalize understanding of preoperative procedures and requirements before surgery.	Do preoperative teaching for patient and family: routine procedures, NPO status, expected tubes and drains, equipment to expect in room, probable length of surgery, where family will wait, pain relief measures, handling of arm on operative side, coughing, deep breathing and leg exercises, ambulation, diet, daily postoperative routine.	Knowledge reduces fear of the unknown and anxiety.	Performed return demonstrations and verbalized understanding of routine and procedures.
Family will express understanding of what will happen preoperatively, where they will stay during surgery, and what to expect after surgery by end of teaching session		Family verbalized understanding of what to expect.	
	Call pastor or chaplain if patient desires a visit.	Clergy can be a positive support in time of stress.	A pastoral visit is scheduled for this afternoon.
	Provide private time for patient and husband and patient and family.	Private time is necessary for serious discussions.	Will have private talk with husband and one with daughters later today. Continue plan.

Critical Thinking Questions

- How would you specifically assess this patient's learning needs?
- How could you assess for any cultural factors that would affect her learning or your teaching?

When preoperative patients are assigned, you must plan your work for the shift carefully to have the patients ready for surgery without neglecting the needs of other assigned patients.

Clinical Cues

At the beginning of the shift, check to see that any ordered preoperative medications are on hand. Often IV medications are to be sent with the patient to the surgical holding area where further preparation of the patient is performed. Check the surgery schedule and estimate the time needed to prepare the patient for surgery.

Implementation

Preoperatively, your time is divided between preparing the patient for surgery and teaching the patient about what will happen and how to hasten recovery. The same-day surgery patient receives teaching from the provider's office nurse or from a surgical intake nurse. Teaching sessions may be scheduled when the patient comes for diagnostic testing. Sending written instructions home with the patient reinforces what has been taught. Before entering the hospital for surgery, the patient

should be given a phone number to call for answers to questions that may arise. Protocols may differ from one facility to another.

Older Adult Care Points

It is particularly important to reinforce instruction and information given to older adult patients. It is best to have a family member present during teaching. The anxiety of surgery, unfamiliar surroundings, diminished hearing and vision, and forgetfulness make learning more difficult and may decrease retention of information. Seek specific feedback periodically of points that are important for the patient to remember. Treat all patients with respect and dignity.

Consent for Surgery

Before the surgeon can perform an operation, written permission signed by either the patient, guardian, or whoever holds power of attorney must be obtained. This written consent protects the surgeon against claims of unauthorized surgery and provides the patient an opportunity to exercise the right of **informed consent**. In most hospitals, the “consent” is a printed form that the patient signs before surgery. The correct surgical procedure is written into the consent form. The surgeon explains the procedure, risks, and benefits; the nurse only witnesses the patient's signature. The patient must be mentally competent and give consent freely and without coercion. The consent form is attached to the patient's chart and is sent to the operating room (OR) with the patient. **The nurse must always check that a consent form has been signed before giving the preoperative medication.** Many hospitals require a signed “Power of Attorney for Health Care” declaring a health care proxy person to be in the chart before surgery.

Legal and Ethical Considerations

Giving Surgical Consent

Mrs. Jones, age 66, was slightly confused as a result of dehydration when she was brought to the hospital. She has signed a surgical consent for a hip replacement, but her daughter feels she was confused when she signed the form and questions its validity. What would you do? How would the surgeon verify that Mrs. Jones was not confused when she signed the form?

Clinical Cues

Patients have the right to change their minds and revoke consent up until the time of surgery. If a patient tells you the surgery is not wanted, delay preoperative preparations and explore the issue with the patient. If it appears the consent for surgery really is being revoked, notify the charge nurse and the surgeon.

Think Critically

Why should the consent be signed before giving any preoperative medication? What happens if a patient has been given the preoperative medication and then it is discovered that the surgical consent form has not been signed?

Food and Fluids

Food and fluids will often be restricted for 8 hours before surgery, and the patient is placed on NPO (*nil per os*, which means “nothing by mouth”) status. A light meal such as toast and clear fluids may be allowed up to 6 hours before surgery. Clear liquids such as black coffee, tea, apple juice, or carbonated beverages may be consumed up to 3 hours before surgery in elective cases. (American Society of Anesthesiologists, 2011). Often the surgeon or anesthesiologist will allow an oral blood pressure medication, heart medication, or anticonvulsant to be taken with a sip of water the morning of surgery. Always check the provider's order before giving anything by mouth in the immediate preoperative period. The purpose of oral restriction is to prevent nausea, vomiting, and aspiration. **Confirm with the patient that the NPO order has been heeded.** Insulin may or may not

be given; check the orders.

Clinical Cues

If a patient has not remained NPO for the prescribed period, surgery may be canceled.

Elimination

If the patient is having abdominal or colon surgery, enemas may be ordered to clear the bowel. Sometimes oral GoLYTELY solution is used. The patient may be placed on a special soft or liquid diet for the 3 days before surgery to decrease the content of the bowel.

When completing the preoperative checklist, ask the patient to empty the bladder (unless a catheter is in place). If the bladder is not empty, relaxation induced by medications and anesthesia causes the urge to urinate. The bladder should be emptied before any sedating medication is given.

Tubes and Equipment. If a nasogastric tube (NG) will be inserted during surgery for postoperative use, explain its purpose, its care, and what it will feel like to the patient. Give an estimate of how long the tube will remain in the stomach. The tube is usually removed when bowel sounds return and nausea has passed. If surgery has occurred in the stomach or intestinal tract, the tube may remain longer. Explain the function of other tubes such as drains, an IV line, oxygen delivery and monitoring devices, a chest tube, and a urinary catheter, as well as their care and probable duration of use.

Think Critically

If a patient has an NG tube in place, what are the necessary assessments to be made by the nurse?

Rest and Sedation

It is desirable for the patient to be as well rested as possible before surgery so the body is not compromised in meeting the stresses of anesthesia and the surgical procedure. A sedative may be ordered for the patient the night before surgery, but the inpatient often must ask for it. Check on the inpatient frequently during the night. If the patient awakens and is restless, sit and listen and try to dispel fears, offer a soothing back rub, or give backup sedation as ordered. A patient scheduled for same-day surgery should take the sedative at home and retire early the night before because it is necessary to arise early to enter the hospital.

Pain Control

Many surgeons order a patient-controlled analgesia (PCA) pump for their patients postoperatively. If a PCA pump is ordered, patients should receive instruction before surgery about the pump and how to operate it. If patients will be receiving injections for pain control, explain that this type of medication is ordered on an as-needed basis every 3 to 4 hours, and that patients must ask for it. Oral pain medication is usually ordered for every 4 to 6 hours as needed. Explain that asking for the pain medication before the pain becomes severe makes it easier to control the pain level. **It is the nurse's responsibility to gather data regarding the patient's pain throughout the shift and to offer interventions for relief.** Teach the patient about the pain scale that is used at the facility (see Chapter 7).

Skin Preparation

The night or morning before surgery, the patient may be asked to shower with a special antibacterial cleanser to remove as many microorganisms from the skin as possible. On the morning of the surgery, hair may be removed from the operative site—this is done either in the surgical holding area or in the OR. As a Core Measure for reducing surgical site infection, use hair clippers only for hair removal before surgery ([The Joint Commission \[TJC\], 2009](#)). Explain  to the patient the hair removal area to be prepared, the hair removal process, and the timing for hair removal. Nail polish is removed so that the pulse oximeter can function correctly when attached to the finger. Makeup is removed; note the presence of permanent makeup on the preoperative checklist. Ask about contact lenses and have them removed as well.

Clinical Cue

Preoperative skin cleansing is best performed with chlorhexidine gluconate solution, because it is more effective than povidone iodine solutions in preventing surgical site infections (Edmiston et al, 2013). A shower or bath using a 2% chlorhexidine gluconate solution may be ordered once or twice before surgery as well.

Preoperative Teaching

Teaching the patient correct breathing, coughing, turning, and leg exercises is a high priority during the preoperative period. It is helpful to have a relative or close friend present for these teaching sessions so this person can later give coaching and encouragement to the patient. Instruct the patient about what to expect before, during, and after surgery. Help same-day surgery patients devise a schedule for doing the necessary exercises.

Older Adult Care Points

Older adult patients should be taught necessary information in short segments to prevent confusion and increase the patient's comprehension. Written reminders of key instructions should be given to the patient.

Venous return is often hampered during the surgical procedure due to the position assumed on the operating table and pooling of blood in the lower extremities. **Stasis** (slowing of flow) of blood places the patient at risk for **thrombophlebitis** (blood clot and inflammation of a vessel). Specific leg exercises help to prevent this complication (Figure 4-1). Explain the importance of doing the exercises, show the patient how to do each one, and ask for a return demonstration. One way to remind patients to do the exercises is to have them exercise whenever a commercial comes on, if they watch TV. The exercises should be done after surgery at least 5 to 10 times every hour while awake, until the patient is up and moving around normally.

Patient and Family Teaching

Postoperative Foot and Leg Exercises

Whenever possible, one or more family members should be included in teaching sessions.

- Flex and extend the right foot, moving the toes upward and downward, four or five times.
- Repeat with the left foot.
- Trace circles to the right with the right foot five times; repeat with circles to the left.
- Trace circles to the right with the left foot five times; repeat with circles to the left.
- Bend the right leg at the knee, sliding the foot back toward the buttocks as far as possible; raise the bent leg off the bed, extend the leg, and dorsiflex the foot; extend the foot and lower the leg to the bed.
- Bend the left leg at the knee, sliding the foot back toward the buttocks as far as possible; raise the bent leg off the bed, extend the leg, and dorsiflex the foot; extend the foot and lower the leg to the bed.
- Tighten the buttocks muscles for a count of 10 and release to exercise the quadriceps muscles.
- Repeat each exercise four more times.

FIGURE 4-1 Teaching foot and leg exercises. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.)

If sequential compression devices or compression stockings are likely to be ordered after surgery, explain to the patient what they are, why they are used, and when they would probably be applied.

Deep Breathing and Coughing. For deep breathing and coughing, it is preferable for the patient to sit up, with the back away from the mattress or chair. This allows for full lung expansion and clearing of excretions. The surgical chest or abdominal incision should be splinted with a pillow (Figure 4-2).

Clinical Cues

A small, firm “coughing pillow” can be made by folding a bath towel or a light blanket and securing it inside a pillow case with the ends tucked inside over the towel or blanket.

FIGURE 4-2 Teaching deep breathing and coughing while splinting the incision. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.)

The surgeon may order use of an incentive spirometer. Instruct the patient in its use and supervise until the patient has mastered the technique.

Patient and Family Teaching

Lung Exercises

Whenever possible, one or more family members should be included in patient teaching.

Deep Breathing

- Sit up away from the mattress.
- Take a deep breath in through the nose, hold for a few seconds, and slowly exhale.
- Repeat four more times.
- Perform every 2 hours during the day and when awakened at night for vital signs.

Forced Exhalation Coughing

- Sit up away from the mattress.
- Splint the abdominal or chest incision:
- Take a deep breath through the nose and cough as you exhale with the mouth open, but covered with a tissue.
- If you cannot move secretions with your cough, use a forced exhalation cough.
- Take a deep breath through the nose and forcibly quickly exhale, producing a “huff” cough.
- Repeat the process using three short “huffs” as you exhale to bring the secretions to the mouth, where they can be expectorated. Repeat until no secretions are audible in the lungs, resting between attempts.
- Perform every 2 hours during the day and when awakened at night for vital signs.

Using an Incentive Spirometer

- Sit up away from the mattress.
- Insert the mouthpiece, covering it completely with the lips.
- Take a slow deep breath and hold it for at least 3 seconds.
- Exhale slowly, keeping the lips puckered.
- Breathe normally for a few breaths.
- Try to increase the inspired volume by at least 100 mL with each breath on the spirometer.
- Once maximal volume is achieved, attempt to inspire this volume 10 times, resting a few breaths between each attempt.
- Clean the mouthpiece of the spirometer when finished.

- During the first 3 postoperative days, try to do this every hour.

Turning. Show the patient how to turn in bed by flexing the legs to relax the abdominal muscles, placing a pillow between the legs, grabbing on to the side of the bed, and slowly turning to the side. This maneuver is also used for getting up out of bed. A trapeze bar for orthopedic patients is very helpful for turning and repositioning.

Family Instructions. Advise the family to come to the hospital 1 to 1.5 hours before surgery. The family should be told about the usual routines, where to wait, the approximate time before the patient may be expected to return, and what to anticipate in the way of tubes, equipment, and patient appearance after surgery. This knowledge keeps the family from thinking the patient has "taken a turn for the worse" when they see the extra equipment for suction, oxygen, or IV therapy in use after surgery. A warning about the occasional delays in starting surgery can keep the family from becoming excessively anxious if the patient is not back at the expected time.

Immediate Preoperative Care

The patient is usually dressed in a clean hospital gown, without underwear, for the operating room. Hair is covered with a surgical paper cap. Long hair should be fixed to minimize tangling, and all hairpins and barrettes must be removed. Ask about body piercings and the presence of piercing jewelry, including the tongue and genital areas. Explain why *all* jewelry must be removed for safety because of the electrocautery used during surgery and the danger of an electrical burn from conduction of electricity through metal.

Jewelry, along with money and credit cards, is given to a family member or relative to keep or is secured in a valuables envelope and placed in a safe, according to facility policy. If a wedding band is to be worn to surgery, tape the ring to the finger without restricting circulation and tape a cotton ball over the stone to prevent loss when the tape is removed. Dentures are removed, placed in a labeled cup, and kept in a designated place, according to hospital policy. Sometimes the anesthesiologist will order the dentures left in place to facilitate the administration of anesthesia by mask. If a hearing aid is left in place, a very visible note should be placed on the front of the chart, and placement of the hearing aid should be noted on the preoperative checklist sheet.

Verify that the identification bracelet matches the chart to avoid any error or mix-up of patients in the operating room. Verify that the procedure site indicated on the surgical consent form is the same as what the patient states. The procedure site will be verified and marked on the patient before transport to surgery or in the preoperative holding area if not done previously.

Clinical Cues

Attend to all items on the preoperative checklist that can be handled ahead of time ([Figure 4-3](#)). This prevents hurrying, which can increase mistakes, and prevents delaying administration of any preoperative medication while the list is completed. Many facilities use an on-line form.

FIGURE 4-3 Preoperative checklist. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders. Courtesy of Peace Health Southwest Medical Center, Vancouver, Wash.)

Often no medication is given before the patient is in the surgical holding area. Most preoperative medications are given by the anesthesiologist. A medication to inhibit gastric acid secretion may be administered intravenously. You may need to send any IV piggyback antibiotic or other medication ordered to the OR with the patient.

Preoperative medications may be given to :

- Reduce anxiety and promote a restful state
- Decrease secretion of mucus and other body fluids
- Counteract nausea and reduce emesis
- Enhance the effects of the anesthetic

Assist in transferring the patient to the stretcher when the transport person comes to take the patient to surgery. Compare the patient's identification bracelet name and numbers with the transport request sheet for accuracy. Check the chart to make certain that everything ordered has been done, and complete final documentation.

Safety Alert

Preventing Falls

If the patient has received a sedative preoperatively, remember to put up the side rails of the bed per facility protocol and lower the bed. Place the call light button within reach and remind the patient not to get up without assistance. These are important patient safety measures after administering sedatives.

Cultural Considerations

Differences in Drug Metabolism

Asian people, and particularly Chinese patients, metabolize psychotropic drugs differently from people of other ethnic groups. Valium causes greater sedation with normal doses. Atropine is also metabolized differently and can greatly accelerate the heart rate. Asian patients should be monitored closely when receiving these drugs.

Older Adult Care Points

Because of decreasing liver and kidney function that occurs with age, older adult patients, especially those older than 75 years, will need reduced dosages of preoperative narcotics and sedatives. Observe for signs of toxicity.

Think Critically

How would you handle a situation in which a patient scheduled for an abdominal procedure has put back on underwear or jewelry after you finished doing the preoperative checklist?

Preparation of the Patient Unit

While patients are in surgery, prepare the room for their return. Make the bed with fresh linen; include a draw sheet between the shoulder and the knee area that can be used as a lift sheet to reposition the patient. For abdominal or perineal surgery, place an underpad at the hip area to catch excess drainage. Fan-fold the top covers to the far side of the bed or to the bottom of the bed. Raise the bed to the height of the stretcher that will return the patient, and arrange furniture so that the stretcher can be pulled up alongside the bed. Place the IV pole at the head of the bed.

Gather an emesis basin, tissues, frequent vital signs sheet or postoperative record, intake and output (I&O) sheet, small towel and washcloth, and pen and place them on the bedside table or console ([Figure 4-4](#)). Connect oxygen and suction equipment if their need is anticipated. A thermometer, sphygmomanometer, pulse oximeter, and stethoscope should be close at hand on the patient's return to the unit. If a PCA pump, sequential pneumatic compression devices, or a passive range-of-motion machine will be needed, see that they are obtained and ready.

FIGURE 4-4 Room prepared for surgical patient's return.

■ Evaluation

Evaluation is accomplished by determining whether the nursing goals have been met. If the patient is properly prepared for surgery, kept NPO, reasonably calm, and knowledgeable about the procedure and what is expected, the general goals have been met. If the preoperative medications were not given on time or the patient was not ready for transport at the appointed time, review your steps to see where improvement can occur. Data are gathered to determine if expected outcomes written for individual problem are being met (see [Nursing Care Plan 4-1](#)).

The Surgical Team

The surgical team consists of the surgeon, physician's assistant, surgical assistants, anesthesia care provider, circulating nurse, and scrub person or scrub technician. The surgeon is the head of the surgical team and may be a physician, an oral surgeon, or a podiatrist. The **first** surgical assistant is another physician, a physician's assistant, a surgical resident, or a specially trained and authorized RN or surgical technician. Other assistants may be RNs or LPN/LVNs. The surgeon, physician's assistant, surgical assistants, and scrub nurse or scrub technician are sterile members, perform a surgical scrub or rub, and wear sterile gowns and gloves. They work within the sterile field.

The Surgical Suite

ORs are removed from other areas of the hospital, and access is restricted to OR personnel and surgical patients. The OR is maintained as a positive pressure environment to reduce the entrance of microbes that might cause infection. The surgical suite is divided into three distinct areas to help keep the ORs as microbe free as possible. The unrestricted zone is essentially the control desk area. Street clothes may be permitted here. Semi-restricted zones include the hallways and outer regions of the ORs. The circulating nurse and anesthesia care providers work in these areas. Clean scrub clothes and caps are required. The restricted zone is the area surrounding the operating table and instrument trays and table. Personnel wear scrub clothes, sterile gowns, caps, shoe covers, masks, and sterile gloves within this area. Asepsis is the responsibility of all surgical personnel.

The temperature in the OR is kept at 66° to 70° F (18.9° to 21.1° C) to discourage microbial growth and to keep the surgical team comfortable under the bright lights and in the layers of surgical clothing. Cabinets, instrument tables, instrument trays, and disposal buckets are usually made of stainless steel that can be easily cleaned and disinfected. The restricted area is scrubbed down with disinfectant after each procedure. The entire room is kept scrupulously clean.

The Surgical Holding Area

The patient is transported to the holding area in the surgical suite. The holding area nurse, often the circulating nurse, greets the patient and verifies the patient's identification (Figure 4-5). He verifies that all preoperative orders have been accomplished, the signed surgical consent form is present, and the risk assessment is documented and he reviews the medical record and the preoperative checklist. The correct surgical site markings are checked. The Universal Protocol to prevent wrong-site surgery is followed in the holding area and in the OR (TJC, 2009). The nurse offers emotional support and answers any questions. The anesthesiologist may greet the patient, start an IV line if one has not been established, administer preoperative medications, and prepare the patient for anesthesia. When the OR is ready, the patient is transferred to the operating table. Patient identification is verified again by the circulating nurse.

FIGURE 4-5 Patient in surgical holding area.

Roles of the Circulating Nurse and the Scrub Person

A surgical technician or a specially trained nurse (LPN/LVN or RN) may be the scrub person. This person functions within the sterile area of the operating room (Box 4-3, Figure 4-6). **Sterile technique is maintained at all times. Any break in sterile technique should be immediately**

pointed out by the circulating nurse or any member of the OR team and remedied.

Box 4-3

Major Functions of the Scrub Nurse or Technician

- Gathers all equipment for the procedure
- Prepares all sterile supplies and instruments using sterile technique
- Gowns and gloves surgeons on entry into operating room
- Assists with sterile draping of the patient
- Maintains sterility within the sterile field during surgery
- Hands instruments and supplies to the operating team during surgery, anticipating what is needed
- Maintains a neat instrument table
- Labels and handles surgical specimens correctly
- Maintains an accurate count of sponges, sharps, and instruments on the sterile field; verifies counts with the circulating nurse before and after surgery
- Monitors for breaks in sterile technique and points them out
- Cleans up after the surgery is over

FIGURE 4-6 Scrub nurse setting up the instrument table in the operating room.

The circulating nurse is responsible, along with the anesthesia care provider, for maintaining the safety and dignity of the patient and bringing needed items to the operating team, as well as many other duties (Box 4-4). The circulating nurse is the communication link between the OR and those outside the surgical suite.

Safety Alert

Time-Out

Before surgery begins, while all members of the team are present, a “time-out” occurs during which a final verification of the correct patient, procedure, site, and implants (if applicable) is performed. Any questions or concerns must be resolved before the procedure begins. ☺

Box 4-4

Major Functions of the Circulating Nurse

- Coordinates care, oversees the environment, and cares for the patient in the operating room
- Greets patient and performs patient assessment
- Verifies that consent is signed and accurate and that surgical site is correctly marked
- Checks medical record and preoperative forms for completeness
- Sets up the operating room; adjusts lights, stools, and discard buckets; and ensures supplies and diagnostic support are available
- Gathers, counts, and checks all equipment and supplies that are anticipated to be used, ensuring its safe function
- Opens sterile supplies for the scrub nurse
- Provides needed padding and warming or cooling devices for the operating table
- Assists with tying the surgical team's gowns
- Assists with the transfer of the patient to the operating table and positions the patient
- Places the electrocautery ground pad under patient if electrocautery is to be used
- Assists the anesthesia induction provider
- May prep the patient's skin before sterile draping occurs
- May insert a Foley catheter
- Handles labeling and disposition of specimens
- Coordinates activities with radiology and pathology departments
- Monitors urine and blood loss during surgery and reports findings to the surgeon
- Supplies, monitors, and documents the infusion of ordered fluids
- Observes for breaks in sterile technique and announces them to the team
- Monitors traffic and noise within the operating room
- Communicates information on the surgery's progress to family during long procedures
- Documents care, events, interventions, drugs, fluids, and findings
- Assists with final count of sponges, sharps, and instruments with the scrub person
- Helps transfer the patient to the gurney and accompanies the patient to the recovery area, providing a report of the surgery and patient condition to the recovery nurse
- Verifies the count of equipment is the same after surgery as before

The patient is positioned with padding to prevent injury to nerves and to minimize pressure over bony prominences. Serious injury and pressure ulcers can develop from improper positioning or lack of padding for a surgical procedure (see [Chapter 42](#)). Safety straps are secured to safeguard the patient.

Anesthesia

Anesthesia (the loss of sensory perception) has been in use for surgical procedures since the 1840s. Newer anesthetics and techniques make anesthesia safer than ever, but **there is still a risk any time a patient is anesthetized**. The goals of anesthesia administration are to (1) prevent pain; (2) achieve adequate muscle relaxation; (3) calm fears and ease anxiety; and (4) induce forgetfulness of an unpleasant experience. Anesthetics are administered in a number of ways to achieve these goals (Table 4-3). Patients are classified according to their age, physical condition, and risk status and are assigned a risk potential. The choice of anesthesia depends on the type of surgical procedure to be performed and the risk potential. The anesthetic to be used is chosen by the anesthesia care provider, although it is discussed with the patient. The anesthesia care provider may be an anesthesiologist, another physician, or a certified registered nurse anesthetist (CRNA) who is supervised by an anesthesiologist.

Table 4-3
Types of Anesthesia

TYPE	USE	ADVANTAGE
General		
Inhalation	Extensive surgery for which it is desirable for patient to be unconscious with relaxed muscles	Well controlled with assisted ventilation; few side effects
Intravenous	Shorter surgery; rapid induction	Little postoperative nausea or vomiting
Regional		
Spinal	Surgery in lower half of body; for patients unable to undergo general anesthesia	Patient can be conscious; does not require fasting No nausea or vomiting from anesthesia
Epidural	For gynecologic procedures and childbirth	No diet restrictions postoperatively
Nerve block	Foot surgery and some orthopedic surgeries	Patient is conscious; can cooperate with instructions
Local	Minor surgical procedures	Can produce good pain control for many hours postoperatively; patient may remain conscious Numbs an area for a short period of time
Procedural/Conscious Sedation		
	Surgery of short duration for which unconsciousness is undesirable	Reversal is rapid Patient is unaware but can breathe without assistance Little if any nausea or vomiting Amnesia of surgery
Other		
Hypnosis	Surgery for patients who are unable to have general anesthesia and where regional anesthesia is inappropriate	No drug side effects
Cryoethermia	Surgery for patient who cannot tolerate other anesthesia, such as in life-threatening trauma	Provides decrease in pain

Go to Evolve for a table listing the types of anesthetic agents and their uses, advantages, and nursing implications.

General Anesthesia

General anesthesia is induced by the administration of an inhalant gas or by medication introduced intravenously. During general anesthesia, the patient is in a deep sleep state with muscle relaxation and is not aware of the surroundings. An oral or nasal endotracheal tube may be placed to maintain the airway. Placement of a laryngeal mask is another option. There are three stages of general anesthesia:

- 1. Induction:** Unconsciousness is induced.
- 2. Maintenance:** Period during which the surgical procedure is performed.
- 3. Emergence:** Surgery is completed and the patient is prepared to return to consciousness; neuromuscular blocking agents are reversed.

Older Adult Care Points

The physiologic changes that occur with aging affect the way drugs are taken up, utilized, and excreted. Obtaining an accurate height and weight of older adult patients is very important for calculation of anesthetic agents and medication dosages. Adverse drug responses are increased in the older adult population. In general smaller dosages of drugs are required, and fat soluble drugs in particular have a longer duration of action and a slower elimination period.

Regional Anesthesia

Regional anesthesia is accomplished by administering a nerve block. It is often more economical than general anesthesia. Regional anesthesia may be accomplished by injecting the spinal, epidural, caudal, or peripheral nerve area. The block anesthetizes the local area or the area distal to the block. Spinal or epidural blocks are typically used for high-risk patients undergoing pelvic or lower extremity surgery; epidural blocks are widely used in obstetric procedures.

Procedural or Conscious Sedation Anesthesia (Moderate Sedation)

A local anesthetic agent or regional anesthesia to numb the area plus IV sedation is used to provide systemic analgesia and sedation during a surgical procedure. The combination can be used for any procedure that can be done with local or regional anesthesia and is becoming increasingly common. The patient is monitored closely for blood pressure changes, oxygen saturation levels, and heart activity. Recently carbon dioxide levels have begun to be monitored by **capnography** (measurement of inhaled and exhaled carbon dioxide). Capnography provides a tracing that is a graphic representation of exhaled CO₂. The Microstream machine allows CO₂ monitoring without intubation with a nasal cannula-like device.

Complementary and Alternative Therapies

Music's Effects

Music that the patient likes is known to have a calming effect on preoperative patients. Research studying the use of music delivered by earphones to a patient during surgery has shown that music may reduce the amount of anesthesia and analgesia needed ([University of Kentucky, 2012](#)). The patient appears to become more relaxed and less anxious. Before and after surgery, listening to a CD with preferred music or with no recording on it through earphones appears to lower anxiety and pain, probably because the earphones decrease outside sensory stimulation.

Local Anesthesia

Local anesthesia is used for minor procedures such as superficial tissue biopsies, surface cyst excision, insertion of a pacemaker, and insertion of vascular access devices. A patient who has had local anesthesia is transferred directly to the nursing unit and does not need care in the PACU (also called the postanesthesia recovery room [PAR or PARR] or postanesthesia recovery unit [PARU]) (see [Chapter 5](#)).

Potential Intraoperative Complications

Potential intraoperative complications of surgery include:

- Hemorrhage
- Infection
- Fluid volume excess or deficit
- Hypothermia
- Malignant hyperthermia
- Injury related to positioning

No one with an active infection should be in the operating room. Surgical asepsis is practiced with great care to prevent contamination of the surgical site. Counts of sponges, needles, and instruments are performed to verify that no equipment has been left in a wound where it might cause a postoperative infection or complication.

Many associations and agencies have banded together to promote a program to decrease surgical infections and complications. Core Measures[®] and National Patient Safety Goals include proper hair removal, timely antibiotic administration, blood glucose control, prevention of thromboembolic events, and prevention of adverse cardiac events (Bratzler, 2009).

Intravenous fluids are carefully regulated by the anesthesia care provider and the surgeon. The cool atmosphere, cool IV fluids, inhalation of cool anesthetic gases, and exposure of body surfaces will lower a patient's normal temperature. Body temperature is monitored during surgery to ensure that it does not become dangerously low. Sometimes hypothermia is desirable for certain lengthy procedures to decrease metabolic needs of the body. However, if the patient's temperature drops too low, warmed IV fluids may be administered, or a body warming device may be used. Unless contraindicated, surgery patients are warmed with forced air during surgery. Hypothermia can adversely affect cardiac function and may make the body more susceptible to infection as well as increase bleeding and delay wound healing. Keeping the body at a normal temperature has been found to decrease postoperative wound infection and is especially important during colon surgery (Danelli et al, 2009). Prophylactic antibiotics work^{best} when given in the operating room (Rothrock, 2015).

Malignant hyperthermia is an inherited disorder. In patients with malignant hyperthermia, muscle metabolism and heat production increase rapidly and uncontrollably in response to the stress of surgery and some anesthetic agents. Fever, tachycardia, cyanosis, tachypnea, muscle rigidity, diaphoresis, hypotension, and irregular heart rate develop. If not treated quickly, cardiac arrest can occur. The circulating nurse monitors the patient's temperature along with the anesthesia care provider. If the temperature begins to rise rapidly, anesthesia is discontinued and the surgical team takes measures to correct the physiologic problems.

During a surgical procedure, the patient is placed in one position for an extended period of time. Such positioning places the patient at risk for injury, such as problems of immobility and pressure damage to the skin and underlying tissue. A variety of materials are used for padding pressure areas and stabilizing the patient's body. The circulating nurse must understand the risk factors for each surgical position and must pad joints and pressure areas accordingly. Joint problems and pressure ulcers can develop days after surgery from damage that occurred during the surgical procedure.

Get Ready for the NCLEX® Examination!

Key Points

- Surgical procedures vary in reason, urgency, degree of risk, and extent (see [Table 4-1](#)).
- The use of lasers, fiberoptic endoscopes with high-resolution video cameras, operating microscopes, and robotic technology has revolutionized surgery.
- Autologous transfusion or bloodless surgery techniques are reducing problems that can be caused by blood transfusions from outside donors.
- A thorough assessment is performed by the nurse, and any risk factors for surgery are identified (see [Focused Assessment](#)).
- Older adult patients are at much greater risk from surgery and anesthesia than younger adults.
- Cultural factors and preferences should always be assessed and considered.
- An appropriate individual nursing care plan is formulated for the preoperative period.
- The surgeon must obtain informed consent from the patient before surgery is performed.
- Preoperative procedures are performed in a timely manner.
- The method to be used for postoperative pain control is explained and discussed with the patient.
- Preoperative teaching of exercises to be performed postoperatively is very important; the patient is taught turning, leg, deep breathing, and coughing exercises.
- Immediate preoperative care includes checking to see that all jewelry and metal objects have been removed from the patient.
- A signed surgical consent form is checked before preoperative medication is administered.
- Once preoperative sedation (if ordered) is administered, the patient is cautioned to stay in bed to prevent falls.
- The patient's identity and the correct surgical site are carefully checked and marked before the patient is transported to surgery.
- After the patient leaves for surgery, the patient's room is prepared for postoperative care.
- A Universal Protocol is followed to prevent wrong-site surgery.
- Several measures are instituted to prevent surgical site infection and other complications.
- The OR is kept as microbe-free as possible.
- Surgical asepsis is the responsibility of the entire OR staff.
- A “time-out” occurs just before the start of the surgical procedure to recheck the patient's identity, the surgical procedure to be performed, and the site of the surgery.
- The scrub person and the circulating nurse, along with the surgeon and anesthesiologist or CRNA, provide care for the patient while in the operating room.
- The circulating nurse and the scrub person have distinctly different roles.
- Anesthesia is used to prevent pain, to achieve adequate muscle relaxation, and to calm fear, allay anxiety, and induce amnesia of an unpleasant experience.
- Inhalant gases and IV medications are used to induce general anesthesia, and the patient progresses through stages of induction to total anesthesia.
- Regional anesthesia, procedural (moderate) sedation, or local anesthesia is used for many surgical procedures.
- There is a risk of several complications during the intraoperative period.
- Patients are positioned carefully and pressure points and joints are padded to prevent injury.
- The circulating nurse, anesthesia care provider, and surgeon observe for symptoms of complications, and measures are taken immediately to avert a problem.

Review Questions for the NCLEX® Examination

1. An advantage of robotic surgery is that the surgeon has:
 1. an assistant at the computer guiding instruments.
 2. an unobstructed view of the operative site.
 3. use of a laser to perform the operation.
 4. ability to make precise movements of the instruments.

NCLEX Client Need: Physiologic Integrity: Reduction of Risk Potential

2. Surgical risk factors include: (*Select all that apply.*)

1. obesity
2. malnutrition
3. age of 51 years
4. diabetes mellitus
5. dehydration
6. osteoarthritis
7. smoking or excessive alcohol use
8. cardiovascular or respiratory problems

NCLEX Client Need: Physiologic Integrity: Reduction of Risk Potential

3. Regarding informed consent for a surgical procedure, the nurse is responsible for which aspect(s)? (*Select all that apply.*)

1. Verifying that the consent has been signed and witnessed before sending the patient to surgery
2. Explaining the risks and benefits of the procedure

3. Determining the mental capacity of the patient
4. Administering any preoperative medications after verification that the consent has been signed
5. Answering general questions regarding postoperative care

NCLEX Client Need: Safe and Effective Care Environment

4. In discussing options for fluid resuscitation during major surgery, the provider indicated availability of bloodless surgery. Bloodless surgery may include which intervention(s)? (*Select all that apply.*)

1. Administration of Epogen
2. Administration of volume expanders
3. Induction of hypothermia
4. Banking blood before surgery
5. Autologous transfusion

NCLEX Client Need: Physiological Integrity

5. While reviewing the morning vital signs of a preoperative patient, which patient information warrants immediate notification of the surgeon?

1. Temperature 99.5° F (37.5° C)
2. Serum potassium 3.2 mEq/L
3. Bronchovesicular breath sounds
4. Blood pressure 135/80 mm Hg

NCLEX Client Need: Safe and Effective Care

6. The nurse reinforces the importance of turning, coughing, and deep breathing to a preoperative patient. Which patient statement indicates a need for further instruction?

1. "I could place a pillow to brace my abdominal incision to reduce pain with coughing."
2. "I would lie still in bed to reduce the risk of injuring my surgical

wound."

3. "Coughing would help reduce pneumonia."
4. "Immediately getting out of bed speeds up recuperation."

NCLEX Client Need: Health Promotion and Maintenance

7. The following nursing interventions occur in the preoperative preparation of a patient undergoing a hip replacement. Place the interventions in order of priority. (*Priority setting.*)

1. Have the patient shower with the prescribed antisepsis preparation.
2. Check that the surgical consent has been signed and is in the chart.
3. Confirm patient compliance with the nothing by mouth (NPO) status.
4. Complete the preoperative checklist.
5. Have the patient empty the bladder.
6. Check for proper marking of the surgical site.

NCLEX Client Need: Safe and Effective Care Environment

8. When teaching a patient using an incentive spirometer, the nurse determines that the patient's technique is correct if the patient is:

1. exhaling forcibly after holding the breath for 30 seconds.
2. using the spirometer for 5 breaths every hour.
3. taking slow, deep breaths and holding each for at least 3 seconds.
4. exhaling forcibly into the spirometer.

NCLEX Client Need: Health Promotion and Maintenance

9. While transferring from the preoperative area to the surgical suite, the patient asks, "Am I going to make it?" An appropriate response by a nurse would be:

1. "Everything will be alright."

2. "Didn't your physician discuss the possible adverse outcomes of the procedure?"
3. "You seem anxious. Tell me more about how you are feeling."
4. "Your physician has performed the procedure several times."

NCLEX Client Need: Psychosocial Integrity

10. During major surgery, the patient is considered at risk for:

1. Injury related to placement in one position for extended period of time.
2. Altered nutrition because of prolonged fasting.
3. Hypervolemia from irrigation and IV fluids used in surgery.
4. Hypertension because of continuous infusion of fluids.

NCLEX Client Need: Physiologic Integrity

11. The person in the operating room responsible for labeling and handling surgical specimens correctly is the _____.*(Fill in the blank.)*

NCLEX Client Need: Safe and Effective Care Environment

12. After same-day surgery, the patient is ready to go home when:

1. there is an adult there to drive the patient home.
2. the patient is alert, ambulatory, and able to empty the bladder.
3. pain is controlled with oral analgesia.
4. nausea has passed and the patient is taking fluids.

NCLEX Client Need: Safe and Effective Care Environment

13. Cefazolin (Ancef) 1 g IV is ordered to infuse over 1 hour during surgery. It has been mixed in a 50 mL piggyback bag. If the tubing delivers 15 gtt/mL, how many drops per minute should be infused? _____

NCLEX Client Need: Safe and Effective Care Environment

Critical Thinking Questions

Scenario A

Your patient is scheduled for abdominal surgery this morning. You are assigned two other patients

to care for as well. One of these patients is stable and will be going home. The other patient is going for a computed tomography (CT) scan at 9:30 A.M.

1. Describe in detail how you would plan your morning care for these three patients.
2. Your surgical patient shares with you that she is having second thoughts about having this surgery. How would you handle the situation?
3. You notice that the patient scheduled for surgery is wearing a St. Christopher medal under her gown as she returns from emptying her bladder. You had told her to remove it earlier. How would you handle this situation?

Scenario B

On your first day on the surgical unit, you are assigned a patient who is scheduled for surgery at 10:00 A.M. The following preoperative medications are ordered: Lotensin 10 mg PO with sip of water and Cefazolin 250 mg IV 1 hour before incision.

1. What would you check in the patient's chart as part of her preoperative preparation?
2. What steps would you take to complete the preoperative checklist and charting for this patient? When would you start the preoperative preparation?
3. When would you give the dose of Lotensin? How would you handle the dose of Cefazolin?

Scenario C

A patient is scheduled for right hip surgery. You have been asked to have her sign the surgical consent form, because her surgeon forgot to have her do it when he saw her last evening.

1. What should you do before asking the patient to sign the consent form?
2. She asks when and how she will be "prepped for surgery." What would you tell her?
3. She inquires as to when she will be able to see her family after surgery. What would you tell her?

CHAPTER 5

Care of Postoperative Surgical Patients

Objectives

Theory

1. Describe the care of a patient in the postanesthesia care unit (PACU).
2. Compare differences in the care of a patient undergoing general anesthesia and one having spinal anesthesia.
3. Formulate a complete plan of care for a postoperative patient returning from the PACU.
4. Discuss measures to prevent postoperative infection.
5. Prioritize measures to promote safety for postoperative patients.

Clinical Practice

6. Identify how to promote adequate ventilation of the lungs during recovery from anesthesia in the PACU.
7. Perform an immediate postoperative assessment when a patient returns to the nursing unit.
8. Apply interventions to prevent postoperative complications.
9. Assess for postoperative pain and provide comfort measures and pain relief.
10. Promote early ambulation and return to independence in activities of daily living.
11. Perform discharge teaching necessary for postoperative home self-care.

Immediate Postoperative Care

Postanesthesia Care Unit

When surgery with general anesthesia is completed, the patient is usually transferred to the PACU adjacent to the surgical suites (Figure 5-1). Patients who have had spinal anesthesia for a major procedure go to the PACU also. Very critically ill patients, such as those recovering from open heart surgery, are often taken directly to the intensive care unit for anesthesia recovery. Surgical patients who had procedural sedation or a local or regional anesthetic usually recover in the ambulatory surgery area. The PACU nurse receives a verbal report from the anesthesia care provider about the procedure, blood loss, anesthesia administered, fluids infused, medications administered, and any problems encountered.

FIGURE 5-1 A nurse caring for a patient in the postanesthesia recovery unit.

The patient is immediately attached to the cardiac and pulse oximeter monitors, and oxygen is usually administered if the patient had general anesthesia. Oxygen helps eliminate the anesthetic gases and helps meet the increased metabolic demand for oxygen caused by surgery. Any respiratory problems are immediately addressed, because maintenance of airway and adequate ventilation take priority. An oral airway may be in place, because the anesthesia medications often cause the tongue to occlude the airway. Alternatively, the airway can be opened by moving the jaw forward (Figure 5-2). Suction is turned on and readily available to clear secretions. If needed, mechanical ventilation is provided. Warm blankets are placed over the patient, vital signs are assessed and compared with baseline readings, and a full neurologic assessment is performed. Neurologic assessment includes level of consciousness; orientation; sensory and motor status; and size, equality, and reactivity of the pupils. The patient may be asleep, drowsy but arousable, or awake.

FIGURE 5-2 Jaw-thrust maneuver to open the airway. The fingers are placed behind the angle of the jaw, lifting the jaw forward. As the jaw moves, the tongue comes forward, opening the airway. (From Black JM, Hawks JH: *Medical-surgical nursing: Clinical management for positive outcomes*, ed. 8, Philadelphia, 2009, Saunders.)

Determine intake and output (I&O) to assess the function of the urinary system. Closely monitor urinary output. Check all intravenous (IV) lines for patency, verify the solutions and the flow rate are correct, and inspect wound drains and evacuation devices for proper function. Assess dressings for unexpected drainage.

Surgical recovery can take from 2 to 6 hours. Because patients are coming out of anesthesia through various stages and are unstable, keep the environment as quiet as possible. Briefly communicate with the staff in hushed tones. The patient may wake up confused and may need reorientation and reassurance that the surgery is over, that he is in the recovery room, and that his family member or relative has been notified. Once the patient is awake, family members are sometimes allowed to visit for a few minutes so that they are assured that their loved one is alright and recovering. Assess for return of the gag reflex by determining whether the patient can swallow his secretions.

Assessments are performed at least every 15 minutes or according to the status of the patient. Assessment for complications of the particular surgery and anesthesia are ongoing. The patient remains in the PACU until the vital signs are stable and the patient is awake and able to respond to stimuli. A form of the Aldrete scoring system may be used to determine readiness for transfer. Activity, respiration, circulation, consciousness, skin color, and oxygen saturation are each given a score. A patient with a score of 9 or 10 is ready for transfer to the nursing unit. Report is given to the staff nurse (Box 5-1).

Think Critically

What is the number one priority of care for a patient in the PACU?

Box 5-1

Postanesthesia Care Unit Report to Nursing Unit Nurse

General Information

- Patient name, age
- Diagnosis
- Allergies
- Stability level

Surgical Data

- Surgeon's name
- Surgical procedure performed

- Length of surgery time
- Unexpected surgical events
- Vital sign trends during surgery
- Anesthetic administered
- Medications administered during surgery and recovery
- Amount of blood loss and replacement

Postanesthesia Care Course

- Vital signs and oxygen saturation
- Urine output
- Intravenous solutions and blood products administered, with amounts
- Tubes, drains, and equipment in use
- Results of any intraoperative laboratory or diagnostic tests (note whether patient or family has been told pathology results)
- Pain status and time of last dose of analgesia
- Any problems encountered

For many procedures the patient may be transferred from the operating room (OR) directly back to the same-day surgery unit. Monitor the patient's respirations, circulation, vital signs, neurologic status, fluid balance, wound drainage and dressings, and comfort level. When the vital signs are stable, the patient is allowed to sit up and then is ambulated. If discharge criteria are met, the patient may be discharged when able to ambulate unassisted and empty the bladder. Recovery time in the same-day surgery unit usually takes 1 to 3 hours. Discharge teaching is begun before the surgery and continues once the patient is again alert. Written instructions are always sent home with the patient. If the patient has undergone sedation, another adult driver must provide transportation home after same-day surgery. Advise surgery patients who have received anesthesia or procedural sedation not to resume normal activities or make important decisions for at least 24 hours after surgery. The phone number of the surgeon and signs and symptoms to report are written on the postoperative instruction sheet.

Think Critically

How would you assess a patient to determine whether or not the gag (swallowing) reflex has returned sufficiently after sedation to allow him to have a few ice chips?

Nursing Management

Assessment (Data Collection)

After the patient is transferred from recovery, check identity, settle the patient in bed, and perform an initial postoperative assessment. **Airway, breathing, and circulation are always the top priorities.** This provides a baseline against which frequent postoperative assessment data can be compared to prevent or quickly detect signs of complications. Vital signs are taken more frequently if they are unstable; this is a nursing judgment.

Focused Assessment

Postoperative Assessment

AREA	ASSESSMENT	SCHEDULE
Airway	Lung sounds, depth and quality of air movement	Auscultate lungs initially; respiratory rate q15min until easily arousable; then assess quality of respirations with vital signs assessment
	Respiratory rate	
Oxygen saturation	Oxygen delivery at rate ordered and patency of system	Note per vital signs schedule and whenever in room
		Check oxygen delivery system with initial assessment and each shift
Circulation	Auscultate heart; check peripheral pulses and sensation, especially distal to surgical site; assess skin color	Initially, q4h × 2, then with vital signs; if surgery was on an extremity, assess each time vital signs are measured
Mental status	Level of consciousness and orientation	Initially and then with full vital signs
Vital signs	Temperature	Check initially; then q8h once stable
	Blood pressure, pulse, and respirations	Check q15min × 1 h; q30min × 4; q1h × 4; q4h × 24–48 h; or per agency protocol
Fluid status and hydration	Intravenous infusion site and flow rate	Check initially and when in room
	Intake and output	Check each shift
	Skin turgor; oral membranes	Check initially and each shift
Surgical site	Check for bleeding; mark boundaries of drainage on dressing with the time; assess wound drainage in containers	Initially and q1h × 4; then with vital signs
Gastrointestinal	Auscultate bowel sounds; assess abdomen	Initially, then q8h
	Check nasogastric drainage color, character, amount	Check drainage whenever in room
Tubes	Check for patency and function of each	Initially; then with vital signs and after turning
Kidney function	Assess urine output from Foley catheter; must void within 8 hr if no Foley in place	Initially and q1h × 4; then if >30 mL/hr, q4h
Pain	Use a pain scale and observation of nonverbal behaviors	Initially and with vital signs; assess at least q3h
Skin	Pressure areas over bony prominences	Initially and q2h
Safety	All equipment is intact and safely functioning	Initially and each shift

Assignment Considerations

Postoperative Vital Signs

Because postoperative patients need close vigilance in the early postoperative period, it is best not to assign the taking of frequent vital signs to a UAP for the first couple of hours. Other parameters besides the measurement of vital signs need to be checked on a frequent schedule. After the first couple of hours, the task of vital sign measurement can be assigned to a UAP proficient in obtaining accurate measurements. Remind the UAP of exactly what to report: temperature elevation above 99.8° F (37.1° C), blood pressure (BP) alteration of a specific amount down or up from the baseline, tachycardia, and respiratory rate above or below normal range.

Monitoring for signs of the various surgical complications that may occur is a major nursing responsibility. The first 72 hours after surgery require frequent observations to detect signs of postoperative complications.

Nursing Diagnosis

Patient problems commonly used for postoperative patients who have undergone general anesthesia include the following:

- Altered gas exchange due to the effect of anesthesia on the lungs
 - Altered breathing pattern due to analgesia and pain
 - Altered skin integrity due to surgical incision
 - Potential for infection due to surgical wound
 - Potential for injury due to sedation, decreased level of consciousness, or excessive blood loss
 - Acute Pain due to disruption of tissue
 - Alteration in airway clearance due to inability to breathe deeply and cough without discomfort
 - Fluid volume deficit due to fluid loss and nothing by mouth (NPO) status
 - Potential for constipation due to opioid analgesics, decreased mobility, and decreased peristalsis
 - Altered self-care ability due to decreased mobility, use of tubes, and presence of dressings
 - Potential for altered myocardial tissue perfusion due to surgery, anesthesia, and positioning in the OR
 - Strained coping ability due to loss of body part or change in body image
 - Altered urinary elimination due to effects of anesthesia or presence of catheter
- For patients who have undergone spinal anesthesia, also include :
- Altered mobility due to effects of spinal anesthesia
 - Potential for injury due to decreased sensation and movement in lower extremities

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

■ Planning

The expected outcomes depend on the individual specific patient problems. General *nursing* goals include:

- Maintain patent airway and adequate respiratory exchange.
- Maintain adequate tissue perfusion.
- Promote normal physiologic body function.
- Prevent injury.
- Promote comfort and rest.
- Promote wound healing.
- Promote psychological adjustment to lifestyle or body image changes.
- Prevent postoperative complications.

When planning your work for the shift, allow time for frequent postoperative assessments. Careful planning is essential so that proper care for the early postoperative patient does not override the needs of other patients.

■ Implementation

Maintain Ventilation

Postoperative patients are at risk for respiratory problems from the effects of anesthesia on the lungs, being in one position for the duration of surgery, and limited mobility in the immediate postoperative period. **Maintaining a patent airway is a priority measure to promote ventilation.** Unless contraindicated, the patient must be positioned on the side or with the head turned to the side to prevent aspiration until fully recovered, alert, and with the gag reflex intact. Monitor oxygen saturation closely, and administer oxygen as ordered.

▣ Older Adult Care Points

Providing adequate pain control for older patients has been shown to prevent respiratory complications, because patients whose incisional pain is controlled will breathe more deeply and are more able to follow instructions for respiratory care.

Some degree of **atelectasis** (collapse of alveoli in the lungs) exists after anesthesia. A mild hypoxia is usually present for about 48 hours after surgery. A large percentage of all patients who have had either abdominal or thoracic surgery suffer from increasing atelectasis and pneumonitis. **If any area of the lung remains atelectatic for more than 72 hours, hypostatic pneumonia from retained secretions is likely to occur.** A low grade fever in the first 24 to 48 hours often indicates atelectasis.

Hypostatic pneumonia results when lack of movement or of position change causes stasis of secretions, which become a breeding ground for bacteria. Auscultate the lungs carefully for abnormal sounds indicating retained secretions, assess the rate and depth of breathing, and encourage the patient to deep breathe and cough every 2 hours to promote airway clearance. Coughing to remove secretions may be contraindicated for patients who have had a hernia repair or eye, ear, brain, jaw, or plastic surgery. Check the surgeon's orders. If the patient cannot cough effectively, instruct him to "huff" cough (see [Chapter 4](#)). If the patient is too weak to remove secretions, tracheal suctioning is indicated.

Ensure that the patient turns every 2 hours, which changes the distribution of gas and blood flow in the lungs and helps move secretions. Early ambulation is ordered to promote ventilation.

The use of an incentive spirometer is especially helpful to prevent atelectasis and hypoventilation (see [Chapter 4](#)). It should be used every hour while the patient is awake for the first 24 hours after surgery, and every 2 hours thereafter. Older adult patients may need extra coaching to master the spirometer technique.

Older Adult Care Points

The risk of hypoventilation is greater in older adults because lung expansion may be hampered by calcification of costal cartilage and weakened respiratory muscles.

A pulse oximeter may be used to determine blood oxygenation. Monitor oxygen readings periodically and report oxygen saturation (SaO_2) readings below 95%.

Maintain Circulation and Tissue Perfusion

When considerable blood is lost during surgery, a blood transfusion may be ordered. Autologous blood may be transfused if the patient donated blood several weeks before surgery or if the patient's blood was collected as it was lost during surgery. This blood is filtered and returned to the patient. Be vigilant for signs of shock and check for visible hemorrhage by measuring the amount of blood on dressings. (See [Prevent Postoperative Complications](#) and [Chapter 44](#).)

If surgery involves an extremity (arm, leg, foot, or hand) or if a procedure has been performed on the pelvic area, the distal or peripheral pulse is checked during each full assessment. Swelling at the surgical site can compress vessels and decrease blood flow distal to the surgical site. The skin distal to the surgical site should be warm to the touch, and there should be brisk capillary refill in the fingers or toes. Color, movement, and sensation of the fingers and toes should be checked to detect nerve or blood vessel compression from swelling and edema.

Blood pressure (BP) and pulse should be compared with preoperative values to determine whether there are significant changes. An increase in pulse may indicate that internal bleeding is occurring, but it can also signify incomplete pain control. BP that falls below the patient's normal baseline level may indicate major bleeding.

Core Measures (The [Joint Commission \[TJC\], 2014](#)) require antithrombosis therapy after many surgeries. The use of sequential compression devices (SCDs) on the legs is recommended. SCDs alternately compress and release, squeezing the legs and propelling blood along the vessels, increasing venous return from the legs and helping prevent stasis of blood in the lower extremities ([Figure 5-3](#)). The SCDs should be checked frequently to ensure proper fit and function. They should be removed at least once per shift to allow air circulation to the skin or for bathing and full skin inspection ([Gould et al, 2012](#)). As danger of **thrombosis** decreases, compression stockings may take the place of the SCDs. The stockings must be fitted correctly and should be checked frequently to ensure that they fit smoothly. Orders for ambulation are written as soon as the patient is able to be up and walking.

Clinical Cues

When compression stockings are ordered to be worn to surgery, they should be applied at least 2 hours preoperatively. Problems occur if the stockings are not fitted correctly, particularly with thigh-high stockings.

FIGURE 5-3 Sequential compression devices in place to prevent thrombus formation.

Low-molecular-weight subcutaneous heparin injections may be ordered as a general precaution and for any patient who has a history of **thrombophlebitis** (clot and inflammation in a blood vessel) or is at high risk for thrombosis. Patients undergoing hip surgery usually receive heparin. Thrombophlebitis may not occur until after the fifth day of bed rest, when stasis has allowed a clot to form and irritate the vein. Question the patient about pain or tenderness in the legs. If the patient complains of leg pain, gently assess the skin for increased warmth and notify the surgeon.

⚠ Safety Alert

Preventing Embolus

Never massage the patient's legs, which might dislodge a blood clot and cause an embolus that could lodge in the lungs, heart, or brain, causing a pulmonary embolus, myocardial infarction, or stroke.

💡 Think Critically

The initial vital sign readings for your patient on return from surgery were BP 138/86, pulse 76, respirations 14, temperature 97.7° F (36.5° C). An hour later they were BP 126/74, pulse 80, respirations 14, temperature 98.0° F (36.7° C). What action, if any, should you take?

Prevent Injury

Safety is a primary concern until the patient is fully recovered from anesthesia. Always leave the bed in the low position after administering care. Remind the patient to call for assistance as needed and be certain the call bell is within reach. Core Measures (The Joint Commission, 2014) require the use of interventions to prevent falls. Remember that you are the patient's advocate while he is still recovering from surgery and anesthesia or is under the influence of narcotic analgesia. Be certain that all appropriate safety measures are listed on the patient's care plan.

Reassure patients who have had spinal anesthesia that it is normal for the legs to feel numb and heavy, and that feeling will soon return to normal. Maintain a flat position with only a pillow until feeling returns. Sense of position in space will return to the legs first, followed by sensation to deep pressure, voluntary movement, and finally feeling of superficial pain and temperature. A feeling of "pins and needles" in the legs is common. The patient is susceptible to hypotension until all effects of the spinal anesthesia are gone. Lying flat for 6 to 8 hours may decrease the chance of post-spinal anesthesia headache. If a headache develops, staying flat in bed reduces the pain. Keep IV fluid

running as ordered. Encourage the patient to increased fluid intake, including those containing caffeine. The patient can turn the head to the side and sip from a straw while someone else holds the container. Fluids and caffeine raise the vascular pressure at the spinal puncture site and help to seal the hole.

Think Critically

How would care for a patient who has had spinal anesthesia differ from care for a patient who has had general anesthesia?

Many surgical procedures last several hours, which means that the patient has been lying motionless, in a fixed position, on a hard table for a considerable time. Check pressure points related to the position that the patient was in during surgery and provide padding and appropriate positioning for areas that are painful (see [Chapter 41](#)).

Think Critically

Your postoperative patient was placed in a right side-lying position during surgery. Which specific places should you check for signs of pressure problems? How would you position a patient who is complaining of pain in the right hip, as well as pain in the left flank where the surgery occurred?

Older Adult Care Points

Because skin is fragile and older adults have less subcutaneous tissue, check bony prominences carefully for signs of breakdown. Joint strains can occur from the positioning necessary for certain types of surgery; perform position changes slowly and gently.

Prevent Infection

Use aseptic technique when caring for postoperative patients. Good hand hygiene is the primary means of preventing infection. Dressing changes are performed with strict sterile technique while the patient is in the hospital; the patient may use clean technique at home. Encouraging fluid intake to flush the bladder will help prevent a bladder infection in patients who were catheterized or have an indwelling catheter. Turning, coughing, deep breathing, and ambulation will assist in preventing **pneumonia** (inflammation and accumulation of exudate in the lung) from retained secretions and lack of movement. Aseptically handling drains and aseptically emptying wound drainage devices prevent the entry of microorganisms.

[TJC Core Measures \(2014\)](#) state that if the patient is receiving a prophylactic antibiotic, it must be discontinued within 24 hours after surgery. Assess the surgical wound area each shift and assess for signs of infection (e.g., local pain, increased tenderness, warmth, redness, or drainage of purulent material). Monitor the blood count for increasing leukocytes (white blood cells [WBCs]) and the body temperature for an unexpected increase. Keeping blood glucose within normal limits helps prevent wound infection ([Neal, 2010](#)).

Maintain Fluid Balance and Elimination

Urine output is closely monitored after surgery. If the patient has an indwelling catheter, observe the urine in the bag every hour in the early postoperative period. Report a urine flow of less than 30 mL/hr to the charge nurse. Check the catheter to ensure that it is not kinked and that the connecting tubing is not lying beneath the patient. A patient without a catheter in place must void within 4 to 8 hours depending on the type of surgery and the anesthesia used. If the patient is unable to empty the bladder spontaneously, obtain a bladder scan and, if needed, an order for catheterization. **If flow is less than 60 mL over a 2-hour period, the surgeon must be notified.**

Assignment Considerations

Urinary Output

When a UAP is assigned to turn the patient every 2 hours, remind the UAP to check that the tubing

of any indwelling catheter is not under the patient or crimped. If the UAP is assigned the task of emptying the Foley catheter bag at the end of the shift, ask that you be notified if there is less than 30 mL of urine per hour for the shift in the output. Verify that the UAP knows to maintain sterility of the urinary catheter system and to wipe the spout with an alcohol sponge after emptying the urine bag.

Patients usually return from surgery with an IV infusion running. Depending on the type of surgery, IV fluids may be continued for a few days or may be discontinued after the fluid has infused. Check orders to see that the correct solution is running. **No potassium additive should be given until the urine flow is at least 30 mL/hr.** Potassium may cause hyperkalemia if kidney function is not adequate. Assess the IV site for patency, flow rate, and complications each hour. Document all IV fluids administered as intake on the I&O record.

As soon as the patient is conscious and the gag reflex has returned, offer a few ice chips or sips of water, unless there is an order to maintain NPO status. Document all oral intake, as well as IV fluids administered. At the end of each shift, calculate and document the difference between the intake and output. Because fluids were lost during surgery, the body will initially retain fluid. Postoperatively, the output will slowly increase until it is more than the intake; after 2 to 3 days, fluids should again be balanced.

Clinical Cues

A cup of ice equals $\frac{1}{2}$ cup of water.

Anesthesia may cause nausea and vomiting. Keep the emesis basin close by, and position the patient on the side to prevent aspiration. Check the orders to determine on which side the patient can be positioned. The surgeon usually writes an order for medication in the event of excessive nausea or vomiting. **To prevent stress on the incision and sutures, it is best to medicate the patient before actual vomiting occurs.**

Apply a cool cloth to the forehead and back of the neck, rinse the mouth, rid the room of odors, and provide a quiet environment to help reduce nausea. After emesis, mouth care should be provided. If vomiting is uncontrolled with medication, a nasogastric (NG) tube, which suction stomach contents and prevents fluid and electrolyte loss, may need to be inserted.

Older Adult Care Points

Fluid and electrolyte shifts may cause confusion in an older adult patient after surgery. The skin and vessels in older adults are more fragile, so the IV site must be assessed frequently for signs of infiltration. Adjustment to fluid shifts is more difficult, and older adults are very prone to postural hypotension when changing to a standing position. Be sure to provide adequate support.

Promote Gastrointestinal Function and Nutrition

Surgeons often keep the patient NPO and place an NG tube after abdominal procedures, because handling of the gastrointestinal (GI) tract and general anesthesia cause peristalsis to halt, which means that secretions will not flow through the system properly. The NG tube removes gathering secretions. When an NG tube is in place, check that the tube is positioned and functioning properly and that the suction is set according to orders. Assess the amount of drainage produced every 1 to 2 hours. If the drainage turns dark brown and grainy, it should be checked for blood using a special reagent. Report the presence of blood to the surgeon.

A healthy surgical patient may be kept on nothing but IV fluids for several days without developing a serious nutritional problem. If extensive tissue repair is required for healing, supplemental nutrition by enteral or parenteral feeding may be started (see [Chapters 3 and 27](#) for details of enteral and total parenteral nutrition). A patient who is NPO and kept on IV fluids will lose some weight, because there are insufficient calories in the IV fluids to meet total daily requirements. A liter of 5% dextrose in water contains only 200 calories.

After surgery that required general anesthesia, the patient will not be allowed to eat until bowel sounds have returned because of the risk of developing **paralytic ileus** (failure of forward movement of bowel contents).

Clinical Cues

When permitted by the surgeon, chewing sugarless gum can speed bowel recovery after abdominal surgery. Gum chewing has also been shown to be effective for recovery from paralytic ileus ( [Wronski, 2014](#)).

At least once per shift, or according to hospital policy, listen for bowel sounds in all four quadrants. Once they are heard, the surgeon usually orders clear liquids, followed by full liquids, then a regular diet if the preceding diets have been tolerated. The patient may be allowed to eat right away after spinal anesthesia.

Clinical Cue

Having the postoperative patient chew gum frequently tends to encourage the return of bowel function.

Discomfort from abdominal distention and considerable flatus may occur after general anesthesia, because peristalsis ceases. Taking only small amounts of liquid or food at a time, drinking only tepid liquids, and refraining from drinking with a straw helps keep flatus to a minimum, and ambulating helps move and evacuate gas. If permitted, the patient can try resting in a slight Trendelenburg's position, with the legs and rectum higher than the stomach, which may assist in evacuation of flatus.

Once the patient is eating again, a bowel movement should occur within 2 to 3 days. If this does not occur, an order for a suppository or laxative may be needed to stimulate a bowel movement. Patients receiving narcotic analgesics may become constipated and require stool softeners or laxatives to produce normal bowel movements.

Think Critically

Name four specific interventions to prevent constipation in a postoperative patient who is receiving narcotic analgesics for pain.

Promote Comfort

Pain and discomfort interfere with rest and inhibit the processes of healing and repair. Although analgesic drugs are almost always prescribed for postoperative patients, comfort measures also should be used. Nonsteroidal anti-inflammatory drugs (NSAIDs) and nonnarcotic analgesics work on both the peripheral nervous system and the central nervous system (CNS) to control pain and may be used to augment opioids. Opioids tend to depress respirations and the cough reflex and therefore may contribute to the development of pulmonary problems. Opioids also can increase the possibility of nausea and vomiting. Using other drugs in combination with opioids helps to control pain with the fewest side effects.

Pain must be reduced so that the patient will rest, turn, cough, and deep breathe frequently, and medication should be given consistently for the first 24 to 48 hours postoperatively. **Assess pain level and effectiveness of analgesia using a pain scale at least every 3 hours.** Remind the patient to request medication before the pain becomes severe, such as at 3 to 4 on the pain scale.

If the patient complains of pain on transfer to the unit, refer to the notes from the recovery unit nurse. Note any medications administered both preoperatively and postoperatively. **When droperidol plus fentanyl (Innovar) is given preoperatively, narcotic pain medication should be reduced by half for 8 hours postoperatively to prevent serious respiratory depression.** If respirations are within normal limits and there is no contraindication to doing so, medicate the patient promptly with the ordered analgesic. If it is too soon to give more analgesia, reposition the patient, be sure the bladder is not distended and causing discomfort, check that the patient is warm enough, and use other comfort measures to relieve the pain, such as distraction and imagery. Note when analgesia is due and have it ready to administer at the appointed time.

Teach relaxation techniques that can help decrease the patient's discomfort (see [Chapter 7](#)). Pain medication may be administered by subcutaneous or intramuscular injection, intravenously, epidurally, or by intermittent administration of local anesthetic into the pleural space with an

intrapleural catheter. Three methods commonly used for pain control are the patient-controlled analgesia (PCA) pump, the epidural catheter, and the continuous peripheral nerve block for extremity pain. Pain, methods of pain control, and pain medications and their administration are discussed in greater detail in [Chapter 7](#).

Maintain Temperature

Operating rooms are kept very cool so that the staff members working under the bright lights do not become overheated and growth of organisms is inhibited. The patient's temperature in this environment often decreases, especially during prolonged abdominal surgery in which the peritoneal cavity has been open for a long period. Warming during surgery is recommended, and the Core Measures specifically state the importance of warming the patient undergoing colon surgery ([TJC, 2014; IHI, 2013a](#)). Postoperatively, the patient may feel cold and should be kept warm with extra blankets or warmed bath blankets applied under the top covers. Placing socks on the patient's feet may help. Some anesthetic agents may cause tremors as they are metabolized. If uncontrollable shivering occurs, contact the surgeon for medication orders.

Dressings on extremities should be checked to be certain that they are not so tight that circulation is impaired. Check the pulse, skin temperature, sensation, and movement distal to the surgical site to evaluate circulation (neurovascular assessment). You should be able to slip your little finger between a dressing and the extremity. Dressings that are too tight cause pain.

Occasionally, continuous hiccoughs occur after surgery, making the patient quite uncomfortable. Having the patient breathe into a paper bag will often relieve the hiccoughs, and sedatives and tranquilizers are sometimes prescribed to promote relaxation and reduce irritation of the phrenic nerve. Severe, persistent cases of hiccoughs may require surgical interruption of impulses along the nerve pathways to remove the cause of the spasms of the diaphragm.

Complementary and Alternative Therapies

Stopping Hiccoughs

An alternative treatment for hiccoughs is to massage the earlobes. Massage activates the acupressure points, interrupting the hiccup reflex. Other commonly used remedies include:

- Fill a glass with at least 4 oz of water. Lean over a sink and drink the water from the back side of the glass. Drink continuously until the glass is empty.
- Stick a finger in each ear, and hold your breath.
- Drink from a glass that someone else is holding for you.
- Breathe into a paper bag deeply 20 times.
- Place a teaspoon of sugar or peanut butter on the tongue and let it slowly dissolve; the hiccoughs will be gone when the sugar or peanut butter has dissolved.

Promote Rest and Activity

Patients need sleep after surgery. Keep the room quiet and group nursing activities to prevent waking the patient more often than necessary. At least every 2 hours, the patient must do leg exercises and change position. Orders for ambulation may begin within several hours after surgery. Raise the head of the bed first and let the body adjust to the position change. Then sit the patient on the side of the bed, allowing the legs to dangle over the side with the feet on the floor or a foot stool. After a few minutes, slowly assist the patient to stand. Assist the patient to walk around the room, or for at least a few steps. Use a gait belt and have someone assist you if the patient is very weak. Pain medication can be timed to decrease pain during ambulation if it does not make the patient too groggy.

Emphasize that exercise is vital to prevent circulatory problems and offer praise for all efforts. Keeping blood from pooling in the extremities helps prevent thrombus formation and **embolus** (a thrombus or clot that travels and lodges elsewhere in the body). Continue to ambulate, in the

hospital or at home, on a set schedule until the patient is able to do so independently. In many hospitals, physical therapy orders will be written and the physical therapist will be responsible for ambulating the patient and overseeing range-of-motion exercises.

If the patient is on strict bed rest, range-of-motion exercises must be performed at least four times a day. The patient may do active range of motion on most joints, but passive range of motion must be done on joints the patient is unable to exercise unless physical therapy visits have been ordered. Family members also may help with these exercises.

Promote Wound Healing

Surgical incisions most often heal by primary, or first, intention (Table 5-1). Adequate rest, sufficient blood supply, and proper nutrition all promote wound healing. See Evolve for a review of the wound healing process. Rest decreases the metabolic rate and allows nutrients to be used for healing rather than activity. **Proteins** provide the amino acids that are the building blocks of tissue and are vital to the healing process. Blood transports amino acids and other elements needed for rebuilding tissue and is essential to healing. Good circulation ensures that blood reaches the wound. **Vitamin C** is necessary for collagen production, the formation of capillaries that bring blood to the healing tissues, and for resistance to infection. The minerals **zinc**, **copper**, and **iron** also assist in the formation of collagen.

■ Nutrition Considerations

Foods High in Vitamin C and Protein

FOODS HIGH IN VITAMIN C	FOODS HIGH IN PROTEIN
• Citrus fruits and juices	• Meats: chicken, beef, pork, lamb*
• Strawberries	• Cottage cheese
• Cantaloupe	• Milk*
• Tomatoes	• Cheese
• Bell peppers	• Peanut butter
• Cabbage	• Beans
• Turnip or collard greens	• Eggs
• Broccoli	• Ice cream
• Mangos	• Grain products: breads, pasta
• Peaches	• Tofu; soy products
• Pineapple	
• Potatoes	

*Meats and milk products contain the highest amounts of protein.

■ Older Adult Care Points

- Older adults often have chronic diseases that interfere with oxygenation, transport of nutrients to the cells, and removal of waste from the cells.
- Vitamin and mineral deficiencies are common in older adults and contribute to poor wound healing.
- Regeneration of tissue takes more time in older adults, partially because of the slower metabolic rate that occurs with age.

Factors Interfering With Wound Healing. Mechanical injury from friction, pressure, or abrasion—such as can occur when tape is removed—disrupts the healing tissue and prolongs wound healing. Physical injury destroys granulation tissue, which is the framework on which new cells grow and mature to form a covering for the wound. Handle all wounds gently and shield them from injury. When dressings are removed from a wound, take care not to dislodge granulation tissue. **Smoking decreases the amount of hemoglobin available to carry oxygen to the healing tissues and prolongs healing time.** (See the Evolve website for a review of the wound healing process.)

Table 5-1

Phases of Primary Intention Wound Healing*

PHASE	ACTIVITY

Phase I	
Acute inflammatory reaction (3-4 days)	Process of hemostasis. Constriction of blood vessels, platelet aggregation and the formation of fibrin, and epithelial cell migration. Phagocytosis occurs. Scab forms.
Phase II	
Proliferation and granulation (third or fourth day to 2-3 wk)	Macrophages clear debris, fibroblasts synthesize collagen, capillary networks are built, granulation tissue is formed. Closure by contracture begins.

*A surgical incision most often heals by primary intention. Many accidental wounds and some infected wounds heal by secondary or tertiary intention.

The presence of pathogenic organisms in a wound prolongs the inflammatory process and delays healing. Anti-infective drugs are sometimes given postoperatively to prevent wound infection and should be administered as ordered to maintain appropriate blood levels of the drugs. Corticosteroids taken for a chronic condition will slow the healing process, because they suppress the immune and inflammatory response.

Excessive stress, apprehension, and emotional disturbances seem to make the body more vulnerable to invasion by foreign organisms by depressing the immune system. When under excessive stress, the body also is less able to mobilize the elements and cells that promote healing.

Interventions for Wound Care. The surgical wound should be inspected during dressing changes, or at least once a day. Assessment includes observing the incision line for signs of excessive swelling, formation of a **hematoma** (blood-filled swelling), formation of a **seroma** (serum-filled swelling), redness, or tearing of the skin or other signs of separation of the edges of skin that have been sutured together. Normally, a surgical wound is sealed within hours, and little drainage is expected. Report and document evidence of bleeding, **purulence** (pus), or any other sign that the wound is not healing properly. Document the appearance of any drainage. Drainage may be serous (clear or very light yellow), serosanguineous (reddish yellow), or sanguineous (blood red). Documentation should include whether sutures or staples are intact and the wound edges are well approximated.

The best way to prevent hospital-acquired infection of a surgical wound is always to wash your hands before doing wound care or touching the patient, to use aseptic technique and Standard Precautions for dressing changes, and to change the dressings as ordered. Additional factors that may slow wound healing in a postoperative patient include vomiting, abdominal distention, and strenuous respiratory efforts, such as coughing and forcefully exhaling breaths of air without proper splinting of the incision. The wound should be properly splinted for coughing to prevent dehiscence of the incision (see [Figure 4-2](#)).

Dressings. **Surgical dressings should be checked each time vital signs are taken for the first 24 hours after surgery, every 4 hours during the next 24 hours, and then at least every 8 hours as long as the surgical wound is covered with a dressing.** If a wound is not expected to drain, but drainage is evident, the surgeon should be notified. If drainage is outlined and the time and date noted, you can tell if the wound is draining more than it should over a period of hours. The surgeon usually does the first dressing change. If the dressing becomes saturated before this, it should be reinforced by placing more dressing material over the area. If it is within the orders, remove outer dressings—leaving those in direct contact with the wound—and secure new outer dressings in place. When there is excessive drainage, the dressing probably will require reinforcing every 4 hours. Changing the dressing more often than once a shift is not recommended because of the dangers of introducing infectious agents, of traumatizing the wound, and of interfering with tissue regeneration.

Each time the dressing is changed as ordered, the amount and characteristics of drainage on the dressing should be noted and documented. If the wound is infected, the odor of the drainage can give a clue as to the kind of organism causing the infection. A musty odor is characteristic of aerobic organisms. An acrid (sharp, stinging) or putrid (foul) odor is characteristic of anaerobes. Anaerobic infections are commonly seen after colorectal and vaginal surgery. An infected wound should be cultured to see what organism is causing the infection.

Drains. Drains are used to (1) prevent accumulation of fluids or air at the operative site; (2) protect suture lines; and (3) remove specific fluids, such as bile, cerebrospinal fluid, or drainage from an abscess. Drains not attached to a suction device are attached to a drainage bag or have dressings placed to catch the fluid. An example of a drain is the **Penrose**, which is inserted into the abdominal cavity or any other area where an abscess, fistula, or other condition requires drainage ([Figure 5-4](#)). A T-tube drain may be placed in the common bile duct after surgery on the gallbladder or liver.

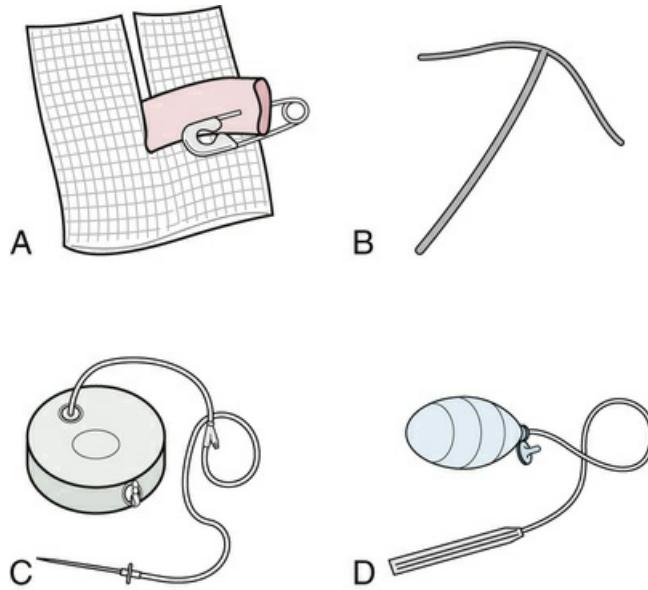

FIGURE 5-4 Wound drains. **A**, Penrose drain. **B**, T-tube drain. **C**, Hemovac. **D**, Jackson-Pratt.

Some drains are connected to an apparatus that creates continuous suction to facilitate removal of fluid and gas. If a drain is kinked, the accumulated fluid and gas can cause pain, create dead air space (which delays healing), damage the healing tissue at the suture lines, and delay healing by compressing surrounding capillaries and cutting off oxygen supply to the cells.

One kind of drain system is the closed-wound suction device (e.g., Hemovac). The drainage catheter is connected to a spring-loaded drum and is collapsed at least once each shift to create the desired suction, which pulls fluid into a collection area of the device (see [Figures 5-4, C](#), and [5-5, A](#)).

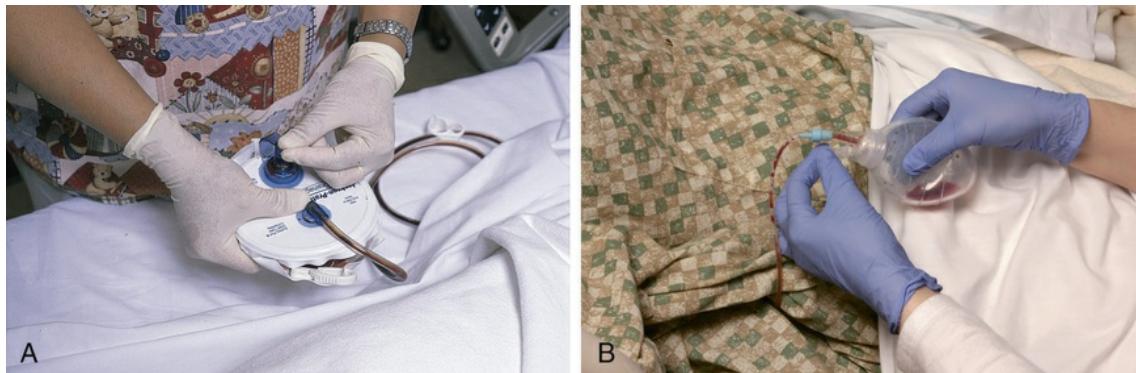

FIGURE 5-5 Reactivating surgical wound suction devices by compressing the suction device after emptying the reservoir. **A**, Hemovac. **B**, Jackson-Pratt. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.)

Jackson-Pratt suction devices are about the size of the bulb on a blood pressure cuff and have a valve on top. The valve is opened to allow removal of fluid and to collapse the bulb; the valve is then closed to create negative pressure, which provides the suction. As drainage accumulates in the bulb, it is emptied and recompressed (see [Figures 5-4, D](#), and [5-5, B](#)). This procedure should be done to Jackson-Pratt suction devices at least once per shift.

Removing Sutures and Staples. When an order is written to remove sutures or staples, check the order, gather the proper equipment, inform the patient about the procedure, correctly identify the patient, wash hands, don gloves, and inspect the incision carefully. For a long incision or an incision over a joint, remove every other suture or staple first ([Figure 5-6](#)). If the edges of the incision do not pull apart, remove the rest of the sutures or staples. Often **Steri-Strips** (small, reinforced strips of adhesive) are applied to hold the incision together until healing is complete.

FIGURE 5-6 Surgical staples are removed with a special implement.

Prevent Postoperative Complications

Table 5-2 summarizes the major postoperative complications and the nursing interventions to prevent them. Some complications are immediately life-threatening.

Table 5-2
Postoperative Complications

PROBLEM	SIGNS AND SYMPTOMS	PREVENTIVE INTERVENTIONS
Atelectasis	Decreased breath sounds over areas not aerating; dyspnea	Deep breathing and coughing; use of incentive spirometer; early ambulation; teach to cough properly.
Pneumonia: hypostatic, aspiration, or bacterial	Fever, malaise, increased sputum, purulent sputum, cough, flushed skin, dyspnea, pain on inspiration; abnormal breath sounds, crackles, rhonchi	Deep breathing, coughing, and frequent turning; early ambulation; incentive spirometer use; range-of-motion exercises if unable to ambulate; medication if bacterial.
Paralytic (adynamic) ileus	No bowel sounds 24–36 hr after surgery or fewer than 5 sounds/min	Monitor bowel sounds; encourage early ambulation; nothing by mouth as ordered. Do not feed until bowel sounds return.
Thrombophlebitis	Pain or warmth in calf of leg, swollen leg, area on leg warm to touch; possible temperature elevation	Encourage leg exercises; keep the patient well hydrated; encourage ambulation; use anti-embolism stockings or devices.
Urinary retention	Distended bladder; inability to void spontaneously	Palpate bladder; encourage voiding; if unable to void within 8 hr per order obtain a bladder scan and if needed an order for catheterization; medicate to increase urinary sphincter tone as ordered.
Urinary tract infection	Dysuria, frequency, foul-smelling urine	Force fluids when allowed; encourage frequent voiding; keep catheter clean and patent; use aseptic technique to empty drainage bag.
Wound infection	Redness, swelling, pain, warmth, drainage, fever, increased leukocytes, rapid pulse and respirations (fever 72 hr after surgery indicates infection in some system or in the wound)	Assess wound characteristics and drainage. Monitor white blood cell count and temperature. Use aseptic technique for wound care; encourage adequate nutrition and fluids; encourage activity.
Pulmonary embolus	Shortness of breath, anxiety, chest pain, rapid pulse and respirations, cyanosis, cough, bloody sputum	Anti-embolism stockings, adequate fluid intake, frequent turning or ambulation, preventive anticoagulant if ordered; leg exercises.
Hemorrhage and shock	Evidence of copious bleeding; decreased blood pressure, elevated pulse, cold clammy skin, decreased urinary output	Give blood or volume expander; stop bleeding. Place in shock position with feet and legs elevated and head flat; administer ordered medications to raise blood pressure; administer oxygen; measure vital signs frequently.
Wound dehiscence or eversion	Discharge of serosanguineous drainage from wound and sensation that "something gave"; separation of wound edges with intestines visible through abdominal incision	Teach to splint properly for coughing. Place patient supine with knees flexed; cover wound with sterile saline-soaked gauze or towels; return to operating room for repair; monitor for shock.
Fluid imbalance	Signs of overhydration: crackles in lungs, edema, weight gain Signs of dehydration: weight loss, diminished pulse, dry mucous membranes, decreased tissue turgor	Control intravenous flow rate. Monitor intake and output; correct imbalances. Output will be less than intake for first 72 hr after surgery with general anesthesia. Auscultate lungs each shift. Monitor weight; check for edema.
Malignant hyperthermia	High temperature, cardiac dysrhythmias, muscle rigidity, hypotension, tachypnea, and dark cola-colored urine	Genetic predisposition; can only monitor and treat symptoms; apply cooling blanket and ice packs. Give dantrolene as ordered.

Modified from deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.

Wound Infection. Infection of a wound can occur after any surgical procedure, but it is more common in wounds caused by accidental injury and in wounds that were already infected at the time of surgery. A prophylactic antibiotic after surgery may be ordered to prevent a wound infection. **If an infection is going to develop, it usually becomes apparent 2 to 7 days postoperatively.** Most patients will already be at home when postoperative infection becomes evident.

Clinical Cues

Subjective complaints that may indicate infection include fatigue, loss of appetite, headache, nausea, or general malaise or pain. Objective signs may include pain, redness, swelling and induration in the area, purulent drainage, fever, increased pulse rate, elevated WBC count, and swollen lymph nodes in adjacent areas.

If an infection occurs, cultures are obtained and appropriate antibiotics are given for a specific length of time. Wound irrigations may be ordered for an open infected wound. Sterile normal saline is the most common solution for this purpose. The wound may be packed with dressings moistened with the sterile saline solution.

A noninfected wound should not be cleaned or irrigated with anything but sterile normal saline; other substances irritate the tissue and slow healing. Transmission-based isolation precautions or contact precautions are instituted when a wound is infected (see Chapter 6). Gowns and gloves are worn when performing dressing changes or when irrigating infected wounds. If splattering is likely, protective eyewear and masks are also worn. Soiled dressings and supplies are bagged in plastic barrier bags to be deposited in a biohazard trash receptacle. **Dressings from an infected wound should never be placed in the patient's room trash container.**

Dehiscence and Evisceration. When caring for a patient who has undergone abdominal surgery, you must be alert for possible disruption or separation of some or all the layers of the surgical wound. This is called **dehiscence** (Figure 5-7). If the wound completely separates and the contents of the abdominal cavity (viscera) protrude through the incision, the condition is called **evisceration** (see Figure 5-7).

Clinical Cues

Dehiscence can occur at any time during the postoperative period, but it most commonly occurs between the fifth and twelfth postoperative days—when the patient is feeling stronger and more active, but healing is not complete, or when infection has occurred. When checking an abdominal surgical wound, be particularly aware of any drainage on the dressing. There is often a noticeable increase in the amount of serosanguineous drainage on the dressing before the separation of the wound layers becomes apparent. Subjectively, the patient may not notice any symptoms until there is a feeling of “giving way” in the wound.

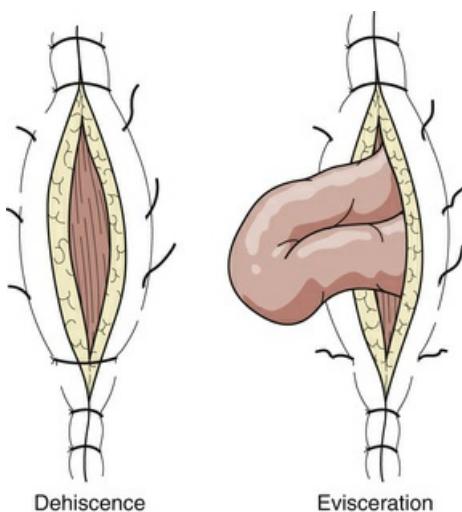

FIGURE 5-7 Complications of wound healing: dehiscence and evisceration. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, Philadelphia, 2013, Saunders.)

Wound separation or disruption usually is brought on by a sudden strain or stress on the suture lines (e.g., when the patient sneezes, coughs, or has an episode of retching and vomiting). **Patients most at risk for dehiscence and evisceration are those who are diabetic, obese, malnourished, or dehydrated; have a malignancy; have experienced multiple traumas to the abdomen; or have an infected wound.** Abdominal distention and broken sutures are other factors in wound disruption. Wound dehiscence and evisceration create an emergency that requires immediate surgery and are very serious complications. After dehiscence and evisceration occur and before reparative surgery, the patient should lie supine with the knees flexed. The wound should be covered with a sterile towel or sterile dressings moistened with sterile normal saline. Positioning with the knees flexed prevents abdominal muscle strain.

Home Care Considerations

In Case of Dehiscence or Evisceration

If dehiscence or evisceration occurs at home, moisten sterile gauze with sterile water (or fresh water if sterile is unavailable) and place it over the exposed bowel to keep the bowel membrane moist. Immediately notify the home care agency or the surgeon, call someone to help, and have the patient lie supine with the knees flexed and the moistened dressings in place.

Think Critically

Identify seven assessment findings that together would indicate a wound infection.

Hemorrhage and Shock. The two most common complications of anesthesia and surgery are shock and infection. Shock, which can quickly develop into a life-threatening emergency, presents the most immediate danger to the patient. Shock disrupts normal physiologic function and can result from (1) failure of the heart to function as a pump (**cardiogenic shock**), such as in cardiac arrest (see [Chapter 20](#)); (2) a low volume of blood (**hypovolemic shock**), such as in hemorrhage; (3) collapse of the blood vessels as a result of faulty nervous system regulation (**neurogenic shock**) (see [Chapter 44](#)); (4) **anaphylaxis** (severe, allergic reaction), such as in hypersensitivity to a drug or other allergen (see [Chapter 11](#)); and (5) sepsis, occurring when toxins from bacteria relax and dilate blood vessels, resulting in a drop in blood pressure (see [Chapters 6 and 44](#)).

In the immediate postoperative period, the patient is most likely to suffer from cardiogenic, hypovolemic, or neurogenic shock. However, any of the five kinds of shock are possible after anesthesia and surgery. The symptoms of shock depend to some degree on the cause of circulatory failure.

Clinical Cues

Early signs of impending hypovolemic shock from hemorrhage are thirst, restlessness, tachycardia, and tachypnea. Changes in the vital signs may be the only warning sign of neurogenic and cardiogenic shock.

As shock progresses, BP begins to drop and pulse rate increases. Pulse may be bounding at first but becomes thready and indistinct as circulatory collapse occurs. Skin becomes cold and clammy, and pallor becomes evident. There may be air hunger with cyanosis of the lips and nail beds as a result of tissue hypoxia. As shock deepens, blood pressure continues to fall, and the patient loses consciousness, eventually becoming comatose. Untreated shock is fatal.

Both general and local anesthesia can bring about circulatory collapse. If there is evidence of shock, the patient should be placed in the supine position with the lower extremities elevated to add blood volume to the vital organs. **Patients in cardiogenic shock are placed in Fowler's position to lower the diaphragm and increase oxygenation as long as they do not become too hypotensive.** Pain contributes to the progression of shock; however, administering large doses of narcotics can decrease blood pressure further. Sometimes patients who develop shock also develop disseminated intravascular coagulation, a life-threatening disorder evidenced by bleeding from many sites (see [Chapter 17](#)).

Intravenous fluids and medications are important to prevent and treat shock. Supplemental oxygen is usually given to combat tissue hypoxia and cardiac response. See [Chapter 44](#) for specific treatments for shock.

Malignant Hyperthermia. **Malignant hyperthermia (MH)** is a rare but life-threatening complication of general anesthetic agents, including halothane, isoflurane, enflurane, and succinylcholine. MH occurs from a biochemical reaction in genetically predisposed persons. Signs of MH include high temperature, cardiac dysrhythmia, rigidity of the jaw or other muscles, hypotension, tachypnea, and dark cola-colored urine. A late sign of MH is an extremely high temperature of up to 111.2° F (44° C). Notify the anesthesiologist and surgeon immediately if any of these signs occur. If it is not treated swiftly and effectively, MH is fatal. Dantrolene is the drug of choice to treat this condition. The patient is immediately placed on a hypothermia blanket, ice bags

are applied to the armpits and groin to cool the core of the body, and iced saline IV solutions and cold-solution enemas may be administered (Chapin, 2013).

Promote Psychological Adjustment

When surgery alters physical appearance, the patient may not only be concerned about the ability to perform self-care postoperatively but also may have considerable changes in body image, particularly if there is extensive scarring. If part of an extremity, an organ, or part of a breast has been surgically removed, the necessary psychological adjustment is considerable and takes a long time.

■ Communication

Recovering from Abdominal Surgery

Mrs. Wilson is a 74-year-old woman recovering from abdominal surgery. Although her body language tells her nurse she is experiencing pain, she has denied any need for pain medication since she administered her patient-controlled analgesia dose 3 hours before.

Nurse: "Mrs. Wilson, I would like to see you able to cough more vigorously, move about in bed more, and walk around more frequently. I think that if you would use your pain pump more often, you would be more comfortable doing your exercises and coughing."

Mrs. Wilson: "I'm not that uncomfortable, and those medications always cause problems for me."

Nurse: "Problems?"

Mrs. Wilson: "Yes, I get really constipated."

Nurse: "The doctor has a stool softener ordered for you to help prevent constipation, and by increasing fluids, we should be able to control that. Do you have other problems with the pain medication?"

Mrs. Wilson: "Yes, it makes me light-headed and unsteady on my feet."

Nurse: "If the pain medication makes you light-headed, we can switch you to a different medication, and one of us will stay with you when you are out of bed to see that you do not fall."

Mrs. Wilson: "I'm very afraid of falling, breaking a hip, and adding to my troubles."

Nurse: "By taking the medication and being more comfortable, you'll feel more like doing your exercises. That's how you can help prevent postoperative complications such as pneumonia or blood clots."

Mrs. Wilson: "I certainly don't want pneumonia or a blood clot!"

Nurse: "Moving about more will also increase circulation and help your wound to heal faster."

Mrs. Wilson: "Okay, I'll take the pain medication if it will help me prevent complications."

Assess the patient for signs of ineffective coping, including withdrawn, depressed behavior; less attention to grooming than before; and poor communication efforts. If these signs occur, work with the patient to identify areas of concern and collaborate with other health team members to develop a plan of assistance. Help the patient by encouraging discussion of feelings regarding what has been removed and the effect it might have on the patient's life. Be an active listener; gradually focus the patient on the positives in life rather than on the loss incurred. It helps to refer the patient to a support group of people who have undergone a similar experience and are also learning to cope.

■ Evaluation

Evaluative statements regarding previously stated goals and expected outcomes might include:

- Lungs clear to auscultation; respirations 18
- Pulse 82, BP 136/86, peripheral pulses present
- Pain controlled for 4 hours with analgesia; states pain medication controls pain for about 4 hours
- Incision clean, dry, and without redness
- Patient expresses gladness that periods of pain and malaise will be gone
- No signs of thrombophlebitis or infection

Each nursing care plan is evaluated on whether the individual specific outcomes have been met. Further examples of evaluation are in [Nursing Care Plan 5-1](#).

Nursing Care Plan 5-1

Care of a Patient Who Has Had a Simple Mastectomy

Scenario

Mrs. Talbot, a married 38-year-old woman and the mother of two children ages 16 and 14 years, underwent a simple mastectomy with sentinel node biopsy as treatment for a 4.5-cm malignant tumor.

Problem Statement/Nursing Diagnosis

Altered skin integrity/*Impaired Skin Integrity related to surgical wound*

Supporting Assessment Data

Objective: Right mastectomy; dressing on right chest.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Wound will be free of signs of infection at discharge.	Keep Jackson-Pratt suction functioning properly.	Suction is needed to pull drainage from operative site.	No signs of infection. Incision clean, dry, and without reddening.
Wound will heal completely within 6 weeks.	Note character and amount of drainage; document.	Helps detect excessive bleeding.	Draining small amounts of serosanguineous fluid.
	Reinforce dressing as needed.		No need for dressing reinforcement.
	Assess for excessive bleeding q1hr for 4 hr, then q2hr for first 24 hr.		Small amount of serosanguineous drainage in Jackson-Pratt.
	Assess pulses in arm q2hr to detect excessive swelling in arm.	Swelling in arm can cause nerve damage.	Minimal swelling in arm; pulses are 2+.
	Monitor temperature and white blood cell (WBC) count.	Temperature and WBC count trends will show if infection is developing.	No increase in temperature or WBC count.
	Assess wound for signs of infection with each dressing change.	Sterile dressing helps prevent infection.	Wound clean and dry without signs of infection.
	Change dressing q8-24hr as needed.		Surgeon changed dressing this afternoon. Continue plan.

Problem Statement/Nursing Diagnosis

Incisional pain/*Pain related to surgical incision*

Supporting Assessment Data

Subjective: Complains of incisional pain and discomfort.

Objective: Right mastectomy; rates pain at 4 on pain scale.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Pain will be controlled by analgesia as noted by patient.	Instruct on use of patient-controlled analgesia (PCA).	Knowledge is needed to use PCA effectively.	Using PCA appropriately.
	Assess pain level q3-4hr.	Assessing pain level will show whether pain is adequately controlled.	Pain level consistently below 4.
	Provide comfort measures.	Comfort measures increase effect of analgesia.	Straightened bed; brought warmed blanket.
Pain is controlled by oral analgesia by discharge.	Administer analgesics as ordered.		Continue plan.

Problem Statement/Nursing Diagnosis

Potential for altered gas exchange/*Risk for Impaired Gas Exchange related to inhalation anesthesia*

Supporting Assessment Data

Objective: Had general anesthesia. Restricted mobility.

Subjective: "I don't like using the incentive spirometer. Do I have to cough? It hurts."

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will not have atelectasis by end of postoperative day 2.	Have patient use incentive spirometer q1hr while awake.	Incentive spirometer use opens alveoli; decreasing atelectasis.	Using incentive spirometer; barely diminished breath sounds in lung bases.
	Have patient cough q2hr.	Coughing clears secretions from lung irritation caused by anesthesia.	Coughed secretions are clear.
Lung sounds will be clear at discharge.	Auscultate lungs q8hr.	Auscultation determines status of breath sounds.	Lungs clear.
	Encourage ambulation.		Ambulated ×2.
	Monitor temperature, respirations, and oxygen saturation.		Continue plan.

Problem Statement/Nursing Diagnosis

Potential grief/Risk for Grieving related to loss of body part and perception of femininity

Supporting Assessment Data

Objective: Right mastectomy.

Subjective: Expresses concern about husband's reaction to surgery.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will verbalize feelings of self-worth and confidence.	Have patient list her strengths and positive attributes.	Focusing on strengths can help counter feelings of loss.	Is patient verbalizing feelings of confidence and self-worth? Not yet.
Patient will discuss sadness over loss of breast.	Encourage sharing of sad feelings and fears with husband.	Talking openly with husband may provide reassurance.	Expressed sadness over breast loss to husband.
	Talk with husband privately about his feelings.	Involvement will show her he still cares for her.	Husband reluctant to speak about the surgery or his feelings so far.
	Involve husband in patient's care.		
	Encourage daughters to discuss their feelings and fears with patient.		Daughters have not been in yet today.
	Encourage independence in patient.	Independence increases self-confidence.	Brushed her teeth. Continue plan.

Critical Thinking Questions

1. You auscultate the patient's lungs the evening after surgery, and sounds are diminished in the bases. What do you think it means?
2. What would you do if the radial pulse in the arm on the same side as the breast surgery becomes weaker and harder to detect?

Discharge Planning

With same-day surgery and early release from the hospital after inpatient surgery, it is vital that discharge planning be started at admission or several days before the surgery. Assess needs for home care. Will the patient need assistance with bathing, meals, or dressing changes? It may be necessary to arrange home health care with an aide to assist with bathing, and with a nurse to assess the patient's condition and provide wound care. Equipment, such as oxygen, suction, or an IV pump, may need to be ordered before discharge so that the transition to home goes smoothly.

Cultural Considerations

Performing Wound Care

Although not overly modest, traditional Chinese people may hesitate in touching their own bodies, so it is important to assess who will perform wound care and change dressings at home. A home health nurse may need to be accessed, or teaching of another family member may be important.

Family or relatives must be included in discharge planning and teaching. Often it is a family member who will do the dressing changes, monitor for side effects of medication, alert the surgeon to signs of complications, and provide general support to the patient during recovery.

When the patient is discharged, review specific instructions regarding care at home, including care of the incision or wound, diet requirements, activity level allowed, medications, and signs and symptoms of complications to report to the health care provider. Make certain the patient understands when to see the provider for follow-up. Send home sufficient supplies of items needed for dressing changes, and tell the patient and family where more items can be obtained. Make every attempt to ensure that the patient does not go home with unanswered questions.

Patient Teaching

Discharge Instructions for a Same-Day Surgery Patient

Diet

- Type of diet and importance of proper nutrition for healing
- Dietary restrictions, if any
- Avoiding alcohol for first 24 hours after anesthesia
- Special dietary recommendations
- Recommended fluid intake

Activity

- Recommended exercise and frequency
- Instructions for special equipment: crutches, walker, cane, splint, etc.
- Schedule for deep breathing, coughing, and leg exercises; how long to continue these activities; splinting the incision when coughing and getting out of bed
- Recommended rest periods
- Activity restrictions (i.e., driving, intercourse, and lifting)
- Application, use, and care of anti-embolism stockings

Wound Care

- Hand hygiene
- Dressing changes and frequency
- Cleansing of wound; irrigations
- Drainage observations
- Signs to report
- Use of heat or cold packs for discomfort
- Supplies and where to obtain them

Temperature Monitoring

- Record time and temperature
- Report temperature greater than 100° F (38° C)

Bathing

- Type of bath
- Frequency

Medications

- Analgesics
- Antibiotics
- Sedatives
- Vitamin supplements
- Other medications

Precautions Related to Anesthesia or Side Effects of Medication

- Caution regarding using machinery
- Caution regarding making decisions for 24 hours
- Drug interactions
- Potential for constipation
- Potential for urinary retention

Signs and Symptoms to Report

- Elevated temperature
- Increasing malaise
- Severe pain or swelling
- Bleeding through bandage

- Decreased sensation below surgical site
- Severe nausea and vomiting
- Failure to urinate within 8 hours

Other

- Scheduled follow-up appointment with the surgeon
- Expectation for return to usual activities
- Expectation for return to feeling normal

Think Critically

An older adult patient who has had a hip replacement and who has chronic lung disease is being discharged home to the care of a 78-year-old spouse. Which health care professionals would you collaborate with to plan appropriate continuing care for the patient?

Community Care

The patient may be given follow-up care at an outpatient clinic, physician's office, subacute care unit, rehabilitation unit, extended-care unit, or at the patient's home. The nurse case manager will coordinate the care of the whole team, collaborating with the social worker, physical therapist, respiratory therapist, nurse's aide, dietitian, pharmacist, physician, and other health care professionals. The nurse assesses the patient's condition and progress, performs treatments and procedures such as wound care, and reinforces teaching about the signs and symptoms of complications. The quality of nursing care delivered postoperatively often is the factor that prevents complications and rehospitalization.

Some surgeons discharge patients who are ambulatory and normally self-sufficient, thinking that patients themselves can do complicated wound care. Most patients need assistance with anything more than a simple dressing change, which is particularly true if the patient lives alone. The nurse must verify that the patient can adequately perform self-care and collaborate with the patient, provider, social worker, and community agencies to secure the assistance the patient needs.

Home Care Considerations

General Points for Home Care for Postsurgical Patients

- Knows about each medication to be taken and when to take it
- Understands the diet, any restrictions, and guidelines for fluid intake
- Understands that alcohol must be avoided for 24 hours after surgery
- Verbalizes restrictions on activity and instructions for use of any special equipment such as crutches, splint, walker, and so forth
- Understands not to drive or make important decisions for 24 hours after anesthesia
- Verbalizes the type of bath permitted and how to protect the wound
- Can demonstrate cleansing and dressing of the wound; verbalizes where to obtain supplies
- Verbalizes signs and symptoms to report to the surgeon
- Understands how to schedule a follow-up appointment with the surgeon
- Understands written instructions for all essential points of care and consultation

Get Ready for the NCLEX® Examination!

Key Points

- Nurses in the recovery unit monitor patients very closely until they are fully aroused from anesthesia.
- Maintaining a patent airway is the highest priority.
- The nurse is vigilant for signs of complications and performs frequent assessments during the postoperative period.
- Nursing interventions are aimed at providing pain control, comfort, and fluid balance; protecting the patient from injury; maintaining vital functions; and preventing infection.
- The nurse tries to prevent or intervene in the many potential complications from surgery.
- Discharge planning begins at admission and covers all areas of basic needs, wound care, and activity restrictions.
- Written instructions regarding all aspects of postoperative care should be sent home with the patient.

Review Questions for the NCLEX® Examination

1. When prioritizing safety measures for a postoperative patient in the PACU, the nurse would:
(Place in order of priority.)

1. Observe for urine flow of at least 30 mL per hour.
2. Position the unconscious patient on the side to prevent aspiration
3. Check for a patent airway and the rate and depth of respiration.
4. Check infusing IV fluids for the correct fluid and flow rate.
5. Observe the dressing for any blood saturation.
6. Monitor drains for excessive fluid drainage.

NCLEX Client Need: Physiological Integrity

2. A nurse performing an assessment of a newly postoperative patient notes the following: temperature 104.9° F (40.5° C), BP 90/60, pulse 58, respirations 30, rigidity of the jaw muscles, and dark urine. The priority nursing action would be to:

1. instruct the patient to relax and take deep breaths.
2. notify the surgeon immediately.

3. administer pain medications.
4. give a tepid sponge bath.

NCLEX Client Need: Safe and Effective Care Environment

3. On arrival from the PACU, the patient complains of severe thirst. The nurse finds that the patient is increasingly restless, tachypneic, and tachycardic. Considering the findings, what would the nurse likely suspect?

1. Hypovolemia
2. Cardiogenic shock
3. Normal response to anesthesia
4. Pain medication overdose

NCLEX Client Need: Physiological Integrity

4. The nurse knows that care for the patient having spinal anesthesia differs from that of the patient undergoing general anesthesia in that during recovery: (*Select all that apply.*)

1. the patient will be unresponsive immediately after surgery.
2. muscles in the lower part of the body will be flaccid immediately after surgery.
3. the patient is able to eat immediately upon return to the nursing unit.
4. monitoring for a patent airway is a top priority in the PACU.
5. the patient will be alert upon entry to the PACU.
6. nausea may be a problem during recovery from anesthesia.

NCLEX Client Need: Physiological Integrity

5. The nurse knows that an older adult patient who had open reduction and internal fixation of the right femur is at risk for infection because of the surgical incision and repair and lessened immunity that occurs in older age. A desired result of interventions for this risk would be that the:

1. nurse will monitor changes in temperature and laboratory values during the shift.

2. nurse will teach the signs and symptoms of wound infection before discharge.
3. nurse will teach aseptic techniques to the patient before discharge.
4. patient will not develop a wound infection before discharge.

NCLEX Client Need: Safe and Effective Care Environment

6. To promote wound healing, the nurse instructs the postoperative patient to eat foods high in protein. Which food choice by the patient warrants further patient teaching?

1. Caesar salad with French bread and milk
2. Tuna sandwich, carrot strips, and watermelon chunks
3. Broccoli cheese soup, crackers, and an orange
4. Broiled chicken breast, steamed broccoli, and mashed potatoes

NCLEX Client Need: Physiological Integrity

7. One measure by the nurse to promote early patient ambulation and a return to independence in activities of daily living is to:

1. open cartons and items on the food tray while the patient has an IV infusing.
2. provide a bedside commode for toileting in the initial postoperative period.
3. encourage visitors to play cards or board games with the patient.
4. assist the patient to walk to a chair in front of the sink to bathe areas easily reached.

NCLEX Client Need: Health Promotion and Maintenance

8. While caring for the postoperative patient, the nurse must reinforce which measure(s) to reduce the incidence of complications? (*Select all that apply.*)

1. Use the incentive spirometer every hour while awake.
2. Ambulate the designated distance six times a day.

3. After deep breathing, cough effectively every 4 hours.
4. Turn or change position at least every 2 hours.
5. Assess for pain and provide prompt relief.

NCLEX Client Need: Safe and Effective Care Environment

9. What action(s) by the nurse would be appropriate when caring for a postoperative patient with a Jackson-Pratt wound drain? (*Select all that apply.*)

1. Assess the wound drain for patency.
2. Measure amount of drainage.
3. Compress the bulb to reestablish pressure.
4. Rinse the bulb with sterile water after emptying.
5. Notify the surgeon when there is no drainage.

NCLEX Client Need: Physiological Integrity

10. The patient is prescribed anti-embolism stockings before discharge. The patient asks the nurse, "Why do I need these stockings?" The best response would be:

1. "Your surgeon ordered these stockings."
2. "These help prevent formation of clots in the legs."
3. "These massage your legs to make you feel better."
4. "You sound upset. Do these stockings bother you?"

NCLEX Client Need: Health Promotion and Maintenance

11. Which patient statement to the nurse indicates a need for further teaching regarding the use of a patient-controlled analgesia (PCA) pump?

1. "I control my pain medication by pressing the button."
2. "To a certain extent, I control the amount of pain medication I can have."
3. "I need to tell the nurse if the pain is not controlled well."

4. "I need to call the nurse when I need pain medication."

NCLEX Client Need: Physiological Integrity

12. A 38-year-old woman who has undergone bilateral radical mastectomy is withdrawn and quiet. She is afebrile with no apparent complaints of pain. Her dressings are dry and intact. Pulses are full on both upper extremities. Considering the data, the major problem at this time would be:

1. Pain in the surgical area.
2. Potential surgical site infection
3. Distress over loss of her breasts.
4. Concern about her children at home.

NCLEX Client Need: Psychosocial Integrity

13. After a surgical procedure, a priority point for the nurse to emphasize to the patient when performing discharge teaching for self-care is:

1. eating sufficient protein and vitamin C to promote healing.
2. always washing the hands before starting a dressing change.
3. ambulating on a set schedule each day, extending the distance a little.
4. obtaining at least 8 hours of sleep each night.

NCLEX Client Need: Health Promotion and Maintenance

Critical Thinking Questions

Scenario A

Ms. Simpson just had a colon resection for a tumor, and you are assisting with her care in the PACU. She is waking up but is still groggy and her breathing is somewhat shallow. She has a large dressing on the left side of the abdomen.

1. What would you do to improve her respiratory status?
2. Describe the method used to ensure an open airway.

Scenario B

You are assigned to care for a 37-year-old man who just had a same-day surgical repair of a ventral hernia with spinal anesthesia.

1. How does the care of this patient differ from that of a patient who had inhalation or general anesthesia?

2. If this patient has difficulty voiding after surgery, how could you assist him?
3. If he develops a spinal headache, what measures could be taken to decrease his discomfort?

Scenario C

Mrs. Saunders is a 58-year-old woman who underwent an abdominal hysterectomy and exploration for cancer of the uterus. She returned to the nursing unit from surgery 1 hour ago and has an IV infusion running into the right forearm. Her BP has gradually fallen from 138/88 to 102/62. She is restless, complains of thirst, and is anxious.

1. What assessments would you make?
2. What actions would you take? In what order would you perform these actions?

Scenario D

Mr. Jackson is a 68-year-old man with a history of asthma and frequent respiratory infections. He is recovering from chest surgery.

1. What are his increased risks from hypostatic pneumonia?
2. What nursing actions would you implement to help prevent this complication?
3. What signs and symptoms would indicate that he might have hypostatic pneumonia?

CHAPTER 6

Infection Prevention and Control

Trena Rich

Objectives

Theory

1. Examine the factors that increase the risk of infection.
2. Discuss how the body uses its natural defensive mechanisms to protect against infection.
3. Explain how fever plays a role in the prevention of infection.
4. Describe the classic signs of infection.
5. Distinguish situations that require the use of Transmission-Based Precautions.
6. List the types of personal protective equipment and analyze situations for whether they should be used.
7. Describe factors that make older adults more susceptible to infections.
8. Analyze factors that may impair the process of healing and repair of damaged tissue.

Clinical Practice

9. Care for a patient whose condition requires Transmission-Based Precautions.
10. From a day's patient assignment, determine the risk factors for infection for each patient.

KEY TERMS

acquired (äk-KWÍ-ĕrd, p. 103)

agent (Ä-gént, p. 99)

Standard Precautions (STĀN-děrd prě-KĂW-shŭnz, p. 108)
susceptible (sŭs-SĒP-tĭ-bŭl, p. 99)
Transmission-Based Precautions (p. 108)
vectors (VĚK-tĕrz, p. 107)

The Infectious Process and Disease

Normal flora (microorganisms that normally exist in the body and provide natural immunity against certain infections) are most often found on or in body systems that have some form of contact with the outside environment ([Table 6-1](#)). Normal flora prevents the most harmful microorganisms from colonizing the body. Understanding how the body defends itself against infection, and how to prevent further exposure to **pathogenic** (disease-producing) microorganisms, is crucial to provide safe and effective nursing care.

Table 6-1

Normal Flora of the Body*

SITE	NORMAL FLORA
Eye	<i>Corynebacterium</i> species <i>Neisseria</i> species <i>Staphylococcus aureus</i> <i>Staphylococcus epidermidis</i> <i>Streptococcus</i> species
Upper respiratory tract (nose, mouth, throat)	<i>Corynebacterium</i> species <i>Enterobacter</i> species <i>Haemophilus</i> species <i>Klebsiella</i> species <i>Lactobacillus</i> species <i>Neisseria</i> species <i>Staphylococcus</i> species <i>Streptococcus viridans</i> Various types of anaerobes
Skin	<i>Corynebacterium</i> species <i>Staphylococcus aureus</i> <i>Staphylococcus epidermidis</i> <i>Streptococcus</i> species Yeasts such as <i>Candida</i> and <i>Pityrosporum</i>
Small bowel and colon	<i>Bacteroides</i> species <i>Clostridium perfringens</i> <i>Enterobacter</i> species (i.e., coliform) <i>Escherichia coli</i> <i>Streptococcus faecalis</i>
Vagina	<i>Corynebacterium</i> species <i>Klebsiella</i> species <i>Lactobacillus</i> species <i>Proteus</i> species <i>Pseudomonas</i> species <i>Staphylococcus</i> species <i>Streptococcus</i> species

*The central nervous system, lower respiratory tract, and upper and lower urinary tracts are normally sterile. This table lists only those organisms most commonly found in the various body systems. They can also cause illness or infection if they are able to invade another system within the body.

Modified from deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, St. Louis, 2014, Saunders.

An **infection** is the presence and growth of pathogenic microorganisms, in a **susceptible** (lacking resistance) host, to the extent that tissue damage occurs. Infection can be **communicable** (passed from one person to another directly, through touch, or indirectly, by using a contaminated object) or noncommunicable. **Disease** is one possible outcome of an infection. Once an infection has occurred, the person is considered communicable until the organism is no longer **shedding** (to lose by natural process) from the body. This period of communicability varies by the type of pathogen involved and the host's ability to fight off the infecting **agent** (any substance capable of producing an effect, whether physical, chemical, or biologic). Bacteria, for example, after entering the body, must find a way to attach to a **host** (an organism in which another, usually parasitic, organism is nourished and harbored) cell to multiply. Once the organisms have found a place to multiply, they can then spread through the body via the circulatory or lymphatic system. **The development of an infection is dependent on the interrelationship among the host, the agent, and the environment.**

Factors That Influence Infectious Disease

Many factors concerning the host determine the type of response the body will have to an invading pathogen. **Risk** of exposure is influenced by the lifestyle, occupation, and socioeconomic status of the host. The underlying disease state, as well as the immunologic and nutritional status of the host, influences the **degree** of resistance or susceptibility the body will have to the pathogen.

Environmental factors can also increase the likelihood of developing an infection ([Figure 6-1](#)). Other factors that influence infection or disease are listed in [Box 6-1](#).

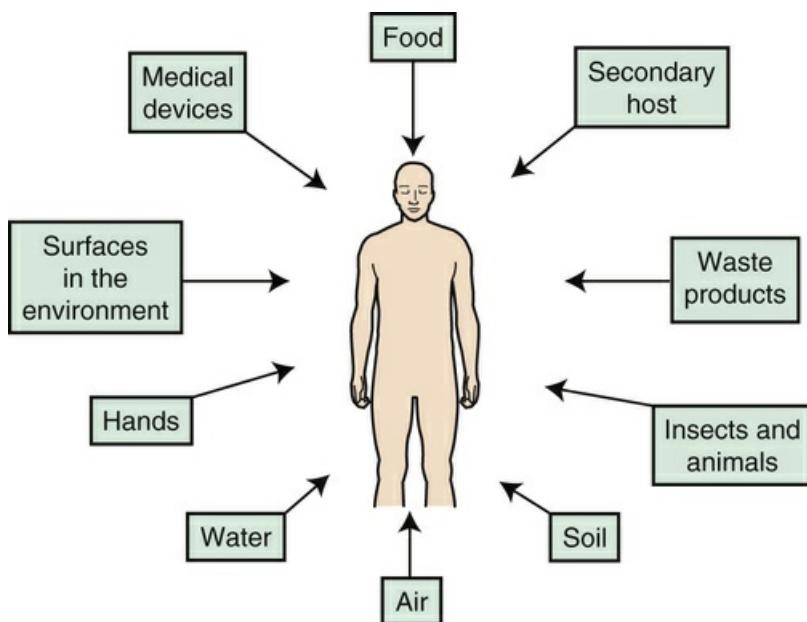

FIGURE 6-1 The environment and the spread of infection. (Redrawn from Sattar SA, Springthorpe VS. In Rutala WA (Ed.): *Disinfection, sterilization and antisepsis*. Washington, DC, 2010, Association for Professionals in Infection Control and Epidemiology.)

Box 6-1

Factors That Influence Infection and Disease

Host

Intrinsic (genetic predisposition [born with it])

- Age, sex, race
- Chronic diseases (e.g., diabetes mellitus)

Extrinsic (environmental)

- Personal behaviors (e.g., drugs, alcohol, hygiene, sexual practices)
- Occupation
- Socioeconomic status

Agent

Virulence: Dosage and duration of exposure to the infecting agent(s)

Biologic: Bacterial, fungal, viral, protozoal microbes can be involved

Chemical: Organic and inorganic, pesticides, pharmaceuticals

Physical: Ionizing radiation, cold, heat, electricity, noise

Environment*

Coexisting chronic disease (e.g., hypertension, diabetes mellitus)

Overcrowded living environment (e.g., dormitory or prison setting)

Travel to country with endemic diseases (e.g., tuberculosis)

Vectors (e.g., mosquitoes, flies, ticks, fleas)

*Environment includes not only the body, but also where an individual lives and works.

Data from Mandell GL, Bennett JE, Dolin R (Eds.): *Mandell, Douglas, and Bennett's principles and practice of infectious disease*, ed. 7, Philadelphia, 2009, Saunders; Arias KM: *Quick reference to outbreak investigation prevention and control in health care settings, critical issues in patient safety*, ed. 2, Boston, 2010, Jones & Bartlett; Brachman PS, Abrutyn E: *Bacterial infections of humans: Epidemiology and control*, ed. 4, New York, 2009, Springer.

Disease-Producing Pathogens

Any microorganism capable of producing disease is known as a **pathogen**. Once pathogens have entered the body, many are able to adapt to their new environment, enhancing survival and increasing their likelihood of causing illness or disease. Pathogens can be transmitted from one person to another through one of three routes: **airborne**, **contact**, or **droplet**. Hand hygiene is the primary way to prevent the spread or transmission of pathogenic microorganisms. Following respiratory etiquette by covering your cough or sneeze and performing hand hygiene afterward help prevent the spread of infection.

Categories of Microorganisms

Nine categories of microorganisms are known to cause infection in humans: bacteria, viruses, protozoa, Rickettsia, Chlamydia, fungi, mycoplasmas, helminths, and prions.

Bacteria.

Bacteria are classified into three major categories according to their shape, gram-staining properties, and requirements for oxygen. Round or spherical bacteria are referred to as *cocci*, rod-shaped bacteria are referred to as *bacilli*, and spiral or corkscrew-shaped bacteria are called *spirochetes*. Some bacteria grow in chains (streptococci), some grow in pairs (diplococci), and some grow in clusters (staphylococci).

Bacteria that require oxygen to live and reproduce are **aerobic**; those that cannot tolerate the presence of oxygen are **anaerobic**. When bacteria enter the body, they trigger the immune system to produce **antibodies** (proteins that fight and destroy antigens). Some bacteria produce poisonous substances called **endotoxins** (toxins that are found within the bacteria and are released when the cell breaks apart); others produce **exotoxins** (excreted by both gram-negative and gram-positive bacteria).

Different bacteria thrive under different environmental conditions. Some form **spores** (a protective covering over the original cell) to protect themselves against destruction from heat, cold, lack of water, toxic chemicals, and radiation. Examples of spore-forming infectious diseases are anthrax and botulism. Other bacteria thrive best in water, such as *Pseudomonas* species or *Legionella*. The bacterium that causes tuberculosis can survive for years in many environments. Some bacteria, such as *Staphylococcus aureus*, can survive in very high temperatures.

Different methods can prevent infection and its spread. A physiologic response can stimulate the immune system to produce a fever and trigger the body's immune response to destroy the invading pathogenic microorganism through **phagocytosis** (ingestion and digestion of bacteria). Cleaning, sterilizing, or boiling inanimate objects, such as a glass or surgical instruments, can prevent the spread of infection after the items are used by or on a patient. The correct antimicrobial agent must be given and the entire dose regimen completed as prescribed to prevent the risk for developing infection with a multidrug-resistant organism (MDRO).

Viruses.

Viruses are not cells. They do not have cell walls and do not reproduce like other microbes. They cannot be treated with antibiotics or antifungals. They are composed of either deoxyribonucleic acid (DNA) or ribonucleic acid (RNA); have an outside coating made of protein; and are dependent on the cell they have invaded to survive and reproduce. Some viruses use the cytoplasm from the cell they have attacked to develop an "envelope" that makes it harder for the body's immune system to

destroy them. Viruses have the ability to keep changing their protein markers, called *antigens*, making it difficult for the virus to be neutralized or killed by white blood cells (WBCs). Once viruses have established themselves in the body, they can trigger an immune response that is harmful to the cells. They can also damage cells by preventing protein synthesis from occurring. New viral elements can be released into the circulation either by the virus breaking down the wall of the cell it has invaded and releasing copies of its genetic material or from small offshoots that have burst, thereby infecting other cells.

Viruses are classified as one of three types: (1) latent, which can reside in the body for years without producing symptoms and then suddenly cause an acute flare-up of symptoms (e.g., herpes simplex); (2) **oncogenic** (cancer causing), which have the ability to alter the cell walls to the point where the cells become malignant; and (3) active, which enter the body, invade a number of cells, and infect the body (e.g., influenza and severe acute respiratory syndrome, which are discussed in [Chapter 14](#)).

Viruses and bacteria vary in their resistance to destruction by chemical disinfectants, but most are easily inactivated or destroyed by heat. However, some of the hepatitis viruses must be boiled as long as 30 minutes at a temperature at or above 185° F before they can be considered nonpathogenic. It is important to note that antibiotics do not help fight a viral infection, but antiviral agents, such as acyclovir, can help limit the virulence of a viral infection if taken at the first signs of illness.

Protozoa.

Protozoa are one-celled parasitic organisms that have the ability to move. There are four main types, named by their method of travel within their environment. They are called amoebas, ciliates, flagellates, or sporozoa. These microorganisms are typically found in water and soil. Many protozoa species have the ability to lie dormant. Although thousands of species exist, only a few are pathogenic to humans. To cause disease, some protozoans have to be ingested, whereas others are introduced into the body through the bite of a vector (a carrier), such as a mosquito.

Rickettsia and Chlamydia.

Rickettsia are small, round or rod-shaped bacteria that are often transmitted by the bites of body lice, ticks, and fleas. Chlamydia is also a bacterium and is typically transmitted via close contact, especially sexual. Both are dependent on a living host.

Fungi.

Fungi are very small, primitive organisms that grow on living plants, animals, and other decaying organic material. They thrive in warm, moist environments. Fungal infections in humans are called *mycoses* and are classified into three main types: (1) cutaneous mycoses, which grow in the outer layer of the skin; (2) subcutaneous mycoses, which involve the deeper layers of the skin, subcutaneous tissues, and sometimes bone; and (3) systemic or deep mycoses, involving internal organs.

Fungal infections are difficult to eradicate once they have invaded a host, because fungi tend to form spores that are resistant to ordinary antimicrobial agents. Antifungal agents can be given topically or systemically but can be toxic to the liver and the nervous system; therefore the course of treatment must be carried out cautiously and over a long period.

Fungal infections commonly found in immune-competent hosts include coccidioidomycosis (caused by *Coccidioides immitis*), histoplasmosis (caused by *Histoplasma capsulatum*), and blastomycosis (caused by *Blastomyces dermatitidis*). They are all systemic mycoses caused by inhalation of airborne spores. Once in the lung, the spores take root and then can spread to any part of the body. However, most fungal infections are self-limited and do not cause clinical disease.

Opportunistic fungal infections (infections that occur in a person with a depressed immune system) are more typically found in patients who have some form of immune compromise and typically include species from *Candida*, *Cryptococcus* (can infect any organ in the body, including the brain and the meninges), and *Aspergillus* (found in soil, dust, and decomposing organic material).

Mycoplasmas.

Mycoplasmas, once believed to be a virus, are very small organisms that do not have a cell wall. They are more like an extracellular parasite because they attach themselves to epithelial cells that line the body cavities and outer surfaces, such as the skin. They tend to be slow growing. For example, *Mycoplasma pneumoniae* can take up to 3 weeks to incubate before signs or symptoms begin to appear.

Other Infectious Agents

Helminths.

Helminths are worms (round, flat, or hooklike) and flukes. All are parasitic and are typically spread via the fecal–oral route. Pinworms are most commonly found in children and cause significant itching in the perianal area because the eggs are laid outside the rectum. Flatworms, such as a tapeworm, can grow up to 50 feet long and live in the intestines. Hookworm and fluke infestations can easily penetrate the skin, are found in the blood, and invade organs such as the liver and lungs. Flatworms and flukes can cause significant weight loss and debilitation.

Prions.

Although quite rare (one case per 1 million), prions are usually spread through eating meat, especially brain tissue, that has been infected or, in even rarer cases, through corneal transplantation from a donor who had a prion infection (Centers for Disease Control and Prevention, 2014). Prions are extremely resistant to the typical methods used for killing most viruses, bacteria, and fungi. These organisms require a type of special cleaning and sterilization that can be especially hard on surgical instruments.

The Body's Defense Against Infection

The four primary lines of defense the body has against infection are (1) the skin, (2) normal flora, (3) the inflammatory response, and (4) the immune response.

Think Critically

In the work environment, where do you think you are most likely to come in contact with pathogens that might cause infection? What precautions can you take to prevent or decrease your risk of exposure?

Skin

Mechanical and Chemical Barriers to Infection

Mechanical barriers.

Mechanical barriers are intact skin and mucous membranes. They are the primary defense the body has against invading microorganisms and infection. Skin, being the largest organ of the body, serves as a first line of defense against harmful agents in the environment. It functions as a protective covering for the more delicate and vulnerable underlying tissues and organs.

The portals of exit and entry provide the means by which pathogens move in and out of the body. For example, pathogens typically exit or enter the body where the skin and mucous membranes meet, such as through the mouth, nose, and gastrointestinal or genitourinary tracts, as well as through a cut in the skin.

Chemical barriers.

Chemical barriers assist the skin and mucous membranes in fighting off invasive organisms by the secretion of tears, saliva, and mucus. Lactic and fatty acids, which inhibit the growth of bacteria, are excreted via sweat and the sebaceous glands. Secretions from the mucous membranes lining the respiratory, gastrointestinal, and reproductive tracts contain an abundance of a bactericidal enzyme called *lysozyme*. This same enzyme is found in tears and saliva. Stomach acid and digestive enzymes kill off most swallowed microorganisms. Mucus produced by the respiratory tract helps capture a variety of inhaled particles. *Cilia* (tiny hairs), which line the respiratory tract, trap organisms and debris and then propel them up and out of the body with a wavelike action.

Think Critically

What effect might medications such as esomeprazole (Nexium) and omeprazole (Prilosec), which are proton pump inhibitors and reduce stomach acid, have on a person's general health? How will this affect a patient's ability to fight off pathogenic microorganisms that may be swallowed?

Protective and Defensive Mechanisms Against Infection

Our bodies have two forms of **immunity** (the body's ability to be unaffected by a particular disease or condition) against infections. They are **innate** (born with, or natural) and **acquired** (develops throughout life) (Box 6-2). See Chapter 10 for more detail. When the body's defense mechanisms are stressed or exhausted, it is more susceptible to infection. Heredity, the degree of natural resistance, and one's own immune status are the greatest determinants of infection, but personal habits and behaviors are also factors to consider. General health, state of nutrition, hormone balance, immune status, and the presence of a chronic disease, such as diabetes mellitus, may influence the degree of susceptibility a person may have to infection.

Box 6-2

Innate and Acquired Immunity

Innate Immunity

- The body senses the presence of pathogenic microorganisms
- Genetic predisposition to respond to invasion in a specific way
- Responds rapidly to invasion of pathogenic microorganisms
- Elements consist of antibodies, phagocytes, natural killer cells, and mast cells

Acquired Immunity

- Cellular and humoral immunity are activated through T-cell and B-cell receptors
- Genetic rearrangement occurs throughout life
- Develops slowly once the body has been initially invaded
- Provides the body with protection with each subsequent exposure to the same pathogens
- Is the basic component for immunity induced via vaccination
- Elements consist of antibodies and cytotoxic and helper T cells

Adapted from Munford RS: Sepsis. In Mandell GL, Bennett JE, Dolin R (Eds.): *Mandell, Douglas, and Bennett's principles and practice of infectious disease*, ed. 7, Philadelphia, 2009, Saunders.

Fever.

Fever is one of the primary mechanisms the body has to prevent infection from an invading microorganism. Once the immune system has determined that an invasion is being attempted, it signals the hypothalamus in the brain to raise the body temperature to fight off the infection. The increased metabolic and oxygen demand at the cellular level that results from the increased body temperature causes an increased heart and respiratory rate. Shivering occurs to increase the core body temperature, but the surrounding environment feels cooler than the new core body temperature, and the patient may complain of "freezing to death." It is at this point in the inflammatory response that fever is noticeably increased. In an attempt to decrease the body's temperature through evaporation, **diaphoresis** (sweating) occurs, and the patient may not want to be covered by a blanket or sheet. This increased heat in the body creates a hostile environment to the microorganisms, and an intact immune system is able to destroy them efficiently. Once the threat of infection is no longer present, the immune system again signals the hypothalamus, and the body is able to start cooling down on its own.

Think Critically

A patient asks you to explain what causes a person to have an increased temperature. Would the age of the patient be a factor you should consider in your teaching?

Nutrition.

Poor nutrition predisposes a person to develop an infection, because the body may not have sufficient protein stores to generate enough antibodies to help fight off an infection. The very young and older adults have less-efficient immune systems, which is why it is important to ensure that these age groups have received the appropriate vaccinations and immunizations. Excessive stress also influences a person's immune status. Stress can increase blood cortisol levels, which will decrease the anti-inflammatory response of the body.

Older Adult Care Points

Many older adults do not have sufficient protein in their diet because of monetary concerns or because of physical limitations that interfere with their ability to prepare a proper meal. Referral to

a home delivery meal program may help increase dietary intake of protein and other essential nutrients to help fight off infection.

Antigens.

An antigen is a form of protein found on the outside of cells that allows the body to identify it as “self” (native) or “nonself” (foreign). Antigens can stimulate the immune response to wipe out microorganisms.

Antibodies.

Antibodies, also known as immune globulins (Ig), are one part of acquired immunity. They have many functions, such as neutralizing toxins and killing invading pathogens. There are five types of antibodies: IgM, IgG, IgA, IgE, and IgD ([Table 6-2](#)). IgE has the ability to bind to mast cells and basophils and to release histamine and heparin. This in turn stimulates a hypersensitive reaction, as seen in bronchial asthma or systemic anaphylaxis.

Table 6-2
Types of Antibodies

ANTIBODY	DESCRIPTION
IgM	<ul style="list-style-type: none">Appears first if the body is exposed to an antigenBinds to the antigen and works to clear the pathogen from the body
IgG	<ul style="list-style-type: none">Most abundant immune globulin found in the bodyCrosses the placental barrier, reaching the developing fetusProvides passive immunity until the fetus's own immune system can defend itself
IgA	<ul style="list-style-type: none">Found in tears, mucus, saliva, gastric fluid, colostrum, and sweatPrevents pathogens from attaching to or penetrating epithelial cells, such as the skin
IgE	<ul style="list-style-type: none">Binds to mast cells and basophils and releases histamine and heparinStimulates a hypersensitive reaction, as seen in bronchial asthma or systemic anaphylaxis
IgD	<ul style="list-style-type: none">Works together with IgMAmong other functions, stimulates certain cells in the immune system; overall role in the immune response is unclear

Bone marrow.

The bone marrow is a major component in the body's defense system. Bone marrow plays an important role in the manufacturing of blood products that help the body defend itself against infection. These products are called *leukocytes*, *neutrophils*, *macrophages*, and *lymphocytes*.

Leukocytosis.

Leukocytosis is an increased number of **leukocytes** (white blood cells), usually seen at the beginning of an infection when the person's immune system has not been overly stressed. Leukocytosis is seen more often with bacterial than viral infections. When infection does occur, the bone marrow is stimulated to produce and release more leukocytes to help the body fight infection.

Phagocytosis.

The process of **phagocytosis** is a form of innate immunity. This is the body's first line of defense at the cellular level. Within the first few hours of the onset of the inflammatory process, the monocytes swell up (becoming macrophages) and migrate to the site of inflammation. Neutrophils, which are a type of leukocyte, are also released and have the ability to kill both aerobic and anaerobic organisms. After the macrophages and neutrophils engulf and destroy bacteria and other foreign matter, they die, producing an **exudate** (discharge) that is composed of tissue, fluid, dead cells, and their by-products. This exudate, usually yellow or green in color, is commonly known as *pus* and is a sign of infection.

Macrophages.

Macrophages are *monocytes* (large leukocytes) that have left the bloodstream and have migrated into the tissues. They ingest and destroy pathogens and clear away the cellular debris and dead neutrophils in the latter stages of an infection. Macrophages cleanse the lymphatic fluid as it passes through the lymph nodes and perform a similar action on the blood as it passes through the liver and spleen.

Liver cells.

As part of the innate immune system, about 50% of all macrophage cells can be found in the liver's Kupffer cells. These macrophages act either to prevent invasion by pathogens mechanically or to neutralize the pathogen chemically (through the pH of body secretions). Macrophages also destroy bacteria that have found their way into the blood circulation through the liver's portal system. The body's defense mechanisms against pathogens are summarized in [Table 6-3](#).

Table 6-3
The Body's Mechanism of Defense Against Infection

MECHANISM	FACTORS INVOLVED IN PROTECTION
Innate (natural) immunity	Determined by age, ethnicity, and genetics. Increases resistance to disease.
Antibody-mediated (humoral) immune response (antigen-antibody; B lymphocytes)	Antibodies are produced against invading pathogens and inactivate or destroy them.
Cell-mediated immune response (T lymphocytes)	Sensitized T cells kill or inactivate antigens by chemical release or secretion of substances that destroy the antigen.
Inflammation	Cells damaged by pathogens release enzymes, and leukocytes are attracted to the area; the damaged area is "walled off," and phagocytosis disposes of the microorganisms and dead tissue.
Phagocytosis by white blood cells	Leukocytes, neutrophils, and macrophages (large monocytes) engulf, ingest, kill, and dispose of invading microorganisms.
Fever	Fever may not always occur with an infection, especially with immunocompromised or debilitated patients or patients who have been on long-term corticosteroid therapy. Surface blood vessels constrict, which leads to shivering to hold heat in the body (to kill the invading organisms). Increases metabolic rate, which can be problematic for patients with cardiorespiratory problems because of increased workload on the heart/circulatory system. Fever stops once the anti-inflammatory agents have helped to restore homeostasis.
Normal flora	Present on skin and in mucous membranes of oral cavity, gastrointestinal tract, and vagina. Helps prevent excessive growth of pathogens.
Intact skin	Skin is the first defense; slightly acid pH and normal flora present an unfavorable environment for colonization of pathogens.
Mucous membranes	Mucous membranes, with their mucociliary action, provide mechanical protection against invasion of pathogens. Mucus secretions contain enzymes that inhibit many microorganisms. The respiratory system clears about 90% of introduced pathogens.
Gastrointestinal tract	Peristaltic action empties the gastrointestinal tract of pathogenic organisms. Acidic pH of stomach secretions, bile, pancreatic enzymes, and mucus protects against invasion by harmful pathogens.
Genitourinary tract	Flushing of urine through the system washes out microorganisms. The acidic pH of urine helps maintain a sterile environment in the system.

Normal Flora

The flora that is normally present on the skin and in the mucous membranes, gastrointestinal tract, and vagina coexists with the body and controls the growth of harmful pathogens. When the amount of the normal flora is diminished, other pathogens may cause infection. When the body's immune system is suppressed for any reason, normal flora may grow out of control and cause infection. For example, *Candida albicans* commonly causes a yeast infection (thrush) after treatment with antibiotics, because the normal flora has been destroyed, allowing the *Candida* to flourish. [Table 6-4](#) shows changes in the natural defense mechanisms that occur with age and cause older adults to become more susceptible to infection.

Table 6-4
Changes in Natural Defense Mechanisms That Occur With Age

CHANGE	CONSEQUENCE
Decreased skin turgor and greater skin friability	Skin is more susceptible to friction damage and tearing.
Decreased elasticity and atherosclerosis of peripheral vessels	Decreased blood flow to extremities produces slower wound healing.
Calcification of heart valves	Provides a location for bacteria to attach and cause endocarditis.
Stiffness of thorax from arthritis or aging changes, weakened respiratory muscles, decreased ciliary action from smoking or exposure to air pollution	Decreased ability to maintain good oxygenation leads to less respiratory reserve; a greater tendency to retain secretions occurs because cilia cannot move foreign substances and secretions as easily; cough reflex and effort are diminished.
Decreased gastrointestinal tract motility as muscles weaken; decreased acid production	Acid is insufficient to inhibit growth of pathogens; decreased motility allows organisms to remain in the gastrointestinal tract and multiply.
Prostate changes, bladder prolapse, and urethral strictures	The bladder is not completely emptied at each voiding, which allows for stagnation and provides a medium for growth of pathogens.
Decreased immune response because bone marrow does not produce new blood cells as rapidly	Mobilization of body defenses to fight infection and heal wounds is slower.

The Inflammatory Response

Inflammation is an immediate, localized, protective response of the body to any kind of injury or damage to its cells or tissues. It is considered to be the second line of defense to infection at the cellular level ([Figure 6-2](#)). Three basic purposes of the inflammatory response are to (1) neutralize and destroy harmful agents, (2) limit their spread to other tissues in the body by walling off the organisms, and (3) prepare the damaged tissues for repair.

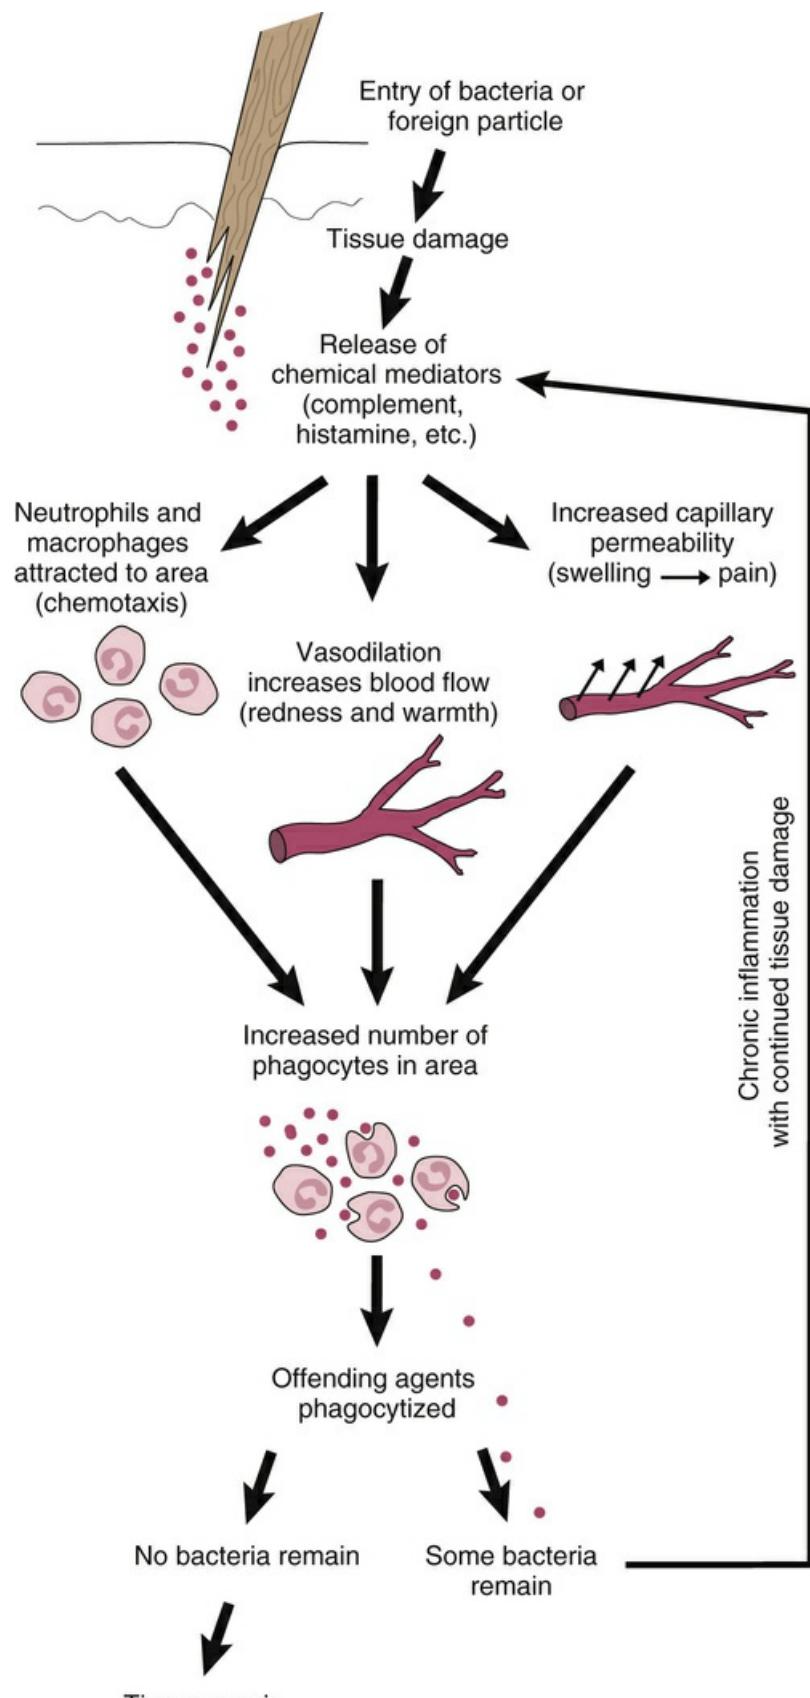

FIGURE 6-2 Steps in the inflammatory process. (From Applegate E: *The anatomy and physiology learning system*, ed. 4, Philadelphia, 2010, Saunders.)

Inflammatory Changes

Changes that are part of the inflammatory response can occur locally, at the site of injury, and systemically. These changes involve (1) the cells of the damaged tissues and adjacent connective tissues; (2) the blood vessels in and near the site of injury; (3) the blood cells, particularly the leukocytes; (4) the macrophages and phagocyte activity; (5) the immune system; and (6) the hormonal system. An inadequate inflammatory response may cause active, systemic infection.

Clinical Cues

The five local signs and symptoms of inflammation are heat, redness, swelling, pain, and limitation or loss of function.

Signs and Symptoms of Inflammation

Local reactions.

Redness and **heat** are caused by the increased blood flow to the affected area. **Swelling** is the result of the increased permeability of the capillaries and the leakage of fluid from the blood into the tissue spaces around the cells. Blockage of lymphatic drainage from the site also contributes to the local swelling. **Pain**, the result of irritated nerve endings, is caused by the chemicals released by the defensive cells and the accumulation of fluid in the area.

Systemic reactions.

Systemic reactions to inflammation are familiar to anyone who has had the flu or another generalized infection. Headache, **myalgia** (muscle aches), fever, diaphoresis, chills, **anorexia** (loss of appetite), and **malaise** (weakness) are some of the more common signs and symptoms experienced with a systemic infection. (Note: An inflammatory response can occur in the absence of an infection, such as rheumatoid arthritis or a histamine response triggered by an insect bite.)

Nursing care for patients who have a systemic infection includes providing for a balanced fluid intake and output, pain relief, and temperature control. Measures to ensure adequate nutrition and rest are used. If there is an inadequate inflammatory response to a systemic infection, bacterial infections may spread elsewhere in the body and delay tissue repair and wound healing.

Chemical Release and Vascular Changes

The complement system is a group of proteins that lie dormant in the body until they have been activated through an encounter with a foreign substance. The activation of these proteins enhances phagocytosis and the inflammatory process. If viral invasion has occurred, the chemical **interferon** is released to protect the cells against further viral invasion. As soon as damage occurs, the blood vessels in the injured area briefly constrict and, as histamine and serotonin are released, then dilate so that more blood is brought to the damaged cells. The walls of the capillaries become more **permeable** (i.e., their pores enlarge) so that water, proteins, and defensive cells such as neutrophils and macrophages can seep into the fluid surrounding the damaged cells to remove pathogens through the process of phagocytosis. One of the classic outward signs of inflammation is leakage of fluid into the spaces around the cells, producing a localized swelling, or **edema**. This results in a “walling off” of the area and delays the spread of pathogens, toxins, and other harmful agents to the rest of the body.

The Immune Response

The third line of defense is the immune response, which attempts to defend and protect the body through a series of complex chemical and mechanical activities. These activities involve (1) the detection of entry by foreign agents as soon as they gain access to the body's cells; (2) immediate recognition of the agents as foreign or alien; and (3) the ability to distinguish one kind of foreign agent from another and to “remember” that particular agent if it appears again years later. The specific antibodies and antitoxins produced by the immune response are transported by the circulatory system to the tissue spaces that surround the site of inflammation. They attack the foreign cells and neutralize the toxins those cells produce. The immune response is discussed more

fully in [Chapter 10](#).

Hormonal Response

Some hormones, such as cortisone, have an **anti-inflammatory** action that limits inflammation to the locally damaged tissues. Other hormones, such as aldosterone, are **proinflammatory**, which means that they stimulate the body's protective inflammatory response. Thus the hormones have a regulatory effect on the inflammatory process so that the response is well balanced and provides maximum benefit. Other hormones, such as those excreted by the adrenal glands, can interfere with healing, and in some cases of severe inflammation, the provider may prescribe an anti-inflammatory drug to relieve these symptoms.

The Chain of Infection

For an infectious disease to be spread from one person to another, certain conditions must be met. Infection occurs through a cyclical interrelated process, like links in a chain ([Figure 6-3](#)). Prevention or control of infection is aimed at interrupting the chain of infection. This can include the performance of hand hygiene or the wearing of gloves to protect the hands or a cover gown to protect one's clothing.

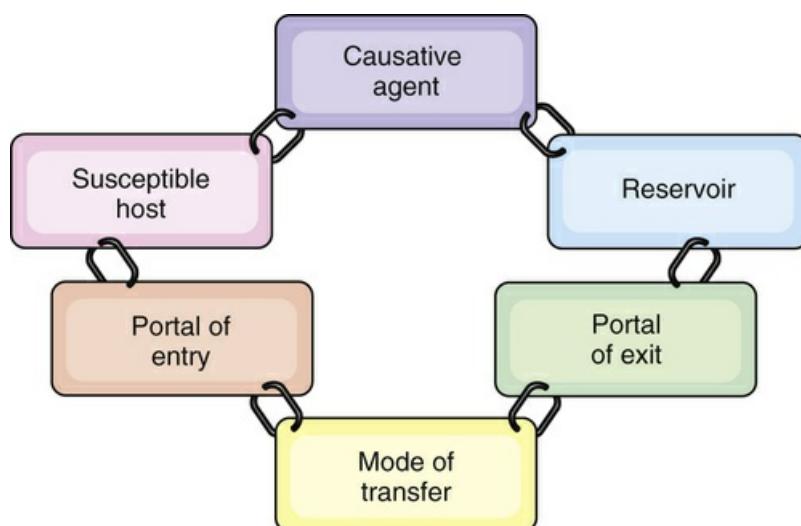

FIGURE 6-3 The cyclical process of infection. Each link of the infection cycle must be present and in the proper sequence to produce disease. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, St. Louis, 2014, Saunders.)

The mechanism of transmission of a pathogenic agent within the environment or to another person is by either direct or indirect contact. **Vectors** such as mosquitoes, fleas, ticks, and flies can transmit pathogens through their bites or stings. (Refer to [Chapter 14](#) for information on West Nile virus and avian flu, which are spread via a vector [mosquitoes or birds].)

The three most important aspects in the infection chain are the interaction of the agent, the host, and the mode of transmission.

A reservoir is any place a pathogen is normally found ([Box 6-3](#)). The reservoir can be **animate** (living) such as people, animals, and insects, or it can be **inanimate** (nonliving), as found in soil, in water, and on surfaces of objects such as a cup or bed rails. The body can be a reservoir because pathogenic organisms can grow and multiply (**colonize**) on the skin or inside the body without causing a specific immune response or an infection. Infectious agents can also be found in body excretions or secretions such as saliva, sputum, urine, feces, and wound drainage. Individuals who have become colonized with a specific pathogen, such as methicillin-resistant *Staphylococcus aureus* (MRSA) or vancomycin-resistant enterococci (VRE), can be asymptomatic carriers (**reservoirs**) and unknowingly spread the infection to others because they are not aware that they have been exposed and are now colonized with an organism that is known to be multidrug resistant. One of the *Healthy People 2020* objectives is to reduce the incidence of MRSA. In the home or community, contaminated or improperly cooked food, stagnant water, or sewage can also be a source of infection.

Box 6-3**Human Reservoirs****Carrier**

The person has the actual infection but does not show any obvious signs or symptoms; he or she typically does not take precautions to prevent the spread of infection and can transmit it to others.

Colonized

The person can transmit the pathogenic organisms by either direct or indirect contact with inanimate objects or within his or her own environment.

Infectious (Symptomatic)

The person has obvious signs and symptoms of infection; he or she is less likely to spread infection, because precautions are usually taken.

Infection Prevention and Control

Preventing and Controlling the Spread of Infection

Hand Hygiene

Hand hygiene is the primary intervention any health care provider can use to control the spread of infection. Hand hygiene can be performed with soap and water, if hands are visibly soiled, or with an alcohol-based hand sanitizing solution for routine decontamination. It is important to note that hand hygiene must be performed *regardless* of whether gloves were used or not. Artificial fingernails, extenders, or gels are not recommended for health care providers who have direct patient contact, because pathogens can be found beneath the nails.

Clinical Cues

Remove any rings or other forms of jewelry before washing hands with soap and water. Hand hygiene should be performed with an approved soap under warm running water, using friction, for at least 15 to 30 seconds. Ensure that the areas in between fingers and the dorsal and palmar aspects of both hands are thoroughly rubbed.

Precaution Categories for Infection Prevention and Control

Standard Precautions

Standard Precautions were mandated by the Centers for Disease Control and Prevention (CDC) in the 1980s (Box 6-4; also see Appendix B). These precautions are designed to prevent the transmission of microorganisms from one patient to another, as well as to protect the health care worker from unnecessary exposure to infection. Standard Precautions are to be used on all patients because their potential for being colonized, or actually infectious, is not always known. Barrier precautions, such as gloves or isolation techniques that include the proper handling and disposal of secretions, excretions, and exudates, can prevent the transmission of pathogens from one person or object to another. The most current CDC Guidelines and Recommendations related to infection prevention and control in a variety of health care settings can be found at http://www.cdc.gov/HAI/prevent/prevent_pubs.html.

Box 6-4

Standard Precautions

1. Use barrier precautions, such as gloves, gown, face mask, and protective eyewear, to prevent exposure of skin or mucous membranes to a patient's blood, body fluid, or other potentially infectious materials while providing care or assisting with a procedure for your patient.
 - a. Change gloves between contact with one body part and another (e.g., respiratory and urinary).
 - b. Discard used gloves in the appropriate waste container; do not wash or reuse them.
 - c. Perform hand hygiene immediately after removing gloves.
2. Prevent injury by needle stick or cuts from sharp instruments.
 - a. Be cautious and attentive any time you are handling a needle or

- sharp instrument.
- b. Do not recap a used needle by hand; scoop the cap onto the needle on a flat surface or deploy the safety device attached to the needle.
 - c. Immediately dispose of a used needle or other sharp instrument in the puncture-resistant container provided for that purpose in the room.
 - d. Replace puncture-resistant containers when they are three-quarters full and as needed; do not attempt to push needles into a container that is too full.
3. Prevent possible self-contamination or exposure through broken skin.
- a. If you have open lesions or weeping dermatitis, do not give direct patient care or handle patient care equipment until the condition has resolved.
4. Prevent possible self-contamination during cardiopulmonary resuscitation.
- a. Use a disposable mouthpiece or resuscitation bag for emergency mouth-to-mouth breathing.
 - b. Wear the appropriate personal protective equipment (PPE) whenever possible.

Transmission-Based Precautions

Transmission-Based Precautions incorporate Standard Precaution techniques with additional protective actions specific to the organism and location involved. These safety measures should be implemented for patients with a suspected or confirmed infection or who are known to be colonized with a highly transmissible organism such as tuberculosis or Ebola. These additional precautions are known as category-specific precautions and include the following: Airborne Infection Isolation, Contact Isolation, Droplet Isolation, and Mandatory Precautions. Health care facilities have information cards that are usually placed on the door to the patient's room to ensure that everyone who enters the room is aware of the safety precautions and the personal protective equipment (PPE) that must be used before entry. Depending on the microorganism involved, the nurse verifies which types of Transmission-Based Precautions should be used. If unsure as to what is required, contact the facility's infection preventionist for guidance. The effectiveness of Standard Precautions and Transmission-Based Precautions depends on rigorous compliance with the infection prevention and control precautions. See [Table 6-5](#) for more information regarding category-specific isolation methods.

Think Critically

What type of Transmission-Based Precautions would be necessary for a patient who is admitted with complications of Ebola? What PPE would you need to assist this patient with activities of daily living? How must it be donned and doffed? See the [Evolve](#) website for Ebola PPE Donning Instructions for more detailed information and pictorial description.

Table 6-5**Category-Specific Isolation Precautions (Transmission-Based Precautions and Expanded Precautions for Ebola)**

PRIVATE ROOM*	MASKS	GOWNS	GLOVES	COMMON DISEASES PLACED INTO ISOLATION CATEGORY
Airborne Infection Isolation				
Always; door to room must be kept closed at all times	Must wear a fit-tested NIOSH-approved N-95 respirator	No, unless draining wounds	No, unless draining wounds	Pulmonary or laryngeal tuberculosis, or draining tuberculosis skin lesions; smallpox, viral hemorrhagic fever, severe acute respiratory syndrome (SARS); measles; varicella, disseminated zoster
Contact Precautions				
Preferred; cohorting of patients with same type of infection is acceptable	Situation dependent	Always; if patients are cohorted, staff must perform hand hygiene and change PPE between patients	Always; if patients are cohorted, staff must perform hand hygiene and change PPE between patients	Open or draining wounds; history of MRSA, VRE, ESBL positive; diarrhea; MDRO infections
Droplet Precautions				
Preferred; cohorting of patients with same type of infection is acceptable	Wear a surgical mask when entering room; patient should wear mask during transport and observe cough etiquette	Not usually	When helping with cough-inducing procedures or discarding of used tissues	Pneumonia, influenza, rubella, pertussis, streptococcal pharyngitis, meningitis caused by <i>Neisseria meningitidis</i> or <i>Haemophilus influenzae</i> type B
Ebola Precautions*				
Requires "buddy" to assist donning/doffing PPE. See detailed instruction in Evolve  Note: information in this table is not in exact order of donning PPE.				
Mandatory	Must wear N-95 respiratory mask, full-face shield, cover hair	*Change into hospital-issued scrubs or disposable scrubs; then don impervious cover gown and hood that covers all of the neck and chest If activities performed in the patient's room are likely to dislodge cuff of gown, secure cuff with coban or tape	Don first pair before donning impervious shoe/leg covers, don cover gown Second pair is donned after face mask, hair cover, and hood are donned	Airborne, Contact Precautions with "buddy" observing all aspects of care being provided to ensure no exposure or contamination has occurred to the nurse in the room caring for a patient with Ebola

*In most cases, patients infected with the same organism may share a room. For any patient in Transmission-Based Precaution isolation (sometimes referred to as Expanded Precautions), limit the time the patient is out of the room; notify receiving unit or department that the patient is in isolation so that appropriate measures can be taken before the arrival of the patient. For a patient infected with Ebola, it is a two-nurse team: one to care for the patient, the other to observe the nurse to ensure that transmission-based precautions, hand hygiene, etc., have not been compromised.

ESBL, Extended-spectrum beta lactamase; MDRO, multidrug-resistant organism; MRSA, methicillin-resistant *Staphylococcus aureus*; NIOSH, National Institute of Occupational Safety and Health; PPE, personal protective equipment; VRE, vancomycin-resistant enterococci.

Personal Protective Equipment

Personal protective equipment (PPE) is the use of a barrier to protect a person from exposure to blood-borne pathogens, body fluids, or other potentially infectious materials. These barriers include, but are not limited to, gloves, cover gowns, facemasks, eye protection, face shields, and respirator masks. Ebola is a virus that is extremely lethal but is only transmitted through direct contact with blood or body fluids. When it comes to caring for a patient with Ebola, the CDC (2015) states: "To protect healthcare workers during care of a patient with EVD, healthcare facilities must provide onsite management and oversight on the safe use of PPE and implement administrative and environmental controls with continuous safety checks through direct observation of healthcare workers during the PPE donning and doffing processes." The precautionary asset on Evolve  shows a nurse in full PPE prior to caring for a patient infected with Ebola. By law, health care facilities are required to provide PPE at no expense to the staff (Occupational Safety and Health Administration Bloodborne Pathogens Standards, 1910.132[h][1]). If you suspect you have a latex allergy, contact your Occupational/Employee Health Services department so that a more detailed assessment can be made. If it is determined that a latex allergy does exist, your facility is required to provide you with the appropriate PPE. Figure 6-4 shows methods for donning and removing PPE.

Clinical Cues

Remember, when you are using PPE, you cannot retrieve common items from your uniform pocket (e.g., pen, alcohol pad, or stethoscope). You must plan ahead and obtain the necessary supplies and equipment before entering the patient's room.

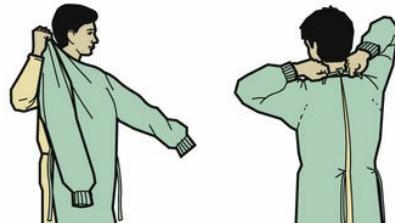

DONNING AND REMOVING PPE

Donning Personal Protective Equipment (PPE)

The type of PPE will vary based on the level of precautions required, such as Standard and Contact, Droplet, or Airborne Isolation Precautions.

Gown

- Fully cover torso from neck to knees, arms to end of wrist, and wrap around the back
- Fasten in back at neck and waist

Mask or respirator

- Secure ties or elastic band at middle of head and neck
- Fit flexible band to nose bridge
- Fit snug to face and below chin
- Fit-check respirator

Goggles or face shield

- Put over face and eyes and adjust to fit

Gloves

- Extend to cover wrist of isolation gown

SAFE WORK PRACTICES

- Keep hands away from face
- Limit surfaces touched
- Change gown and gloves when torn or heavily contaminated
- Perform hand hygiene

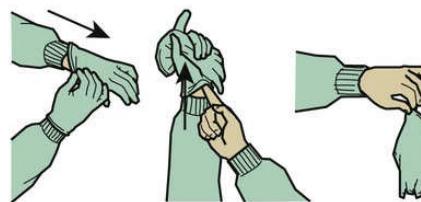

A

Removing Personal Protective Equipment (PPE)

Remove PPE at doorway before leaving patient room, or in anteroom; remove respirator outside of room.

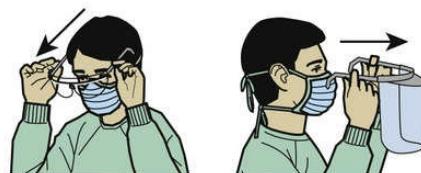

Gloves

- Outside of gloves are contaminated!
- Grasp outside of glove with opposite gloved hand; peel off
- Hold removed glove in gloved hand
- Slide fingers of ungloved hand under remaining glove at wrist

Goggles or face shield

- Outside of goggles or face shield is contaminated!
- To remove, handle by "clean" head band or ear pieces
- Place in designated receptacle for reprocessing or in waste container

Gown

- Gown front and sleeves are contaminated!
- Unfasten neck, undo the waist ties
- Remove gown using a peeling motion; pull gown from each shoulder toward the same hand
- Gown will turn inside out
- Hold removed gown away from body, roll into a bundle, and discard into waste or linen receptacle

Mask or respirator

- Front of mask/respirator is contaminated—DO NOT TOUCH!
- Grasp bottom then top ties/elastics and remove
- Discard in waste container

Hand hygiene

- Perform immediately after removing all PPE!

B

FIGURE 6-4 A, Donning personal protective equipment (PPE). B, Removing PPE.

Protective Environment

Patients with hematopoietic stem cell transplantation require highly specialized forms of expanded isolation techniques. Nurses and all staff who provide care to the transplant recipient receive detailed education and training on the appropriate care. Interventions include special airflow and filtration rooms with positive air pressure, smooth surfaces to aid in disinfection, and minimizing the length of time the patient is outside of the protective environment. Staff must be free from signs and symptoms of illness. For additional information, refer to the facility's policy and procedure manuals or the CDC's website, www.cdc.gov.

Respiratory Hygiene and Cough Etiquette

Two methods of preventing droplets from spreading to others are teaching people to cover their mouth when sneezing or coughing and turning the head away to prevent coughing into someone else's face (Figure 6-5). In addition, educating patients and families to dispose of soiled tissues in waste containers and to perform hand hygiene after contact with actual or potentially contaminated items is important. To prevent the transmission of pathogenic microorganisms to a patient, instruct the patient to avoid contact with others who may have an infection.

FIGURE 6-5 Covering your cough to help prevent the spread of infection.

Transmission of an infectious organism can be interrupted at the portal of entry by using only clean or sterile items when caring for patients. Use of effective hand hygiene techniques by health care workers, visitors, and patients is key in the prevention of infection. Immunization and measures to boost immunity through proper nutrition and a healthy lifestyle also increase a person's resistance to infection. One of the *Healthy People 2020* objectives is to increase the proportion of adults who are immunized for influenza and pneumococcal disease. **Table 6-6** lists factors that can make a host more susceptible to pathogens.

Think Critically

What would you do if, while taking a blood pressure reading, your patient sneezes or coughs and does not cover her nose or mouth? How would you respond? What type of education would benefit the patient? What additional precautions would you need to institute once the patient has left the examination room?

Table 6-6

Risk Factors for Increased Susceptibility to Infection

RISK FACTOR	CONSEQUENCE
Altered defense mechanisms	Body damage from trauma; breaks in the skin or mucous membranes; fractures.
Lower than normal leukocyte (white blood cell) count	Bone marrow suppression from chemotherapy or toxic agents; genetic or acquired agranulocytosis, such as that seen with chemotherapy drugs.
Age	Older adult patients and the very young are more susceptible to infection, probably because of declining or immature immune function.
Excessive stress or fatigue	These states seem to interfere with the body's normal defense mechanisms.
Malnutrition	Poor nutrition interferes with cell growth and replacement, which contributes to decreased immune function.
Alcoholism	Inhibits the immune system.
Preeexisting chronic illnesses, such as diabetes mellitus, adrenal insufficiency, renal failure, or liver disease; serious illness such as pneumonia, peritonitis, etc.	These disease states upset the normal homeostatic balance within the body, impairing the normal defense mechanisms. Serious illness taxes the immune system, causing greater susceptibility to other pathogens.
Immunosuppressive treatment, chemotherapy, or corticosteroid treatment	These treatments depress the immune system or harm the bone marrow, decreasing the number of leukocytes. Corticosteroids depress the inflammatory response, inhibiting one of the body's defense mechanisms.
Invasive equipment or indwelling tubes	Fracture pins, endotracheal or tracheostomy tubes, intravenous cannulas, feeding tubes, and urinary catheters provide a potential route of entry for pathogens.
Smoking or inhalation of toxic chemicals	Inhibits ciliary action of the respiratory tract. Toxic chemicals may damage bone marrow, inhibiting the production of leukocytes.
Intravenous drug abuse	Allows introduction of microorganisms into the bloodstream from contaminated needles or from lack of aseptic technique.
Unsafe sexual practices (not knowing history or health status of sexual partner, not using condoms)	Allows entry of pathogenic organisms through the genital mucosal tissue.
Unsafe handling of needles and sharps	Potential for breaks in the skin through which pathogens may enter.

Adapted from Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient centered collaborative care*, ed. 7, Philadelphia, 2012, Saunders.

Health Care–Associated Infections

A **health care–associated infection (HAI)** occurs when a patient is cared for in any kind of health care setting and acquires an infection. There are specific criteria for the infection to be classified as an HAI, such as length of time in the facility before the onset or appearance of the infection. Because health services are provided in a wide variety of locations, such as acute care facilities, outpatient surgery or dialysis centers, homes, and mobile clinics, it is sometimes difficult to determine where the patient became infected. Detailed documentation is essential in determining whether an infection the patient has was community or health care acquired.

Although inanimate objects such as needles, contaminated surgical instruments, and linens are major sources of infection in these settings, every patient is directly and indirectly in contact with large numbers of health care workers, each of whom could be the source of infection. Therefore, it is important to ensure that appropriate precautions, such as hand hygiene and Transmission-Based Precaution techniques, are followed at all times. **Table 6-7** presents HAI risk factors.

Table 6-7
Risk Factors for Health Care–Associated Infections

RISK	SOURCE OR CAUSE
Impaired host defenses	Invasive tubes (i.e., endotracheal, nasogastric, enteral feeding) Position of the patient (i.e., supine vs. head of bed >30 degrees) Impaired or altered mental status; sedation Malnutrition; malignancy; immunosuppression
Introduction of microorganisms	Bacterial colonization Gastric pH neutralized because of H ₂ -receptor-blocking agents Lack of oral hygiene Acute vs. chronic sinusitis Invasive procedures; open wounds Contaminated respiratory equipment
Overgrowth of virulent organisms	Prolonged or inappropriate antibiotic use Iatrogenic (resulting from health care provider action such as inadequate hand hygiene); multidrug-resistant organism infection Central venous lines (i.e., subclavian, femoral, peripherally inserted central catheter) Comorbid illness (e.g., diabetes mellitus, peripheral vascular disease) Frequent hospitalizations or exposure to invasive therapies Prolonged hospital stays

Adapted from Flanders AS, Collard HR, Saint S: Nosocomial pneumonia: State of the science. *American Journal of Infection Control*, 34:84-93, 2006.

The Cost of Health Care–Associated Infections

Human suffering, prolonged hospital stays, and time lost from work are some of the concerns with an HAI. In a recent study using a large sample of U.S. acute care hospitals, on any given day at least 1 in 25 patients had some form of HAI. This same study found an estimated 722,000 HAIs in 2011 and that 75,000 patients died during their hospitalization (Magill et al, 2014). Another cost is the increased expense of health care delivery. For example, the cost of treating a catheter-related bloodstream infection is estimated to be between \$3700 and \$29,000 (Institute for Healthcare Improvement, 2011). With the passage of the Affordable Care Act, Congress has approved funding for programs such as establishing an HAI Infrastructure, preventing HAIs across the spectrum of health care, and improving the public health department's capacity to provide infection prevention and control (CDC, 2014).

Nursing Interventions to Prevent Health Care–Associated Infections

The primary way to break the chain of infection is careful attention to hand hygiene before and after any direct patient contact, before and after any invasive or sterile procedure, after contact with infectious materials (e.g., wound drainage, feces, urine, or sputum), and before contact with immunocompromised patients. However, for hand hygiene to be effective, you need to know what cleansing product to use. For example, if the patient has an *S. aureus* infection, the health care worker can use either soap and water or an alcohol-based hand sanitizer to cleanse the hands. However, if the patient has a *Clostridium difficile* or *Candida albicans* infection, the health care worker must use only soap and water to cleanse the hands. The alcohol in alcohol-based sanitizers only makes the spores for these organisms “sticky”; it does not kill them. In addition, if a patient with *C.*

difficile is discharged, the housekeeping staff needs to know that the patient had this type of infection so that the appropriate cleaning agents will be used. Reducing catheter-related infections is one of The Joint Commission's 2014 National Patient Safety Goals and a *Healthy People 2020* objective. Interventions for this important goal include hand hygiene, use of a standardized kit for dressing changes, and chlorhexidine-based antiseptic for skin preparation.

Clinical Cue

In accordance with National Patient Safety Goals (The Joint Commission [TJC], 2014), compliance with guidelines for hand hygiene is one of the primary issues for reducing HAIs. Make a point of performing hand hygiene in view of the patient and the family; this increases their confidence in your ability as a caregiver and demonstrates your attention to preventing infection.

Used or contaminated items should not be placed on the floor or remain in an uncovered disposal container in the patient's room. Disposing of infectious materials, such as soiled dressings, full suction containers, and contaminated equipment, in covered, moisture-resistant biohazard containers helps contain microorganisms, as well as odors. Protecting patients from others with respiratory infections and from visitors with other communicable diseases is also appropriate. Table 6-8 reviews the major sites of HAIs, the infectious agents most often responsible, and some of the interventions nurses may take to prevent or control the spread of infection.

Clinical Cue

There are times when the nurse is not quite sure where to dispose of materials used in the treatment of a patient. If the item has blood or body fluids on or in it where you can squeeze, sling, fling, or flick it from or off the material, then it should be disposed of in the biohazard waste container.

Table 6-8
Preventing and Controlling Health Care–Associated Infections

MOST COMMON SITES	NURSING INTERVENTIONS
Urinary tract	Catheterize only when absolutely necessary. Observe sterile technique when catheterizing. Keep drainage system for indwelling catheter closed, off the floor, and below the bladder level at all times to prevent urine reflux. Empty urine drainage bag into a clean container, without contaminating the spout. Wipe the spout with an alcohol pad before securing it. Remove indwelling catheters as soon as possible to decrease risk of infection.
Surgical wounds	Administer prophylactic antimicrobials as ordered. Change soiled dressings and linens promptly and dispose of them in the correct container. Ensure the patient has adequate nutrition and sufficient fluid intake.
Respiratory tract	Encourage the patient to cough, deep breathe, and move. Perform suctioning, tracheostomy care, and other procedures under aseptic technique. Protect the patient from others with colds or other signs of infection.
Bloodstream (bacteremia)	Maintain meticulous aseptic technique in the administration of intravenous (IV) fluids. Follow the recommended procedure for daily care of the insertion site (including the dressing) and IV tubing and catheters. Assess the site for increased redness, pain, or infiltration. Remove and insert new IV sets per facility policy and when indicated.

Along with preventive interventions and appropriate treatments, you must continuously assess the patient to identify early signs of infection or its spread. It is also helpful to review and document each patient's immunization status against such infections as tetanus, pertussis, influenza, hepatitis B, pneumococcal pneumonia, and varicella.

Infection Surveillance and Reporting

Surveillance requires that nurses be alert for signs or symptoms of infection in patients under their care. For example, you should routinely assess patients for unexpected elevation of temperature; malaise; cough; loss of appetite; foul-smelling urine; new-onset diarrhea; and wounds that are red, swollen, painful, or have a foul-smelling discharge. It is important to note the color of the purulent drainage; this is helpful in identifying the kind of organism that may be causing an infection (e.g., *S. aureus* produces a golden discharge, and *Pseudomonas aeruginosa* has bluish green discharge).

Pay particular attention to patients who are more susceptible to infection. These patients include those who (1) are weakened by severe illness or injury; (2) have drainage tubes, intravenous catheters, or other invasive devices for monitoring or treatment; (3) are very young or very old; (4) have had recent surgery; or (5) are immunocompromised. When an infection is suspected, report this to the patient's health care provider. In certain situations, Transmission-Based Precautions may need to be instituted even before culture results are available. If there is a question as to what type

of precautions to initiate, contact the facility's infection prevention and control department.

Medical Asepsis and Surgical Asepsis

Medical Asepsis

Medical asepsis (the goal of which is to reduce microorganisms) includes hand hygiene, separation or isolation of the patient, use of appropriate precautions for the handling and disposing of contaminated articles, and other techniques devised to contain and destroy infectious agents, such as cleansing and disinfection.

Surgical Asepsis

Surgical asepsis (the goal of which is to completely eliminate microorganisms) involves the sterilizing of instruments, skin, and other articles that will be used to perform surgery or other types of sterile procedures. Surgical procedure typically requires that the first line of defense (i.e., the skin) be compromised in some way. Surgical asepsis must also be used when placing an intravenous catheter into a vein, when inserting a Foley catheter into the urinary bladder, during the placement of internal monitoring devices, or during other invasive procedures such as a cardiac angiogram. Hand hygiene for surgical asepsis is more vigorous and must be performed according to the facility's policy and procedure. In a surgically aseptic environment, surgical gowns, face masks, and sterile gloves are necessary and must be put on and removed in a specific way. Procedures being performed at the bedside that require surgical asepsis, such as a central line placement, require that all persons in the room wear a facemask and head cover. The person performing the procedure must also wear sterile gloves and a sterile cover gown. The patient must be covered with sterile drapes, and only sterile equipment and supplies are to be used. The door to the room must be closed throughout the procedure (CDC, 2002).

Sepsis and Septic Shock

If a patient's HAI or community-acquired infection is not adequately treated, the pathogen may enter the bloodstream, causing a bacteremia and sepsis with a systemic inflammatory response syndrome (SIRS). When microorganisms enter the bloodstream, they are carried throughout the body and may invade any tissue or body system. Symptoms of SIRS (commonly referred to as **sepsis**) include, but are not limited to, tachycardia, increased cardiac output, **tachypnea** (rapid breathing), fever, and an elevated WBC count. An altered level of consciousness may also occur. Sepsis is most commonly associated with bacterial invasion from gram-negative bacteria, such as *Pseudomonas aeruginosa*, *Escherichia coli*, and *Klebsiella pneumoniae*, or gram-positive bacteria such as *Staphylococcus aureus* and *Streptococcus pneumoniae*. The toxins secreted into the blood from these pathogens react with the blood vessels and cell membranes, stimulating a massive inflammatory and immune response. Increased capillary permeability with loss of fluid from the vascular space, cellular injury, and greatly increased cellular metabolic rates can result in septic shock. Refer to [Chapter 44](#) for further information on SIRS and septic shock.

Nursing Interventions for Patients with Sepsis

Patients who are at risk for sepsis must be identified and then closely monitored for changes from the baseline assessment, such as a change in mental status, tachycardia, tachypnea, changes in blood pressure, and decreased urine output. The temperature may be normal or elevated, depending on the organism or organisms that are causing the sepsis. Pneumonia and postsurgical wound infections are two conditions that can lead to sepsis if not quickly identified and treated, and some patients, often older adults, experience **hypothermia** (below normal temperature) when septic.

Sepsis is diagnosed from the clinical presentation of the patient and the results of laboratory tests, such as elevated leukocyte count, decreased platelets, and serial blood cultures that may be positive for invading microorganisms. Antimicrobial sensitivities are performed on these pathogens to determine which drugs would be most appropriate to treat the infection. Ensuring that the correct antimicrobial agents are prescribed in a timely manner decreases the risk of the patient developing a multidrug-resistant infection and eliminates the pathogens as quickly as possible.

Clinical Cues

If sepsis is discovered early, the chance of a full recovery is good. Septic shock can progress to the stage of tissue damage from microthrombus formation and disseminated intravascular coagulation (DIC); the prognosis is then poor, and death may soon occur. Closely monitoring a patient who has an infection for signs of sepsis and reporting any such signs to the provider are extremely important.

❖ Nursing Management

■ Assessment (Data Collection)

Detecting infection in a patient requires a thorough nursing assessment. Subjective data can be obtained by asking the patient to describe symptoms and time of onset. Questions should also include whether the patient is having or has had pain, headache, stiff neck, fever, or chills. The interview is based on the patient's complaints; for example, if the patient states that it hurts to go to the bathroom, ask if there is also urgency or burning when trying to empty the bladder. With some signs and symptoms, it may be appropriate to ask if patients have traveled outside the country recently (e.g., amebic dysentery); if they were bitten by any insects before the onset of symptoms (e.g., West Nile virus); or if they have a compromised immune system, either from disease or from drug exposure (i.e., chemotherapy agents). (Refer to [Chapter 14](#) for more information on West Nile virus.)

Clinical Cues

Subjective complaints that may indicate infection include fatigue, loss of appetite, headache, nausea, general malaise, and pain.

Objective data often point to the specific body system affected by the infection but may also include systemic signs such as fever, tachycardia, or tachypnea. Data collection includes assessing vital signs; auscultating the lungs to check for abnormal breath sounds; inspecting the skin for lesions or rashes; and checking the urine for cloudiness, discoloration, abnormal odor, and increased specific gravity. Bowel sounds are auscultated in all four quadrants, and then the abdomen is gently palpated for signs of tenderness. In addition, look for signs of local infection such as redness, swelling, pain or tenderness on palpation or movement, heat in the affected area, and possibly loss of function of the affected body part.

Older Adult Care Points

Many older adults, especially those older than 80 years, have a low baseline body temperature. Because of decreased inflammatory and immune response, their temperature may rise very little in the presence of infection. Small increases in temperature in these patients may be quite significant. Signs of inflammation may not be present or may be milder than what is typically seen in a younger person. A decrease in mental alertness, increased fatigue, or sudden onset of confusion, irritability, or apathy may be clues that an infection is present.

Diagnostic Tests

Laboratory data that may indicate infection include an elevated WBC count, changes in the distribution and number of the various types of leukocytes, elevated erythrocyte sedimentation rate (ESR), and microbiology cultures that test positive for microorganisms.

Bacteriologic tests are performed by culturing specimens of blood, body fluids, or waste products such as feces. When obtaining a culture, be careful to (1) use aseptic technique, where indicated and with sterile equipment; (2) only collect fresh material from the suspected site, avoiding contamination by microbes from nearby tissues and fluids; and (3) use the appropriate container for the sample, making sure the container is correctly labeled and tightly covered to avoid spilling and contamination during transport to the laboratory. Also note on the laboratory requisition form whether or not the patient has been given any antimicrobial agents before the specimen was collected. This is because some microorganisms may have responded to the administered drug and thus be in such low quantities at the time of collection, they may not grow in the culture media. This might cause a delay in the appropriate antimicrobial treatment for the patient.

Sensitivity tests are done in conjunction with microbiology cultures to determine which antimicrobials can most effectively destroy or inhibit the multiplication and growth of the specific infecting microbe. Once this has been determined, the drug that is most likely to kill the invading microorganism needs to be started as soon as possible. Inadequate dosages or delays in administration can lead to a genetic mutation of the pathogen involved or the development of a **multidrug-resistant organism (MDRO)**.

With some infectious diseases, intradermal skin tests are performed to determine the presence of certain active or inactive diseases, such as tuberculosis, coccidioidomycosis, and candidiasis. Radiography (x-rays), computed tomography (CT), or magnetic resonance imaging (MRI) may be used to detect changes in the tissues or organs and to locate abscesses anywhere within the body.

Nursing Diagnosis

The specific type of infection and the problem it presents determine the correct problem statement. For example, if the patient has a urinary tract infection, the more specific problem statement would be *Altered urinary elimination*. In some cases, collaboration with other health team members helps establish the correct problem statement. Appropriate problem statements for patients with infection always include *Potential for infection*. Any patient entering the hospital for surgery or an invasive procedure is at risk for an HAI. Therefore *Potential for infection* should be listed as a problem statement or nursing diagnosis on the patient's care plan. The problem statement Insufficient knowledge due to lack of knowledge about the disease and the problems of infection prevention, and limited ability for self-care should always be considered ([Nursing Care Plan 6-1](#)).

Nursing Care Plan 6-1

Care of a Patient With an Abdominal Wound

Scenario

Mr. Collins is a 28-year-old man who has been diagnosed with a lower abdominal wound infection that is culture positive for methicillin-resistant *Staphylococcus aureus* (MRSA). He is going to be discharged in 2 days.

Problem Statement/Nursing Diagnosis

Wound infection/*Impaired Skin Integrity related to infected abdominal wound*

Supporting Assessment Data

Objective: Drainage from abdominal wound is culture positive for MRSA, a multidrug-resistant organism (MDRO).

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Infection will be controlled and not spread.	Place under Contact Precautions and explain purpose and requirement to patient and visitors.	To prevent the spread of infection to other patients and staff	No evidence of spread of infection
	Assist patient with bath to ensure skin has been cleaned. Change wound dressing as ordered and as needed.	Enables the nurse to do a thorough skin assessment Ensures that the wound is assessed at least daily and nurse can track progression of wound treatment	Bathed Dressing changed, less drainage and redness
	Monitor vital signs, complete blood count, microbiology cultures.	Indicates progress in resolving the infection	Vital signs stable WBC normalizing Outcomes met

Problem Statement/Nursing Diagnosis

Insufficient knowledge/*Deficient Knowledge related to proper wound care at home*

Supporting Assessment Data

Subjective: States, "I don't know how to change the dressing."

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Before discharge, the patient and family member will be able to: Demonstrate proper hand hygiene techniques.	Demonstrate proper hand hygiene techniques and observe patient and family member perform this task.	Providing opportunities for education and training throughout the hospital stay increases the knowledge base the patient or the caregiver can build on.	Patient verbalizes reasons for Contact Precautions; patient and family member demonstrate proper hand hygiene, wound cleansing, and dressing change techniques using medical asepsis; patient and family member verbalize signs and symptoms to report to provider; and patient states that he knows how to take medication and why he must finish the prescription.
State reasons for using Contact Precautions for dressing change.	Discuss reasons for Contact Precautions with patient and caregiver and provide supplemental written or audiovisual materials.	Addresses different learning styles of the adult patient/learner.	Patient and caregiver state they understand the need for contact precautions.
Demonstrate dressing change, maintaining medical asepsis before discharge.	Demonstrate dressing change and wound cleansing procedure; obtain return demonstration from patient and family member before discharge.	Providing hands-on training increases the understanding of wound healing and need for appropriate wound care.	Demonstrated dressing change with correct technique. Will observe practice and return demonstration before discharge.
List signs and symptoms that should be reported to provider.	Instruct patient and family to watch for elevated temperature, increased redness, swelling, pain, or purulent discharge from wound, and to report any such findings to provider.	Knowing what to look for and report decreases the risk of adverse outcomes.	Explained signs and symptoms to watch for and left printed sheet. Will seek feedback before discharge.
State why it is important to complete the course of antimicrobial therapy exactly as directed.	Explain importance of taking medication exactly as prescribed and of finishing entire prescription.	Taking antimicrobials as prescribed decreases the risk of the patient developing an MDRO infection.	Obtained feedback from patient; he states rationale correctly.

Critical Thinking Questions

1. What other nursing methods could you implement that would promote healing?
2. How would you recommend the patient's linens be laundered at home?

■ Planning

The planning phase of the nursing process should take into account the physical strength of the patient and the need for rest. Every effort should be made to maintain the integrity of the skin and mucous membranes so that they continue to serve as effective barriers to infectious agents. Good skin care, oral hygiene, and personal cleanliness are essential. The psychological effect of

Transmission-Based Precautions must be addressed; some patients may feel “dirty” or that people are avoiding them because they have an infectious disease.

Cultural Considerations

Hot and Cold Foods

In some Asian cultures there is a belief that a balance of hot and cold foods should be eaten when a fever or infection is present. Cold foods, such as watermelon or white radish soup, are thought to help the body fight off the infection and regain its balance.

Many Hispanic cultures have a belief that “hot” and “cold” forces are thrown out of balance during an illness. Cold foods, such as dairy products, honey, or fresh vegetables, may be preferred by the Hispanic patient with an infection.

Implementation

Providing a quiet environment with uninterrupted rest periods is important in the recovery process. Relieving the discomforts of fever and muscle aches is accomplished by tepid sponge baths, ice bags placed in the axilla or groin, antipyretics, and massage. Warm compresses and the application of heat, as appropriate, can also promote healing. Mild physical exercise promotes circulation and helps some patients to relax. It can also increase blood circulation to an infected area. This ultimately will help to remove the metabolic wastes that were produced from the body.

Provide patient and family teaching regarding the infection, including:

- The purposes of diagnostic tests, treatments, and special precautions
- Why the family must help maintain medical asepsis to prevent the spread of infection to themselves and others

Administering Antimicrobial Agents

Administer antimicrobial drugs on time to maintain effective blood levels. In addition, monitor the patient for drug side effects and evaluate the progress of the patient to determine whether the drug is effective in eradicating the infection. General nursing actions for the administration of antimicrobial medications are shown in **Table 6-9**.

Table 6-9

General Nursing Implications for the Administration of Antimicrobial Drugs

NURSING IMPLICATIONS	RATIONALE
Before Giving the Antimicrobial Drug	
Check all drugs the patient is receiving for drug interactions with the antimicrobial prescribed.	To prevent toxicity or lack of absorption
Know the reason why the patient is to receive an antimicrobial drug (question the health care provider if the drug does not seem appropriate for the patient).	To help prevent drug administration errors
Check that the dosage of the antimicrobial drug is appropriate for the patient who may have decreased kidney or liver function.	To ensure drug levels do not build up to a toxic level
Verify allergies with the patient before administering an antimicrobial drug.	To prevent allergic reaction or adverse outcomes
Ensure cultures have been obtained before administering the antimicrobial agent. If culture and sensitivity results are available, verify that the drug that was ordered is one to which the organism is sensitive. If it is not, clarify the order with the health care provider.	To ensure medication being given is appropriate for the microorganism involved
Check precautions for administration of the antimicrobial drug, especially when the patient is pregnant or lactating.	To prevent harm to the developing fetus or infant
When Giving an Antimicrobial Drug	
Follow the “Six Rights” of medication administration.	To prevent errors and injury to the patient
Give each dose of an antimicrobial drug as close to the scheduled time as possible.	To maintain a consistent blood level of the drug
Check to see if serum drug levels have been ordered. Ensure that they are drawn as specified by the provider.	To ensure drug dosage is effective and to ensure toxicity will not occur
Possible Side/Adverse Effects	
Know and monitor for the possible side effects of the antimicrobial drug. The most common general side effects are gastrointestinal upset, anorexia, nausea, diarrhea, rash, and photosensitivity.	To aid the nurse in effectively teaching the patient about what to observe for and report to the provider
Monitor patient for signs of allergic reaction, such as rash, hives, itching, drug fever, swelling of the mucous membranes, difficulty breathing, or anaphylaxis.	To ensure appropriate interventions are instituted quickly and to prevent more severe outcomes, including death
Check for signs of superinfection in patients taking high doses of an antimicrobial drug for an extended period of time (e.g., oral thrush, vaginal itching or discharge, diarrhea).	To ensure appropriate countermeasures can be instituted in a timely manner
Patient Teaching	
“Take the medication with a full glass of water.”	To aid with absorption
“Take all of an antimicrobial drug prescription, regardless of whether you feel better and have no obvious signs or symptoms of infection.”	To prevent the development of multidrug-resistant microorganisms
“Take the medication in relationship to meals.” (Different drugs vary in this respect; some need to be taken with food and some should be taken on an empty stomach.)	For best absorption of the drug with minimal gastrointestinal side effects
“Discontinue the drug and notify the health care provider if an allergic reaction occurs.”	To ensure treatment is instituted quickly and to prevent more severe outcomes, including death; may require an alternate type of antibiotic to be prescribed
“Use a sunblock and protective clothing when sun exposure is unavoidable when taking an antimicrobial agent that is known to cause photosensitivity.”	To decrease the risk of sunburn
Unless contraindicated, “Increase fluid intake to 2500–3000 mL/day, especially when taking a sulfa-type drug.”	To prevent crystallization in the kidneys and promote drug excretion

Before administering the prescribed drug, be familiar with the different antimicrobial agent classifications: antibacterial, antiviral, antifungal, and anthelmintic (Box 6-5).

■ Complementary and Alternative Therapies

Prolonged antibiotic use can destroy the normal gastrointestinal flora and cause *Clostridium difficile* to flourish and cause antibiotic-associated diarrhea. Probiotics are available in yogurt or in tablet, capsule, or powder form and may help to restore natural flora. Side effects include mild abdominal discomfort and flatulence. The patient should be encouraged to consult the health care provider before using probiotics.

Box 6-5

Antimicrobial Drug Classifications*

Antibacterial Agents

Narrow Spectrum

Gram-Positive Cocci and Gram-Positive Bacilli

Penicillins G and V

Vancomycin

Erythromycin

Clindamycin

Gram-Negative Aerobes

Aminoglycosides: gentamicin, tobramycin, neomycin, and azithromycin

Cephalosporins

- First generation (e.g., cefazolin [Ancef], cephalexin [Keflex])
- Second generation (e.g., cefaclor [Ceclor], cefotetan [Cefotan], cefuroxime [Zinacef])

Mycobacterium Tuberculosis

Ethambutol

Isoniazid

Pyrazinamide

Rifampin

Broad Spectrum

Gram-Positive Cocci and Gram-Negative Bacilli

Broad-spectrum penicillins (e.g., ampicillin)

Cephalosporins

- Third generation (e.g., cefepime [Maxipime], cefixime [Suprax], cefotaxime [Claforan], ceftriaxone [Rocephin])

Tetracyclines (e.g., doxycycline, minocycline)

Carbapenems (e.g., imipenem, meropenem)

Sulfonamides (e.g., sulfasalazine, sulfisoxazole)

Antiviral Agents

Acyclovir

Amantadine

Azidothymidine

Saquinavir

Antifungal Agents

Amphotericin B

Ketoconazole

Itraconazole

Anthelmintic Agents

Pyrantel

*As with any other drug, it is important for the nurse to know what the drug is and what it is being given for, and to provide close nursing observation, especially if the patient has never received the drug in the past. Teaching the patient signs and symptoms to report is also an important part of providing safe and effective nursing care.

Data from Lehne RA: *Pharmacology for nursing care*, ed. 8, Philadelphia, 2013, Saunders; Skidmore-Roth L: *Mosby's nursing drug reference*, ed. 27, Philadelphia, 2014, Mosby.

There are two primary categories of antibacterial agents: narrow spectrum and broad spectrum. Both kinds inhibit replication and growth of bacterial organisms. The most common side effects are nausea, vomiting, and diarrhea. The narrow-spectrum agents primarily work on a select type of microorganism, such as a gram-positive organism that is susceptible to penicillin. A broad-spectrum antibiotic can attack a larger group of organisms. However, these agents can also cause superinfections because they kill off many of the “good bacteria” in the body. A narrow-spectrum antibiotic is the preferred choice for treatment over a broad-spectrum agent, because it primarily destroys the pathogenic organism and also reduces the risk of developing an MDRO infection.

Antiviral agents interfere with DNA or RNA synthesis required for the virus to duplicate itself. The most common side effects are headache, nausea, vomiting, anorexia, and diarrhea; more severe side effects include acute renal failure, encephalopathy, and bleeding disorders.

Antifungal agents increase permeability of the cell membrane by binding with certain components, leading to decreased nutrient availability to the cell. The most common side effects are headache, fever, chills, nausea, vomiting, and anorexia; more severe side effects include acute kidney and/or liver failure and hemorrhagic gastroenteritis.

Anthelmintic agents cause paralysis of the invading parasite, and common side effects include dizziness, headache, fever, nausea, vomiting, anorexia, diarrhea, and rash.

Supporting Coping Mechanisms

Stress makes the body more vulnerable to invasion by foreign organisms by depressing the immune system. When under excessive stress, the body also is less able to mobilize the elements and cells that promote healing. Nurses should realize that the attitude shown toward a patient and the ways in which you strive to meet the patient's needs could reduce stress and promote healing.

If an illness is lengthy, concerns about work and home responsibilities may cause anxiety or

increase the patient's stress levels. Therefore collaboration with a social worker or case manager for solutions to such problems may be needed.

Patient Teaching for Preventing and Controlling Infection

Appropriate teaching is essential so that the patient and the patient's family will understand why specific precautions are necessary. Before beginning teaching, find out how much the patient or family knows about the patient's condition and the problems that may arise. Nurses have an obligation to teach patients and/or their family how to care for themselves and how to prevent infection through good personal hygiene. In a recent study, patients stated they prefer information that is easy to understand and accessible either in written form or via the Internet ([Gudnadottir et al, 2013](#)).

Patient Teaching

How to Prevent and Control Infection

Teach the patient and family:

- The ways in which the infection is transmitted
- How to perform proper hand hygiene
- Correct techniques for wound care
- The approved method for disinfecting or sanitizing equipment, supplies, and linens
- The correct method for proper handling and disposal of contaminated articles
- Any specific precautions for the type of infection the patient has

A patient taking antimicrobial medications at home must be taught how to take them as prescribed and not to discontinue taking any antimicrobial medication, even if symptoms are gone, until all medication has been taken. Explain to the patient and the family that stopping before the full amount of medication has been taken can lead to a superinfection and possibly readmission to the hospital.

■ Evaluation

Evaluation of the success of interventions includes data indicating:

- Temperature, pulse, and respirations are within normal range.
- WBC count and ESR are within normal limits and cultures are negative (see [Chapter 10](#) for more information on diagnostic tests and normal laboratory values).
- Patient is able to rest comfortably.
- Pain and discomfort are absent or decreased in severity.
- Fluid and nutritional needs are being met.

Community Care

As more nurses work in community settings, opportunities to educate the public about preventing the spread of infection become even more important. Controlling the spread of infectious diseases within the community is accomplished in conjunction with public health officials. Their major goals, and those of nurses who work with them, are to (1) promote sanitary standards in communities, (2) identify persons who are highly susceptible to infection and reduce their chances of developing an infectious disease, and (3) provide immunization programs to protect people against certain communicable diseases.

Home Care

The home care nurse must educate the patient and family members to help prevent infection. All people living in the home should be instructed to wash their hands as soon as they return home from being out in a public place. Microorganisms are picked up on the hands from a variety of items, such as shopping cart handles, elevator buttons, door handles, and cell phones. The incidence of colds and flu might be decreased if, during influenza season, people who are at increased risk for infection stay away from crowded stores and theaters where pathogens are likely to be airborne.

The home care nurse must teach the techniques of medical asepsis to patients and family members to prevent cross-infection from one person to another or the spread of infection in the patient. Hand hygiene is stressed, and family members are taught not to share personal items, especially toothbrushes or razors that might be contaminated by blood. Dishes and eating utensils are washed with soap and hot water or in the dishwasher. The patient's soiled linens, clothing, and towels should be washed as soon as possible or stored in closed plastic bags until washed. Surfaces contaminated with traces of blood, urine, feces, or vomitus should be sanitized using a clean cloth, soap, and hot water, and then recleaned with a 1 : 10 solution of chlorine bleach and hot water. Within the home, the patient and family are taught to contain infectious wastes such as dressings and soiled tissues in a sealed, impermeable plastic bag, to minimize odors. The bags can then be disposed of in the garbage cans outside of the home.

Health Promotion

What You Can Do to Prevent Infections at Home

- Wash your hands often.
- **When:** Before eating; before, during, and after handling or preparing food; before dressing a wound, giving or taking medicine, or inserting contact lenses; after contact with body fluids or blood; after changing a diaper; after using the bathroom; after handling animals or their toys, leashes, or waste; after handling anything contaminated, such as trash, drainage, soil, etc.
- **How:** Wet hands and apply soap, briskly rub hands together for 20 seconds, rinse thoroughly with warm water, and dry with a clean towel.
- Routinely clean surfaces.
- **In kitchen:** Clean counters, cutting boards, and all other surfaces

before, during, and after preparing food, especially meat and poultry. Use hot, soapy water and scrub cutting boards well. Avoid wooden cutting boards, because they tend to hold more bacteria.

- **In bathroom:** Clean and disinfect all surfaces routinely.
- Handle and prepare food safely.
- **Clean:** Clean hands and work surfaces often.
- **Separate:** Do not cross-contaminate one food with another; use separate cutting boards for meat and fresh produce and keep food separate in the refrigerator.
- **Cook:** Cook foods to proper temperatures; use a food thermometer. Find recommended food cooking temperatures at www.isitdoneyet.gov.
- **Chill:** Refrigerate foods promptly. Do not thaw frozen foods on the countertop.
- Get immunized.
- Make sure you and your loved ones get the necessary shots suggested by your health care provider at the proper time, and maintain immunization records for the family. Ask your provider about special programs that provide free shots for your child or elderly parent.
- Use antimicrobials appropriately.
- Take antimicrobials exactly as prescribed by your health care provider. Antibiotics do not work against viruses such as colds or flu.
- Be careful with pets.
- Follow the immunization schedule for your pets as recommended by the vet.
- Clean litter boxes daily and perform hand hygiene immediately afterward.
- Make sure your child does not put any object or hands in his or her

mouth after touching animals.

- Wash hands thoroughly after contact with animals, especially after visiting farms, petting zoos, and fairs.
- Use flea and tick prevention treatment on cats and dogs.
- Avoid contact with wild animals.
- Do not leave food around and keep garbage cans sealed around your home.
- Clear brush, grass, and debris around your home.
- Seal any entrance holes to animal dens, if any are found inside or outside of your home.
- Use insect repellent to prevent ticks.

Maintaining a healthy lifestyle that promotes an intact immune system increases a person's resistance to infection. Obtaining adequate sleep, eating properly, and exercising regularly contribute to increased resistance to illness or infection. Adopting effective stress reduction techniques and using them regularly can also be beneficial.

Long-Term Care

Older adults in long-term care or assisted living facilities often have chronic illnesses that add to their susceptibility. Many older adults have low-grade infections of the urinary, respiratory, or gastrointestinal tract that can be easily passed on to others if hand hygiene is not consistently practiced. Provide assistance to residents to wash their hands before meals and after toileting, before and after being in community rooms such as the dining room or social activities lounge, and any time their hands become soiled. Cleaning incontinent patients promptly and maintaining skin integrity are essential nursing functions. Also, to help decrease the odors caused by incontinence, it is important to secure soiled linens in plastic linens bags before removal from the patient's room.

Get Ready for the NCLEX® Examination!

Key Points

- Normal flora is needed to help prevent harmful microorganisms from colonizing or infecting the body.
- An infection is the presence and growth of pathogenic microorganisms in a susceptible host to the extent that tissue damage occurs.
- The relationship between the host, the agent, and the environment is what determines whether or not an infection will occur.
- A pathogen is any organism that, if allowed to grow, can cause infection or disease.
- There are multiple types of antimicrobial drugs that can be used to fight infection: antibiotics for bacterial infections, antivirals for viral infections, and antifungals for fungal infections.
- The body has mechanical barriers, such as the skin and mucous membranes, and chemical barriers, such as tears or saliva, that help fight against infection.
- Fever is one of the primary immune responses to fighting off invading microorganisms.
- Hand hygiene is the number one way to prevent the spread of infection.
- There are three types of Transmission-Based Precautions: Airborne, Contact, and Droplet. Each requires different PPE and isolation protocols.
- A patient with suspected or confirmed Ebola virus infection requires PPEs to be donned and doffed so that no skin or mucus membranes are exposed to the patient's blood or body fluids at any time during the provision of nursing care.
- Using respiratory hygiene and cough etiquette helps to prevent the spread of infection.
- Blood or other body fluid specimens for culture must be collected before the start of any antimicrobial agent.
- Assess how much the patient already knows about preventing the spread of infection and teach about hand hygiene, the correct use of antimicrobial agents, cleaning of wounds, and keeping the home environment clean.
- The nurse must model scrupulous hand hygiene compliance for patients and family members.

Review Questions for the NCLEX® Examination

1. The nurse is admitting a patient with an infected abdominal wound. Wound cultures are positive for methicillin-resistant *Staphylococcus aureus*. Appropriate nursing care for this patient includes:

1. monitoring temperature and white blood cell count.
2. placing the patient on strict intake and output.
3. instituting respiratory precautions.
4. encouraging ambulation along the hallways.

NCLEX Client Need: Physical Integrity

2. During an assessment, the nurse notes fever, fatigue, general weakness, cold and clammy skin, nausea, vomiting, and diarrhea. What is the prominent nursing problem?

1. Pain
2. Dehydration
3. Hypotension
4. Immobility

NCLEX Client Need: Safety and Infection Control

3. Which patient instruction is most critical to a patient being discharged on antibiotic therapy?

1. "Wash your hands."
2. "Increase fluid intake."
3. "Reduce stress."
4. "Take all the antibiotics as prescribed."

NCLEX Client Need: Pharmacological and Parenteral Therapies

4. The nurse is observing a nursing student who must perform a dressing change for a patient. The nurse would intervene if the student:

1. washes hands with soap under running water, using friction, for 20 seconds.
2. removes rings and jewelry before washing hands with soap and water.
3. washes hands before donning clean gloves to remove the old dressing.
4. prepares supplies, dons sterile gloves, and removes the old dressing.

NCLEX Client Need: Safety and Infection Control

5. When administering an ordered antimicrobial for an infection, the nurse should check the lab

results for:

1. elevated white blood cells.
2. culture and sensitivity.
3. erythrocyte sedimentation rate.
4. fever.

NCLEX Client Need: Pharmacological and Parenteral Therapies

6. The nurse assumes the care of a patient with active pulmonary tuberculosis. Before entering the patient's room, the appropriate nursing action would be to do:

NCLEX Client Need: Safety and Infection Control

7. The need for protective isolation and the parameters are being explained to the patient. She wails, "How can I hug my children when I am locked up in this room?" An appropriate response by the nurse would be:

1. "They can see you through the glass door."
2. "You can communicate through the intercom system or via your cell phone."
3. "All people carry microorganisms and your immune system cannot fight off any infection right now."
4. "It won't be long before you can hug them again, we need to keep you safe from infection."

NCLEX Client Need: Safety and Infection Control

8. Which intervention would the nurse implement for a patient with active pulmonary tuberculosis who is socially isolated related to imposed airborne precautions?

1. Limit the number of visitors to immediate family.
2. Suggest alternative means of contact, such as e-mail and phone calls.
3. Arrange for a nursing assistant to sit with the patient.
4. Reinforce the rationale for airborne precautions.

NCLEX Client Need: Psychosocial Integrity

9. A nurse is caring for an older adult patient and notes a change in mental status. The skin is flushed, warm, and dry. There is a full, bounding pulse and a decreased urine output. In order of priority, which actions should the nurse take? (*Select all that apply.*)

1. Notify the charge nurse of findings.
2. Draw the patient's blood as ordered by the physician for blood cultures.
3. Take a full set of vital signs and compare them to the baseline.
4. Check the patient's history to determine risk for sepsis.

NCLEX Client Need: Reduction of Risk Potential

10. Cross-infection among members of the household who take care of a relative with a severe infection can be prevented by which behavior(s)? (*Select all that apply.*)

1. Sharing personal items.
2. Practicing good hand hygiene.
3. Using a diluted bleach to clean surfaces.
4. Sealing used dressings in impermeable bags.
5. Washing soiled linens weekly.

NCLEX Client Need: Safety and Infection Control

Critical Thinking Questions

Scenario A

Mrs. Compton, age 44, is admitted to the hospital for a hysterectomy. During the admission assessment procedure, you notice a large, draining abscess in her axillary region. She also has a temperature of 100° F (37.7° C), and she tells you that she has not felt well for the past few days.

1. What would be your course of action after this assessment?

Scenario B

Mr. Lopez, age 18, has been admitted to the orthopedic unit after an automobile accident. He has sustained an open fracture of the femur and has been placed in traction.

1. What would be some expected signs and symptoms of inflammation that he might experience?
2. What specific problems might his care present for the nurse?

Scenario C

Mrs. Kay is an older adult woman who comes to the clinic for treatment of an abrasion on her arm that she sustained “while picking up my cat.” She is alert, oriented, and very cheerful and talkative. You notice that she is slightly underweight and that her clothes are not very clean.

1. What additional assessment might you make about the wound and the injury because she mentioned the cat?
2. What changes related to aging are likely to affect Mrs. Kay's natural defense mechanisms to fight infection?
3. Based on the scenario, identify issues that will affect wound healing and self-care for Mrs. Kay.
4. Explain why older adults may have a normal or even subnormal temperature in the presence of infection.

CHAPTER 7

Care of Patients With Pain

Objectives

Theory

1. Review the gate control theory of pain and its relationship to nursing care.
2. Demonstrate an understanding of the current view of pain as a specific entity requiring appropriate intervention.
3. Compare nociceptive and neuropathic pain and nursing care for each.
4. Explain how pain perception is affected by personal situations and cultural backgrounds.
5. Analyze the major differences between acute and chronic pain and their management.
6. Demonstrate the use of the nursing process when caring for patients experiencing pain.
7. Give examples of the different pharmacologic approaches to pain that include the use of adjunctive measures.

Clinical Practice

8. Demonstrate the use of appropriate pain evaluation tools and measures for a variety of patients.
9. Recognize common side effects of analgesics and describe techniques for addressing them.
10. Employ nonpharmacologic approaches to pain management with a variety of patients.

KEY TERMS

- acute pain (ă-KŪT pān, p. 127)
- adjuvant (ÄJ-ü-vänt, p. 127)
- buccal mucosa (BÜK-ăl mū-CŌ-să, p. 136)
- chronic pain (KRÖN-ik pān, p. 127)
- endorphins (ěn-DÖR-fīnz, p. 125)
- epidural (ě-pě-DÜ-rūl, p. 136)
- intractable pain (ĭn-TRÄK-tī-būl pān, p. 136)
- modulation (mōd-ū-LĀ-shūn, p. 125)
- neuropathic pain (nū-rō-PÄTH-ik pān, p. 125)
- nociceptive pain (nō-sē-SĒP-tīv pān, p. 125)

- pain tolerance (pān TÖL-ür-ěnz, p. 127)
- perception (pěr-CĒP-shūn, p. 125)
- phantom pain (FÄN-tüm pān, p. 126)
- placebos (plä-SĒ-bōz, p. 134)
- referred pain (rī-FÜRD pān, p. 131)

transduction (trānz-DŪK-shūn, p. 125)

transmission (trānz-MI-shūn, p. 125)

Theories of Pain

Pain is considered to be not just a symptom, but a specific problem that needs to be treated. *Pain* is defined as a neurologic response to unpleasant stimuli. Pain receptors are abundantly distributed throughout the skin and in many deeper structures of the body. Receptors for pain do not become dulled with repeated stimulation, and under some conditions, repeated stimulation results in an increase in the acuteness of the pain sensation.

Pain is initiated when various chemicals are released from damaged cells, but the actual mechanism of pain is poorly understood. It may be helpful to think of pain as being controlled by a “gate” in the central nervous system (Figure 7-1). When the gate is open, the pain sensation is allowed through. When the gate is closed, the pain sensation is blocked. The **gate control theory** recognizes that stimuli other than pain pass through the same gate. When a large volume of nonpainful stimuli are competing for the gate, pain impulses may be blocked. A high volume of pain, however, may override other stimuli and pass through the gate, causing the individual to perceive the pain.

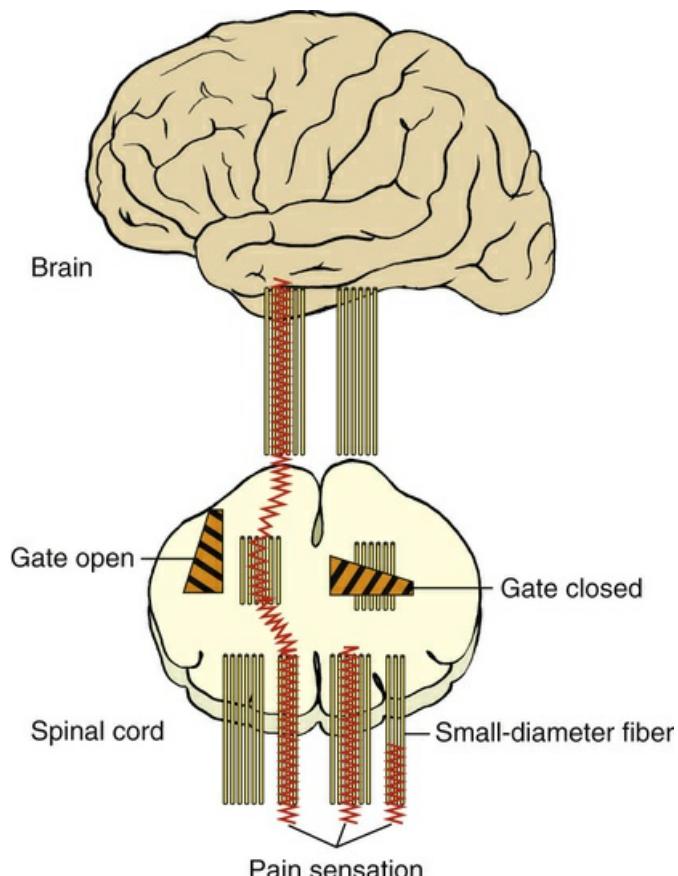

FIGURE 7-1 The gate control theory of pain. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, St. Louis, 2014, Saunders.)

Aspects of this theory relate to nursing practice in several ways:

- Two types of nerve fibers—small-diameter and large-diameter—carry pain stimuli.
- Activity in the small-diameter nerve fibers seems to open the gate, and activity in the large-diameter nerve fibers seems to close it.
- Massage and vibration produce activity in the large-diameter nerve fibers.
- High levels of sensory input create brainstem impulses that seem to close the gate. Distraction in the form of activity or social interaction produces these brainstem impulses.
- An increase in anxiety seems to open the gate, and a decrease in anxiety seems to close it. The fear

that pain will not be controlled may actually increase pain intensity, and knowing that pain can be or is being controlled may reduce pain.

Another way of looking at pain and its management is the idea of “pieces of pain.” The more intense the pain, the greater the number of pieces, and therefore a greater number of pieces of analgesia will be required to control the pain. This idea indicates that inadequate analgesia results in leftover “pieces” of pain, and total relief or control has not been achieved.

The human body produces substances called **endorphins** (endogenous opiates) that attach to pain receptors and block pain sensation. It is unknown how endorphins work, but their properties appear to modify and inhibit unpleasant stimuli, reduce anxiety, and relieve pain. Endorphins may produce feelings of euphoria and well-being. For example, the “runner’s high” may occur because endorphins are released after physical exercise.

Another theory of pain is that there is a “neuromatrix” where pain is a multidimensional experience in which stimuli are influenced by such things as past experience, cultural learning, personality variables, and influences from various body systems. The resulting perceptions of pain result in patterns of nerve impulses and body actions ([Waldman, 2011](#)).

Classification of Pain

Pain can be classified as one of three types: (1) acute pain, such as from trauma or surgery; (2) cancer pain; and (3) noncancer pain (e.g., postherpetic neuralgia, diabetic neuropathy, arthritis). There are two **pathophysiologic** classifications of pain: **nociceptive** and **neuropathic**.

Nociceptive Pain

Nociceptive pain is associated with pain stimuli from either **somatic** (body tissue) or **visceral** (organs) structures. Somatic nociceptive pain arises from injury to tissue where pain receptors called *nociceptors* are located. These nociceptors may be found in skin, connective tissue, bones, joints, or muscles. Trauma, burns, or surgery may cause injuries that trigger somatic nociceptive pain. Visceral nociceptive pain arises from pathophysiologic conditions in visceral organs, such as the organs of the gastrointestinal tract. Pathologic conditions that trigger visceral nociceptive pain include tumors and obstructions of the organs (Table 7-1).

Table 7-1
Physiologic Sources of Pain

PHYSIOLOGIC STRUCTURE	CHARACTERISTICS OF PAIN	SOURCES OF ACUTE POSTOPERATIVE PAIN	SOURCES OF CHRONIC PAIN SYNDROMES
Nociceptive Pain			
Somatic Pain			
Cutaneous or superficial: skin and subcutaneous tissues Deep somatic: bone, muscle, blood vessels, connective tissues	Sharp, burning, dull, aching, cramping	Incisional pain, pain at insertion sites of tubes and drains, wound complications, orthopedic procedures, skeletal muscle tissue	Bony metastases, osteoarthritis and rheumatoid arthritis, low back pain, peripheral vascular diseases
Visceral Pain			
Organs and the linings of the body cavities	Poorly localized Diffuse, deep cramping or splitting, sharp, stabbing	Chest tubes, abdominal tubes and drains, bladder distention or spasms, intestinal distention	Pancreatitis, liver metastases, colitis, appendicitis
Neuropathic Pain			
Nerve fibers, spinal cord, and central nervous system	Poorly localized Shooting, burning, fiery, shocklike, sharp, painful numbness	Phantom limb pain, postmastectomy pain, nerve compression	HIV-related pain, diabetic neuropathy, postherpetic neuralgia, chemotherapy-induced neuropathies, cancer-related nerve injury, radiculopathies

Adapted from Ignatavicius DD, Workman ML: *Medical-surgical nursing: Critical thinking for collaborative care*, ed. 7, Philadelphia, 2013, Saunders.

Four pain processes are associated with nociceptive pain (Figure 7-2) (Pasero and McCaffery, 2011):

1. **Transduction** begins when tissue damage causes the release of substances that stimulate the nociceptors and initiate the sensation of pain.
2. **Transmission** involves movement of the pain sensation to the spinal cord.
3. **Perception** occurs when impulses reach the brain and the pain is recognized.
4. **Modulation** occurs when neurons in the brain send signals back down the spinal cord by release of neurotransmitters.

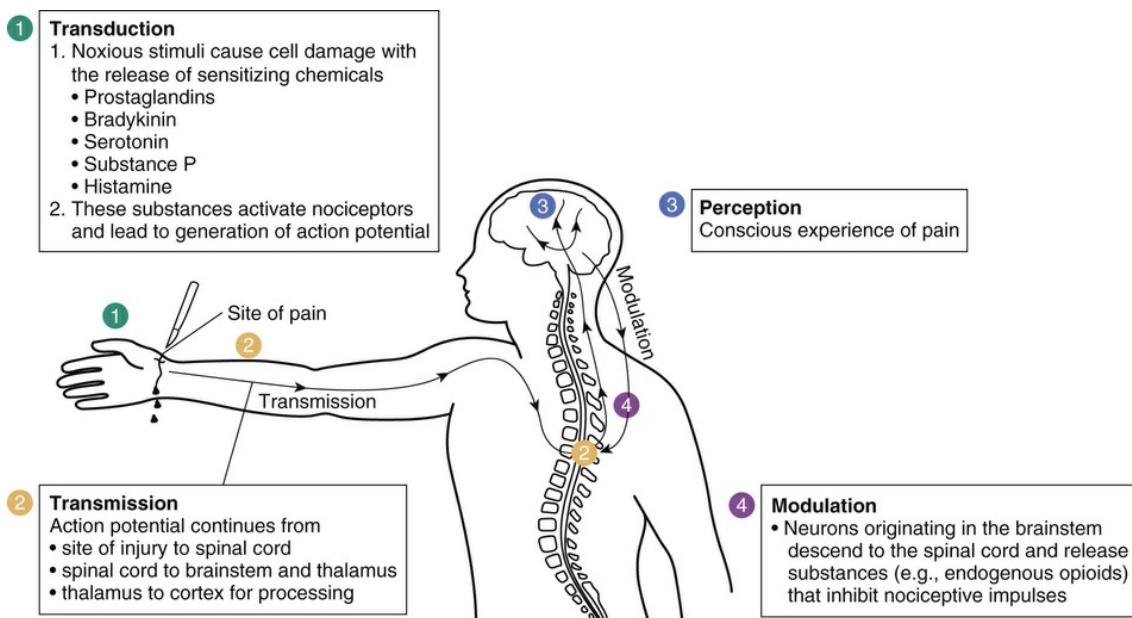

FIGURE 7-2 Nociceptive pain originates when tissue is injured. 1, Transduction. 2, Transmission. 3, Perception. 4, Modulation. (From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2014, Mosby.)

Aspects of nociceptive pain relate to nursing practice in several ways:

- Treatment of nociceptive pain may be directed toward one or all of the four phases.
- Nonsteroidal anti-inflammatory drugs (NSAIDs) work by blocking the production of the substances that trigger the nociceptors in the transduction phase.
- Opioids interfere with the transmission phase.
- Nonpharmacologic treatments, such as distraction and guided imagery, may be effective during the perception phase.
- Drugs that block neurotransmitter uptake work in the modulation stage.

Neuropathic Pain

Neuropathic pain is associated with a dysfunction of the nervous system that involves an abnormality in the processing of sensations. These dysfunctions in the nervous system are often associated with medical conditions rather than with tissue damage. The dysfunction may occur in the peripheral or central nervous system. In peripheral nervous system neuropathic pain, it is believed that pain receptors become sensitive to stimuli and send pain signals more easily. Nerve endings grow additional branches that send stronger pain signals to the brain. As the branches grow, they influence touch and warmth receptors. Other peripheral nervous system conditions may cause neuropathic pain. Neuropathic pain may be the result of damage to nerve roots, such as compression or entrapment. Another dysfunction of the central nervous system occurs when the pain signal that would normally move from the periphery toward the brain reverses, and the signal is sent in the opposite direction. **Phantom pain**, the pain felt in a limb after amputation, is an example.

Aspects of neuropathic pain relate to nursing practice in several ways:

- Analgesics and opioids usually do not relieve neuropathic pain.
- **Adjuvant** medications such as NSAIDs, tricyclic antidepressants, anticonvulsants, and corticosteroids relieve neuropathic pain.

Think Critically

What type of pain do you think a patient with an acute gallbladder attack might be experiencing?

Perception of Pain

Pain is a subjective experience. Only the patient knows the location of the pain, its degree of intensity, and which treatment regimen works and how long it is effective. **This is why the patient must be asked about pain.** Reactions to pain can vary widely from person to person and in the same individual under different circumstances.

Pain threshold is the point at which pain is perceived. Relaxation and distraction strategies can alter the perception of pain. **Pain tolerance** is the length of time or the intensity of pain a person will endure before outwardly responding to it. Tolerance varies among people and is influenced by culture, pain experience, expectations, and role behaviors. People with **acute pain** (of recent onset, lasting less than 6 months) may have physiologic symptoms such as increased pulse and respiratory rates, increased blood pressure, diaphoresis, and increased muscle tension. They may also experience nausea and vomiting. People with **chronic pain** (lasting months or years) may have learned adaptive methods that allow them to have some control over their pain. Symptoms associated with chronic pain include irritability, depression, withdrawal, and insomnia. Coping with any pain takes a lot of energy, and patients who are debilitated are less able to withstand pain than are strong, robust people. Fatigue caused by pain can lead to an increase in pain perception.

Clinical Cues

Patients who have a substance abuse problem are not to be denied pain medication when they experience acute pain. Patients who are being treated for long-term chronic pain often require higher doses of pain medication after surgery or trauma.

Pain causes a variety of physiologic responses, including increased respiratory rate, pulse, or blood pressure; muscle tension; sweating; flushing or pallor; and frowning or grimacing. Although the presence of any of these factors may indicate pain, their absence does not prove the absence of pain.

A person's cultural background influences feelings about pain. In much of Western culture it is considered desirable to have a high pain tolerance, particularly among men. Other cultures promote the idea that to endure pain is natural, or honorable. A nurse whose cultural background approves the "stiff upper lip" approach to handling pain may consider a patient who outwardly expresses pain to be weak or manipulative. By contrast, those patients whose cultural upbringing causes them to hide and deny pain may suffer needlessly unless the nurse can intervene and help them to understand that analgesia will aid the healing process by encouraging movement and decreasing fatigue. **Learning to accept without judgment the various ways of coping with and expressing pain is a very necessary process for nurses.**

Older Adult Care Points

The idea that pain perception diminishes with age is false. In fact, perception of pain may actually increase with age, as the individual becomes frail, has more than one chronic ailment, and has fewer resources for tolerating pain.

Acute versus Chronic Pain

Acute Pain

Patients with acute pain frequently experience fear and anxiety, which can take many forms. They may fear that something is seriously wrong, that they will never get relief from the pain, or that they will become addicted to the pain medication. The anxiety and fear of these patients can be alleviated by first providing adequate analgesia to relieve the pain and then educating them about their pain and the methods that can be used to control pain safely. Including patients in planning their care reassures patients that health care professionals believe them and want to help.

Rely on the patient's report of pain and intervene to promote comfort (Agency for Healthcare Research and Quality, 2013b). Table 7-2 compares acute and chronic pain. Some nurses hesitate to administer pain medication to patients with a history of drug abuse. Such patients may experience acute pain, for example, after surgery. The postoperative period is not the time to withhold pain medication from any patient. Concept Map 7-1 shows the various types and causes of pain.

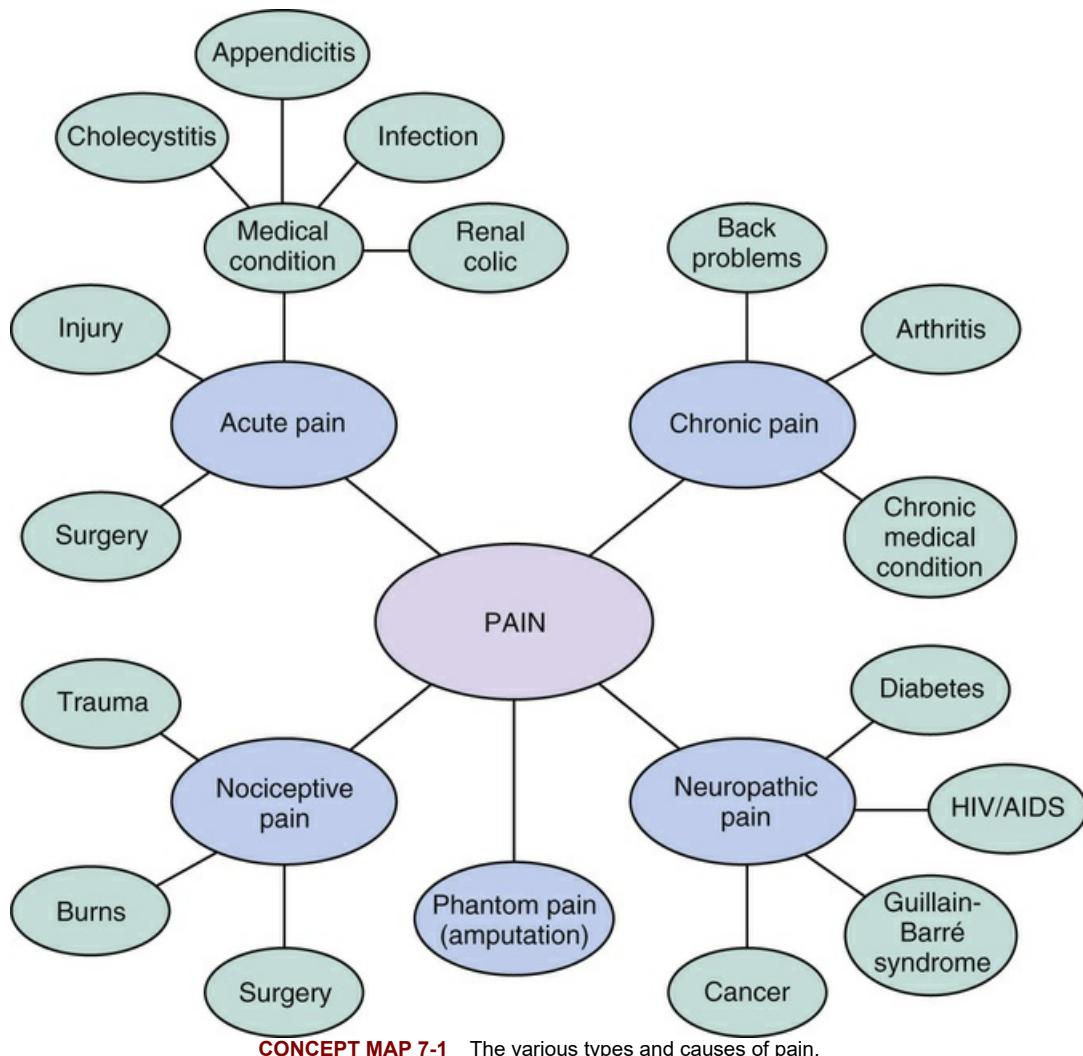

Table 7-2

Acute versus Chronic Pain

	ACUTE	CHRONIC
--	-------	---------

Duration	Hours to days.	Months to years.
Prognosis for relief	Good; may resolve spontaneously or in response to analgesic therapy.	Poor unless complicating factors are removed; spontaneous relief is unusual.
Cause	Relatively easy to identify.	Sometimes the cause is known, but diagnosis may be complex or undetermined.
Psychosocial effects	Usually transient or none. May temporarily disrupt normal activities or routine.	Can affect ability to earn a living, enjoy social activities, or maintain self-esteem.
Effect of therapy	Medication is usually beneficial; surgery is often helpful.	Medications may be helpful, but patient may become dependent. Multiple-medication regimen may be used. Surgery may help but also may worsen the problem.

Chronic Pain

Neuromatrix theory, which hypothesizes that there is an interaction between physiologic mechanisms and psychosocial factors, supports using interventions to treat chronic pain. Behavioral and psychologic interventions may alter how the patient experiences the pain by affecting the patient's emotional state and cognitive process, thereby making the interventions more effective ([Smale and Rayner, 2013](#)). Chronic pain is often associated with depression. People who are in pain most or all of the time commonly resign themselves to the idea that they can never again live a normal life. Research and the work of several outstanding pain centers as well as nurse and provider specialists now offer new pain relief techniques for patients with chronic pain. Many people whose lives were previously dictated by their pain now experience good control and have returned to normal, productive lives.

Older Adult Care Points

Between 60% and 75% of older adults have chronic pain. The most common conditions that cause pain in this group are joint problems from osteoarthritis, degenerative disk disease, osteoporosis, low back pain, and pain from previous fracture sites. The pain may be combined with other chronic diseases and cause debilitation. If their chronic pain is adequately controlled, quality of life is improved ([Molton and Terrill, 2014](#)).

Nursing Management

Assessment (Data Collection)

Because no technology can accurately and objectively measure pain, you must use a combination of evaluation methods, including observation, rating scales, and the patient's self-report of pain. Pain is considered the "fifth vital sign." **Pain is to be assessed every time vital signs are taken by asking the patient to rate any pain and describe its characteristics.**

Observation

Appearance. The patient's face may look tense, drawn, or pale. There may be a grimace or even a look of fear. The body may be in a rigid, nonmoving position.

Behavior. A normally verbal patient may become quiet or withdrawn. One who is normally pleasant may become irritable, demanding, or argumentative. The individual may protect or "cradle" the painful area with the hands or arms or assume a fetal position with the legs drawn up. Tears, refusal of food or drink, or any behavior that is out of the ordinary for the individual may be an indication of pain.

Activity level. A person in pain often reduces activity to a minimum. Staying in bed, creeping slowly from place to place, stooping over during ambulation, and stopping frequently to rest or lean against a support can all indicate pain.

Verbalization. Many individuals in pain may verbalize their discomfort, but it is not always easy to interpret the degree of pain from what is said. Limited vocabulary, lack of experience in verbalizing abstract concepts, fear of disbelief or disapproval, cultural stoicism, and fear of medication side effects or of becoming addicted to the analgesic all can impair the person's ability to communicate the degree of pain.

Physiologic clues. Physiologic clues to pain include rapid, shallow, or guarded respirations; pallor; diaphoresis; increased pulse; elevated blood pressure; dilated pupils; and tenseness of the skeletal muscles. Other problems can also cause these physiologic clues to occur. All physiologic changes must be fully assessed to determine the cause.

Older Adult Care Points

Older patients may not report pain for a variety of reasons, and their pain is often undertreated. They may believe pain is an expected part of aging. They may deny pain because it means they are getting older. They may not report pain because they feel they cannot afford the cost of tests or treatments. Older adults often will say they have “soreness” or “discomfort” rather than pain. Assess further if such comments are made.

Focused Assessment

The Patient With Pain

Ask the following questions while assessing a patient with pain:

Location

- Where is your pain?
- Can you point to the pain?

Characteristics

- Can you describe your pain?
- What words would you use to describe the pain? (Aching, burning, gnawing, sharp, stabbing, shooting, etc.)
- Is the pain constant or does it come and go?

Quantity

- How strong or intense is your pain?
- How strong is your pain on this scale?

Pattern

- How long have you had this pain?
- Did the pain begin during activity, before eating, after eating?
- Did the pain start suddenly?
- Has the pain increased over time?

Associated Factors

- Have you had other symptoms such as nausea and vomiting, shortness of breath, rapid heart rate, sweating?
- What do your family members usually do when they are in pain?
- Do you have any chronic problems that cause pain?

Alleviating Factors

- What have you tried to relieve the pain? (Medication, certain position, application of heat or cold, distraction, etc.)
- Did it work?

Aggravating Factors

- What, if anything, makes the pain increase?

Pain Rating Scales

Several rating scales have been developed to evaluate pain. When using a pain rating scale, it is important that the nursing staff use it consistently and that the patient fully understands how to use it. The type of scale being used and any pertinent information about how the patient uses the scale must be included in the patient care plan.

Numbered scale. Numbered scales ask the patient to rate the degree of pain as a number from 0 to 5 or 0 to 10, with 0 indicating no pain and the highest number indicating the greatest amount of pain imaginable. The numbers in between show graduated levels of pain. The scale may be verbal or drawn on a piece of paper so the person can mark or point to the degree of pain. Number scales can be used very effectively with people who have a good understanding of the numerical concept and who like a strictly logical approach. They are not appropriate for young children, anyone who has difficulty with numbers, or anyone who is confused or disoriented.

Visual scale. Some visual scales use photographs or simple drawings of faces that progress through a series of expressions showing a pain-free state (happy and smiling) through increased discomfort. The final picture shows a face either crying or with an intense grimace ([Figure 7-3](#)).

FIGURE 7-3 Wong-Baker FACES pain rating scale. For coding purposes, numbers 0, 2, 4, 6, 8, and 10

can be substituted for the 0 to 5 system to accommodate a 0 to 10 system. (From Hockenberry MJ, Wilson D:

Wong's essentials of pediatric nursing, ed. 9, St. Louis, 2013, Mosby.)

Color scale. A color scale allows the patient to select colors that represent varying degrees of pain. Colored pieces of paper or plastic (e.g., poker chips), crayons, or markers can be used. The patient selects a color that represents no pain, a color that represents severe pain, and then one, two, or three other colors for pain levels in between. This scale is often used with children, but very young children cannot understand more than three or four possible choices.

Pieces of pain scale. A pieces of pain scale uses five poker chips or other identical, plain objects that represent “pieces” of pain. The patient indicates the degree of pain by selecting the number of chips that equals the intensity of pain being experienced.

Behavioral pain (face, legs, activity, crying, consolability [FLACC]) scale. A behavior pain scale is used with patients who are cognitively impaired or who cannot speak. The nurse assesses the patient’s behavior in categories such as facial expression, limb movement, and activity level ([Figure 7-4](#)). A score from 0 to 2 is obtained for each category, and the category scores are added together to arrive at a pain score total of 0 to 10. It is useful when assessing the pain of confused or nonverbal adults, infants, and young children. The Children’s Hospital Eastern Ontario Pain Scale (CHEOPS) is helpful for children 1 to 7 years of age (see Evolve[®]).

Think Critically

Can you explain the difference between acute and chronic pain to someone?

Face	0 No particular expression or smile	1 Occasional grimace or frown, withdrawn, disinterested	2 Frequent to constant frown, clenched jaw, quivering chin
Legs	0 Normal position or relaxed	1 Uneasy, restless, tense	2 Kicking, or legs drawn up
Activity	0 Lying quietly, normal position, moves easily	1 Squirming, shifting back and forth, tense	2 Arched, rigid, or jerking
Cry	0 No cry (awake or asleep)	1 Moans or whimpers, occasional complaint	2 Cries steadily, screams or sobs, frequent complaints
Consolability	0 Content, relaxed	1 Reassured by occasional touching, hugging, or talking to; distractible	2 Difficult to console or comfort

FIGURE 7-4 Face, legs, activity, crying, and consolability (FLACC) scale used to assess pain in cognitively impaired people. (Copyright 2002, reprinted with permission from The Regents of the University of Michigan.)

Data Collection Difficulties

Much of the data gathered when assessing a patient's pain comes from conversations with the patient, which presents a variety of problems. The first problem is language itself. Concepts of the true meaning of words in a common language may vary greatly from person to person. It is important to discuss the common words used to describe pain and to agree on their meaning ([Table 7-3](#)). It is important for documentation to include the patient's exact words.

Table 7-3
Common Terms to Help Patients Describe Pain

Degree of pain (from least to most severe)	Absent, minimal, mild, moderate, fairly severe, severe, very or extremely severe, excruciating
Quality of pain	Crushing, fingling, itching, throbbing, pulsating, twisting, pulling, burning, searing, stabbing, tearing, biting, blinding, nauseating, debilitating
Frequency of pain	Constant, intermittent, occasional, related to something specific (e.g., only when coughing)

The need to work through an interpreter or to deal with language difficulties when the patient speaks a foreign language compounds the problem of communicating pain. Whenever possible, use a medical professional (rather than a family member) with a good knowledge of both languages as an interpreter. Most hospitals have a list of approved interpreters to assist in these situations. Patients may hide personal, embarrassing, or painful information if the interpreter is a family member or personal friend.

Think Critically

What physical or behavior clues would you look for along with the use of a pain scale for a 22-year-old man admitted with a femur fracture?

Describing the location of pain can be made difficult by the phenomenon of **referred pain** (pain felt in a different part of the body from where it actually originates) ([Figure 7-5](#)). Heart pain may be felt in the jaw or radiating down the arm. Gastric pain may center in the area of the heart rather than the stomach. There also is a tendency not to believe an individual's statement of pain if there is no outward appearance of pain. For example, a patient watching an exciting football game with a

friend may enjoy the game even if his surgical incision is quite painful. The lack of a grimace or of physiologic changes indicative of pain may be viewed as an absence of pain, when in fact the patient is using distraction as a way of coping with the presence of pain. People may fall asleep even though pain is severe, particularly if uncontrolled pain has left them in a state of exhaustion.

Cultural Considerations

Cultural Beliefs That Affect Pain Perception and Treatment

Groups from different cultures may have beliefs about pain that differ from yours. However, just because a person is linked to a particular cultural group, it does not mean that he participates in the cultural practices of that group. Proper assessment of beliefs is important.

PAIN EXPRESSION AND MEANING	PREFERENCES AND ACTION
WHITE (EUROPEAN) Men display strong stoicism. Many fear addiction with opioid use. May dismiss the effects of pain and continue to work and carry out usual activities. May decrease use of pain medication quickly.	Prefer to use nonopioid medications. Many prefer to use relaxation and distraction techniques rather than medication, or just to "tough it out."
HISPANIC Mexican Americans often feel that pain is "God's will" and are stoical. Pain may be seen as a consequence of immoral behavior. For some males, expressing pain shows weakness and may cause lack of respect. Other Hispanic groups tend to be expressive of pain and discomfort and may moan, groan, or cry, and such expression is seen as acceptable.	Many feel that injectable medication is better treatment for pain than a pill. Prayer, heat, and herbs may be used to treat pain.
BLACK (AFRICAN AMERICAN, AFRICAN NATIVE) Pain is often seen as a sign of sickness. May express pain openly, but this varies. Pain may be seen as something to just be endured.	Laying-on of hands and prayer are believed to help relieve pain. May rely on spiritual or religious belief to help endure pain.
ASIAN Varies among subgroups, but generally tend to be stoical. Bearing pain may be seen as a matter of family honor. May describe pain obliquely in terms of body symptoms. Some Filipinos view pain as a part of life and to endure it as honorable. Older adults may fear addiction to pain medication.	May prefer oral or intravenous pain medication; injections may be seen as too invasive of privacy. May use applications of moist heat. Family may request pain medication for the patient.
AMERICAN INDIAN (NATIVE AMERICAN) Many believe that pain is something to be endured and will not ask for pain medication. Pain is often described in general body terms such as "I don't feel good." May not be aware that they can ask for medication for pain.	Many use traditional medicine men and rely on herbal preparations. May tell family or visitors about the pain rather than telling the health care provider.
ARAB View pain as something to be controlled and expect prompt treatment. May describe pain in terms of hot and cold. May express pain more openly to family than to health care providers.	Usually prefer injectable medication rather than pills.

Think Critically

Which pain scale would you use for a 24-year-old patient? Why? Which one would you use for a patient who is cognitively impaired? Why?

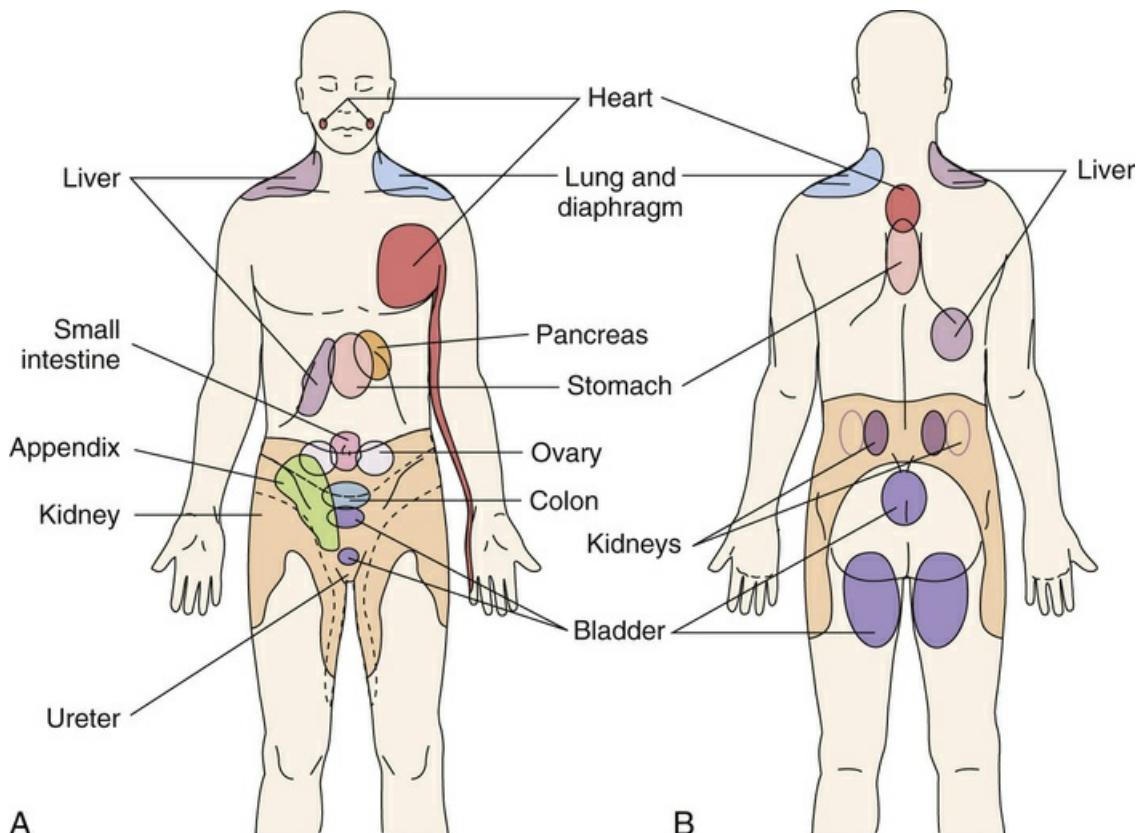

FIGURE 7-5 Usual sites of referred pain. **A**, Front. **B**, Back. (From Monahan FD, Neighbors M, Sands JK, et al: *Medical-surgical nursing: Health and illness perspective*, ed. 8, St. Louis, 2007, Mosby.)

■ Nursing Diagnosis

The nursing problem is pain, either acute or chronic. A specific NANDA-I diagnosis can be used showing a relationship to the cause and defining characteristics (symptoms).

■ Planning

The overall goal is **relief** of pain. If that is impossible to achieve, the goal is **control** of pain. Plan the goals of nursing care by indicating actions that will promote the comfort of the patient during treatment and recovery. Planning should be a team effort that includes the patient and relies on both pharmacologic and nonpharmacologic interventions. Provider input comes as written orders and progress notes and may be available through direct discussion. Include input on pain management from pharmacists, therapists, and other health care professionals. As recovery progresses, update the nursing care plan. The type of medication, method of delivery, and comfort measures will change as the patient's needs change. Planning must address all areas that affect the patient's pain management needs, including family situation, cultural influences, financial constraints, and whether pain is acute or chronic in nature ([Nursing Care Plan 7-1](#)).

Nursing Care Plan 7-1

Care of the Patient With Pain

Scenario

Mr. Jimenez, a 63-year-old patient with a history of a construction work accident, has been admitted through the emergency department after a fall and left hip fracture. A total hip replacement was performed this morning. Orders include morphine sulfate via patient-controlled analgesia (PCA), which has just been started. Mr. Jimenez has complained of pain at 7 on a 0-to-10 scale. His blood pressure and pulse are slightly elevated, but his temperature and respirations are normal. He has been restless and moaning.

Problem/Nursing Diagnosis

Pain/Pain related to surgical incision and replacement of hip.

Supporting Assessment Data

Subjective: Grimaces and moans when moves in bed; moves very cautiously; states muscles feel sore.

Objective: Incision at left hip; hip replacement on 5/17.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will report pain at 0-3 on a 0-to-10 scale within 2 hr.	Teach to use the PCA pump.	Knowledge of how to use the pump allows the patient to use it correctly.	Using pump correctly, but without good relief.
	Encourage relaxation techniques, provide diversionary activities such as television and electronic games.	Relaxation and diversion are known to lessen pain by focusing the mind elsewhere.	Taught relaxation exercise. Does not wish to watch TV at present. Will use electronic poker game.
	Assess for anxiety and concern about job and ability to keep working.	Anxiety and fear can increase the perception of pain.	Expresses concern about being out of work and what will happen to his family.
	Encourage use of the PCA before ambulation, exercise, or repositioning.	Medicating before activity reduces pain from the activity.	Medicated before physical therapy visit.
	Position in good body alignment.	When the body is in correct alignment, joints hurt less.	Repositioned in correct alignment with abduction pillow q2hr.
	Apply cold packs to reduce swelling over large bruise on lower thigh.	Cold reduces swelling by vasoconstriction and also dulls the perception of pain.	Cold pack over thigh for 20 min qhr × 8 hr.
	Observe frequently for pain relief and side effects of medication.	If pain is inadequately relieved, other measures to relieve it can be employed.	No side effects noted other than drowsiness. Pain at 3.
		Knowing if side effects are occurring allows measures to be taken to alleviate or prevent them.	
	Keep abduction wedge in place when supine.	Keeping leg abducted prevents dislocation of the hip and reduces pain.	Wedge in place when in bed.

Critical Thinking Questions

1. If the PCA pump medication is not controlling the pain adequately, what would you do?
2. Considering the age of the patient and the type of surgery, which possible side effects of the analgesia would be of greatest concern? What interventions would you use to try to counter the side effects and prevent problems?

■ Implementation

Reassess all patients for pain at the beginning of each shift, clinic appointment, or home visit and revise interventions based on the findings. Appropriate interventions include providing an analgesic as ordered, using nonpharmacologic measures such as repositioning or massage (adjunctive measures), and reporting to the provider when measures are not effective or have unwanted side effects. Implementation also includes teaching the patient and family how to monitor the effects of treatment. False perceptions of pain may need to be addressed (Table 7-4).

Table 7-4

False Perceptions of Pain

FALSE PERCEPTION	FACT
If pain is really present, there must be a demonstrable cause.	Pain can be present even though no cause can be found. Although damage to the cells does lead to the release of chemicals that stimulate the pain receptors, in many cases pain may be present even if no cellular abnormality can be found. A patient with a migraine headache may or may not suffer less than one with a brain tumor. We cannot say that just because the brain tumor can be shown on a brain scan and the headache cannot, the person with the brain tumor has greater pain than the person with the migraine headache.
A person who has a low tolerance for pain has no self-control and probably is emotionally immature or childish.	Pain tolerance is a physiologic response to pain that is made more complex by psychosocial factors—many of which can be beyond the control of the patient. Tolerance of pain is defined as that duration or intensity of pain the person is willing to endure without seeking relief. Pain tolerance varies greatly from one individual to another and varies in the same individual from time to time. Nurses often place a high value on a patient's ability to feel pain without complaining or asking for relief. Those who value a high pain tolerance usually impose their own values on their patients by ignoring or belittling patient reports of pain. The person who should decide how willing he ought to be to tolerate pain is the one who is suffering pain.
Neonates are too neurologically immature to perceive or remember pain, so analgesia is unnecessary in this age group.	Neonates do perceive and maintain memory of pain. They cry and pull away from procedures such as heelstick blood tests. Male infants cry and struggle when they are circumcised. Neonates with medical conditions that require repeated blood tests begin to cry and pull away as soon as someone grasps the foot if to perform a blood test, indicating a memory of pain from previous heelsticks. Analgesia for neonates is appropriate during procedures or situations that would be known to cause pain in more mature patients.
Older adult patients have a decreased ability to perceive pain, and pain medicines are dangerous for them because of their age.	Ability to express pain may be impaired by decreased cognitive function, but acute pain is still perceived. Advanced age combined with physical impairments, such as decreased kidney or liver function, may reduce tolerance for various medications, but with appropriate dosing and monitoring, older patients can have good pain management without severe side effects. Untreated pain will interfere with sleep, nutrition, healing, and general well-being.
Reactions to acute pain and chronic pain are the same.	In general, acute pain is more often associated with anxiety and chronic pain with depression. Emotional reactions such as anxiety and depression do not cause pain, but they can intensify pain. The management of acute and chronic pain is not the same, as discussed in the chapter text.
Addiction to pain-relieving drugs is always a hazard, and for the sake of the patient, nurses often must withhold a drug even though the patient asks for it.	A very small percentage of patients (probably less than 1% and no more than 3%) become addicted to drugs administered for the purpose of relieving acute pain. Despite an abundance of evidence to the contrary, this mistaken belief about the dangers of addiction persists, causing needless suffering among patients who are denied adequate pain relief.
Placebos (substances prescribed that contain no medication, such as sterile	There is no basis for believing that a patient who finds relief from pain after receiving a placebo has been pretending to have pain or that the reported pain has been "all in his mind." The question of how placebos affect people and why they have a positive response in some and not in others is still poorly understood. However, there has been sufficient study of the subject to show that actual pain is sometimes well relieved by placebos.

saline or sugar pills) are very useful in assessing whether a patient actually has pain.

Preventing complications from medications is an important aspect of implementation. Specific actions include:

- Prominent documentation of any known drug allergies
- Accurate recording of pertinent information obtained during the initial assessment phase, such as current medications and previous experience with pain, analgesics, and adjuncts to pain relief
- Patient and family teaching regarding dose, frequency, the need to first consult with the provider or nurse before taking any other medications to avoid dangerous interactions, possible side effects, and what to report
- Appropriate monitoring of effects of any medications given and prompt notification of the provider should medications fail to relieve pain or should problems occur
- Measures to prevent constipation when taking an opioid medication
- Accurate and complete documentation of any adverse reactions to treatment and communication of that information to other health care providers, to the patient, and to appropriate family members

■ Evaluation

Ask the patient about the effectiveness of the pain control measures. How quickly did relief occur? How long did it last? To what degree was the pain controlled? Were there any unpleasant side effects? Whenever possible, use patient verbalization as the primary evaluation tool. For evaluation, use a pain assessment tool with the patient before the pain is treated and again after treatment to compare the patient's response.

If the patient is unable to verbalize, evaluate the objective signs. For instance, an aphasic stroke patient might thrash, moan, and look fearful when in pain, and evaluation of effective analgesia might include, "Mr. Jones lying quietly, free of facial tension, watching the activity around him. He did not moan when repositioned 1 hour after analgesic given."

☒ Clinical Cues

Evaluation of the effectiveness of the pain control medication used should be based on the route of administration. Medications given by mouth may take 30 to 45 minutes to be effective. Injections are effective within 30 to 45 minutes. Intravenous (IV) medications are effective within 5 to 15 minutes.

■ Documentation

All measures to control pain must be accurately documented:

- Initial pain assessment (location, intensity, and duration of the pain and the method used to assess [e.g., pain scale, patient verbalization]; document aggravating and alleviating factors)
- Measures taken (e.g., analgesic medication, adjunctive measures)
- Evaluation of effectiveness of measures
- Provider notification of problems or concerns and provider response, if applicable
- Related patient or family education provided

☒ Patient Teaching

Managing Pain

Take medication before pain is severe, and take the medication regularly until the pain is well controlled before lengthening the time between doses. Use distraction, imagery, or relaxation exercises to augment the effect of the pain medication.

Example of Pain Documentation

01100. States pain level after physical therapy at 7 on a 0 to 10 scale. Morphine sulfate 10 mg IM in

the rt. deltoid. 45 minutes after injection, states pain level is now 2 to 3. Pulse 72, respirations 16, moving freely in bed. Discussed pain relief needs; suggested that he request pain medication before next therapy session (Signature).

Think Critically

What do you think is the most difficult aspect of evaluating someone's pain?

Management of Pain

Effective pain management is not just a matter of giving the right medicine at the right time. It is a combination of a stepped approach of pharmacologic measures coordinated with nonpharmacologic approaches that together give the individual the greatest possible degree of comfort for the longest possible time (see Evolve^E).

Home Care Considerations

Maintain a Medication Record

To prevent overdosage and toxicity, jot down the time pain medication is taken at home. It is easy to forget just when a medication has been taken.

Pharmacologic Approaches

Analgesics and Routes of Administration

Table 7-5 lists common analgesics by category and action.

 **Table 7-5**

Drugs Commonly Used to Treat Pain

TYPE OF DRUG AND PRIMARY ACTION	ACTION	EXAMPLES	NURSING IMPLICATIONS
Nonopioid analgesics, including nonsteroidal anti-inflammatory drugs (NSAIDs)	Block pain at the peripheral nervous system level	Over-the-counter aspirin, acetaminophen, ibuprofen, [*] ketoprofen, [*] naproxen [*] Prescription naproxen, indomethacin, ibuprofen, ketoprofen	May be present in combination drugs. Various possible side effects of which to be aware. [†] Educate patients not to use in combination with over-the-counter dosage of same medication.
Opioids	Block pain at the central nervous system level	Morphine, meperidine, hydromorphone, codeine, fentanyl	Constipation common, can be severe. Can cause respiratory depression; antidote is naloxone (Narcan).
Medications with nonanalgesic primary actions used as adjuncts to pain control	Various mechanisms of action	Antidepressants: amitriptyline, imipramine, trazodone hydrochloride Anticonvulsants: phenytoin, carbamazepine, gabapentin, pregabalin Stimulants: caffeine, dextroamphetamine Muscle relaxants: carisoprodol, baclofen Chemotherapeutic agents: methotrexate	Varied because of different mechanisms of action. Always be aware of side effects and possible adverse reactions. May cause grogginess.

^{*}Nonprescription dose.

[†]Note: Combination drugs are often used. These may combine two forms of analgesic (e.g., acetaminophen and codeine) or an analgesic with another type of medication, such as an antihistamine. It is important to be aware of what ingredients are contained in combination drugs to avoid administering excessive amounts of one of the components. The patient should receive no more than a total daily dose of 4000 mg of acetaminophen.

Oral analgesics.

An oral analgesic is any substance taken by mouth for the control of pain. Oral analgesics include over-the-counter (OTC) medications such as acetaminophen (Tylenol), aspirin (Bayer), and ibuprofen (Advil, Motrin) and prescription medications such as codeine and morphine. Oral analgesics are available in extended-release forms that can provide 12 to 24 hours of pain relief (naproxen [Aleve]). Mexiletine (Mexitil) may be used for the neuropathic pain of diabetes when adjunctive medications do not work.

Safety Alert

Preventing Acetaminophen Overdose

When administering acetaminophen, check all other medications and OTC drugs the patient is receiving. Many OTC drugs combine acetaminophen with other drugs. Toxicity may occur if more than the total recommended safe dosage of 4000 mg/day is ingested by an adult without liver impairment.

Intramuscular analgesics.

Intramuscular (IM) analgesics are substances injected into muscular tissue to control pain.

Subcutaneous analgesics.

Subcutaneous analgesics are medications injected or infused into **subcutaneous** (fatty tissue just beneath the skin) tissue to control pain.

Topical analgesics.

Topical analgesics are medications placed in a specific area on the skin to be absorbed by the vascular system. Topical anesthetics such as EMLA (a mixture of lidocaine and prilocaine) are used to treat pain from minor procedures such as venipunctures. Capsaicin (Zostrix) (made from a substance in peppers) is used topically for joint and other pain. Fentanyl sublingual spray has been approved by the FDA for use in more severe pain ([Jeffrey, 2012](#)).

Transdermal patches.

Transdermal patches placed on the skin rely on vascular uptake of pain medication. These patches can provide relief from systemic pain and are commonly used with patients who have chronic pain. Transdermal patches containing lidocaine may be used for local pain.

Safety Alert

Pain Patch

Fentanyl patches used for severe pain can cause death from overdose. Oxycontin patches may cause overdose as well. Signs of overdose are difficulty breathing; shallow breathing; extreme sleepiness; and inability to think, talk, or walk normally. Faintness, dizziness, and confusion are other signs.

Clinical Cues

Always remove the old transdermal patch before applying a new one; cleanse the skin where the old patch has been. The patch must be removed before the patient undergoes magnetic resonance imaging (MRI) to prevent a burn from the foil in the patch. Chart the location of the new patch.

Buccal swabs.

Buccal swabs contain medication that is absorbed through the **buccal mucosa** (mucous membrane lining the inside of the mouth) and provides rapid relief from pain. Buccal swabs are commonly used with hospice patients and may be used with other unconscious patients.

Intravenous analgesics.

Intravenous analgesics are substances injected or infused over a prescribed time directly into the vascular system. Ibuprofen, acetaminophen, and diclofenac (NSAIDs) have been released by the FDA for intravenous injection.

Patient-controlled analgesia.

Patient-controlled analgesia (PCA) is an infusion device controlled by the patient that injects the prescribed dose of analgesia. The PCA machine is programmed so that the patient can decide when a dose is given but cannot exceed the maximum dose or minimum time interval ordered by the provider. PCA analgesia is usually given IV, but it may also be administered subcutaneously. Ensure that free-flow protection is in use on the PCA pump so that overdosage is not possible. Morphine and hydromorphone (Dilaudid) are most commonly used for PCA. New guidelines allow “PCA by proxy,” by which a trained and authorized person may press the button on the PCA machine to activate an analgesic dose when the patient is alert but unable to press the button ([D'Arcy, 2013](#)).

Epidural analgesic.

An epidural analgesic such as morphine is medication infused directly into the **epidural** space near the base of the spine using a programmable pump. An anesthesiologist inserts the infusion catheter. Patients receiving epidural analgesia need to be monitored for possible delayed respiratory suppression or apnea, bradycardia, hypotension, urinary retention, nausea and vomiting, and allergic reactions such as itching or hives. Report adverse symptoms to the anesthesiologist immediately, and observe the insertion site for signs of infection, localized allergic reaction, and leaking. Usually an RN performs the thorough assessment and dressing change.

Peripheral nerve catheter.

A peripheral nerve catheter is used to deliver local anesthetic to the sheath of a nerve. These catheters are typically used postoperatively for patients who have had total joint replacement.

Nonanalgesic Medications Used for Pain Control

Antidepressants.

A number of antidepressant medications are effective in controlling some specific types of pain, such as nerve root pain. They may be given alone or in combination with other analgesic medications.

Chemotherapeutic agents and other immunosuppressants.

Occasionally drugs such as methotrexate (Rheumatrex) are used for **intractable pain** or to prevent further inflammation and joint damage in rheumatoid conditions.

Anticonvulsants.

Newer anticonvulsants, such as gabapentin (Neurontin), have been approved for treatment of neuropathic pain. Pregabalin (Lyrica) has been approved for the pain of fibromyalgia. Some patients experience side effects of grogginess and slowed reactions.

Muscle relaxants.

Muscle relaxants, such as baclofen, are often used adjunctively to ease spasm in patients with back pain, multiple sclerosis, and other neurologic and muscular disorders.

Marijuana.

When patients have limited relief from medication, adjuvants, and other nonpharmacologic methods, the provider may prescribe "medical marijuana" in states where its use is legal for the patient to try either for oral ingestion or to be inhaled in smoke. Three puffs a day have been shown to help people with chronic nerve pain resulting from injury or surgery ([Griffin and Nazario, 2014](#)). Marijuana in various forms has been found to be helpful for many cancer patients.

Special Considerations in Pain Management

Pharmacologic analgesics, including OTC drugs, may be administered to patients in a health care facility only under a provider's order to prevent unwanted interactions with other prescribed medications. For example, aspirin, commonly taken for occasional headache and arthritis pain, is a powerful anticoagulant. Aspirin can lead to dangerous complications for someone with a bleeding disorder or who is taking another anticoagulant medication. Acetaminophen in high doses is toxic to the liver and may be contraindicated in patients with a liver disorder. Alerting patients that OTC drugs can have serious interactions with their prescribed drugs is an important part of patient education.

Older Adult Care Points

Older adults commonly have reduced tolerance for medications. Smaller doses of analgesics may give effective relief without causing overwhelming sedation or disorientation. Older adult patients on analgesics must be monitored carefully, and the route of administration is a serious consideration. Intramuscular injections are not recommended for older adults, because diminished muscle and fatty tissue may affect the bioavailability of drugs.

Nurses' Responsibilities

In addition to following the “Six Rights” (right patient, right drug, right dose, right route, right time, right documentation), there are a variety of responsibilities when giving analgesic medications (Box 7-1).

Box 7-1

Nursing Responsibilities When Administering Analgesics

1. Document the drug, dose, route, and time of administration (including location of injection site for intramuscular or subcutaneous injections), and reason for drug administration.
2. Monitor the effectiveness of pain relief after 15 to 30 minutes and at 1- to 2-hour intervals. Document the degree and duration of pain relief in the patient record.
3. If the analgesic is ineffective, determine whether a stronger analgesic is available to the patient and administer per provider order. If no other analgesic is available, notify the provider that the medication is not effective. Also notify the provider if the medication is initially effective but the duration of effect is too short to maintain patient comfort until the next dose may be given.
4. If the analgesic results in unwanted side effects (e.g., depressed vital signs, vomiting, or altered level of consciousness), monitor the patient closely and notify the provider before administering another dose.

Pain is considered the fifth vital sign (temperature, pulse, respiration, blood pressure, and pain). Pain is assessed when vital signs are taken along with assessment for both efficacy of the analgesic given and side effects.

Side Effects and Complications of Pain Medications

Probably the most common—and one of the most distressing—side effect of pain medication is constipation. Analgesics such as morphine, meperidine, and codeine slow peristalsis. Fecal material becomes compacted and dry because of the extended time of passage through the intestines. Measures to prevent constipation should begin with the first dose of the medication.

Patients receiving these medications for any length of time should be monitored carefully for regular, normal bowel movements. **Oral fluids must be increased if possible.** Stool softeners and fiber-based laxatives, such as psyllium (Metamucil), can be helpful if approved by the provider. Miralax also has proven very effective for opioid-induced constipation.

Older Adult Care Points

Help prevent constipation in older adult patients receiving opioid analgesics by encouraging the increased intake of fluids and fiber, administering an ordered stool softener, suggesting prunes or prune juice; and monitoring for bloating, discomfort, and lack of daily bowel movement.

Some side effects of opioids, such as drowsiness and euphoria, generally only last for the first few days and then spontaneously disappear. Allergic reactions, such as itching and hives, must be reported immediately. Discontinue the medication and obtain an alternative order. The patient may need an antihistamine such as diphenhydramine (Benadryl) for relief of itching.

Clinical Cues

Itching from IV or IM morphine or other opioids may be relieved with an injection of nalbuphine (Nubain). An order for the medication is required (Susman, 2013).

Opioid analgesics can depress the respiratory system to the point of apnea (no respiration). Should this occur, resuscitation must begin immediately. In the hospital setting, provide respiratory support and call the code team. In the home, provider's office, or clinic, provide respiratory support

and call 911. The standard treatment for respiratory suppression from an opioid is naloxone (Narcan), an effective opioid antagonist that can be given IM or IV.

The most feared side effect to analgesia—that of addiction to opioids—in reality almost never occurs when pain medications are taken for real pain. **Patients in pain have a right to expect that effective analgesia will be available to them.** Dependence does occur with long-term use of many of the opioid analgesics and they should not be stopped abruptly. When pain can be controlled with nonopioid medications, the patient is tapered off of the opioid analgesic.

Clinical Cues

Because there seems to be an “epidemic” of women who are addicted to prescription opioid pain medications, nurses should seek close evaluation of patients who are on long-term opioids or those who seek more frequent doses of the medication or make more frequent refill requests ([Fiore, 2013](#)).

Legal and Ethical Considerations

Pain Control at the End of Life

Patients and their families often worry that treating the terminally ill with sufficient pain medication to control pain may hasten death. However, no scientific evidence has proven that this can happen when opioids are used to control pain. Health care providers have a moral obligation to adequately treat pain even at the very end of life, and opioids must be administered for the purpose of relieving pain and not to purposefully hasten death ([Reynolds et al, 2013](#)).

Older Adult Care Points

Some drugs are considered especially risky to administer to older adult patients. Tramadol (Ultram) and meperidine (Demerol) lower the seizure threshold and should be used cautiously ([AHRQ, 2013a; Hargas et al, 2012](#)). Consider all other drugs the patient is taking if tramadol or meperidine is ordered.

Nonpharmacologic Approaches

A variety of methods exist for relieving pain without or in addition to medications. Using adjuncts can increase the effectiveness of pain medication and may decrease the frequency at which it is needed .

Sleep

Adequate sleep and rest are major factors in healing. **Rest increases pain tolerance and improves response to analgesia.** Allow adequate time between treatments for naps, and plan care to keep sleep interruptions to a minimum. For instance, take vital signs when the patient is awake to use the bathroom or requests pain medication. It is important to remember that exhaustion will cause a patient to sleep, even while experiencing severe pain, but such sleep is not as therapeutic. Appropriate analgesia combined with adequate rest and other comfort measures promotes healing. Smoothing bedclothes, plumping pillows, adjusting lighting, and repositioning all increase comfort.

Heat

Gentle heat is very soothing for many types of pain. Heat promotes vasodilation of the area, which promotes increased blood supply and movement of nutrients to the affected area. Sources include warm compresses, warm blankets, water-filled heating devices, Hydrocollator pads, whirlpools, tub baths, heat lamps, and chemical self-heating packs. Compresses and packs are usually left in place for 15 to 20 minutes, although gentle heat sources such as water-filled heating devices may be used over longer periods. Always check the temperature before applying heat, and monitor the patient closely for tolerance. To prevent injury to the skin, never apply a warm compress directly to the surface of the skin. The very young and the very old are particularly sensitive to heat. Anyone with an altered level of consciousness or loss of normal sensation may not realize something is too hot,

and those with loss of movement may not be able to move away from the heat source when necessary.

Older Adult Care Points

The skin of older adults is thin and burns more easily. Stroke patients and those with diabetic neuropathy commonly have areas of lost or diminished sensation, and patients with senile dementia may not recognize that something is too hot. Even an alert and oriented older adult may fall asleep and be burned. Monitor any heat application very carefully. **Do not apply heat to any areas where nerve damage or decreased sensation has occurred.**

Menthol.

When applied to the skin, menthol causes warming, which may have an analgesic effect. Mentholated products are usually massaged into the skin, giving the individual the benefit of both massage and warmth. They are available OTC but require a provider's order in a hospital or clinic setting. Do not use menthol with external heating devices to avoid overheating the skin surface. Caution the patient to wash hands well after applying menthol to prevent contact of the menthol with the eyes or mucous membranes.

Cold

Cold is particularly helpful in reducing swelling through vasoconstriction. It also can be effective in relieving muscle spasms and some types of joint pain. Ice massage of sore muscles can be done by freezing water in a paper cup, then tearing away the edge of the cup to expose the ice, leaving the base of the cup as a handle. Some individuals are very sensitive to cold. If cold applications cause shivering, tensing of the muscles, or an increase in pain or spasm, discontinue their use.

Clinical Cues

The effectiveness of cold is maximized in 15 to 20 minutes. Remove the source after that time.

Distraction

Any activity that takes a person's attention away from pain is termed a *distraction*. This includes watching television, talking with friends, using a computer, or playing a game. People have an innate ability to distract themselves from their surroundings or situation. Health care workers may mistakenly interpret patients' ability to distract themselves as proof that there is no pain. Distracting activities can take the patient's mind off of pain momentarily, but distractions do not stop pain. Distraction can be helpful in bridging the time gap between giving an analgesic and the onset of pain relief.

Relaxation

Relaxation, also called "tension release," involves the conscious relaxation of muscle groups. Tension release is typically done as a progression, beginning at the feet and moving up the body, ending with the neck and facial muscles. Initially, you can guide the patient verbally, slowly directing the attention to the next muscle group to be relaxed. After one or two sessions, many patients can effectively provide their own relaxation sequence.

Guided Imagery

Guided imagery involves assisting patients to form mental images of a pleasant environment where they are comfortable and happy. For some, the experience is visual; in their minds they "see" a beautiful place. For others, it is a process of achieving a feeling of comfort and peace. Either is highly effective in giving the patient a brief mental break from pain. These methods often are used during painful procedures, such as bone marrow extraction.

Meditation

Meditation involves the use of a focus point, which may be a sound, a repeated phrase (sometimes called a *mantra*), the sound of the breath as it moves in and out of the body, or a visual image. The

visual image may be a picture or object that the patient gazes at, or it may be an imagined image (e.g., a candle's flame, a leaf moving with breeze, beach waves). Meditation works best when practiced daily.

Hypnosis

Hypnosis, or therapeutic suggestion, should be done by a trained practitioner. It involves the use of focusing and relaxation to induce a trance-like state during which a patient receives suggestions that may be helpful after returning to a normal level of consciousness. Hypnosis should be used only if the subject is comfortable with the idea and is open to its use.

Biofeedback

Biofeedback involves the use of a machine that uses electrodes attached to the skin to measure the degree of muscular tension. The machine has colored lights that change (usually red to yellow to green) and an audible tone that changes in pitch from higher to lower as the patient relaxes. The patient receives visual and auditory confirmation of self-induced relaxation. This technique is particularly effective with people who are highly competitive because it rewards success and allows them to "win" the game.

Music

Music used alone can be highly effective in bringing about relaxation and can be used as a focal point for meditation or to enhance other distracting activities. Nature sounds, including the ocean, running streams, breezes, rain, and birds singing, also can induce relaxation. Headphones allow the patient to be immersed in sound without disturbing others. Headphones with music can be used during loud or long diagnostic procedures such as MRI.

Binders

Binders are helpful for strains, sprains, and wounds or surgical incisions that are packed. They support the tissues during movement, such as ambulation or coughing, which reduces the pain.

Massage

The use of long, firm strokes; short, soft, circular strokes; and occasionally gentle pounding with the sides of the hands stimulates circulation, relaxes muscles, and increases the general sense of well-being. When the painful area has inflammation, or consists of a wound or an incision, massaging another area of the body with gentle but firm pressure helps the patient direct attention away from the pain. Always be guided by the patient's sense of comfort. Use only the degree of pressure that is pleasant and relaxing.

Simple massage can be done by a family member with just a little instruction, giving them an opportunity to assist in the care in a positive and loving way. Massage should not be used on any area that has been reddened by pressure. This tissue is already compromised, and massage can cause further damage through **shearing**, the traumatic pulling of tissue layers away from one another.

Acupuncture and Acupressure

Acupuncture originated centuries ago in China and involves the use of tiny needles inserted into the skin at specific points along lines called *meridians*, a concept similar to that of nerve pathways. In recent years it has gained favor as a pain control measure. Research has shown that acupuncture helps relieve back and headache pain ([Griffin and Nazario, 2014](#); [University of Maryland, 2013](#)). Acupressure involves the use of external finger pressure at the meridian points to achieve similar effects. Both acupuncture and acupressure require extensive training for proper use and should only be done by someone fully trained in these procedures.

Complementary and Alternative Therapies

Pain Relief

Complementary and alternative therapies are used more for pain relief than for anything else. Therapies include relaxation, meditation, biofeedback, yoga, hypnosis, imagery, chiropractic, acupuncture, acupressure, massage, aromatherapy, and herbal preparations and supplements. Research from the National Institutes of Health has proven that acupuncture is effective for many patients for various pain problems.

Transcutaneous Electrical Nerve Stimulation

Transcutaneous electrical nerve stimulation (TENS) uses a small electrical stimulator attached to the skin with electrodes placed around the area of pain. A low current running between the electrodes acts to block pain sensation. The degree of stimulation can be controlled by the patient using dials on the stimulator. The application of TENS requires specific training and must be ordered by a provider (Figure 7-6). Some patients find TENS unpleasant rather than helpful. In such cases, the provider should be notified and an alternative method of pain control selected.

FIGURE 7-6 Instructing the patient on how to use a transcutaneous electrical nerve stimulation (TENS) unit.

Spinal Cord Stimulator

A spinal cord stimulator is implanted in the epidural space adjacent to nerves that innervate the affected body area. This device is used for patients with chronic pain who have not responded to medications or other methods of pain management.

Invasive treatments.

Invasive treatments—such as sympathectomy, rhizotomy, and cordotomy, which sever the nerve conducting the pain—are now uncommon. Advances in pain management, including surgically implanted medication pumps and nerve stimulators, have made these invasive treatments unnecessary in most cases. A dorsal column stimulator may be implanted for pain after failed back surgery and for other pain syndromes. An epidural injection may be used to ease sciatic nerve pain.

The medication dosage given directly to the spinal cord (intrathecal) is about $\frac{1}{10}$ of the oral dose, so patients suffer no central nervous system side effects. They can work and drive while being relieved of severe pain. Epidural injection is recommended no more than two to three times a year, and there is some evidence that these injections make the patient more prone to fracture. The injection does not always work to relieve pain.

Think Critically

What types of nonpharmacologic methods would you use for a patient who is complaining of

shoulder muscle pain after an automobile accident?

Community Care

Community care for pain can take place in a variety of settings, with varying levels of training among direct caregivers. Nurses may need to work with the social worker before discharge to put in place all the necessary measures to control pain for the patient going home. Nurses in the community should help educate people about the complementary and alternative resources available to treat chronic pain.

Extended Care

Extended-care facilities may provide rehabilitative services, long-term care services, or both. Each type of care may include specific pain management needs. Patients undergoing rehabilitation often have acute pain related to therapy, particularly in the early phases. It is important that therapy be scheduled to allow for adequate rest and recovery time. It also is important that analgesic medication be given on a schedule that provides the patient with the greatest pain relief during therapy sessions. This assists the patient to cooperate with therapy, which in turn encourages a more rapid recovery. When planning, always include the patient, who knows best which medication and time schedule provides the most effective pain relief.

Long-term care facilities—also called nursing homes, skilled nursing facilities, transitional care units, and board and care homes—often have patients who live there for the last weeks, months, or even years of their lives. In such settings, the term *resident* is used, rather than *patient*. Residents may have pain resulting from a fall, after dental work, or during a period of illness, and they may have chronic pain from arthritis, degenerative disorders, or cancer. Residents may be mentally alert and oriented, be alert but confused, or have a decreased level of consciousness. Each of these individuals can perceive pain and should be given appropriate analgesics when pain exists.

Nurses can be of great assistance to providers in ordering analgesia by providing accurate information about the type of pain, the frequency, the intensity, and precipitating factors. For instance, a resident with degenerative arthritis and chronic joint pain may benefit from a routine oral analgesic such as acetaminophen or ibuprofen. Those with more severe chronic problems, such as cancer, may benefit from routine time-released medications such as MS Contin (oral morphine sulfate in a time-released tablet). As pain increases, an increased dosage of opioid may be needed to gain relief, but remember that older adults and debilitated individuals may be more drug sensitive. Monitor all medications carefully and work with the provider to ensure that the resident's pain is being appropriately addressed. Ideally, the resident is comfortable, alert, and able to participate in activities of choice. Nurses in the long-term care setting must make pain assessment and management a priority.

Home Care

The number of individuals receiving skilled and professional nursing care at home is increasing rapidly. Early discharge from the hospital is becoming more common, primarily to control escalating medical costs and because people generally are more comfortable and heal more rapidly in their home environment. Patients may go home from the hospital with peripheral or central IV lines providing analgesia. The nurse provides patient and family education on pain management in the home setting, which includes verbal and written instructions about the medication and any equipment used to dispense it. Telephone numbers that give the patient and family access to 24-hour assistance should be prominently displayed.

Just as in an inpatient setting, home care patients must be evaluated for the continued safety and effectiveness of the analgesic medication. Contact the provider any time the medication orders need to be adjusted. Adjuncts to pain management, such as simple massage, relaxation techniques, and the use of pillows, warmth, repositioning, or soft music, are taught to patients and families for use in the home care setting.

PCA medications sometimes are given subcutaneously rather than intravenously, particularly for those patients with poor peripheral venous access who are not candidates for a central line. A tiny needle is placed in the subcutaneous tissue on the abdomen and taped in place. Sites are changed at regular intervals to maintain good absorption of the medication and avoid damage to the tissues.

The increased use of central IV catheters and ports and the availability of oral and topical patch timed-release analgesics are making subcutaneous PCA devices much less common.

Current guidelines for home care by agencies such as Medicare require that case management be done by a licensed professional. This usually is an RN, although a registered physical therapist may fill this role for patients whose only acute need is continued restorative therapy. The role of the LPN/LVN is that of direct patient care under the guidance of the case manager. The LPN/LVN may monitor an ongoing infusion and discontinue the infusion as needed but must report any difficulties immediately to the case manager for intervention. Some states offer IV therapy certification for LPN/LVNs, which allows them to infuse medications.

Always be alert to an increase in pain resulting from changes in the disease process. The provider needs to be notified of the change so that appropriate measures, including adjusting or changing the medications, can take place.

Get Ready for the NCLEX® Examination!

Key Points

- Only the patient knows where the pain is and its degree of intensity.
- Pain is a neurologic response to unpleasant stimuli.
- Pain tolerance varies from one individual to another.
- Pain threshold is the point at which pain is perceived.
- Endorphins can block pain sensation.
- The gate control theory states that when the gate is open, pain sensation is allowed through; when the gate is closed, pain is blocked.
- The two pathophysiologic classifications of pain are nociceptive and neuropathic.
- Nociceptive pain derives from stimulation of somatic or visceral structures.
- There are four phases of nociceptive pain: transduction, transmission, perception, and modulation.
- Neuropathic pain is from dysfunction of the nervous system.
- The patient should be asked to use an appropriate pain scale.
- Cultural factors and beliefs affect each person's perception of pain.
- Pain assessment and data collection include the areas of appearance, behavior, activity level, verbalization, and physiologic clues.
- An interpreter may be required to gather correct data about a non-English-speaking patient's pain.
- Goals of care are (1) relief of pain and (2) control of pain.
- Pharmacologic and nonpharmacologic methods are used to treat pain.
- Neuropathic pain is relieved with NSAIDs, tricyclic antidepressants, anticonvulsants, and corticosteroids.
- False perceptions about pain may affect care (see [Table 7-4](#)).
- Evaluating the effectiveness of measures used to relieve pain is a primary nursing responsibility.
- Always follow the "Six Rights" when administering pain medication.
- Ask the patient about pain level and relief from medication at regular intervals.
- It is important to be knowledgeable about the commonly used analgesics (see [Table 7-5](#)).
- Constipation is a common side effect of opioid analgesia, and preventive measures should be used as soon as a opioid is begun.
- Adequate sleep assists in controlling pain.
- Hypnosis and biofeedback have been proven to be effective for many people for a variety of types of pain.
- Chronic pain is common among older adults in long-term care facilities.

Review Questions for the NCLEX® Examination

1. The nurse administers ketorolac (Toradol) 30 mg IM to a 30-year-old male patient. The gate control theory indicates that the next nursing action to assist in pain control would be to:

1. recap the needle.
2. massage the area.
3. check for pain relief in 45 minutes.
4. encourage an activity that will provide distraction.

NCLEX Client Need: Physiologic Integrity: Basic Pathophysiology

2. In determining the patient's perception of pain, which question(s) by the nurse would be useful in assessing pain? (*Select all that apply.*)

1. "Where are you hurting?"
2. "What pain control measures have worked in the past?"
3. "How would you describe your pain?"
4. "What were you doing before the onset of the pain?"
5. "Are you sleeping adequately?"

NCLEX Client Need: Physiologic Integrity: Basic Care and Comfort

3. The nurse realizes that chronic pain may be handled **differently** from acute pain to:

1. prevent respiratory depression or other unwanted side effects.
2. keep pain below a 5 on a numerical pain scale most of the time.
3. provide the best pain relief with the least side effects and chance of addiction.
4. ensure that good long-term pain control is possible for the patient.

NCLEX Client Need: Physiologic Integrity: Basic Care and Comfort

4. A patient who has osteoarthritis is experiencing right knee pain daily. The nurse knows that this type of pain usually has the best result if treated by:

1. oxycodone.

2. ibuprofen.
3. Lyrica.
4. prednisone.

NCLEX Client Need: Pharmacologic Therapies: Expected Actions/Outcomes

5. A Mexican American woman who was in a minor automobile accident along with her 5-year-old son has a minor laceration on her arm that is not deep. Her son is being examined in the next room. The woman is moaning about the pain in her arm. Factors possibly influencing her perception of pain are probably: (*Select all that apply.*)

1. blood smearing her skirt and blouse from where her arm brushed them.
2. her Mexican American ethnicity and recent entry into the United States.
3. relief that another driver was not hurt in the accident and the car has minor damage.
4. worry about her son possibly sustaining a severe injury in the accident.

NCLEX Client Need: Integrated Processes: Caring

6. An appropriate short-term outcome written by the nurse for a patient with acute pain after surgery would be:

1. the patient will demonstrate use of PCA pump.
2. the nurse will assess for adequate pain relief.
3. the incision will heal without infection.
4. pain will be adequately controlled with a PCA pump.

NCLEX Client Need: Safe and Effective Care Environment: Coordinated Care

7. A patient with chronic pain requiring further measures to decrease pain asks the nurse, "What is a TENS unit?" What is the best nursing response?

1. "It is an implant in the epidural space adjacent to nerves that innervate the affected body area."

2. "It provides a small electrical stimulus to the skin around the area of pain."
3. "It involves the use of external finger pressure at the meridian points."
4. "It supports the tissues during movement."

NCLEX Client Need: Integrated Processes: Teaching and Learning

8. A patient is discharged with a prescription for oral oxycodone with acetaminophen tablets. The nurse should inquire about all other medications the patient will be taking at home, looking for the possible presence of more _____. (*Fill in the blank.*)

NCLEX Client Need: Physiologic Integrity: Pharmacologic Therapies

9. Before the nurse administers an opioid analgesic to a patient, the **most** important nursing action is to:

1. check the blood pressure.
2. provide other comfort measures first.
3. assess for possible constipation.
4. assess the rate and depth of respirations.

NCLEX Client Need: Physiologic Integrity: Pharmacologic Therapies

10. A 25-year-old patient complains of moderate pain at his incision site. The nurse administers morphine sulfate IM. The most appropriate nursing action after the injection would be to:

1. evaluate the effectiveness of the pain medication in 2 hours.
2. encourage him to close his eyes and rest.
3. suggest he play solitaire or watch something interesting on TV.
4. administer ordered ibuprofen orally.

NCLEX Client Need: Physiologic Integrity: Pharmacologic Therapies

11. The nurse is assigned to care for a patient with an epidural for analgesia. Which sign or symptom related to this treatment would require immediate provider notification?

1. Blood pressure 80/60 mm Hg

2. Temperature 99.5° F (37.5° C)
3. Respirations 12/min
4. Urinary output less than 30 mL/hr

NCLEX Client Need: Physiologic Integrity: Pharmacologic Therapies

12. A long-term care nurse is caring for an older adult male patient who appears to be withdrawn and quiet. He grimaces whenever he is touched. The **most** appropriate nursing action would be to:

1. administer pain medication.
2. assess for underlying causes of the patient's behavior.
3. reposition him and check again in 2 hours.
4. notify the provider.

NCLEX Client Need: Health Promotion and Maintenance: Aging Process

Critical Thinking Questions

Scenario A

Jo Ann Patterson, a 56-year-old woman, has suffered shoulder pain from an old healed fracture for several years. When the pain is too severe to be controlled with acetaminophen, her provider recommends that she use the oral opioid analgesic he prescribed. However, Jo Ann does not want to continue taking drugs that she "might become addicted to."

1. How would you respond to Jo Ann's statement regarding her fear of addiction to the pain medication?
2. What other measures could you suggest for management of Jo Ann's pain?

Scenario B

Tom Johnson, an African American construction worker, had a bowel resection 3 days ago. He is determined to get back to work quickly and is cooperative about ambulation. He refuses pain medication, stating, "I don't need it." You note that he stops frequently to lean against the wall, walks stooped over, and grimaces when no one is looking.

1. Why might Tom be refusing pain medication?
2. What information might you share regarding pain control and getting well after major surgery?
3. What suggestions might you make to Tom regarding his comfort?

Scenario C

Jim Tolliver, age 32, sprained his left ankle while playing football with his friends this morning. He consults his neighbor (who is a nurse) about what to do because it is hurting a lot.

1. What should his nurse neighbor do first?

2. What should be suggested to Jim regarding home treatment?
3. What precautions should the neighbor take regarding further treatment?

CHAPTER 8

Care of Patients With Cancer

Objectives

Theory

1. Analyze organization of neoplastic (abnormal tissue) growth.
2. Identify at least five factors that may contribute to the development of a malignancy.
3. List at least four practices that can contribute to prevention and early detection of cancers.
4. Include the recommendations of the American Cancer Society in a plan for routine checkups and detection of cancers into patient education.
5. Explain the advantages and disadvantages of the various treatments available for cancer.
6. List the major problems for a patient who is coping with side effects of radiation or chemotherapy for cancer, and state the appropriate nursing interventions.
7. Apply knowledge of the stages of the grieving process experienced by a patient dying of cancer to the patient's coping level.

Clinical Practice

8. Devise an individualized plan of care for a patient receiving chemotherapy.
9. Formulate a teaching plan for a patient who has bone marrow suppression from cancer treatment.
10. Institute nursing interventions to help a patient cope with the common problems of cancer and its treatment.
11. Use appropriate nursing interventions to help patients and families deal with the psychosocial effects of cancer and its treatment.
12. Employ nursing interventions to help cancer patients cope with death and dying.

vesicants (VĒ-si-kĕntz, p. 163)

The Impact of Cancer

Cancer is a group of diseases that characteristically grow in an uncontrolled manner with the spread of abnormal cells. In many instances, however, the growth can be controlled by specific treatment. In the early 1900s, there was little hope for survival once cancer was detected. Now, approximately 4 of 10 people who are diagnosed with any type of cancer will be alive in 5 years, which is a 50% improvement since 1975.

Excluding basal and squamous cell skin cancer, about 1,658,370 new cases of invasive cancer will be diagnosed in 2015 ([American Cancer Society \[ACS\], 2015](#)). It is estimated that more than an additional 1 million people in 2015 will be told that they have squamous or basal cell skin cancer. The current rate of cancer is about the same as it was in 1977, indicating little advance in the rate of cancer occurrence. The **incidence** of lung cancer in men declined during the past two decades, and the incidence in women has just begun to decrease. Thus, for the first time, the death rate from lung cancer is the same in both men and women. However, approximately 1000 adolescents begin smoking every day; if this continues, approximately 5.6 million children under 18 years of age today will eventually die of smoking-related illness, including lung cancer ([U.S. Department of Health and Human Services, 2014](#)). The incidence of colorectal cancer declined 4.1% among adults 50 years of age and older but increased by 1.1% for those younger than 50 years. However, the incidence of breast cancer has increased over the past three decades, a trend that is mostly attributed to improved detection.

Death rates for many other major cancers have stabilized or declined since the 1930s. However, cancer still accounts for one in four deaths in the United States today. About 589,430 people died of cancer in 2014 (1600 people per day) ([ACS, 2015](#)). On the other hand, there are 14.5 million living Americans who have a history of cancer, and 68% of them were diagnosed more than 5 years ago. **That means that 68% of cancer patients are surviving!** Because of earlier detection and improvements in treatment methods, patients who are diagnosed today may have much higher survival rates. Individuals are more likely to survive cancer if it is treated in its earliest stages. In fact, the American Cancer Society (ACS) estimates that if all the cancers that are detectable early **were diagnosed in localized stages**, the 5-year survival rate would be 95%. [Figure 8-1](#) shows the leading sites of new cancer cases and deaths.

Leading Sites of New Cancer Cases and Deaths – 2015 Estimates

Estimated New Cases*		Estimated Deaths	
Male	Female	Male	Female
Prostate 220,800 (26%)	Breast 231,840 (29%)	Lung & bronchus 86,380 (28%)	Lung & bronchus 71,660 (26%)
Lung & bronchus 115,610 (14%)	Lung & bronchus 105,590 (13%)	Prostate 27,540 (9%)	Breast 40,290 (15%)
Colon & rectum 69,090 (8%)	Colon & rectum 63,610 (8%)	Colon & rectum 26,100 (8%)	Colon & rectum 23,600 (9%)
Urinary bladder 56,320 (7%)	Uterine corpus 54,870 (7%)	Pancreas 20,710 (7%)	Pancreas 19,850 (7%)
Melanoma of the skin 42,670 (5%)	Thyroid 47,230 (6%)	Liver & intrahepatic bile duct 17,030 (5%)	Ovary 14,180 (5%)
Non-Hodgkin lymphoma 39,850 (5%)	Non-Hodgkin lymphoma 32,000 (4%)	Leukemia 14,210 (5%)	Leukemia 10,240 (4%)
Kidney & renal pelvis 38,270 (5%)	Melanoma of the skin 31,200 (4%)	Esophagus 12,600 (4%)	Uterine corpus 10,170 (4%)
Oral cavity & pharynx 32,670 (4%)	Pancreas 24,120 (3%)	Urinary bladder 11,510 (4%)	Non-Hodgkin lymphoma 8,310 (3%)
Leukemia 30,900 (4%)	Leukemia 23,370 (3%)	Non-Hodgkin lymphoma 11,480 (4%)	Liver & intrahepatic bile duct 7,520 (3%)
Liver & intrahepatic bile duct 25,510 (3%)	Kidney & renal pelvis 23,290 (3%)	Kidney & renal pelvis 9,070 (3%)	Brain & other nervous system 6,380 (2%)
All sites 848,200 (100%)	All sites 810,170 (100%)	All sites 312,150 (100%)	All sites 277,280 (100%)

*Excludes basal cell and squamous cell skin cancers and in situ carcinoma except urinary bladder.

Physiology of Cancer

The human body is continuously producing new cells to replace those that are worn out and to repair damage done to cells by illness and injury. An abnormal replication of cells results in a **neoplasm** (new growth of tissue, or tumor), which is not beneficial. The word **benign** indicates a neoplasm that is usually harmless. Benign growths are almost always **encapsulated** (surrounded by a fibrous capsule). The capsule prevents the release of cells and restricts their spread to other parts of the body. Benign growths can, however, create problems if they press against and interfere with the normal structure and function of nearby organs.

The cells of **malignant** (uncontrolled growth that can lead to death) growths are quite different from normal cells. Cells that exhibit malignant growth are known as *cancer*. Cancerous growth changes a cell's **deoxyribonucleic acid (DNA)** makeup and function and the DNA structure and function of cells that are replicated; hence cancer cells do not look like or behave like normal cells (Figure 8-2).

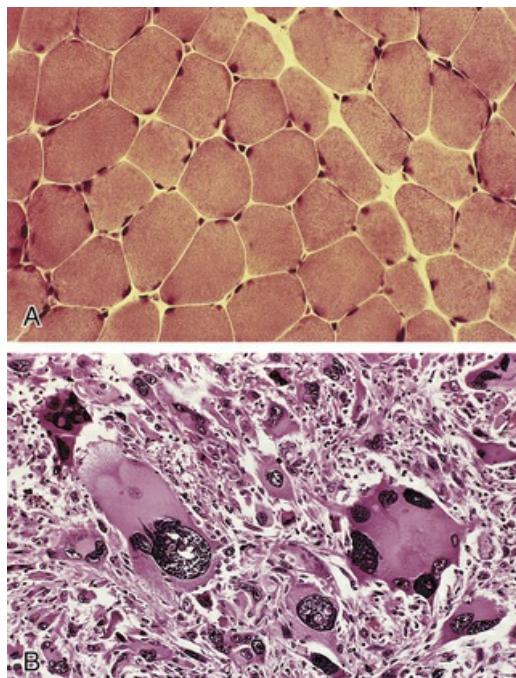

FIGURE 8-2 Normal and malignant skeletal muscle cells. **A**, Normal skeletal muscle cells. Note that cells are well differentiated and similar in appearance. **B**, Malignant tumor cells in skeletal muscle (rhabdomyosarcoma). (From McCance KL, Huether SE, Brashers VL, Rote ND: *Pathophysiology: The biologic basis for disease in adults and children*, ed. 6, Philadelphia, 2010, Elsevier.)

The nucleus of a malignant (cancer) cell is large and irregular. Dividing cells fail to follow the rules that regulate the reproduction of normal cells. Malignant cells do not seem to "know" when to stop multiplying. The offspring of cancerous cells **proliferate** (multiply) in great numbers, and they grow more disorganized, often forming tumorous masses. Some cancerous cells take on new characteristics, so that they do not resemble the cells of the original tissue. The malignant cells invade neighboring tissues and travel to other parts of the body. There they establish another colony of malignant cells. Their demand for nutrients depletes the supply of nourishment available for normal cells. This spread of tumor cells is called **metastasis** (movement of cancer cells from the original cancer site to other areas of the body). **Not all malignant cells metastasize, but most do.**

Think Critically

Can you compare and contrast the aspects of a benign versus a malignant tumor?

Classification of Tumors

Tumors are often classified according to the organs or tissues from which they first began to grow; alternatively, tumors can be classified according to the substances of which they are formed. The suffix *-oma* means “tumor”; this suffix is used in the names of various kinds of growths or swellings. Remember that *-oma* simply means “tumor”; the suffix *-oma* can designate any swelling, including a swelling in which there is a collection of fluids, as well as a swelling containing malignant cells. For example, **hematoma** (another word for bruise) is a combination of *hema-*, meaning “blood,” and *-oma*, meaning “a swelling or collection of fluid or cells.”

The prefixes used in classifying neoplasms indicate the kind of tissue in which they originate. For example, a tumor arising from fatty (lipoid) tissue is called a *lipoma*. A *fibroma* is a tumor composed of fibrous tissue. A *leiomyofibroma* contains both smooth-muscle tissue and fibrous connective tissue. Lipomas, fibromas, and leiomyomas are the most common types of benign growths.

Malignant growths are divided into four main types. A **sarcoma** arises from mesenchymal tissues (bone, muscles, and other connective tissues). A **carcinoma** originates in epithelial tissues (skin and mucous membranes). These kinds of cancers make up most cancers of the stomach, uterus, lungs, skin, and tongue. **Leukemia** and **lymphoma** are cancers of the blood-forming system. Malignancy of the pigment cells of the skin is called **melanoma**.

These are the main groups of cancers. More accurate naming can be achieved by adding modifying prefixes. For example, *osteosarcomas* arise from bone (*osteo-*), and *adenocarcinomas* arise from glandular (*adeno-*) structures.

Metastasis

Metastasis refers to the movement of malignant cells from the site of origin to another site. Malignant cells can metastasize by traveling in the blood and body fluids, in much the same way as do bacterial cells. It also is possible for free malignant cells to be directly transplanted from one organ to another during surgery when gloves and instruments that have these cells on them serve as vehicles for their transportation. Another way in which malignant cells can "contaminate" normal tissues and organs is by entering a body cavity and coming in contact with a healthy organ. For example, malignant cells may break off from a diseased organ, enter the abdominal cavity, and attach themselves to an ovary or the **mesentery** (tissues that connect the internal organs to the abdominal cavity wall) (Figure 8-3).

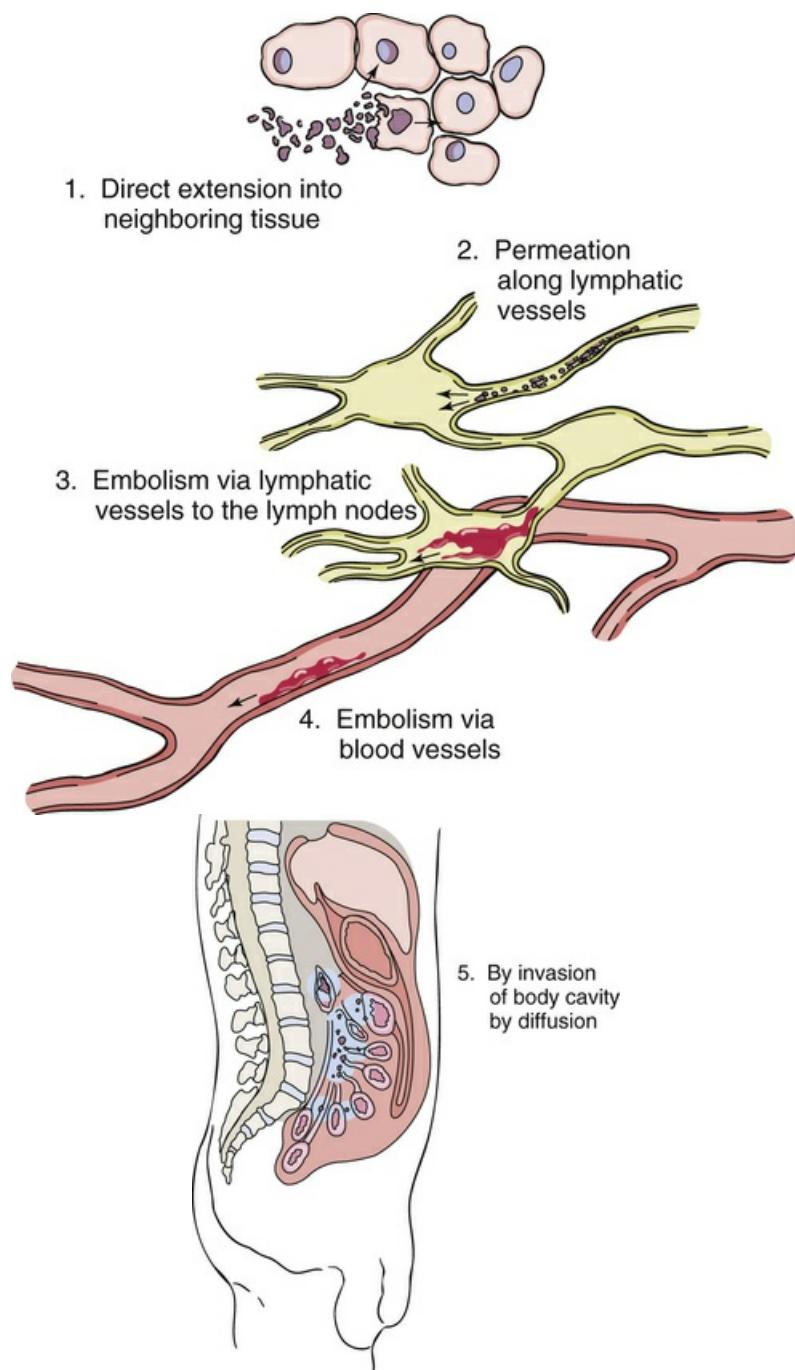

FIGURE 8-3 Modes of dissemination of cancer. (From Monahan FD, Neighbors M, Sands M, et al: *Medical-surgical nursing: Health and illness perspective*, ed. 8, St. Louis, 2007, Mosby.)

The **prognosis** (prediction of survival) for a patient with a malignancy depends on how much the malignant cells have attacked body tissues. A localized growth is one that remains at the original site (**in situ**) and has not yet released its cells, even though the growth may have invaded underlying tissues. At this stage the disease is much more easily destroyed.

A **regional** malignancy is one in which cells from the original malignancy have spread to the body area around the tumor, such as to nearby lymph nodes. The spread has been limited by the body's protective mechanisms. These cells may continue to grow and multiply, and if the regional cancer is not successfully treated, malignant cells will eventually break away and spread throughout the body. This creates an **advanced** cancer that is often fatal.

A new way to detect and measure malignant cancer cells is by CellSearch, a test developed to measure the circulating tumor cells in the blood. This test can detect just one tumor cell among 40 million circulating blood cells. At this point in time the test is being used to help determine the efficacy of treatment, but future uses may include cancer screening.

One system that identifies cancers by how much the malignancy has spread is the **TNM staging** system. The three basic parts of the system are *T* for primary tumor, *N* for regional nodes, and *M* for metastasis. The number written beside each letter indicates how much the malignancy has spread and attacked other tissues (see Evolve[®]). For example, T1, N0, M0 means that the tumor is small and localized (no involvement of regional lymph nodes and no metastasis). A label of T1, N2, M1 indicates a small (T1) tumor with moderate regional involvement (N2) that has metastasized to one distant site or organ (M1).

Causative Factors

All cancer results from defects in the DNA of genes. These defects either are inherited or are caused by **mutation** (a permanent change in the DNA sequence of a gene) during a person's lifetime from exposure to chemicals or radiation. Several cancer-causing genes (**oncogenes**) are discovered each year. Oncogenes are mistakes in the instructions inside a cell's genetic code, whereby newly created cells are no longer normal. The defective gene tells the new cells to multiply at a higher rate. Also, the defective coding prevents newly created defective cells from dying and being reabsorbed. This results in a tumor, or mass.

Tumor suppressor genes are healthy, normal genes that control the growth of cells in the body. Each person's body has a different ability to withstand the effects of cancer-causing substances (**carcinogens**), to mount a healthy immune response, and to repair damaged DNA. It is hoped that discoveries in molecular biology will allow individual risk profiles to be drawn that could be used to counsel people to avoid certain occupational and environmental exposures or to develop protective therapies.

In the external environment, many harmful agents exist that are known to be carcinogenic, and others are strongly suspected. **Among these harmful agents are certain chemicals, sources of radiation, and viruses** (Table 8-1). There are also some internal factors that affect an individual's ability to cope with malignant cells. Hormones play an undetermined role in the development and progress of cancer, and several inherited genes have been discovered that increase a person's chance of getting certain types of cancer.

Table 8-1
Common Carcinogenic Substances

SUBSTANCE	TYPE OF CANCER
Asbestos	Lung, peritoneal, pericardial
Benzene	Acute myelocytic leukemia
Tobacco	Lung, mouth, pharynx, larynx, esophagus, pancreas, bladder, kidney, colon, liver
Alcoholic beverages	Mouth, pharynx, larynx, esophagus, liver
Radon	Lung
Ionizing radiation	Leukemia, tumors of most organs
Sunlight (ultraviolet rays)	Skin
Diethylstilbestrol (prenatally)	Vaginal
Estrogens, synthetic	Endometrial
Androgens, synthetic	Liver
Vinyl chloride	Liver
Aromatic amines	Bladder
Arsenic (inorganic)	Lung, skin
Chromium	Lung
Nickel dust	Lung, nasal sinuses
Chronic hepatitis B or C infection	Liver
Human T-cell lymphotropic virus type 1 (HTLV-1)	Adult T-cell leukemia and lymphoma
Human papillomavirus (HPV)	Cervix, vagina, vulva, penis, anus, mouth, throat
Phenacetin	Renal pelvis, bladder
Alkylating agents (used for chemotherapy)	Acute myelocytic leukemia
Cyclosporine (used to prevent transplant rejection)	Non-Hodgkin lymphoma

Although cancer can strike at any age, older people are more susceptible. **Immunocompetence**, or the capability of one's immune system to deal with foreign cells—bacterial, viral, or malignant—decreases with aging and is an important factor in the development of cancers. As a result, the single biggest risk factor for cancer is age.

Chemical Carcinogens

More than 200 years ago (in 1775), Sir Percival Pott linked the occurrence of cancer to a substance in the environment when he observed that cancer of the scrotum was common among the chimney sweeps of London. He attributed this high incidence of cancer to repeated accumulations of soot on the skin of these young men, whose occupation required continuous contact with the coal soot in the chimneys they cleaned. Since that time, almost 500 different chemical carcinogens have been identified.

Think Critically

When you go shopping, can you identify additives used in your food that are carcinogenic? How can you reduce your exposure to them and decrease the risk of cancer?

Many of the cancer-producing substances in the environment are related to occupations that involve repeated exposure to these substances through handling or inhalation. **Petrofluorocarbons (polychlorinated biphenyls or PCBs) and some pesticides (e.g., DDT) are known carcinogens.** These and other such chemicals decrease immunocompetence. For example, cancer of the skin often is related to the handling of pitch, asphalt, crude paraffin, and petroleum products. Lung cancer is linked to irritating substances in the air, such as tobacco smoke, asbestos, radon, and chemical wastes from industry and automobiles. Benzene, an ingredient in older unleaded gasoline, is linked to leukemia. These are just a few of the chemical agents that can contribute to the development of cancer in humans.

Chewing tobacco has been directly related to cancer of the tongue and structures of the mouth and throat. **Cigarette smoking is a known direct cause of cancer of the lung and is believed to be linked to esophageal, pancreatic, bladder, kidney, liver, and colon cancers.** Cigarette smoking is even more deadly than previously understood. In early 2014 the surgeon general's office released a report implicating tobacco use in several other diseases, including diabetes, colon cancer, and liver cancer ([U.S. Department of Health and Human Services, 2014](#)).

Health Promotion

Effects of Smoking

Encourage individuals who use tobacco to quit. Ninety percent of lung cancers in men and 79% in women are related to smoking. Use of tobacco in conjunction with the intake of alcohol is related to several other types of cancer.

Immunosuppressive drugs used to suppress organ transplant rejection are a cause of non-Hodgkin lymphoma. Synthetic estrogens are linked to a higher incidence of endometrial cancer. Many cancer drugs affect the immune system and can predispose the patient to other types of cancer.

Promoters

Promoters are substances that are not carcinogenic alone but cause known carcinogens to lead to cancer at a faster rate. Alcohol is such a substance. When nicotine is present, cancers occur at a faster rate in those who are heavy consumers of alcohol than in those who use nicotine but do not drink alcohol. It is estimated that 90% of all head and neck cancers are related to a combination of tobacco and alcohol use.

Physical Carcinogens

Radiation

Radiation may originate from x-ray machines and radioactive elements or from the ultraviolet rays of the sun. These rays are capable of penetrating certain body tissues and causing the development of malignant cells in the affected area. The relationship of intense and prolonged exposure to these rays and the production of cancer cells was first discovered when there was a high incidence of cancer, particularly leukemia, among people who pioneered studies of x-rays or worked with radium or uranium. Survivors of the atomic blasts at Hiroshima and Nagasaki at the end of World War II had an unusually high incidence of leukemia.

There is continued concern about the danger that excessive radiation in the environment presents, especially the long-term effects that are not immediately apparent but may eventually prove to be related to malignancy. In addition to leukemia, cancers of the skin, bone marrow, breast, lung, and thyroid are believed to be closely linked to exposure to radiation.

The ultraviolet rays of the sun can produce skin cancer. The deterioration of the Earth's ozone layer is causing more ultraviolet rays to reach the earth than in the past, which compounds the problem. The susceptibility of the individual also is a factor: people with fair complexions have less protective pigment and therefore are more likely to develop skin cancer from ultraviolet radiation than are people with darker skin.

Radon Gas

Areas that have more radon emission from the soil have a higher incidence of malignancy in the population than do areas that are low in radon.

Viruses

The first cancer-causing virus was discovered in 1911, but it was not until recent years that extensive research has been directed toward establishing a link between **viruses** and **malignancy**. Experiments involving animals have demonstrated that a number of cancers can be produced in animals by injecting them with a filtrate from virus-infected malignant growths. **The hepatitis B virus is carcinogenic for liver cancer.** The Epstein-Barr virus causes Burkitt lymphoma. Cases of adult T-cell leukemia and lymphoma are caused by human T-cell lymphotropic virus. Several types of the human papillomavirus (HPV) cause cervical carcinoma or are related to throat and mouth cancer in nonsmokers. In fact, there are at least 10 cancers that have been identified as being driven by a virus. These viruses are known as **oncoviruses** because of their ability to cause cancer.

After the **transformation** (change into something else) of a normal cell into a precancerous state, the malignant cell requires many conditions favorable to its multiplication and growth into a cancerous tumor. **Viruses are capable of introducing new genetic material into a normal cell and transforming it into a malignant one.** Furthermore, cell reproduction can be altered when viruses interact with carcinogens. Viruses such as the human immunodeficiency virus (HIV) can damage the immune system and decrease immunocompetence, causing the body to become more susceptible to the growth of abnormal cells. Such damage also reduces the body's ability to fight off cancer-causing viruses, such as HPV. Some cancers—such as Kaposi sarcoma—are only seen in HIV-infected or severely immunocompromised patients (see [Chapter 11](#) for more information).

Genetic Predisposition

Research is revealing that there is a genetic predisposition to various types of cancer. It has been known for many years that breast cancer is more likely to occur in women who have a close female relative who developed breast cancer before age 50. Gene markers have been found for colon cancer, breast cancer, prostate cancer, pancreatic cancer, and leukemia. However, only 5% to 10% of cancers are related to a directly inherited gene. The remaining cancers are caused by genes that are damaged (mutated) throughout the lifetime and are not inherited. Some people are more susceptible to these mutations. These genes do not directly cause cancer, but the people who have the genes are at a much higher risk for cancer. For example, the breast cancer genes, *BRCA1* and *BRCA2*, increase a woman's risk for breast cancer, but other factors may also determine whether a woman will actually get breast cancer.

Because of this uncertainty, several assessment tools have been developed to estimate a woman's risk for breast cancer. These tools, which include the Gail model, the Claus model, and at least five other tools, ask the women to supply information about well-known predictors for breast cancer (family history, personal history) and provide an estimate of the women's risk. There are tools for other kinds of cancer as well.

Cultural Considerations

Race Factors

Some populations are at a higher risk for certain types of cancer. For example, of the four types of melanoma, African Americans are most susceptible to the acral lentiginous type, whereas whites are least susceptible to it. Lentigo maligna melanoma is found most often in Hawaii.

With the completion of the Human Genome Project, scientists are working to identify the genes that are related to specific cancers ([Perrett, 2012](#)). Currently, research is focused on finding genetic markers—or oncogenes—for other forms of cancer. Such markers, or the proteins they produce, could identify high-risk individuals who then might undergo more vigorous, regular diagnostic testing to detect any malignancy in the very earliest stages.

Contributing Factors

Intrinsic Factors

Age, sex, and race are considered “predisposing factors” for certain types of cancers. Predisposition simply means that, statistically, certain types of cancer strike particular age, sex, or racial groups more frequently than others. For example, prostate cancer is far more common in black males than in white males. Breast cancer is more prevalent in white women than in Asian women. As for age factors, approximately 76% of cancers occur in people aged 55 years and older.

Stress

Another factor that seems to play a role in the development of cancer is stress. Considerable stress over long periods has an adverse effect on the immune system; stress can make the immune system less effective in ridding the body of invading organisms and decreases the body's ability to destroy abnormal cells.

Diet

Most experts agree that approximately 30% of cancers could be reduced through proper nutrition and exercise. There is strong evidence that healthy diet and normal body weight are crucial in the control of cancer. Cancers of the breast, colon, rectum, endometrium, esophagus, uppermost abdomen, gallbladder, pancreas, liver, and kidney are all linked to excess weight and obesity. Although there is no universal agreement about the role of fiber in the prevention of malignancy, high-fiber foods such as fruits, vegetables, and cereals are recommended as a wholesome substitute for fatty foods.

Measures to Prevent Cancer

Nurses can be instrumental in educating the public about ways to prevent cancer. **Each nurse should teach patients the following measures at every opportunity.**

Diet and Nutrition

Encourage maintenance of normal weight. Obesity is considered a risk factor in many cancers. It also makes early detection of many cancers difficult. One study noted that men and women who were overweight by 40% or more have a 33% and 35% greater risk, respectively, for developing cancer than do persons with normal weight.

Nitrite and nitrate food additives are also known to be cancer **stimulators** (encouraging cancer). However, research has indicated that if foods containing nitrites are eaten in combination with foods containing vitamin C (ascorbic acid), the formation of nitrosamines is blocked. This means, for example, that if orange juice is consumed along with a meal containing bacon, there is less chance of carcinogenic nitrosamines damaging the body. In this instance the vitamin C is a cancer **inhibitor** (discouraging cancer).

Think Critically

If you saw that a package of meat contained nitrates, what other chemical would you expect to find in the package?

Nutrition Considerations

Minimizing the Risk for Cancer

- Eat a varied diet and balance caloric intake with exercise to maintain a healthy weight.
- Limit red meat and processed meat intake. Eat fatty fish twice a week to increase omega-3 intake. Limit other fat intake, particularly saturated and *trans* fats. Substitute olive oil for cooking and salad dressings where possible.
- Eat five or more servings of a variety of vegetables and fruits each day. Include cruciferous vegetables, those containing beta-carotene, tomatoes, onions and garlic, citrus fruits, and red and blue fruits and vegetables (cabbage, broccoli, Brussels sprouts, kohlrabi, cauliflower, carrots, yellow squash, sweet potatoes, red grapes, berries, and red cherries).
- Choose whole-grain foods over processed (refined) grains; include beans, whole-grain cereals, flaxseed, breads, and pastas to increase fiber intake daily.
- Keep alcohol consumption moderate: no more than two drinks or two glasses of wine or beer per day (one drink for women). No alcohol is best.
- Avoid smoked, salt-cured, nitrite-cured, and charred (blackened) foods.

From American Cancer Society: ACS guidelines on nutrition and physical activity for cancer prevention, 2015. Retrieved from www.cancer.org/healthy/eathealthygetactive/index.

These recommendations are from a report by a special committee on nutrition and cancer and are based on studies conducted for more than 20 years by the ACS's research program. Although no direct cause-and-effect relationship between diet and cancer has been demonstrated, there is ample evidence that avoidance of obesity and modification of the diet can help prevent some types of cancers.

Think Critically

Can you identify three specific changes you could make in your personal diet that might decrease your cancer risk? What would you add to the diet, or what would you stop eating?

Alcohol

Moderation in the drinking of alcohol is recommended, because alcohol consumption alone has been shown to increase risk for several cancers. Excessive alcohol consumption also can lead to liver damage, and possibly to liver cancer.

Environment

Because groundwater is often contaminated with chemicals from fertilizers, pesticides, and industrial wastes, it is wise to know the chemical makeup of the local water supply. If the geographic area is highly contaminated, filtered or bottled water might help prevent further damage to immunocompetence, and thereby decrease the incidence of cancer.

Patient Teaching

Avoiding and Limiting Exposure to Carcinogens

- Knowing which substances used in the household, yard, and areas of recreation and at the place of work are carcinogenic and using protective measures against them can decrease exposure.
- The use of protective clothing, gloves, and mask as appropriate when spraying pesticides or chemicals or using chemical cleaners or strippers greatly decreases exposure.
- Being certain the area is well ventilated when using chemical cleaners indoors is protective.
- Thoroughly washing the hands and any exposed skin after using compounds containing carcinogenic chemicals provides protection.
- Using an appropriate sunscreen and protective clothing when outdoors, avoiding sunburns, and avoiding tanning salons and sunlamps greatly decreases the incidence of skin cancer.
- Australians have the highest rate of skin cancer in the world and have developed a saying that is a good way to instruct your patients: **slip, slap, slop, strap**—**slip** on protective clothing, **slap** on a hat, **slop** on some sunscreen, and **strap** on sunglasses.
- Avoiding swimming and water sports in contaminated waters and avoiding eating fish from waters that have chemical contamination limit exposure.
- Washing or rinsing fruits and vegetables before preparing them for eating or cooking decreases exposure to agricultural pesticides.

Identifying High-Risk People

Studies of individuals who have developed cancer—their medical history, lifestyle, and family history—have shown that some people are more likely to develop certain kinds of cancer. Table 8-2 shows information on high-risk groups published by the ACS to develop an awareness of the need for frequent and thorough examinations to detect cancer early in those who are susceptible to developing a malignancy.

Table 8-2

Major Risk Factors for Cancer

TYPE OF CANCER	RISK FACTORS	SIGNS
Lung	<ul style="list-style-type: none">• Heavy smoker >50 yr• Smoked a pack a day for 20 yr• Started smoking at age 15 yr or	Persistent cough, blood in the sputum, chest pain, recurring pneumonia or bronchitis

	<ul style="list-style-type: none"> earlier • Exposure to environmental smoke • Exposure to asbestos, arsenic, certain chemicals in the workplace • Radiation or radon exposure • History of tuberculosis 	
Breast	<ul style="list-style-type: none"> • History of breast cancer • History of some forms of breast biopsy • Close relatives with history of breast cancer • Early menarche; late menopause • Never had children; first child after age 30 yr • Lengthy exposure to cyclic estrogen • Higher educational and socioeconomic status • Consumption of alcohol 	Lump in breast, nipple discharge, thickening, dimpling, nipple retraction, pain or tenderness of the nipple
Colon and rectum	<ul style="list-style-type: none"> • History of rectal polyps • Rectal polyps run in family • History of inflammatory bowel disease 	Blood in stool; alteration in bowel pattern (e.g., constipation alternating with diarrhea)
Uterine and cervical	<ul style="list-style-type: none"> • Frequent sex in early teens or with many partners • History of HPV • Low socioeconomic status • Poor care during or after pregnancy • Smoking or history of smoking • Exposure to in-utero DES 	Unusual bleeding or discharge
Uterine and endometrial	<ul style="list-style-type: none"> • Estrogen therapy • Tamoxifen therapy • Late menopause (after age 55 yr) • History of infertility or failure to ovulate • Diabetes, high blood pressure, gallbladder disease, obesity • Pelvic irradiation 	Unusual bleeding or discharge
Skin	<ul style="list-style-type: none"> • Excessive exposure to sun or tanning booth • Fair complexion • Work with coal tar, pitch, or creosote 	Change in the size, color, or appearance of a mole or spot on the skin; scaliness, oozing, bleeding or change in appearance of a bump or nodule; spread of pigmentation beyond the border; change in sensation of any skin lesion
Oral	<ul style="list-style-type: none"> • Heavy smoker and drinker • Use of smokeless tobacco • Poor oral hygiene • HPV 	White patch in the mouth or on the tongue; nodules
Ovary	<ul style="list-style-type: none"> • History of ovarian cancer among close relatives • History of breast cancer • History of never having children 	None until well advanced
Prostate	<ul style="list-style-type: none"> • Age >65 yr • Black ancestry • History of family incidence of prostate cancer 	Difficulty urinating; hesitancy, blood in the urine; need to urinate frequently; pain in lower back, pelvis, or upper thighs
Stomach	<ul style="list-style-type: none"> • History of stomach cancer among close relatives • Diet heavy in smoked, pickled, or salted foods • Some link with blood group A 	Nonspecific; indigestion, feeling of fullness or pressure; pain and weight loss are late signs
Pancreas	<ul style="list-style-type: none"> • Smoking or other recreational drugs 	No signs
Bladder	<ul style="list-style-type: none"> • Smoking 	Painless blood in the urine; need for frequent urination
Leukemia	<ul style="list-style-type: none"> • Down syndrome • Exposure to excessive radiation • Exposure to benzene (unleaded gas) • HTLV-1 infection • Philadelphia chromosome 	Frequent infections, easy bruising, fatigue, weight loss, nosebleeds, paleness

DES, Diethylstilbestrol; HPV, human papillomavirus; HTLV-1, human T-cell lymphotropic virus type 1.

Detection of Cancer

Cancer is a group of diseases. It can strike any organ of the body, affect different organs with different functions, and present an untold number of symptoms as it progresses. To be able to identify the symptoms of cancer in its earliest stages, it is important to be aware of its warning signals. The purpose of screening large segments of a population is to identify as many people with cancer as possible.

Health Promotion

Warning Signs of Cancer

- Unusual bleeding or discharge
- A sore that does not heal
- A change in bowel or bladder habits
- A lump in the breast or other part of the body
- A nagging, persistent cough
- An obvious change in a mole
- Difficulty in swallowing

Older Adult Care Points

Older adults have a higher risk for developing cancer; their immune system is not as efficient as that of a younger person. Many of the cancer screening programs are suggested to begin at age 40 or 50.

At physical examination, certain tests are conducted to determine whether a malignancy is present. Recommendations of the ACS for routine checkups and early detection of cancer are shown in **Table 8-3**.

Table 8-3
Screening Guidelines for the Early Detection of Cancer in People With No Symptoms and Average Risk

CANCER SITE	POPULATION	TEST OR PROCEDURE	FREQUENCY
Breast*	Women, age 20+	Breast self-awareness	All women should be familiar with their own breasts and how they normally look and feel. Women should be encouraged to contact their health care providers with any changes.
		Mammography	Begin mammography at age 40, if desired. <ul style="list-style-type: none">• Age 45-54: annual• Age 55 and older: biannual or annual, if desired• Continue mammography as long as life expectancy is 10+ yr.
Cervix†	Women, ages 21-65	Pap test Human papillomavirus (HPV) DNA test	<ul style="list-style-type: none">• Cervical cancer screening should begin at age 21.• Women ages 21-29 should be screened every 3 yr with conventional or liquid-based Pap tests.• Women ages 30-64, should be screened every 5 yr with both the HPV test and the Pap test (preferred), or every 3 yr with the Pap test alone (acceptable).• Women ages 65+ who have had normal results for the last 10 yr should discontinue testing and never restart.• Women who have had a total hysterectomy should stop cervical cancer screening.• Women vaccinated against HPV should follow the same cervical screening guidelines for all ages.
Colorectal‡	Men and women, age 50+	Fecal occult blood test (FOBT) with at least 50% test sensitivity for cancer	Annual, starting at age 50. Testing at home with adherence to manufacturer's recommendation for collection techniques and number of samples is recommended. FOBT with the single stool sample collected on the clinician's fingertip during a digital rectal examination is not recommended. Guaiac-based toilet bowl FOBTs also are not recommended. [§]
		Fecal immunochemical test (FIT) with at least 50% test sensitivity for cancer, or stool DNA test	Annual; starting at age 50 using the multiple stool take-home test. [§]
		Flexible sigmoidoscopy (FSIG)	Every 5 yr, starting at age 50. FSIG can be performed alone, or consideration can be given to combining FSIG performed every 5 yr with a highly sensitive gFOBT or FIT performed annually. [§]
		Double contrast barium enema (DCBE)	Every 5 yr, starting at age 50. [§]
		Colonoscopy	Every 10 yr, starting at age 50. [§]
		CT colonography	Every 5 years, starting at age 50. [§]
Endometrial†	Women, at menopause	At menopause, women at average risk should be informed about risks and symptoms of endometrial cancer and	For some women, history may dictate annual endometrial biopsy.

		strongly encouraged to report any unexpected bleeding or spotting to their physician	
Lung [¶]	Current or former smokers ages 55-74 in good health with at least a 30 pack-yr history, are still smoking or have quit within the past 15 yr	Low-dose helical CT (LDCT)	Clinicians with access to high-volume, high-quality lung cancer screening and treatment centers should initiate a discussion about lung cancer screening with apparently healthy patients ages 55-74 who have at least a 30 pack-yr smoking history, and who currently smoke or have quit within the past 15 yr. A process of informed and shared decision making with a clinician related to the potential benefits, limitations, and harms associated with screening for lung cancer with LDCT should occur before any decision is made to initiate lung cancer screening. Smoking cessation counseling remains a high priority for clinical attention in discussions with current smokers, who should be informed of their continuing risk of lung cancer. Screening should not be viewed as an alternative to smoking cessation.
Prostate [*]	Men, ages 50+ (African American, age 45) Should make an informed decision with a health care provider whether or not to be tested	Prostate-specific antigen test (PSA), with or without digital rectal examination (DRE)	Men who have at least a 10-yr life expectancy should have an opportunity to make an informed decision with their health care provider about whether to be screened for prostate cancer, after receiving information about the potential benefits, risks, and uncertainties associated with prostate cancer screening. Prostate cancer screening should not occur without an informed decision-making process. Research has not shown the benefits to outweigh the harm.
Cancer-related checkup	Men and women, ages 20+	During a periodic health examination, the cancer-related checkup may possibly include examination for cancers of the thyroid, testicles, ovaries, lymph nodes, oral cavity, and skin, as well as health counseling about tobacco, sun exposure, diet and nutrition, risk factors, sexual practices, and environmental and occupational exposures

[§]From American Cancer Society (ACS): American Cancer Society Guidelines for the Early Detection of Cancer 2015, <http://www.cancer.org/healthy/findcancerearly/cancerscreeningguidelines/american-cancer-society-guidelines-for-the-early-detection-of-cancer>

^{\$}Positive tests should be followed by colonoscopy.

[¶]From the National Cancer Institute (NCI): <http://www.cancer.net/cancer-types/lung-cancer-non-small-cell/screening>

One widely used technique to detect cancer is to examine cells under a microscope to determine whether they are malignant or premalignant. This technique is called **cytology**, and the most widely used cytology test is the Papanicolaou (Pap) smear to detect cervical cancer. A **cytologic examination** can be performed by obtaining a sample of secretions containing cells that have been released from adjacent tissue. The technique involves either scraping or brushing a sample of cells from the area or collecting body secretions that contain cells, such as cervical discharges, sputum, gastric washings, pleural fluid, or urinary washings. A specially trained technologist or pathologist examines the cells microscopically. If “suspicious” cells are found, the patient is referred to a health care professional for more extensive diagnostic tests. Another screening technique, used for colorectal cancer, is the simple test for **occult blood** (hidden blood) in the stool. This can be obtained through a fecal occult blood test (FOBT) or a newer test called the fecal immunochemical test (FIT). The person simply collects one or more stool specimens (depending on the particular test being used), applies a thin smear on the container provided, and returns the specimens to the health center, clinic, or clinical laboratory. **Occult blood in the stool is not always an indication of cancer of the bowel or rectum.** Other conditions also can produce this symptom.

Other procedures used to identify lesions that are possibly malignant include radiologic studies, endoscopy, sonography, magnetic resonance imaging, computed tomography, clinical laboratory testing of enzymes and other substances in the blood, and studies specific to the system in which the cancer is suspected. Research continues to identify proteins produced by mutated DNA that might be used to diagnose various types of cancer. Tests for viruses are now being done to identify increased risk for some cancers. For example, a test for the presence of high-risk types of HPV is available to identify women at risk for cervical cancer.

Diagnostic Tests

Biopsy

Biopsy of a tumor and examination of the cells obtained are the most certain techniques for establishing a diagnosis of malignancy in most neoplasms. Malignancies involving blood cells, such as in leukemia, are diagnosed by examining these cells. A **biopsy** is the removal of living cells for the purpose of examining them under a microscope. The cells may be removed by surgical **excision** (cutting out) of a small part of a tumor, by the **aspiration** (suction) of cells through a needle introduced into the growth, or by brush biopsy. If the tumor is small, the entire growth may be

removed. A pathologist examines the specimen obtained under the microscope.

If the sample is taken in the operating room and the surgeon is waiting for the results to determine the extent of surgery needed to remove all the malignant cells, the tissues may be frozen for quick examination. This technique is called *preparing a frozen section*.

New procedures, such as fine-needle aspiration (FNA) and **percutaneous** (through the skin) large-core breast biopsy, are used for diagnosing breast cancer without the disfigurement of traditional surgical breast biopsy. Breast biopsy is combined with imaging techniques such as ultrasound to verify correct placement of the biopsy needle. Then FNA is combined with computer analysis of the samples obtained.

Radiologic Studies

Mammography is a radiologic examination of the breast that is useful in diagnosing malignant growths, and x-ray films are particularly helpful in diagnosing bone and hollow organ tumors. Mortality rates can be cut by 20% to 33% when routine mammography screening is performed ([ACS, 2014](#)). Newly developed three-dimensional (3D) mammograms (also called *tomosynthesis mammography*) are available in 46 states. However, there is no evidence of lower mortality, and because they previously delivered twice the radiation compared with traditional mammogram, they were only recommended in selective cases (e.g., dense breasts) where the benefit would outweigh the risk. Recently newer techniques have made it possible to create the 3D images using the same radiation as the two-dimensional (2D) images. This makes tomosynthesis mammography superior to 2D mammography because it (1) better detects small invasive carcinomas and (2) reduces the rate of patient recalls ([Kopans, 2014](#)).

The respiratory, digestive, and urinary tracts can be visualized on a radiograph if a **radiopaque** (not penetrated by the x-rays) substance is used. The substance passes through the hollow organ and, because it is radiopaque, the inner structure of the organ is clearly demonstrated on the radiograph.

Another radiologic technique involves the use of a radioactive substance (**radionuclide** or **isotope**) that is given to the patient before the x-ray filming. The isotope is a “tumor-seeking” chemical that searches for a tumor and may concentrate around it. A special scanning apparatus records information about the concentration of the isotope in the area being examined. If the substance is concentrated in a tumor, the growth shows up as a “hot spot” on the screen of the scanning apparatus. If a tumor does not accept the isotope, the normal tissue around the tumor concentrates the isotope, and the tumor shows up as a “cold spot.” This technique is commonly used in the investigation of thyroid tumors.

A commonly used radiologic scanning technique is **computed tomography (CT)**. This method is noninvasive and involves relatively small amounts of radiation exposure for the patient.

In CT, the x-ray source moves past the patient in one direction while the film moves in another. In this way, 3D cross-sectional images, or “slices,” of tissue can be obtained. Tumors, as well as other abnormal structures within the body tissues, can be seen in this way.

Another imaging technique is called *magnetic resonance imaging (MRI)*. As in CT, MRI produces views of “slices” of tissue. MRI can sometimes “see” tumors and abnormalities that other techniques miss. It is currently used as a breast screening tool—in addition to mammography—only for patients at high risk for breast cancer (because of increased radiation exposure) based on family history. MRI can also be used in real time to monitor cancer treatments. Patients with pacemakers, certain metal fragments, clips, or shrapnel in the body cannot use MRI because the powerful magnets used in this technique can bend and twist metal and can damage the body.

Endoscopy

An endoscope is an instrument used for direct visualization of internal body parts. It is designed so that it can be inserted and passed along the interior of hollow organs and cavities.

Types of endoscopes include the colonoscope for the colon, the bronchoscope for the trachea and bronchi, the laparoscope for the contents of the abdominal or pelvic cavity, and the cystoscope for inside the bladder. During an endoscopy, a sample of cells may be taken from a suspicious area so they can be examined more precisely under a microscope (biopsy).

Laboratory Tests

No single blood test can establish a definite diagnosis of cancer, but certain tests are used to obtain specific information. A complete blood count is helpful in diagnosing leukemia. The presence of a high level of prostate-specific antigen (PSA) may indicate prostate cancer. Current recommendations include offering a baseline PSA test for men older than 50 years, to be repeated at various intervals depending on the patient's risk factors. Guidelines for performing a PSA test are provided in [Box 8-1](#).

Box 8-1

Prostate-Specific Antigen (PSA) Test

- The patient should have no sexual activity for 24 to 48 hours before the test.
- Do not perform the test until after a urinary tract infection is cleared.
- Do not perform the test after recent urinary tract surgery.
- Collect a blood sample before digital examination.
- Prostatic acid phosphatase is collected to confirm an elevated PSA.
- The phosphatase level gives information about the extent of disease.
- Alkaline phosphatase is often elevated with bone cancer and liver metastasis.

Specialized tests for **tumor markers** have been developed. These tests detect biochemical substances synthesized and released into the bloodstream by tumor cells. However, these are not 100% accurate for diagnosing tumors. Therefore **tumor markers are mainly used to confirm a diagnosis, determine the response to therapy, or to detect a relapse**. CA-125 is used to detect the presence of ovarian cancer or its recurrence after therapy. Carcinoembryonic antigen (CEA) and CA 19-9 are tests used to detect the recurrence of gastrointestinal, pancreatic, and liver cancer after initial treatment, and CA 27-29 is used most commonly to follow the progress in breast cancer treatment and later to check for recurrence.

❖Nursing Management

■ Assessment (Data Collection)

The first step is to find out whether the patient has been informed of the diagnosis and what is known about the illness and treatment. Some patients may suspect they have cancer but do not want to discuss it. Even those who have been informed may choose not to talk about it. The fact that a patient cannot discuss her illness or seek help in dealing with the problems it presents may indicate how frightened she is and how much she needs help and understanding. The nurse must assess how the disease is affecting the patient's body and life to plan comprehensive care.

A thorough assessment of the system where the cancer is located and a good general physical assessment provide a baseline for evaluation of changes in physical function caused by the cancer. A psychosocial assessment of the patient and family or significant others provides data that indicate psychosocial needs and resources for support and care.

Finally, the nurse should determine how to assist the patient to make the most of the personal resources and abilities that the patient currently possesses. This could mean helping with adjustment to the emotional effects of only recently receiving the diagnosis of cancer, or it could require helping the patient to deal with the pain and discomfort of advanced malignancy and to prepare for a peaceful death.

■ Nursing Diagnosis/Problem

Patients with cancer can develop complex problems, depending on the stage of the disease; a large number of nursing problems or nursing diagnoses may be appropriate. Specific problems are chosen for the body systems and functions in which the disease or tumor is causing disruption of

homeostasis. Common general patient problems associated with a diagnosis of cancer can be found in Box 8-2.

Box 8-2

Common Nursing Problems for Patients With Cancer

- Altered nutrition due to increased metabolic demand and nausea, vomiting, diarrhea, or mucositis
- Potential for infection due to bone marrow depression
- *Pain, acute or chronic*, due to effects of tumor on body structures or cancer therapy
- Altered skin integrity due to surgical or radiation therapy
- Altered body image due to weight loss or hair loss
- Potential for injury to patient, staff, and visitors due to exposure to a radioactive implant
- Altered physical mobility due to restricted activity secondary to a radioactive implant
- Diarrhea and dehydration due to effects of cancer treatment
- Constipation due to effects of chemotherapy
- Altered urinary elimination due to radiation therapy or secondary to effects of chemotherapy
- Fatigue
- Insufficient knowledge of drugs and their potential side effects
- Altered self-care ability due to weakness and fatigue
- Fear of dying
- Limited coping due to the significance of cancer
- Altered family coping due to anxiety over patient's prognosis

■ Planning

Specific expected outcomes are written for each nursing problem/diagnosis chosen, as appropriate for the patient ([Nursing Care Plan 8-1](#)). Planning is a collaborative process that includes the patient, the family, the physician, the oncologist, the nurse manager, the social worker, and other specialists on the health care team. The home care nurse, the infusion therapy company nurse, and the pharmacist often are involved in care and should be included in the planning process. The nurse manager typically consults with the other members of the team and coordinates the plan of care.

*** Nursing Care Plan 8-1**

Care of the Patient With Cancer

Scenario

Mr. Pole is receiving chemotherapy for leukemia. This is his third round of weekly intravenous treatments. His platelet count is down to 185,000; he has had difficulty eating as a result of mucositis and anorexia. He states that he is mildly nauseated most of the time. He is 15 lb underweight.

Problem/Nursing Diagnosis

Potential for/Risk for infection related to bone marrow suppression

Supporting Assessment Data

Objective: Receiving chemotherapy drugs that suppress bone marrow.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will remain free of infection.	Monitor WBCs.	Neutropenia is a sign of immunosuppression. More susceptible to infection when <3000 and granulocyte count is <2000.	WBCs 3200.
	Assess for signs of infection every shift.	Elevated temperature may indicate infection.	Temp. 98.8° F (37.1° C); no signs of infection.
	Teach good hygiene, mouth care, hand hygiene before meals and after using bathroom.	Hand hygiene prevents spread of infection.	Patient washing hands appropriately and using good hygiene.
	Use protective isolation techniques if needed.	If neutrophil count <500, protective isolation is necessary.	Isolation not yet initiated.
	Encourage good nutrition and hydration.	Good nutrition and hydration minimize irritation.	Taking sufficient food and fluid; continue plan.
	Give Neupogen as ordered.	Neupogen raises the WBC and neutrophil count.	Neupogen 300 mcg subcutaneously given 1 time/day.

Problem/Nursing Diagnosis

Potential for injury/Risk for injury related to impaired blood clotting ability

Supporting Assessment Data

Objective: Receiving chemotherapy (chemotherapy treatment lowers platelets and extends bleeding time).

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will remain free from hemorrhage.	Monitor blood count; assess for bleeding of gums or bruising and bleeding into joints every shift.	Blood count plays an important role in blood clotting and bleeding.	WBCs 3200; platelet count 180,000.
	Observe for signs of bleeding: hematuria, melena, etc.		No signs of bleeding.
	Refrain from needle sticks as much as possible.		
	Give stool softener as ordered to prevent straining at stool and bleeding. Prevent rectal bleeding. Do not take temperature rectally.	Hard stools can initiate bleeding in the rectum.	Stool soft; continue plan. Stool softener administered. Oral temp: 98.8° F (37.1° C).
	Brush teeth with very soft brush or tooth sponge. Do not floss.	Prevent bleeding gums.	Appropriate dental hygiene.

Problem/Nursing Diagnosis

Altered nutritional status/Imbalanced nutrition: less than body requirements related to nausea, vomiting, and mucositis.

Supporting Assessment Data

Subjective: "I feel nauseated."

Objective: Chemotherapy administration.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will verbalize relief from nausea.	Keep room odor free; give mouth care before meals.	Odors may aggravate nausea.	
Patient will be able to eat with minimal discomfort.	Give ordered antiemetic before and during chemotherapy.	Antiemetics help prevent chemotherapy-induced nausea and vomiting (N&V).	Antiemetic 45 min before meals.
Patient will maintain present weight.	Assess mouth and mucous membranes every shift. Give meticulous mouth care q2h.	Sore mouth may reduce food intake.	Mucous membranes reddened, but intact. Mouth care: 7, 9, 11, 1, and 3 o'clock.
	Use distraction, meditation, relaxation techniques.	N&V may be reduced with behavioral interventions.	Has not vomited this shift.
	Give small, frequent meals.	Experts recommend these dietary interventions.	Enriched shake taken between meals.
	Encourage added calories in meals and food supplements between meals.		

Problem/Nursing Diagnosis

Altered body image/Disturbed body image related to alopecia and weight loss

Supporting Assessment Data

Subjective: "I look awful; I don't want any visitors to see me."

Objective: Loss of considerable amount of hair from head.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will adjust to new body image within 3 wk as evidenced by verbalization.	Encourage him to maintain sense of humor.	Humor is a positive coping strategy.	
	Use caps, head bandanna, and eyebrow pencil as needed.	Hair covering may reduce negative body image.	Checking on purchase of wig; family is bringing head scarves.
	Assure him that hair will eventually grow back.		
	Encourage verbalization of feelings; focus on strengths.	Verbalization is a positive coping technique.	Talking more about feelings regarding weight loss and appearance.
	Establish and maintain trusting relationship.		
	Assess spiritual needs; help patient achieve spiritual consolation.		Continue plan.
	Encourage him to obtain clothing that fits.		

Problem/Nursing Diagnosis

Fear/Fear related to diagnosis of cancer

Supporting Assessment Data

Subjective: "Do you really think the treatment will cure my cancer? I'm afraid that I'll go through all this and it will just come back in a few months."

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will verbalize fears and develop coping mechanisms to decrease fear.	Encourage verbalization and identification of specific fears.	Verbalizing fears makes them easier to face.	Is verbalizing fears; encouraged to do same with family.
	Help him to explore ways to cope with fears.	Knowing what to expect helps people plan.	Used to meditate; encouraged to do so.
	Assess spiritual needs; contact minister or other as patient desires.	Patients have their own beliefs about death.	Began teaching imagery techniques.
	Offer support by active listening, offering hope in some form, and being there for patient.	Active listening provides comfort and strength.	Continue plan.
	Encourage expression of fears to significant others.	When significant others are aware of the patient's fears, they have a better understanding of behavior.	

Critical Thinking Questions

1. What is a nursing problem that may apply to a patient who is receiving chemotherapy?
2. Why should the nurse be concerned about infection in a patient who is receiving chemotherapy?

■ Implementation

See [Nursing Care Plan 8-1](#) and the following sections for specific interventions.

■ Evaluation

Evaluation is based on determining whether the expected outcomes specified for the patient are being met or have been met. Constant assessment for signs of complications, side effects of therapy, nutritional status, and pain status is necessary. The nursing care plan must be changed when the interventions initially chosen are not effective in meeting the desired outcomes. Collaboration with the patient and the other members of the health care team is important to the success of care plan changes.

Common Therapies, Problems, and Nursing Care

There are three traditional modes of therapy for malignancies: surgery, radiation, and chemotherapy. Hormone manipulation, immunotherapy with biologic response modifiers, and bone marrow or stem cell transplantation are treatments combined with traditional therapies.

Each of the modes of treatment may be used individually or in combination with one or more of the other methods available. For example, chemotherapy may be used as an adjuvant (assisting treatment) after surgical removal of a tumor. The methods of treatment are chosen after consideration of many factors and are prescribed with the best interests of the patient in mind.

Surgery

Surgery may be performed for a variety of reasons:

- To obtain a biopsy specimen
- As prophylaxis (preventive treatment), such as in the removal of the ovaries of a woman whose mother had ovarian cancer
- To determine the effectiveness of therapy by looking to see whether the initial tumor is reduced in size
- For palliation (offering relief), as in **debulking** (removing as much as possible) a tumor to prevent pressure on adjacent structures or obstruction of vessels or the gastrointestinal tract
- As an attempt at cure

Reconstructive surgery also is associated with cancer treatment. A woman who has lost a breast to mastectomy may have the breast reconstructed. Other extremely mutilating forms of cancer surgery require reconstructive procedures after the initial procedure. Flap grafts in a patient who underwent radical neck surgery for cancer of the throat are an example.

Surgical removal of a malignant growth is the oldest method of treatment. It works very well for tumors that are easily accessible. Adjacent tissues that may contain malignant cells also are excised. Regional lymph nodes often harbor malignant cells, which can then travel to distant parts of the body and establish a new cancer site if not removed. Newer surgical procedures and techniques have significantly reduced the need for extensive surgical removal of adjacent tissues and structures. Radical mastectomy, for example, involves removal of the entire breast along with underlying pectoral muscle tissues and lymph nodes under the arm on the affected side. This procedure has been replaced almost completely by a modified radical mastectomy, or lumpectomy and sentinel node biopsy, combined with radiation and/or chemotherapy, which is far less traumatic and mutilating. If there is no evidence of metastasis, some patients are good candidates for simple removal of the tumor (**lumpectomy**). The use of radiation and/or chemotherapy during, after, and sometimes before surgery has decreased the need for extensive removal of adjacent tissues and is associated with decreased recurrence.

Radiation Therapy

The source for radiation therapy is either a linear accelerator or a radioactive element or substance. The purpose of radiation is to destroy malignant cells (which are more sensitive to radiation than are normal cells) without permanent damage to adjacent body tissues.

Ionizing radiation can have both an immediate and a delayed effect on malignant cells. Ionizing radiation can damage the cell membrane immediately, causing **lysis** (bursting) or decomposition of the cell, or it can cause a break in both strands of the DNA in the cell's nucleus. **When a cell is damaged in this way, it will not die until it attempts to divide and replicate itself. The rate at which a particular kind of cell undergoes mitosis determines whether the effects of radiation will occur in a matter of days, months, or years.** This explains the delayed effects and side effects of radiation that might not be evident at the time of treatment but appear later. Normal cells have a greater ability to repair the DNA damage than do malignant cells. Some tissues are more sensitive to radiation than others, and this is taken into account when the physicist-provider calculates the dose of radiation needed to eradicate the tumor. The other factors considered are the sensitivity of the tumor to radiation, its location, and its size. Once calculated, the dose is **fractionalized**, meaning

it is divided over many days, to deliver the optimal dosage with the least amount of effects to normal tissues. The course of radiation is spread over a period of days to weeks. The **rad**, or **radiation absorbed dose**, is the unit used for measuring dosages of radiation.

Teletherapy and brachytherapy are the two types of radiation delivery used to treat cancer. Teletherapy is **external**—the source of radiation is outside the patient. Brachytherapy is **internal**—the source of radiation is a radioactive element or substance that has been implanted or injected into the body, to provide low doses in focused areas.

Because of improvements in tumor localization, beam direction, megavoltage machines, planning and prescribing the field to be irradiated, and determining the precise dosage needed, radiation therapy is far more beneficial and less harmful than it was when it was first pioneered. With the **linear accelerator** and its partner, the **cyclotron**, the damage to normal tissue can be minimized by keeping the dosage or degree of penetration accurate and by aiming the rays from several different angles. The latter technique increases the concentration of the rays in the area of the tumor with a minimum of damage to overlying tissues. Cobalt-60 machines deliver gamma rays, and these machines are now much more efficient and precise than they were in the early years of radiation therapy.

External Radiation Therapy

The linear accelerator used for external radiation therapy produces extremely high-energy x-ray and electron beam irradiation that bombards the malignant cells and destroys them. Because malignant cells divide at an abnormally high rate, they are more susceptible to destruction than normal cells.

Modern radiation therapy has considerably reduced side effects. Because DNA is the critical target for radiation damage, the increased knowledge about DNA gained from the Human Genome Project has also helped streamline radiation therapy. The use of **stereotactic** (exact positioning in space) surgery is effective for small brain tumors ([Figure 8-4](#)). Many cancer research institutions have lead-lined surgical suites where intraoperative radiation therapy may be delivered directly to the affected area after tumor removal and before the incision is closed. Depending on the dosage (rads) given, the patient may not need to receive further radiation. This method has proven beneficial for cancers of the head and neck, abdomen, pelvis, and extremities and for patients with operable pancreatic cancer.

FIGURE 8-4 Cyberknife used to deliver radiation to a small brain tumor. It is particularly useful for recurrence of tumor. (Courtesy Cyberknife Center, Southwestern Washington Medical Center, Vancouver, Wash.)

Nursing care of patients undergoing external beam radiation therapy.

Nursing care goals related to cancer radiation therapy include (1) helping the patient and family

cope with the diagnosis of cancer and treatment with radiation therapy and (2) teaching the patient and family how to recognize and manage the expected side effects of radiation.

Helping patients cope with radiation therapy.

A lack of knowledge about the side effects of radiation and how to cope with them can greatly add to the anxiety and stress that the patient feels. It is not unusual for a layperson to have some misconceptions about how radiation works, whether a patient can present a hazard to others while undergoing treatment, when the patient will begin to experience its effects, and how long it will be before the patient begins to recover from them.

Before the first treatment, the patient is told what therapeutic effects are anticipated, what it is like to have a treatment, and what is expected of her during the course of therapy. Because the patient will probably be treated on an outpatient basis, she should be encouraged to keep her scheduled appointments and notify the clinic if cancellation is necessary. Someone should accompany the patient for initial treatments—preferably a family member or a close and trusted friend—who can provide emotional support. It is essential that time be set aside for the nurse to establish a trusting relationship with the patient, to prompt and answer any questions about therapy, and to provide an avenue for communication throughout the course of treatment. Assurance that the source of radiation is in the machine only and that it is not possible to “contaminate” others with radioactivity should be provided.

Clinical trial enrollment may be available for patients who wish to help out future patients. A comprehensive list of current clinical trials is available on the National Cancer Institute (NCI) website at <http://www.cancer.gov/clinicaltrials>.

Patient Teaching

Skin Care During Radiation Treatment

- Shower or wash the area once a day using warm water and mild soap; use a hand to wash the affected area rather than a washcloth. Dry with a soft, clean towel; pat, do not rub the skin.
- Limit cold and sun exposure; when outdoors use a sunscreen with a sun protection factor (SPF) of at least 15.
- Do not use lotion, salve, or alcohol on the affected area unless prescribed by the radiologist.
- Do not remove any of the markings for radiation treatment.
- Wear loose, 100% cotton clothing over the irradiated area.
- Do not shave the area or use an electric razor without the radiologist's permission.

Skin care during radiation therapy.

With the advanced methods and computerized delivery of radiation, there is much less trauma to the skin from radiation therapy than in previous years. The patient must understand that should skin damage occur, it is usually only temporary. In preparation for radiation therapy, the provider will outline the area to be exposed to radiation by marking it with indelible ink. The exposed area will need special care. Most clinics and hospitals have written procedures and precautions to be used to prevent unnecessary trauma to the exposed areas of skin.

Although skin damage is rare now, the degree of reaction of the skin to radiation is individual and should be assessed daily, either by the patient or by a knowledgeable person.

Think Critically

Can you list the points to be covered for care of the skin when teaching a patient who is to undergo external radiation therapy?

Teaching the patient and family how to recognize and help manage expected side effects is

particularly important when the patient is not hospitalized. She will feel more in control if she is able to participate in assessing her condition and planning and implementing her care at home. It is unfair to expect either the patient or her family to remember everything they are told about her care. Therefore it is essential that they have some written information to refer to once they leave the clinic. They also should be encouraged to write down any questions they might have before the next visit, and to note any points on which they feel they need more information.

Internal Radiation Therapy

Radiation from **radioactive elements** has the same ionizing effect as that from linear accelerators; the only difference is the source of radiation. Internal radiation therapy, called **brachytherapy**, involves introducing a radioactive element into the body and may be administered in different ways: (1) it can be placed in a **sealed** container and inserted into a body cavity at the tumor site or placed directly into the tumor, or (2) it may be administered in an **unsealed** form and taken orally or injected by syringe.

To be effective, the radiation source must come into direct contact with the tumor tissue for a specified time. Most implants emit a lower level of radiation while in constant contact with the tumor cells. **Because the radiation source is within the patient, radiation is emitted for a period and can be a hazard to others. Nurses caring for patients receiving internal radiation must take extra precautions (Box 8-3).**

Box 8-3

Precautionary Measures When a Patient Is Receiving Internal Radiation Therapy From a Sealed Source

- Place the patient in a private room.
- Place a sign on the patient's door indicating that the patient is receiving internal radiation therapy.
- Observe principles of time and distance. Limit time spent in the room. Work as quickly and as efficiently as possible. Avoid standing near the part of the patient's body where the radioactive element is located; stand at the shoulders or the feet depending where the implant is located.
- Check all linens, bedpans, and emesis basins routinely to see if the sealed source has been accidentally lost from the tissue.
- If a sealed source is dislodged, but has not fallen out of the patient's body, notify the x-ray department at once. If the source has fallen out, **do not pick it up with your bare hands**. Use forceps and place it in a lead container.
- Most patients are placed on bed rest and instructed to remain in certain positions so that emanations from the element will reach the correct area.
- Visitors should spend limited time in the room.
- No children or pregnant women should visit.

As soon as an element becomes radioactive, it begins to lose its characteristic of radioactivity. The rate at which it becomes less radioactive is called its *half-life*, which is the amount of time it takes for half of its radioactivity to dissipate. The half-life of radium is about 1600 years, whereas the half-life of iodine is only about 8 days. Cesium-137 is a radioactive element with a half-life of 30.17 years, and is frequently used to treat malignancies of the mouth, tongue, vagina, and uterine cervix. **It is important that nurses caring for a patient receiving sealed or unsealed sources of radiation know the element used, its half-life, and the ways in which it might be eliminated from the body.**

Some isotopes are given orally and others are administered into a body cavity. The isotopes are unsealed sources of radiation. If radioactivity is a hazard, it is a problem only for the duration of the half-life of the isotope. The substance is eliminated through body secretions such as urine, feces,

sweat, sputum and vomit. Examples of unsealed sources include iodine-131, which is in a solution and is swallowed by the patient, and phosphorus-32 and gold-198, which are administered by injection. Because the thyroid gland readily takes up iodine, thyroid malignancies are often treated with iodine-131 delivered to the site of the tumor, where it can be more effective. The major hazard from radioactive iodine is in the patient's urine, but iodine is also excreted in the feces and sweat; therefore special precautions must be taken according to hospital policy (Box 8-4).

Box 8-4

Precautions When Caring for the Patient Receiving Internal Radiation From an Unsealed Source

- Observe the principles of time, distance, and shielding for radiation protection.
- Wear gloves when handling bedpans, bed linens, and the patient's clothes.
- Dispose of urine, feces, and vomitus according to policy.
- Handle dressings with forceps and dispose of them according to policy.
- Follow hospital procedure for disposal of patient's bed linens and clothing.

Principles of Radiation Protection

In general, the amount of radiation a nurse might receive while caring for a patient being treated with internal radioactive elements depends on three factors: (1) the distance between the nurse and the patient, (2) the amount of time spent in actual proximity to the patient, and (3) the degree of shielding provided.

Distance is an important factor in reducing exposure to radiation. Doubling one's distance from a radioactive element reduces the exposure to one fourth, and tripling the distance reduces it to one ninth (Figure 8-5). Time spent near the source of radiation can be controlled if the nurse who plans his nursing carefully so that he can spend less time with the patient without sacrificing the quality of care given. The total time spent with a radioactive patient should be less than 30 minutes per 8-hour shift.

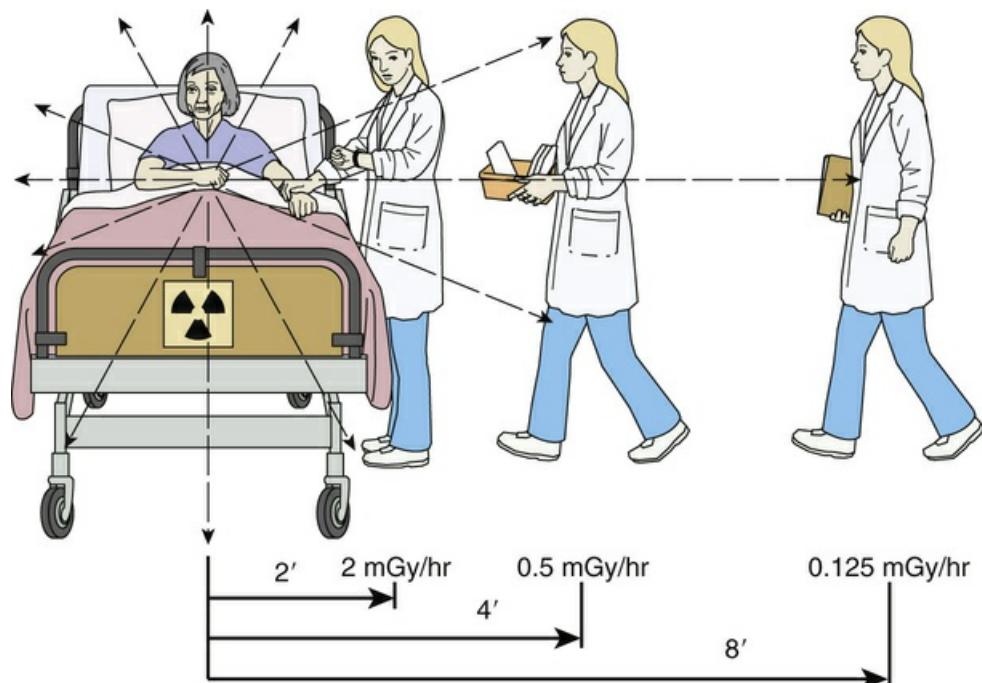

FIGURE 8-5 Time, distance, and shielding in radiation exposure. The nurse nearest the source of radioactivity (the patient) is more exposed; at 2 feet, exposure is more than 15 times that of exposure at 8 feet. *mGy*, Milligray.

Shielding from radiation exposure must take into account the type of rays being emitted. The denser the shielding material, the less the possibility of penetration by the rays, and the better the protection. A lead shield that is 1-cm thick offers the same amount of protection as 5 cm of concrete or 30 cm of wood. Lead aprons give protection from diagnostic x-rays but do not provide adequate shielding from the **gamma rays** emitted by radium, cesium-137, and cobalt-60. Anyone in proximity to—or in contact with—a source of radiation should wear a radiation dosimeter badge (Figure 8-6). This badge measures the radiation dose that the individual has received through exposure to the source.

FIGURE 8-6 Radiation dosimeter badge worn by personnel who might be exposed to radiation.

Hospitals where sealed sources of radiation are implanted into the body tissues to treat malignancies usually have written policies and procedures to guide personnel who are responsible for patient care. After the provider removes the source, the patient is no longer in need of special precautionary care. Special observations are necessary, however, in the event a systemic reaction develops. Table 8-4 lists the most common side effects of radiation therapy. For appropriate nursing care of problems related to radiation therapy, see the section on common problems related to cancer or cancer therapy.

Table 8-4
Common Side Effects of Radiation Therapy

TYPE AND AREA	EFFECT
External Radiation	
Head and neck	<ul style="list-style-type: none"> Irritation of oral mucous membranes with oral pain and risk of infection Loss of taste Irritation of the pharynx and esophagus with nausea and indigestion Increased intracranial pressure
Chest	Inflammation of lung tissue with increased susceptibility to infection
Abdomen	Nausea, vomiting, diarrhea, anorexia
Pelvis	<ul style="list-style-type: none"> Diarrhea Cystitis Sexual dysfunction Urethral and rectal stenosis
General side effects	<ul style="list-style-type: none"> Skin: Change in texture and/or color; moist desquamation (rare); alopecia Blood: Bone marrow depression with leukopenia, anemia, and thrombocytopenia Depressed immune function Fatigue
Internal Radiation	
General effects	<ul style="list-style-type: none"> Elevated temperature Cervical implant: Urinary frequency, diarrhea, nausea, vomiting, anorexia Head and neck implant: Mucositis, oral pain and risk of infection, anorexia

Chemotherapy

Oncologists have a wide variety of drugs from which to choose when planning a course of treatment for a patient with cancer. They may choose to give a particular drug alone, or in combination with other drugs. Chemotherapy may be used with other forms of therapy; for example, therapy may follow surgery and may occur before, during, or after radiation treatments, or with immunotherapy.

Among the drugs used to treat malignancies are the **antineoplastic agents** (Table 8-5). The overall effect of antineoplastic drugs is to decrease the number of malignant cells in a

generalized malignancy (such as leukemia) or to reduce the size of a localized tumor and thereby lessen the severity of symptoms. Antineoplastic drugs are **cytotoxic** (poisonous to cells), and their damaging effects are not limited to malignant cells. However, normal cells do not reproduce in exactly the same way as malignant cells and are able to repair themselves more rapidly and effectively. Steroids often are used in combination with antineoplastic drugs for cancer treatment.

Table 8-5

Common Antineoplastic Drug Classes, Actions, and Major Side Effects

CLASSIFICATION AND EXAMPLES	ACTION	MAJOR SIDE EFFECTS*
Alkylating Agents		
Cyclophosphamide, doxorubicin, mechlorethamine, ifosfamide, melphalan, chlorambucil, busulfan, streptozocin, carmustin, lomustine, dacarbazine, temozolamide, thiotapec, altretamine, platinum (cisplatin, carboplatin, oxaliplatin)	Attach "alkyl groups" or organic side chains to the proteins in the cell, poisoning it; inhibit cell division	Bone marrow depression, nephrotoxicity with some Nausea, vomiting, diarrhea, dermatitis; hyperpigmentation Platinum: Hearing loss
Antimetabolites		
Methotrexate, 6-mercaptopurine, 6-thioguanine, 5-fluorouracil, capecitabine, gemcitabine, cytarabine, fludarabine, pemetrexed	Interfere with a specific cell phase, thereby preventing replication Some inhibit enzymes that make essential cellular constituents; others attach to DNA, interfering with replication	Bone marrow depression, stomatitis, intestinal ulceration, nausea, vomiting, diarrhea
Antitumor Antibiotics		
Bleomycin, dactinomycin, doxorubicin, epirubicin, idarubicin, daunorubicin, plicamycin, mitomycin-C, mitoxantrone	Injure cells by direct interaction with DNA, causing distortion Interfere with DNA or RNA synthesis	Bone marrow depression, some cause cardiotoxicity; stomatitis, alopecia Bleomycin: Pneumonitis and pulmonary fibrosis
Mitotic Inhibitors		
Vincristine, vinblastine, vinorelbine, etoposide	Interfere with mitosis Act during M phase of cell cycle to prevent cell division	Vincristine: Peripheral neuropathy, constipation Vinblastine: Bone marrow depression
Miscellaneous Agents		
Altretamine, asparaginase, etoposide, hydroxyurea, procarbazine, mitotane, teniposide, paclitaxel, imatinib mesylate, epirubicin, docetaxel, cladribine, rituximab, interleukin-2, interferon-alfa	Work in a variety of ways; consult information for each drug	Bone marrow depression is the major side effect of all except asparaginase and mitotane Asparaginase: Pancreatic dysfunction Mitotane: Central nervous system depression Paclitaxel: Peripheral neuropathy
Hormone-Related Agents		
Anti-estrogens (fulvestrant, tamoxifen, toremifene), aromatase inhibitors (anastrozole, exemestane, letrozole), progestins (megestrol acetate), estrogens, anti-androgens	Lowers circulating hormone levels to prevent hormone-related tumors	Hot flushes; deep venous thrombosis; cancer

*Each drug has specific side effects. Consult information regarding each individual drug before administration.

Drug combinations are used to treat certain types of cancers because different drugs are effective at different times in the growth and replication cycle of the tumor cell. This method offers the best chance of killing the most malignant cells. Chemotherapy is the preferred treatment for various kinds of leukemias, some lymphomas, multiple myeloma, and many types of tumors that result from metastasis.

Techniques of administration of antineoplastic agents include intra-arterial, intraperitoneal, intraventricular, and **intrathecal** (within a space of the spine), as well as intravenous infusion. Cancers of the liver, ovary, and brain have sometimes shown better remission with intraventricular or intraperitoneal infusion treatment. An advance in chemotherapy has been the use of lower doses of multiple drugs to treat various types of malignancies. Because side effects are lessened when lower doses of a drug are used, several drugs can be used in combination to hit all phases of the cell cycle, destroying more malignant cells.

Often a central line or implanted injection port is used to administer chemotherapy drugs that are to be given over several weeks or months (Figure 8-7). The nurse cares for the central line and its insertion site according to hospital policy, using strict aseptic technique.

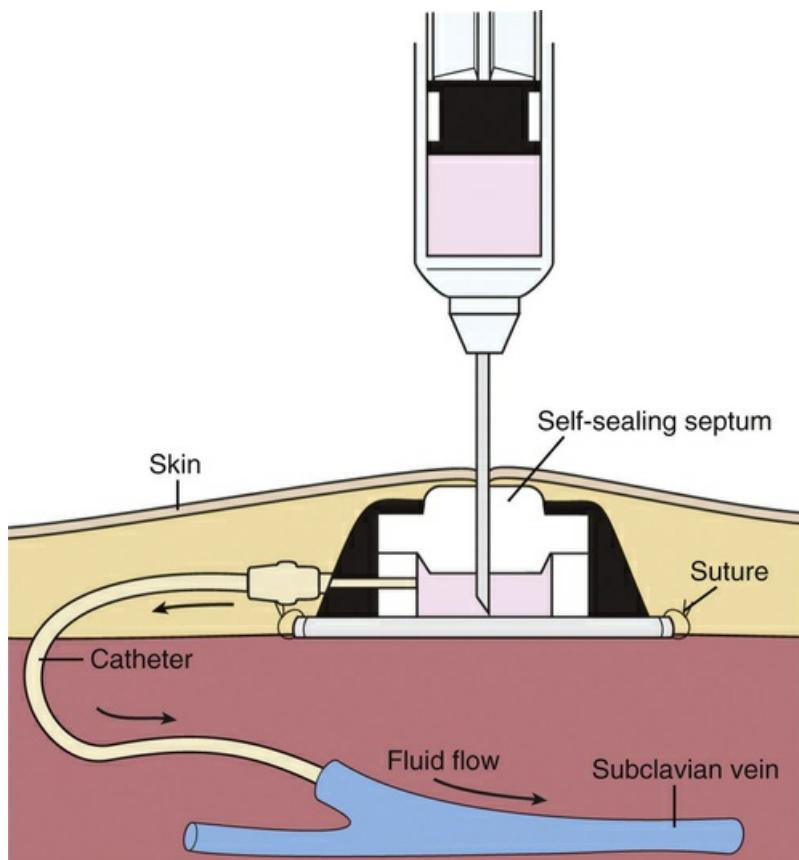

FIGURE 8-7 Implanted infusion port for administration of chemotherapy drugs or continuous morphine drip. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, St. Louis, 2014, Saunders.)

Many antineoplastic drugs are **vesicants** (chemicals that cause tissue damage on direct contact) that can cause severe local injury if they escape from the vein into which they are administered. Administration should be only into veins that have good blood flow. If **extravasation** (escape from the vein into the tissue) occurs, the infusion is stopped immediately. The type of treatment required depends on the drug and amount that is extravasated. **Should extravasation occur, consult the pharmacist, the policy and procedures manual, and the provider.**

Some antineoplastic drugs have toxic effects that must be monitored. Table 8-6 presents the assessments necessary to detect various types of organ toxicity. One drug, dexrazoxane (Zinecard), appears to be heart-protective for patients receiving the cardiotoxic drug doxorubicin (Adriamycin). If a drug is toxic to the reproductive system, the patient should make a decision about banking sperm or eggs before beginning chemotherapy.

Table 8-6
Assessment for Toxic Effects of Chemotherapy*

SIDE EFFECT	INTERVENTION
Bone marrow suppression	Monitor red and white blood cell count and differential count for numbers of neutrophils and granulocytes; check platelet count.
Cardiotoxicity	Monitor for signs of congestive heart failure, such as pulmonary crackles, shortness of breath, tachycardia, weight gain, and peripheral edema. Monitor ECG.
Neurotoxicity	Monitor for weakness, paresthesias, sensory loss (particularly in feet), and decreased reflexes. Constipation and urinary hesitancy are other signs.
Pulmonary toxicity	Evidenced by pulmonary infiltrates and pulmonary fibrosis on x-ray. Monitor respiratory status closely; auscultate for decreased breath sounds and for crackles.
Hepatotoxicity	Monitor liver function tests: AST, ALT, bilirubin.
Nephrotoxicity	Monitor kidney function tests: creatinine and blood urea nitrogen. Monitor urine output.
Ototoxicity	Monitor for tinnitus or hearing loss.

*Many antineoplastic drugs are toxic to various organs of the body. Whenever a specific drug has one of these toxicities, include the specific assessment parameters for that toxicity in your regular assessment.

ALT, Alanine aminotransferase; AST, aspartate aminotransferase; ECG, electrocardiogram.

Nursing Care of Patients Receiving Chemotherapy

Nursing management of a patient receiving chemotherapy requires special knowledge and skills

beyond those of basic nursing. An oncology nurse is a specialist who is able to give comprehensive nursing care because of years of study and experience. A full discussion of care of patients receiving chemotherapy is therefore beyond the scope of this text. There are, however, some general principles that can be helpful to a nurse who encounters a patient receiving a course of chemotherapy for cancer or a patient who is experiencing some of the toxic side effects of antineoplastic drugs.

Not all antineoplastic drugs produce every toxic side effect, and the oncologist plans therapy so that destruction of malignant cells is maximized and toxicity is minimized. **The toxicity associated with chemotherapy is most evident in the cells of the body that have a short life span and therefore must continuously reproduce to provide the body with the normal cells it needs. These types of cells include the blood cells, hair follicles, and epithelial cells of the mucous membranes lining the digestive tract. Most chemotherapeutics are excreted in the body fluids, so precautions should be taken. Remember, most of these drugs are teratogenic (can cause birth defects), so they should be avoided during pregnancy.**

Some of the side effects of chemotherapy are similar to the expected effects of radiation (see Table 8-5). Although the causes of the problems are different, assessment of the patient and symptomatic relief measures are the same. See [Nursing Care Plan 8-1](#) for nursing interventions for selected problems that may be experienced by a patient receiving chemotherapy for cancer.

Hormone Therapy

Hormone therapy is used as an adjunct to other types of cancer therapy. It can slow tumor growth or prevent cancer recurrence. When a hormone is added to the body, the balance of naturally produced hormones changes. **Giving large amounts of one hormone prevents the uptake of other hormones. Thus if the tumor growth is aided by one type of hormone, giving another type prevents the uptake of the growth-promoting hormone and slows the progress of the tumor.** Tamoxifen and aromatase inhibitors such as letrozole (Femara), used against certain types of breast cancer, are examples of synthetic hormone therapy. They have been shown to be chemopreventive for women with high risk factors and improve survival after breast cancer ([National Cancer Institute, 2012](#)).

Side effects of hormone therapy depend on the type of hormone used. Androgens and anti-estrogen receptor drugs produce masculinizing effects, such as facial and chest hair. Menses may stop and breast tissue will shrink. These drugs cause fluid retention in women. Acne is another side effect of the androgens. Hypercalcemia and liver dysfunction can occur with prolonged therapy. Men taking estrogens or progestins to combat prostate cancer may experience a feminizing effect with decreased facial hair, a redistribution of body fat, breast development (**gynecomastia**), smoothing of the facial skin, and the risk of thrombus formation. Over time, some testicular and penile atrophy may occur, and it may become more difficult to attain and maintain an erection.

Immunotherapy Using Biologic Response Modifiers

Biologic response modifiers (BRMs) are agents that manipulate the immune system in the hope of controlling or curing a malignancy with little or no toxic effect on normal cells. These agents either stimulate or suppress immune activity. The BRMs include interferons, interleukins, colony-stimulating factor (CSF), monoclonal antibodies, vaccines, gene therapy, and nonspecific immunomodulating agents. They essentially make the immune system function better. BRMs stimulate the immune system to recognize cancer cells and to institute action to destroy them. Some BRMs, such as CSF, work by enhancing a quicker recovery of the bone marrow after radiation or chemotherapy. CSF stimulates bone marrow to function more quickly. Neumega (interleukin-2) is a drug that stimulates thrombocyte (platelet) production. This drug is used to decrease the bleeding tendencies induced by chemotherapy and could help create new chemotherapy protocols that are more effective against cancer cells.

Two types of BRMs are used to fight cancer: interleukins and interferons. **Interleukins help the immune system cells recognize and destroy abnormal cells. Interferons slow cell division in cancer cells, stimulate natural killer cells, delay the appearance of oncogenes, and assist cancerous cells to revert to more normal cells.** Both interleukins and interferons are manufactured using recombinant (artificial DNA sequence) DNA technology. Interleukin-2 is used for patients with melanoma, renal cell carcinoma, and lymphoma. Interferons are used effectively against

leukemia, melanoma, multiple myeloma, carcinoid tumors, and renal carcinoma. Both interleukins and interferons are very expensive to manufacture.

A second group of BRMs includes monoclonal antibodies (**MoAbs**) and tumor necrosis factor, both of which have direct antitumor effects. Genetic engineering techniques can produce the monoclonal antibodies, and thus this form of therapy holds much promise for the future. Rituximab (Rituxan) and trastuzumab (Herceptin) are examples of MoAbs that have been approved by the U.S. Food and Drug Administration. Rituxan is used in the treatment of non-Hodgkin lymphoma, and Herceptin is used for the treatment of metastatic breast cancer in patients who produce an excess amount of a protein called HER-2.

The third group of BRMs contains agents that have varying functions. This group includes cancer vaccines, which may stimulate the immune system to attack the cancer cells (therapeutic) or stimulate the production of antibodies against a cancer-causing virus (prophylactic). Also included are nonspecific immunomodulating agents that may stimulate the immune system and either restore depressed immune function or increase immune inflammatory responses.

Bone Marrow and Stem Cell Transplantation

Bone marrow transplantation (BMT) is mainly used to correct the severe bone marrow damage caused by chemotherapy or radiation. Sometimes whole-body irradiation is used to treat a hematopoietic cancer such as leukemia or Hodgkin disease. Irradiation of this sort totally incapacitates the body's bone marrow, and the patient would die if blood cells could not again be manufactured. Stem cells may be transplanted to overcome the devastating effects of chemotherapy or total body irradiation before bone marrow transplant. BMT and stem cell treatment are discussed in [Chapter 16](#).

Gene Therapy

As research reveals the genes believed to be responsible for various types of cancers, the possibility of gene splicing or replacement becomes a reality. Genetic engineering to cure disease is still in its infancy, but scientists are working to make it a reality for cancer patients. The genes *BRCA1* and *BRCA2* are implicated in about half of the cases of inherited breast and ovarian cancer. Research has shown that when healthy *BRCA1* genes are injected into mice that have faulty *BRCA1* genes, tumor growth is slowed. This has proven true for other genes implicated in other types of cancer. Someday gene therapy may be the major treatment for cancer.

Evaluating the Effectiveness of Medical Treatment

The oncologist conducts an ongoing evaluation of each patient's status to determine how effective the prescribed treatment has been and to plan for a future course of therapy should it be needed. It is particularly important to know whether there has been a reduction in the size of the tumor and an abatement of the patient's symptoms. This is the purpose of **second-look surgery**.

One test for monitoring the effectiveness of treatment is a measurement of CEA levels. This antigen is a glycoprotein that is produced during fetal life but is not normally present after birth. Its production may resume again, however, and CEA levels can be increased by some kinds of liver disease, heavy cigarette smoking, and especially by gastrointestinal and colorectal cancers. Because of the many and diverse conditions that can elevate CEA levels, the test cannot be used to diagnose cancer. However, it can be used as a tumor marker to evaluate the effectiveness of treatment, because CEA levels usually fall to within the normal range about 1 month after successful treatment of cancer. Other tumor markers, such as PSA for prostate cancer and CA-125 for ovarian cancer, are used to track the success of treatment and recurrence in those cancers.

Complementary and Integrative Medicine

Normally, standard treatments and therapies should be employed as the primary cancer treatment, but many patients choose to supplement their care with complementary therapeutic approaches, also known as complementary and integrative medicine (CIM). There are many such approaches, but the most common are alternative medical systems, such as traditional Chinese medicine (including acupuncture), Ayurveda, homeopathy, and naturopathy; mind-body interventions, which include meditation, hypnosis, dance, music, and art therapy; biologically based treatments, such as herbal and plant therapies, nutrition, and biologic pharmacology; and manipulative and body-based methods, which include chiropractic and osteopathic manipulation and massage therapy. The latest CIM program to be introduced at MD Anderson is health psychology ([MD Anderson Cancer Center, 2014](#)).

In CIM, the therapies are used in addition to—but not as a replacement for—traditional Western (allopathic) medicine. When patients choose to use these approaches, the health care professional and the patient work together to find the therapies best suited to the patient's needs. It is important to form a partnership to promote the patient's health and well-being.

Common Problems Related to Cancer or Cancer Treatment

The problems that can be experienced by cancer patients are complex and depend on both the location and type of cancer and the therapy used to treat it. A discussion of the most common problems and the related nursing care is presented here.

Anorexia, Mucositis, and Weight Loss

Many cancer patients experience an alteration in taste. Commonly the first thing noticed is that red meat does not taste good. The taste of sweets also is altered. **Anorexia** (loss of appetite) often is associated with changes in taste and with inflammation of the mouth and tongue, which can cause the patient great difficulty in eating and drinking. The loss of appetite can quickly lead to deficiencies of protein and calories. **A patient with anorexia can experience a significant weight loss (2 or more pounds per week) and may suffer from severe malnutrition.** A synthetic substance derived from the female hormone progesterone, megestrol (Megace), has proven to work well to stimulate the appetite. A thorough routine for mouth care to minimize damage and anorexia should be started several days before the beginning of chemotherapy or radiation therapy to the head and neck. Radiation to the head or neck will produce some inflammatory changes in the mouth and often also in the pharynx and esophagus. Measures to combat this expected reaction include frequent oral intake of liquids that are not chemically irritating, the use of artificial saliva, and frequent and consistent mouth care.

Patients are encouraged to drink water as often as possible to help alleviate the discomfort of dryness of the mouth and tongue. However, drinking water will not completely resolve the problem. Artificial saliva combats mouth dryness in a different way and helps keep the mucous membranes soft and moist. It also helps to buffer the acidity in the mouth and thus to reduce irritation of the oral mucosa. Artificial saliva is available as a spray (Salivart) and a gel (Biotène Oral Balance) and can be used by the patient as often as desired. It can be found at a local pharmacy or obtained from most online drugstores.

Patients undergoing chemotherapy may experience **mucositis** (irritation and inflammation of the mucosa) in the mouth. A major goal of mouth care (other than protection of the mucosa) is preservation of the teeth and prevention of gum infections. To accomplish this, the patient should be encouraged to accept as much responsibility as possible for frequent and consistent oral hygiene. She probably will need to be taught how to brush her teeth using a soft brush or tooth sponges (toothettes) and to employ gentle strokes. She also should be taught how to irrigate her mouth to remove debris and counteract acidity. The solutions most often used for this irrigation are normal saline, mild solutions of peroxide (1 : 5 ratio), or a bicarbonate of soda and salt solution ($\frac{1}{4}$ to $\frac{1}{2}$ tsp of baking soda and $\frac{1}{8}$ to $\frac{1}{4}$ tsp salt in an 8-oz glass of water). Fluid intake must be increased to 3000 mL/day. Because of the risk of infection, toothbrushes should be rinsed with a bleach solution or hydrogen peroxide and then rinsed with water before reuse. Running toothbrushes through the dishwasher is another option for disinfection.

Relief of the mouth pain of mucositis or **stomatitis** (inflammation of the mouth) is provided by special topical compounds (such as Xylocaine Viscous) that are “swished and spit.” Such compounds contain a topical anesthetic and an anti-inflammatory agent. **The patient is instructed not to swallow this solution.** The patient should avoid spicy foods, alcohol, and tobacco while undergoing treatment. The metabolic demand of malignant growth, the anorexia, and the mucositis that makes eating difficult all contribute to weight loss. Weight loss also can occur in cancer patients because of disturbances in their metabolism, whereby the body metabolizes its own proteins for energy instead of using the carbohydrates available in the diet or in body fat. The body has to work hard to repair normal cells after cancer treatment. Initially, the patient's weight should be noted and recorded and compared with her ideal weight. Her protein intake should be increased. Small, frequent feedings, attention to preferences for foods, and a pleasant and restful environment during meals are often helpful. Supplemental feedings to provide additional protein and calories can help prevent excessive weight loss and protein deficiency. Supplements taste better if they are served in glass or plastic rather than out of a metal container. The ACS has patient pamphlets available on

ways to increase nutritional intake.

Nausea, Vomiting, and Diarrhea

Radiation therapy of the abdomen or lower back often produces nausea, vomiting, and diarrhea starting 7 to 10 days after the beginning of treatment. Various antineoplastic drugs also can produce these side effects. Antiemetic regimens should be chosen based on the potential of the chemotherapy regimen to cause nausea. Dose and timing vary for the antiemetic agents, but the regimen (consisting of several different drugs) is usually started 30 minutes to an hour before doses of chemotherapy and continued for 1 to 2 days afterward. Antiemetics are used for nausea and vomiting resulting from radiation therapy as well. A commonly used class of antiemetics, serotonin antagonists, acts on the chemoreceptor trigger zone for vomiting and has proven very beneficial for chemotherapy patients, even for previously resistant chemotherapy-induced nausea and vomiting.

Eating before treatment seems to decrease nausea. Eating toast or crackers before arising or engaging in activity during periods of nausea may decrease vomiting. Liquids, liquid supplements, or easily digested foods are given at 3- to 4-hour intervals in small amounts. Foods and liquids should be high in protein and calories, bland, lukewarm, and to the patient's taste. Meals should be eaten slowly and food chewed thoroughly. Carbonated drinks and tea are tolerated better than other liquids but should be consumed 1 hour before or after meals, not with meals. It is best for the patient not to lie down for at least 2 hours after a meal. Caffeine and rich or fatty foods should be avoided. The patient's environment should be free of bothersome smells, sights, or sounds. If food odor is nauseating, consider serving cold meals. Chewing gum or sucking on hard or sour candy, candied ginger, or ice helps reduce nausea in some patients. Nursing care involves providing comfort measures and mouth care. If nausea strikes, breathing slowly and deeply through the mouth may prevent vomiting. The patient is monitored for dehydration and electrolyte imbalances when excessive vomiting occurs.

Diarrhea may occur from radiation to the abdomen, lower back, or pelvis. Many chemotherapy drugs cause diarrhea, because they affect the cells of the intestinal mucosa, causing inflammation. Treatment involves avoiding high-fiber foods that encourage rapid evacuation from the bowel and adding low-fiber foods such as bananas and cheese to the diet. Cleansing the rectal area and applying petroleum jelly, A&D ointment, or Desitin cream helps decrease discomfort and protects the skin from breakdown. The provider may prescribe a medication to decrease the number and frequency of bowel movements. The nurse must monitor the patient for signs of dehydration and electrolyte imbalance.

Constipation

Certain antineoplastic drugs, such as vincristine, vinblastine, and paclitaxel, cause constipation. Increasing fluids (as allowed), adding fiber to the diet, administering stool softeners and fiber laxatives, exercise, and monitoring vigilantly for the beginning signs of constipation are the usual measures taken. Suppositories or enemas may be necessary.

Cystitis

Cytoxan and ifosfamide may cause cystitis. The nurse monitors for hesitancy, urgency, and pain during urination. The urine is checked for cloudiness and signs of **hematuria** (blood in the urine). Fluids are increased to 2 to 3 L/day. The patient is encouraged to empty the bladder frequently. The antineoplastic drug is administered in the morning and/or early afternoon so that most of it can be flushed from the bladder before bedtime, which helps the patient sleep through the night.

Immunosuppression, Bone Marrow Suppression, and Infection

Suppression of the bone marrow is the major reason doses of chemotherapy must be limited. When the marrow is suppressed (that is, its cell production is slowed), few new erythrocytes, leukocytes, or platelets are produced. This reduction decreases oxygen-carrying power, and the patient experiences hypoxia and fatigue. Decreased platelets cause an increased risk of bleeding. A low leukocyte count means lower immune function and lower ability to fight infection.

All antineoplastic drugs cause some degree of bone marrow suppression, but some can cause

severe suppression. The amount of suppression is dose related. Severe suppression is a life-threatening side effect for the patient. The suppression usually is temporary, and improvement in bone marrow function occurs within weeks to months of completed therapy. The white blood cell (WBC) count is monitored; a count of less than $3000/\text{mm}^3$ indicates neutropenia. Filgrastim or sargramostim is given to raise the neutrophil count and the WBC count. Often, administration of these agents begins before the WBC count drops too low.

The anemia resulting from antineoplastic therapy places an increased workload on the heart and lungs as these organs attempt to oxygenate the body adequately. When the platelet count reaches a low of $50,000/\text{mm}^3$, any small injury can lead to an episode of prolonged bleeding. At $20,000/\text{mm}^3$, spontaneous bleeding that is difficult to control may occur. Therefore, at a count of $100,000/\text{mm}^3$, the next dose of chemotherapy is withheld. If the count is less than $50,000/\text{mm}^3$, bleeding precautions are observed (no invasive procedures), and if the count is less than 10,000 to $15,000/\text{mm}^3$, the patient is transfused.

The increased danger of infection is an indication to the nurse to become very attentive to good, frequent, and thorough hand hygiene and to maintain strict asepsis in all aspects of patient care. If the neutrophil count is below 500 mm^3 , follow the policy and procedures for protective isolation to prevent infection.

Patients with thrombocytopenia can take measures to help lower the risk of bleeding. An infusion of platelets may be administered if the count falls to $20,000/\text{mm}^3$. The patient must be handled gently. Using a lift sheet helps in turning and repositioning the patient. Needle sticks for injections, laboratory specimens, and intravenous line starts are kept to a minimum. The smallest gauge needle possible for the task should be used. Pressure is applied to the site for 5 to 10 minutes or until bleeding stops. All urine and stool should be tested for the presence of blood. Abdominal girth is measured daily to check for internal bleeding. Ice is applied to any area that is bumped or injured.

Patient Teaching

Cancer Treatment and Infection Prevention

- Wash your hands well with an antimicrobial soap or alcohol-based hand rub:
- Before eating
- After using the toilet
- After blowing your nose
- After handling items many people have handled, such as railings, money, shopping carts, library books, newspapers, and pieces of mail
- After touching a pet
- After spending time out in public
- Do not share personal care items (razor, toothbrush, toothpaste, washcloth, towels, deodorant, hand lotion, lipstick, etc.).
- Clean toothbrushes by running them through the dishwasher or soaking them in a bleach or hydrogen peroxide solution.

- Stay away from people with respiratory or other infections.
- Bathe daily if possible; use an antimicrobial soap.
- Examine the mouth daily for sores or white patches; perform mouth care frequently.
- Examine the skin, especially the feet, for signs of broken areas daily.
- Wash dishes, utensils, and items used in cooking in hot sudsy water or run them through a dishwasher.
- Drink only fresh, bottled water.
- Do not reuse drinking cups or glasses without washing them.
- Keep lips moist with lip balm or petroleum jelly to avoid cracking.
- Stay out of crowded places.
- Eat only canned or cooked foods.
- If leukocyte count is extremely low, maintain a low-bacteria diet by avoiding salads, raw fruits and vegetables, undercooked meat, pepper, or paprika.
- Do not handle garden flowers, plants, or earth.
- Do not clean out cat litter boxes or bird cages.
- Have someone else change the water in flower arrangements if they are allowed.
- Monitor temperature daily.
- Be careful not to nick or scratch the skin.
- Report the following signs of infection to the provider immediately:
 - Temperature over 100° F (38° C)
 - Persistent cough
 - Colored or foul-smelling drainage from wound or nose
 - Presence of a boil or abscess
 - Cloudy, foul-smelling urine or burning on urination

The diet is modified to avoid irritating foods. Stool softeners are given to keep the stool soft and to prevent the Valsalva maneuver that occurs with constipation. No rectal suppositories or enemas are given, and rectal temperatures are contraindicated.

Patient Teaching

Prevent Bleeding and Bruising in the Patient With a Low Platelet Count

- Use a soft toothbrush and brush lightly; do not floss.

- Use only an electric razor or depilatory for shaving.
- Prevent constipation by increasing fluid and roughage in the diet; take a stool softener if needed.
- Caution health care workers not to use a tourniquet to obtain blood specimens.
- Inform health care workers of normal blood pressure so that cuff is not pumped up excessively.
- Avoid nonprescription drugs that inhibit platelet function: aspirin, ibuprofen (Motrin, Advil), Alka-Seltzer. Check for salicylates that inhibit platelet function in all analgesic and cold medicines.
- Move around carefully to avoid bumping into things; avoid contact sports or any sport where falling is a risk.
- If a bump or injury occurs, apply ice to the area for 1 hour.
- Avoid tight, constricting clothing or shoes.
- Do not wear jewelry with sharp edges.
- Use ample lubrication for intercourse; avoid anal intercourse.
- Avoid blowing the nose or picking at it; if you must blow, blow gently without occluding either nostril.

Immunosuppression may be treated with CSFs, such as granulocyte-macrophage colony-stimulating factor (GM-CSF), granulocyte colony-stimulating factor (G-CSF), or in limited cases epoetin (EPO), to increase leukocytes, granulocytes, and erythrocytes. Granulocyte-stimulating factors are questionable for patients with a cancer of the blood-forming organs, such as leukemia (unless whole-body irradiation has occurred), because there is a possibility that more abnormal cells will be produced. Granulocyte-stimulating factors are used after total body irradiation for Hodgkin disease, acute lymphocytic lymphoma, and non-Hodgkin lymphoma. They are given after the BMT has been completed.

Think Critically

You came to work with a slightly scratchy throat and a drippy nose this morning. The charge nurse has assigned you to a cancer patient who has bone marrow suppression. What would you do in this situation?

Hyperuricemia

Antimetabolite drugs cause an increase in uric acid in the blood as cancer cells are destroyed. A high fluid intake helps prevent problems of the **hyperuricemia** (high uric acid in the blood) that occurs. Allopurinol may be prescribed at the beginning of therapy to decrease the incidence of gout caused by the hyperuricemia.

Fatigue

The fatigue that occurs from immunosuppression treatment itself requires an adjustment of lifestyle. Physically, the patient may feel tired and lack energy. She may find that she is impatient and irritable, and she may withdraw from her social environment. This decrease in activity may lead to a decline in function that is irreversible.

The nurse must instruct the patient about how to manage fatigue. Fatigue management includes avoiding unnecessary bed rest, maintaining a good balance between energy and activity, minimizing emotional distress, maintaining activities of daily living, using energy-saving devices, and prioritizing activities. Maintaining a good nutritional status with high protein intake will help keep up energy levels. Supplemental feedings between meals often are necessary to ensure

adequate calorie intake. Fluids should be increased to 3 L/day on day 3 of chemotherapy, unless contraindicated, to help flush the waste materials of killed cancer cells from the body and to decrease the toxicities of the antineoplastic drugs. Explain that fatigue is a normal result of cancer treatment, and that fatigue may continue for 2 to 3 months after completion of therapy. Light exercise such as walking tends to increase the energy level (Herrington & Dinh, 2015).

Alopecia

Hair loss (**alopecia**) resulting from chemotherapy is temporary. Occasionally, radiation therapy to the head causes permanent hair loss. Although some techniques—such as using ice caps or a tourniquet around the scalp during the administration of chemotherapy—have been somewhat effective, oncologists do not recommend them. The reduction of circulation of the drug to the area may prevent the killing of cancer cells that are harbored in the blood or lymph vessels in the scalp and head.

Hair regrowth begins about a month after chemotherapy ends. The patient must be told that the new hair may be different in texture and color from the original hair. Before hair loss occurs, the patient may choose a wig or head cover to wear until the hair is regrown. Some offices of the ACS have wigs available for loan that have been donated by former patients. Today it is popular to “sport” the baldness that results from treatment. Whatever your patient decides, help her understand that society supports her as a unique individual.

Pain

For many cancer patients, pain is a daily reality. Pain reduces appetite, limits activity, and interferes with sleep. Most cancer pain (90%) can be relieved or at least controlled by a combination of measures. Often, however, the pain of cancer is undertreated. [Chapter 7](#) discusses all the modalities to control patients' pain. Acupuncture has been validated as being useful to help control cancer pain (Paley et al, 2011). [Table 8-7](#) lists current oral and intravenous medications proven effective against cancer pain. By putting aside worries about addiction to opiates, believing the patient's reports of pain and what relieves it, and concentrating on humane treatment of cancer patients, the nurse can be the instrument for helping the patient achieve a pain-free or pain-controlled existence. Adjunctive medications used along with analgesics to help control cancer pain may include steroids, antidepressants, and antiseizure drugs and can be very effective. Pain should be reassessed 15 to 30 minutes after parenteral drug administration and 1 hour after oral drugs are given. Medication doses should be scheduled regularly and around the clock to maintain a therapeutic drug level to prevent pain recurrence.

 **Table 8-7**

Drugs Commonly Used to Treat Cancer Pain

DRUG	BRAND NAME	DURATION (hr)	DOSAGE (mg)	SIDE EFFECTS
Common Oral Pain Relievers: Mild to Moderate Intensity				
Acetaminophen	Tylenol	3-4	650	Hepatic
Aspirin	Many brands	3-5	550	GI
Codeine	Many brands	3-5	32	CNS, GI
Hydrocodone combination	Vicodin	3-4	5	CNS, GI
Ibuprofen	Motrin, Advil	3-5	400	GI
Ketoprofen	Orudis	5-7	50	GI
Naproxen	Naprosyn	2-8	250	GI
Oxycodone	Roxicodone	3-6	5	CNS, GI
Piroxicam	Feldene	24	20	GI
Propoxyphene	Darvon	4-6	65	CNS
DRUG	BRAND NAME	DURATION (hr)	PARENTERAL DOSE (mg)	ORAL DOSE (mg)
Common Opioid Pain Relievers: Moderate to Severe Intensity				
Morphine	Generic	4-5	2.5-10	10-30
Controlled-release morphine	MS Contin	6-12	—	15
Hydromorphone	Dilaudid	3-4	1-4	2-8
Fentanyl	Duragesic	1-2	0.1	0.025
Oxycodone	Roxicodone	4-6	—	5-15
Controlled-release oxycodone	OxyContin	12	—	10
Codeine sulfate	Generic	4-6	—	15-60

CNS, Central nervous system; GI, gastrointestinal.

Nonpharmacologic Interventions

Nonpharmacologic interventions are combined with oral, topical, and parenteral analgesia to achieve relief or good control of pain. Pain must be (1) assessed and documented regularly; (2)

discussed openly with family, and the reports of pain believed and understood; (3) addressed with options that are appropriate for the setting and for family; and (4) treated with interventions in a timely fashion. **The main factor in pain treatment is to continue to seek a combination of interventions or different treatments until the pain is under control.** The pain regimen used should be known to be effective for cancer pain. Pain control or relief greatly increases the quality of life for cancer patients.

Think Critically

The pain control regimen for an assigned cancer patient is not working well. Can you write a role-play situation that would show your classmates how you would interact with the provider to obtain better pain control for your patient?

Patients With Metastatic Disease

Some cancer patients experience metastasis. **Table 8-8** shows the most common locations for metastasis for major cancers. Treatment options are usually the same as for primary cancer. Nursing care becomes more complex as more body systems are affected. To rule out metastasis, the patient is periodically assessed by the provider, and bone scans are performed to detect metastasis to locations in the skeleton.

Table 8-8
Common Sites of Metastasis for Different Cancer Types

CANCER TYPE	SITES OF METASTASIS
Breast cancer	Bone* Lung* Liver Brain
Lung cancer	Brain* Bone Liver Lymph nodes Pancreas
Colorectal cancer	Liver* Lymph nodes Adjacent structures
Prostate cancer	Bone (especially spine and legs)* Pelvic nodes
Melanoma	Gastrointestinal tract Lymph nodes Lung Brain
Primary brain cancer	Central nervous system

*Most common site of metastasis for the specific malignant neoplasm.

From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 7, St. Louis, 2013, Elsevier.)

Fear and Ineffective Coping

A patient who is newly diagnosed with cancer faces enormous stress. **Knowledge about the disease, treatment options, and what will be experienced during each type of treatment greatly decreases fear in patients and families.** Knowing what to expect allows people to plan and feel confident that they will have some control over their experience. An assessment of the patient's and family's usual coping techniques is important in formulating the overall plan of care.

When a patient has been diagnosed with cancer, pay attention to the patient's partner. Give the partner enough knowledge to decrease anxiety, and the patient will be calmer. Be honest about the adverse effects of chemotherapy, immunotherapy, radiation therapy, and other treatments, but take a positive approach. Indicating that many patients feel a little nauseated with chemotherapy, but that there is medication that controls nausea very well, is better than telling the patient that there will not be any problems with the chemotherapy.

The nurse must consider psychosocial and spiritual care when working with a cancer patient, because the disease will affect every aspect of life in some way. The nurse's job is to be supportive, to assist the patient to use strengths in planning and fighting the disease, and to coordinate family strengths to support the patient to continue with daily life.

Speak with the patient and partner about sexual concerns. Intimacy is to be encouraged. Unless the patient is recovering from surgery, has pathologic fractures, or is severely immunosuppressed,

sexual intercourse should not be a serious problem. If sexual function has been altered by surgery or treatment, help the patient find other means of sexual expression and gratification.

Referral to a social worker may be needed to coordinate resources for treatment and care assistance. Care of the cancer patient is a collaborative process that involves many members of the health care team. Family, friends, community groups, and people with an interest are among the sources of support and encouragement that the cancer patient might need for self-care and to attain some level of independence and peace of mind.

Local chapters of the ACS and American Lung Association have a wide variety of services available to professionals and laypersons who are caring for cancer patients. These include an annotated bibliography of public, patient, and professional information and education materials, pamphlets and booklets, and audiovisual programs. Materials can be obtained by writing to or calling the nearest ACS division. There are more than 3000 local ACS unit offices in the United States and Puerto Rico.

Learning as much as possible about the particular kind of cancer advises the patient of available options. Knowledge of the latest and most effective treatments should be gained before making a decision about treatment. Contacting the NCI for the latest information is wise.

Throughout treatment, the patient should be actively seeking information. The patient must trust the provider and the hospital or treatment facility. Trust is not developed on the basis of someone else's recommendation alone. Encourage the patient to maintain a sense of humor and to look for a little pleasure and enjoyment in life on a daily basis to counteract the hours consumed by treatment.

Oncologic Emergencies®

An oncologic emergency can occur when a tumor grows so large it is compromising function of adjacent structures or when metabolic processes or normal coagulation processes are disrupted. There are six major oncologic emergencies:

1. *Tumor lysis syndrome*: Rapid release of by-products from cell destruction by cancer therapy; first sign is an elevated potassium level, which may cause renal failure, cardiac dysrhythmias, or asystole.
2. *Hypercalcemia*: Calcium level rises above 11 mg/dL because of bone deterioration and release of secretion of parathyroid hormone by a tumor.
3. *Disseminated intravascular coagulation (DIC)*: Caused by abnormal activation of clot formation, resulting in widespread blood clotting (consumptive coagulopathy) and organ damage, followed by depletion of platelets and blood coagulation factors. This results in excessive bleeding.
4. *Pericardial effusion and cardiac tamponade*: Invasion of cancer cells into the pericardial sac, causing fluid secretion into the sac.
5. *Spinal cord compression*: Related to metastatic tumor and bone collapse, causing impingement of the spinal cord.
6. *Superior vena cava syndrome*: Occurs in lung cancer when affected lymph nodes block circulation in the vena cava.

When these emergencies occur, immediate action must be taken to prevent severe injury or death.

Care for a Dying Cancer Patient

Psychological Process of Death

Although an increasing number of cancer patients are being cured, cancer is still the second leading cause of death in the United States. Sometimes cancer cannot be eliminated. It is estimated that 589,430 Americans died of cancer in 2014 ([ACS, 2015](#)). That amounts to 1600 patients who die of cancer every day. Oncology nurses need to understand the grief process and the process of death and dying, and they need to apply knowledge about these processes compassionately when caring for cancer patients.

Grieving

Elisabeth Kübler-Ross introduced the world to the stages of grief and dying when her landmark book, *On Death and Dying*, was published in 1969. Kübler-Ross suggested that people go through several predictable junctures as they learn to adapt to the processes of loss or impending death. Not everyone goes through all the stages, nor do people go through stages in any set order. These five stages may apply to the grieving process when a body function or part is lost (such as a lost breast from cancer), a loved one dies, or one's own death is approaching ([Box 8-5](#)).

Box 8-5

Kübler-Ross' Stages of Dying

Denial (This can't happen to me!)

Anger (Why *me*?)

Bargaining (Yes *me*, but ...)

Depression (It *is* me, I give up ...)

Acceptance (I'm ready ...)

Fear

The patient feels and expresses many powerful emotions as she grieves the loss of her life. Almost all dying patients face varying levels of fear ([Box 8-6](#)). Caregivers are almost never successful in directly making patients less afraid of death through talk. The nurse is most helpful to the patient in just "being there" for the patient and expressing caring. A nurse who is compassionate and soothing provides comfort and strength for the patient. In the same way, when a patient displays behavior that is upsetting to the family, the nurse can explain to the family that patients go through these stages and the behavior is not because the family has done something wrong. These are times that both the patient and family are in great need, and nursing support can be profoundly comforting.

Box 8-6

Common Fears of Dying Patients

Almost all dying patients face varying levels of fear, which may include fear of:

- The unknown
- Abandonment and loneliness
- Loss of relationships
- Loss of experiences in the future

- Dependency and loss of independence
- Pain

When nurses care for dying patients regularly, they cannot help but reflect on their own mortality. It is important to review one's beliefs about death and dying and reaffirm those beliefs. In this way, it is possible to support patients who may have their own beliefs about the mysteries of death. [Table 8-9](#) provides some common spiritual beliefs and practices.

Table 8-9
Spiritual Beliefs and Practices Regarding Death

EXISTENCE OF DEITY	END-OF-LIFE (EOL) RITUALS	AFTERLIFE?	SPECIAL BELIEFS SURROUNDING EOL
Christianity			
Roman Catholic			
One triune deity: Father, Son, and Holy Spirit	Last Rites ("Anointing of the Sick")	Soul goes to purgatory, followed by eternity in heaven or hell	Catholics may be cremated, but the cremains must be interred, not scattered or kept.
Protestant			
One triune deity: Father, Son, and Holy Spirit	No special rituals Minister may perform extreme unction	Consequences of actions on Earth dictate whether soul goes to heaven or hell, and it happens immediately after death	Beliefs vary among sects; in general, cremation and autopsies are allowed.
Judaism			
One God	<i>Halakhah</i> (contains accepted Jewish laws and customs of death and mourning)	Immortality of the soul; belief in afterlife among the Orthodox	Euthanasia, suicide, and assisted suicide are strictly forbidden. The body is never left alone until burial. Autopsy is discouraged. The body must not be cremated.
Buddhism			
No	Rituals to ensure that the consciousness leaves the body	Progression of the soul	Sick patients must not know they are dying.
Hinduism			
Multitudes of gods and goddesses—being of ultimate oneness	<i>Antyesti samskara</i> (death rites) The Hindu dies at home, if possible Family member chants a mantra at moment of death	Progression of the soul—cycles of rebirth	<i>Mahaprashtana</i> (a vision of a tunnel of light). Death is a blissful time. Excessive drugs are avoided. Body is cremated; only men go to cremation site.
Islam			
One God (Allah), powerful but unknowable	Family members or an Imam (clergy) read Koran and offer prayers	Another world after death	Dying person should face Mecca before and after death.
American Indian/Alaska Native			
Common concept is dual divinity: creator and mythical individual	May have Christian or aboriginal traditions May smoke ceremonial pipe	In general, no precise belief May believe in reincarnation, or progression to another world	Traditional natives object to incorporation of their religious beliefs into other spiritual paths or into commercial affairs.
African American			
Most believe in one deity	Important to incorporate prayer in coping with illness	Depends on actual religion, but most believe in an afterlife	More likely to request life-sustaining therapies. Spiritual beliefs incorporated into treatment. Provider is God's instrument.

Take a periodic inventory of your ability to provide care without "burnout." If you come to the point where you can only provide care in a detached and distant manner, you can no longer be supportive, compassionate, and understanding. When this happens, it is time to take a break or to move on and let others provide care for the dying patient.

Palliative Care

Patients are living longer with cancer than they have in the past. Extended time means steps must be taken to maintain as high a quality of life as possible for the dying cancer patient.

Palliative care, also called *comfort care*, is directed at meeting the needs of the dying patient by providing comfort while maintaining a high quality of life. Nurses who care for a dying patient have a unique opportunity to become an intimate part of the patient's life. The dying patient can be supported physically and emotionally, while the nurse maintains a professional role.

Whether assisting the patient in the hospital or at home, certain comfort measures are required. Palliative care requires a specialized body of knowledge and skill that can be difficult to obtain and maintain if the nurse is not routinely applying the skills. Clinical issues in both settings involve the following.

Anticipatory Guidance

The nurse can prepare the family and patient by anticipating the death to come: giving them guidance about physical changes, symptoms, complications that may arise, and decisions about possible hospice care. There are two stages of dying. In the **preactive phase**, patients know they are dying and exhibit this knowledge by withdrawing from social activities and attempting to put their affairs in order. This may take weeks or months. Patients often report seeing loved ones who have already died. They become restless, have slow wound healing, and begin to have dependent edema (swelling in extremities, or even the entire body). When patients enter the **active phase** of dying

(the final 2 to 3 days) they exhibit specific signs in breathing patterns and other body functions that indicate that death is imminent. Following are some active dying symptoms and associated nursing activities.

Terminal Hydration

A dying patient gradually reduces fluid intake. Dehydration can also increase as a result of the disease process. Also, a dry mouth and a feeling of thirst may be induced by the drugs being administered. The nurse must help educate the patient and family as to both the benefits and burdens of hydration. Many times, the course is for the patient to choose what to take, and also to be allowed to refuse further nourishment. This is termed *patient-endorsed intake*.

End-Stage Symptom Management

Many expected symptoms are related to metabolic changes at the end of life. The last few days of patient life have been studied extensively. Recognize these latter symptoms and either alleviate them or help explain them to the patient and family. Because comfort is the goal of palliative care, administering only oral medications is the preferred choice. However, this may not be possible as death draws near, and it is also the goal to allow a pain-free death. In some cases it may be possible to administer transdermal and/or rectal pain medications.

Pain.

Transdermal fentanyl has helped eliminate the burden of pain at the end of life. Sometimes this regimen is supplemented with rescue doses of morphine. Studies have shown that pain relief, either total or at least enough to make the pain tolerable, is possible 75% to 97% of the time.

Dyspnea.

When patients are near death, they often subjectively feel as if they cannot get enough air. It is difficult to determine what causes this feeling, but several measures can be taken. The patient can be placed in Fowler's position, activities reduced, and air temperature adjusted, and medications such as bronchodilators can be given. Morphine may be given to ease breathing. It is important for the nurse to remember that this feeling can be very frightening for both the patient and family members, and aggressive treatment to lessen discomfort is important.

Death rattle.

Noisy ventilation is heard when patients can no longer clear their throats of normal secretions. Family members are often alarmed and are afraid the patient will choke to death. In these cases, scopolamine or atropine, drugs that are known to reduce secretions, may be used to quiet the patient and quiet the breathing.

Delirium.

Dying patients may experience hallucinations and/or altered mental status. Nurses must first search for causes such as pain, positional discomfort, or bladder distention and address those physical problems. Next, the nurse should discuss the delirium with the patient's family and encourage the family to talk to the patient in quiet tones while remaining calm.

Nursing Resources

The palliative care nurse is an important element for the patient's and family's comfort during this transition. In September 2004, a certification examination for LPN/LVNs was launched by the National Board for Certification of Hospice and Palliative Nurses (NBCHPN). Detailed information is available by calling 1-888-519-9901 or visiting the NBCHPN website (see Online Resources).

Get Ready for the NCLEX® Examination!

Key Points

- Cancer cells begin growing as a result of a change in normal body cells, probably a mutation in their DNA.
- Malignant cells can spread to other areas of the body.
- Tumors are classified according to the organs or tissues in which they first develop.
- All cancer results from defects in the DNA of genes.
- Harmful agents that are carcinogenic exist in the environment.
- Some people may have a genetic predisposition to some types of cancer.
- Age, sex, and race are considered predisposing factors for certain types of cancers.
- Changing certain lifestyle characteristics, such as quitting smoking, maintaining normal weight, reducing alcohol usage, avoiding and limiting exposure to carcinogens, and eating a varied diet, can lower the risk of cancer.
- Cytology, biopsy, radiologic studies, and laboratory tests are common methods used to diagnose cancer.
- Tumor markers detect biochemical substances synthesized and released into the bloodstream by tumor cells and are used mainly to confirm a diagnosis or determine response to a cancer therapy.
- Treatment modes of therapy for malignancies may include surgery, radiation, chemotherapy, hormone therapy, immunotherapy, and gene therapy.
- Nurses must protect themselves from overexposure to radiation. One of the most important areas of the patient's body to protect from radiation is the skin.
- Antineoplastic chemotherapy drugs are effective at different times in the growth and replication phases of the tumor cell cycle.
- Many antineoplastic drugs can cause tissue damage on direct contact, so the nurse must take care to protect patients from extravasation and administer the drugs into veins that have good blood flow.
- Biologic response modifiers manipulate the immune system to stimulate or suppress activity. These drugs assist the body in destroying cancer cells with minimal effect on normal tissue.
- Bone marrow and stem cell transplantation are used to correct damage caused by chemotherapy or radiation.
- Nausea, vomiting, diarrhea, and constipation are common complaints of cancer patients and require vigilant care.
- Cancer treatment may suppress the patient's bone marrow, and the patient may develop thrombocytopenia, requiring therapy to be ceased for a period of time.
- The main factor in pain treatment is to continue to seek a combination of interventions or different treatments until the pain is under control.
- Many cancer patients and their families go through the five stages of grief that are recognized in patients experiencing loss.
- Palliative care is providing comfort for the dying patient and maintaining a high quality of life throughout the death process.

Review Questions for the NCLEX® Examination

1. There are two types of tumors: benign and malignant. A difference between the two types is:
 1. malignant cells have a nucleus that is small and regular in shape, whereas benign cells are large and irregular.
 2. malignant cells do not know when to stop multiplying, whereas benign cells have controlled patterns of reproduction and follow signals to stop.
 3. malignant cells do not invade adjacent tissue, whereas benign cells sometimes do.
 4. malignant cells reproduce exact copies, whereas benign cells become more disorganized with each succeeding generation.

NCLEX Client Need: Physiologic Integrity

2. A 40-year-old woman is scheduled for external radiation therapy for breast cancer. To help the patient cope with her illness and the effects of radiation therapy, what should the nurse help her to focus on? (*Select all that apply.*)
 1. Complying with scheduled radiation therapies
 2. Taking precautions on exposing other family members
 3. Protecting the skin by applying lotion
 4. Wearing snug-fitting clothing
 5. Understanding the therapeutic effects and side effects of the treatment

NCLEX Client Need: Psychosocial Integrity

3. The nurse reinforces patient instructions regarding neutropenic precautions. Important topics should include which of the following? (*Select all that apply.*)

1. Pregnancy
2. Diet restrictions
3. Hand hygiene
4. Social isolation

NCLEX Client Need: Safe and Effective Care Environment

4. Your patient will begin chemotherapy next week. Based on the understanding of the effects of chemotherapy, what patient education would be appropriate?

1. Advise the patient to use good birth control methods, because most chemotherapeutic agents are teratogenic.
2. Teach the patient that the toxicity associated with chemotherapy is most evident in cells that have a long life span, so the patient can expect to have continuous muscle aches while undergoing chemotherapy.
3. Most antineoplastic drugs produce most of the possible side effects, so expect to be very sick during the entire span of treatment. Show the patient how to take nausea medication as prevention.
4. Most therapeutics are excreted in the stool, so precautions should be taken.

NCLEX Client Need: Safe and Effective Care Environment

5. Pain is not unique to cancer but is a common occurrence in cancer patients. An important point to keep in mind when employing pain control efforts is to:

1. always try one type of intervention at a time and give it a chance to work before switching to a different intervention.
2. seek a combination of interventions to offer the best pain control.
3. try to avoid opioids to protect the patient from drug addiction.
4. refer the patient for psychological counseling if pain becomes an issue.

NCLEX Client Need: Physiologic Integrity

6. Before chemotherapy, a female patient expresses concerns regarding hair loss. She says that her partner will no longer love her because she will not be as attractive. An appropriate nursing problem statement would be:

1. Fear of rejection due to anticipated loss of hair.
2. Inability to cope with perceived loss of relationship.
3. Lack of power over effects of chemotherapy.
4. Deficient skin integrity related to hair loss.

NCLEX Client Need: Psychosocial Integrity

7. A terminally ill female patient reminiscing about the “good old days” becomes increasingly confused. She talks of seeing relatives who have died. Which nursing intervention(s) would be appropriate? (*Select all that apply.*)

1. Discuss the patient's behaviors with the family.
2. Force oral fluids.
3. Encourage the family to talk to the patient in quiet tones.
4. Promote a calm environment.
5. Apply physical restraints.

NCLEX Client Need: Physiologic Integrity

8. The family members attending to the needs of a dying patient express distress regarding the noisy breathing. An important nursing action would be to:

1. increase pain medications.
2. administer atropine.
3. reassure family members.
4. consult a priest or a minister.

NCLEX Client Need: Psychosocial Integrity

9. A patient is scheduled for bone marrow biopsy to confirm the diagnosis of leukemia. As the

nurse reinforces provider instructions regarding the procedure, an appropriate nursing statement regarding bone marrow biopsy would be:

1. "It is performed in the operating room."
2. "It is a painless procedure."
3. "It introduces a needle to aspirate tissue samples."
4. "It requires a surgical incision."

NCLEX Client Need: Physiologic Integrity

10. A patient who recently had chemotherapy for lung cancer complains of uncontrollable nausea and vomiting with accompanying loss of appetite. An appropriate problem statement would be:

1. Deficient coping ability
2. Deficient knowledge.
3. Anticipatory grieving.
4. Inadequate nutrition.

NCLEX Client Need: Physiologic Integrity

Critical Thinking Questions

Scenario A

An acquaintance tells you that she has had a mole on her back for several years and it appears to be getting larger and darker. She states she is worried about the fact that it is getting bigger, but says that she is scared to go to her provider. She does not have health insurance and is worried about paying for the visit.

1. What is your obligation as a nurse in encouraging this person to see a provider at once?
2. What suggestions could you make about obtaining a medical opinion without incurring a lot of expense?

Scenario B

Ms. Allen went to her provider for a regular physical checkup and was told that she had malignant cells in the cervical secretions obtained from her Pap test. She had a biopsy of the cervix, and this, too, proved to contain malignant cells. She was admitted to the hospital, Cesium-137 was implanted in the cervix, and Ms. Allen was kept in bed in a private room during the treatment.

1. If you were assigned to give morning care to this patient, what special precautions would you take to protect yourself from excessive radiation?
2. What would be some signs and symptoms that you would watch for to determine whether Ms. Allen is having either a local or a systemic reaction to radiation?

Scenario C

Mary is a 19-year-old college student receiving chemotherapy for Hodgkin disease.

1. Identify psychosocial problems you would expect Mary to have, and state the measures you would suggest to help her deal with them.

Scenario D

Alisha is a 40-year-old mother undergoing radiation therapy for ductal carcinoma of the breast. She has heard that acupuncture might help the xerostomia (dry mouth) that she is experiencing. She has tried mouthwashes and various toothpastes, but still has the problem, and her breath odor is interfering with her social life. She asks you for your opinion regarding acupuncture.

1. What should you tell Alisha about acupuncture and alternative approaches to this problem?
2. If you do not agree with complementary or integrative medicine, what is your obligation as a nurse in this situation?

CHAPTER 9

Chronic Illness and Rehabilitation

Objectives

Theory

1. Demonstrate understanding of relevant nursing issues for patients with chronic illness.
2. Examine and identify patients at risk for problems associated with immobility.
3. Describe the effect of immobility on each of the major systems of the body and identify how they are interrelated.
4. Explain the general goals for a resident in a long-term care facility and how to meet those goals.
5. Compare the role differences of LPN/LVNs in long-term care facilities with their role in acute care settings.
6. Describe the types of rehabilitation programs that might be found in a large city.
7. Apply the goals of rehabilitation to patients with varying levels of disability.
8. Identify the members of the rehabilitation team and the collaborative care-giving process and state the role of each.
9. Explain the differences in philosophy and attitude required in the home care setting and the hospital.

Clinical Practice

10. Choose specific interventions to assist a patient with a chronic illness who is home-bound and has issues of loneliness.
11. Discuss with the charge nurse the measures that are used for safety and fall prevention in a long-term care facility.
12. Observe a rehabilitation team conference to see how a collaborative care plan is created or updated.
13. From assessment data, identify areas of psychosocial need for a home care patient and his or her family.

KEY TERMS

- disability** (dīs-ă-BIL-ĕ-tē, p. 179)
handicap (HÄN-dĕ-kăp, p. 179)
hemiparesis (hĕm-ĕ-pă-RĒ-sĭs, p. 187)
impairment (ĭm-PÄR-mĕnt, p. 178)
orthostatic hypotension (ōr-thō-STĀT-ĕk hī-pō-TĒN-shŭn, p. 184)
rehabilitation (rē-hă-bil-ĕ-TĀ-shŭn, p. 188)

resilience (rī-zīl-yēns, p. 178)

sundowning (SŪN-doun-īng, p. 187)

Patients with chronic illnesses and disabilities are cared for in long-term care facilities, rehabilitation institutes, at home, at outpatient clinics, at rehabilitation agencies, and in providers' offices. When working with patients who have a chronic illness or who are disabled, nurses need to be skilled in providing care and comfort, promoting self-care for independent living, fostering quality of life, and promoting **resilience** (the ability to cope with events that affect the patient's well-being).

Chronic Illness

Chronic illness affects millions of people. Diabetes, hypertension, heart disease, cancer, neurologic disorders (such as multiple sclerosis and stroke), asthma, arthritis, back disorders, and musculoskeletal deformities (such as those from arthritis and osteoporosis) all require continuous care. Although many people with a chronic illness can lead an active and productive life, about 133 million people in the United States—45% of the population—have chronic illnesses or disabilities that interfere with normal function. A chronic illness, such as diabetes, can result in a physical impairment. For example, a lower limb is amputated as a result of diabetes every 30 seconds in the United States ([Partnership to Fight Chronic Disease, 2013](#)). People, and particularly older adults, may have more than one chronic illness, which makes treatment and care very complicated. The terms *impairment*, *disability*, and *handicap* are used in relation to patients who have a chronic illness. **Impairment** refers to dysfunction of a specific organ or body system. **Disability** indicates a difficulty in performing certain tasks because of impairment, and having a **handicap** means that there is a physical or mental defect or characteristic that prevents or restricts a person from participating in a normal life or limits the capacity to work; a handicap is usually related to a disability.

When chronic illness causes the loss of function, usual roles may be changed. The person may no longer be able to be the primary income provider or hold the positions in the workforce or community that formerly were held. Changes in the person's role affect the family as well. Daily patterns are altered to accommodate treatments and therapy and to cope with the problems of the disability. Sorrow is felt for all that has been lost. The patient may wonder, *Why did this happen to me?* Spiritual distress may be experienced as the person is faced with the limitations of the illness or disability that has occurred. Holistic care that addresses spiritual and psychosocial needs as well as physical needs is essential.

Patients with a chronic illness often feel powerless, especially during the phases of diagnosis and early treatment. Patients realize that the chronic illness will dictate much of their course in life, and that they have less control over what is happening to their body. Nurses can improve the patient's resilience. Support for the patient's usual coping techniques—and teaching new ways to cope—help the patient effectively deal with the illness and the changes in life patterns it brings. Be instrumental in instilling hope for a good quality of life and fostering resilience despite the illness ([Edward, 2013](#)).

Preventing the Hazards of Immobility

Patients are immobilized to varying degrees and for different amounts of time. A multiple-trauma patient may be on bed rest for several weeks. A patient with advanced multiple sclerosis may be able to move around only with a wheelchair. A patient who experiences great difficulty breathing from advanced lung disease or heart disease may have very little energy and thus may not move around much. Patients with a spinal cord injury or brain damage from a stroke may be immobile for the rest of their lives. Patients who have pain or who have arthritic joints that cause pain with movement also tend to be less mobile. Patients who have any disorder requiring bed rest are at risk. All of these patients are subject to the problems of immobility.

Evaluate each patient situation and determine whether the patient is at risk for problems related to immobility. **Even if the patient is going to be immobile for only a few days, measures should be taken to prevent secondary problems.** Patients with disorders causing immobility should be assessed for the degree of risk for the various problems of immobility, and interventions to prevent them should be initiated ([Box 9-1](#)). **Early effects of immobility include a decrease in muscle strength, generalized weakness, easy fatigue, joint stiffness, decreased coordination, abdominal distention, and various metabolic changes detectable by laboratory test.** [Table 9-1](#) presents the more severe problems with measures for prevention when lack of activity occurs for more than a few days.

Box 9-1

Disorders That May Cause Immobility

- Multiple sclerosis
- Stroke
- Spinal cord injury
- Lower extremity amputation
- Head injury
- Multiple trauma
- Fractures of the knee, leg, ankle, hip, pelvis, or spine
- Neuromuscular disorders: muscular dystrophy, amyotrophic lateral sclerosis, poliomyelitis, cerebral palsy, myasthenia gravis, etc.
- Congenital deformities
- Burns
- Advanced metastatic cancer
- Advanced stages of chronic disorders such as Parkinson disease, Alzheimer disease, or Huntington chorea
- Severe rheumatoid arthritis, osteoarthritis, and other forms of arthritis

Table 9-1
Prevention of the Common Hazards of Immobility

COMPLICATION	PREVENTION
Musculoskeletal	
Contractures	Range-of-motion exercises
Footdrop	Foot support while in bed, range-of-motion exercises, high-top tennis shoes
Osteoporosis	Range-of-motion exercises, ambulation if possible (walking)
Susceptibility to fractures	Weight-bearing exercises
Muscular atrophy	Passive or active range-of-motion exercises
Gastrointestinal	
Constipation	Increased activity level, Increased fluid and fiber intake
Cardiovascular	
Decreased cardiac output	Range-of-motion exercises
Increased venous stasis	Exercise, support hose or anti-embolism stockings
Thrombus formation	Exercise, support hose or anti-embolism stockings
Embolism	Avoidance of leg massage, low-molecular-weight heparin
Neurologic	
Disorientation	Sleep-wake schedule in accord with light-dark pattern, Reorientation (to person, place, and time), Control of sensory stimulation, Avoidance of sudden position changes, tilt table
Renal/Urinary	
Calculi	Decreased dietary calcium level, Increased fluid intake, Maintenance of acidic urine
Infection	Increased fluid intake, use intermittent catheterization instead of indwelling if possible
Respiratory	
Pneumonia	Frequent repositioning in wheelchair or bed, respiratory exercises

The prevention of problems related to immobility begins the moment a patient first becomes ill or injured. Preventive actions must continue as long as the patient needs health care. The systems of the body work together as a whole and lack of activity affects more than one system. The effects vary depending on the general health of the individual, his age, the degree of immobility, and the length of time of inactivity or bed rest. Lack of mobility may begin a cycle that leads to an ever-increasing loss of independence for the patient. As he becomes less able to move, the patient becomes more dependent, and as he becomes more dependent, he is less able to care for himself—which in turn leads to even more adverse effects from immobility. You can avoid the beginning of such a cycle by helping the patient maintain normal functioning of each body system to the highest degree possible ([Nursing Care Plan 9-1](#)).

Older Adult Care Points

Although a lot of older adults are active in their daily lives, many do not engage in daily exercise

activity. When immobilized, these patients quickly lose what strength and flexibility they had, because muscle fibers atrophy quickly. It is much more difficult for these patients to regain mobility.

Assess the patient daily, looking closely at each body system in which a problem related to immobility might occur. Know the signs and symptoms of each type of problem and understand how to intervene to decrease or prevent it. The assessment details and nursing care for each problem are discussed in the relevant chapters of this text.

Older Adult Care Points

Older adults are at greatly increased risk for problems of immobility because of the changes in the various body systems that normally occur with aging. Monitor closely for pressure sores, as well as hypostatic pneumonia, constipation, urinary problems, and inadequate nutritional intake resulting from anorexia. Attention to range-of-motion exercises is very important and often neglected.

Nursing Care Plan 9-1

Care of an Immobilized Resident

Scenario

Carl Sanders is an 83-year-old man with weakness and debilitation and who has several chronic diseases. He has been transferred to a long-term care facility after a hospitalization for pneumonia.

Problem Statement/Nursing Diagnosis

Altered mobility/*Impaired physical mobility related to weakness, debility, illness, and age.*

Supporting Assessment Data

Objective: Needs assistance to turn, reposition in the bed, or walk.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Resident will maintain present joint mobility.	Perform range-of-motion (ROM) on joints qid.	Regular ROM prevents frozen joints.	Active ROM done twice this shift.
Resident will perform active ROM of arms by discharge.	Assist to turn and reposition q2h.	Repositioning helps prevent pressure ulcers and hypostatic pneumonia.	Repositioned q2h.
	Place in high Fowler position for meals; assist to chair for lunch.		Up in chair for meals. Breath sounds clear on right side; slightly diminished in left base.

Problem Statement/Nursing Diagnosis

Altered skin integrity/*Impaired skin integrity related to immobility and pressure over left trochanter.*

Supporting Assessment Data

Subjective: "I can't move very much."

Objective: Too weak to reposition self; stage I pressure ulcer over left trochanter.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Resident will have no evidence of more pressure damage to skin.	Turn at least q2h and more frequently if possible.	Relieves pressure on dependent areas.	Position adjusted q1h.
	Use supports for positioning and cushioning for relief of pressure.	Prevents pressure ulcers and keeps body in good anatomic alignment.	On pressure relief mattress; pressure relief cushion in chair.
Stage I pressure ulcer will heal within 3 wk.	Keep reddened area clean and moist, with colloidal dressing in place; inspect every shift.	Cleanliness prevents infection. Clear film dressing seals in moisture while allowing inspection.	Clear dressing in place; reddening decreasing.
	Inspect all pressure points q4h.	Identifies skin problems.	Pressure points inspected q4h. No new reddened areas.
	Use turning sheet to turn patient.	Helps prevent shearing injuries from sliding resident on sheet.	Turning sheet used for turning.

Problem Statement/Nursing Diagnosis

Constipation/*Constipation related to immobility.*

Supporting Assessment Data

Subjective: "I feel constipated."

Objective: Only small amount of hard, dry stool passed once in last 4 days.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Resident will have normal bowel pattern by discharge.	Administer oil retention enema as ordered followed by suppository; monitor results.	Oil will soften stool. Suppository stimulates bowel movement.	Oil retention given; held for 20 min. Had large bowel movement (BM); suppository not needed.
	Assist to bedside commode after breakfast every day. Provide privacy.	Sitting on commode and privacy promote ease of BM.	Assisted to commode after enema. Privacy provided.
	Give stool softener daily as ordered.	Keeps stool soft.	Received stool softener.
	Increase fluids to 8 oz/hr while awake.	Keeps stool soft.	Took in at least 6 oz of fluid each hour; continue plan.
	Increase fiber in diet.	Adds bulk, helping to prevent constipation.	Ate a bran muffin at breakfast.
	Offer warm prune juice each morning.	Stimulates bowel and softens stool.	Warm prune juice taken before enema.

Problem Statement/Nursing Diagnosis

Potential for injury/*Risk for injury related to possible falls.*

Supporting Assessment Data

Objective: Unable to walk without falling; gets confused after dark and tries to get out of bed.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Resident will not sustain fall in hospital.	Place call light and personal items within reach. Answer call light promptly.	Helps prevent him from trying to get out of bed without assistance.	Call bell and personal items on bed and bedside table within reach.
	Place an alarm device on the bed.	Alerts staff to attempt to get out of bed without assistance.	Bed alarm in place and functioning.
	Frequently reinforce instructions not to get up without assistance.		Reinforced not to get up without assistance q2h.
	Assist to bedside commode and back to bed.	Prevents falling.	Assisted to bedside commode after enema.
	Keep low light on in room at night to decrease confusion.	Light helps maintain orientation to room.	Placed instruction on Computer Care Plan.
	Check on resident frequently; anticipate needs.	Anticipating needs helps keep resident from arising without assistance.	Checked on resident every hour during this shift.

Problem Statement/Nursing Diagnosis

Altered mobility/*Impaired mobility related to weakness and debility.*

Supporting Assessment Data

Subjective: "I've really been sick; I'm so weak."

Objective: Unable to stand alone or transfer to chair; Lungs just cleared of secretions; breathes shallowly.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Resident will perform breathing exercises q2h while awake.	Assist to sitting position for deep-breathing exercises, use of spriometer, and coughing q2h.	Lungs can expand better when thoracic cage is not against the mattress.	Assisted to sit up and perform deep breathing and coughing. Used spriometer q2h.
Lung fields will remain clear.	Encourage adequate fluid intake.	Keeps secretions more liquid and easier to expectorate.	Taking more fluid per hour (6 oz).
	Encourage to take deeper breaths during each commercial break when watching TV.	Aerates lower alveoli.	Encouraged to remember to take deep breaths during commercials on TV.
	Auscultate lungs each shift.	Detects changes in lungs.	Lungs clear on right side; slightly diminished sounds at left base.
	Turn q2h.	Helps prevent hypostatic pneumonia.	Turned q2h while in bed.
Patient will return to ambulation and other ADLs when possible	Assist to sit in chair.	Ambulation increases respiratory activity.	Short stays in chair, increasing as tolerated.
	Facilitate transfer training	Independence supports increased resilience.	Patient requires less assistance over time.
	Involve patient and family/caregiver in plan for progressive exercise	Involving patient and family increases resilience.	Patient increases activity as tolerated.

Problem Statement/Nursing Diagnosis

Potential for altered peripheral tissue perfusion; immobile for many days/*Risk for ineffective peripheral tissue perfusion related to venous stasis.*

Supporting Assessment Data

Subjective: "I've been mostly in bed for over a week."

Objective: Has been inactive and in bed most of the time for the past 10 days. History of previous thrombophlebitis in right leg.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Resident will not have evidence of thrombophlebitis or deep venous thrombosis.	Encourage active ROM of legs, feet, and ankles q2h while awake.	Muscle movement compresses blood vessels, propelling blood to the heart.	Performing active ROM of legs, feet, and ankles after breathing exercises q2h.
	Keep TED hose smoothly in place	Elastic hose place pressure on vessels,	TEDs reapplied after bath.

	except for 30 min while bathing.	encouraging venous return to the heart.	
	Encourage extra fluid intake.	Fluid prevents dehydration and hemoconcentration.	Offered fluid each time care provided.
	Assess for Homans sign once per shift.	Homans sign may indicate a thrombus (clot).	No positive Homans sign.
	Visually inspect legs for reddening or swelling.	Reddening, swelling, or pain may indicate a thrombus or thrombophlebitis.	No reddening or swelling of legs and ankles.

Problem Statement/Nursing Diagnosis

Potential for infection/*Risk for infection of the urinary tract related to immobility.*

Supporting Assessment Data

Subjective: "I've had several bladder infections in the past."

Objective: Has been immobile for 10 days; Urine is concentrated and slightly cloudy.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Resident will not develop a urinary tract infection.	Increase fluid intake to at least 3000 mL/day.	Promotes more urine flow.	Is increasing fluid intake this shift.
	Encourage fluid intake hourly until 2 hr before bedtime.		Offering fluids each time care is given (q1-2h).
	Assess for bladder distention q4h.	Helps determine whether bladder is being emptied sufficiently.	No bladder distention; voiding sufficient quantities.
	Observe characteristics of urine for signs of infection.	Cloudy, foul-smelling urine may indicate infection.	Urine is yellow, clear, and without foul odor.
	Measure intake and output.	Helps evaluate fluid intake.	Intake 1800 mL this shift. Output 1465 mL this shift.

Problem Statement/Nursing Diagnosis

Potential for social isolation/*Risk for social isolation related to lack of social interaction.*

Supporting Assessment Data

Subjective: "I'm really sick of being in bed."

Objective: Confined to bed most of time without visitors; Roommate is aphasic and cannot communicate verbally.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Resident will maintain social contact.	Bring phone to resident and assist to call family members and friends.	Phone calls maintain contact with family and friends.	Phoned wife this morning. Says will call friend later this evening.
	Ask volunteers to play cards with him.	Playing cards with another provides social interaction.	Requested volunteer to play cards for late afternoon.
	Visit his room frequently.	Stopping in room provides social contact.	In room q1h.
	Set up a schedule with family members for visits.	Spread out visits to help dispel loneliness.	Wife is trying to set up visiting schedule.

Critical Thinking Questions

1. What other psychosocial problems might this resident have?
2. Once he is stronger and able to walk with assistance, what measures could you take to help prevent him from falling?
3. What types of activities will help him to restore his muscle strength?

Chronic Illness and Rehabilitation Care

A chronic illness may develop after an acute illness or an accident. Some patients are transferred to a transitional unit or long-term care facility for a period of weeks for recovery after the most acute phase of illness or injury has passed. Many older adults who have several chronic problems and deficits in self-care enter long-term care facilities for the remainder of their lives. Other patients may enter a rehabilitation facility for an extended time. Some patients are discharged home to continue with rehabilitation services as an outpatient.

Long-Term Care

In long-term care facilities, an RN usually is the director of nurses. The RN supervisor manages the care for the entire facility on a 24-hour basis and delegates tasks to LPN/LVNs. An LPN/LVN often is the charge nurse, and certified nursing assistants (CNAs), patient care assistants, or restorative

aides provide much of the basic direct care to the residents. An occupational therapist, physical therapist, speech pathologist, respiratory therapist, activity therapist, or other professional provides services as needed. A physician or advanced practice nurse supervises each resident's care program. Although the RN ultimately is responsible for the nursing care plan of each resident, the LPN/LVN charge nurse often is the person who admits the resident and initiates the care under the direction of the RN. Collaboration with the RN is necessary to ensure that the plan is appropriate and complete. The LPN/LVN performs treatments, performs wound care, regularly assists with gathering assessment data from the residents, organizes the shift's workload, administers medications, documents assessment findings and care given, assists with updating the nursing care plans, and assigns care tasks to patient care assistants. The LPN/LVN oversees care for a group of residents for a shift. The LPN/LVN assigns tasks to the patient care assistants. Those tasks may include assistance with toileting, bathing, feeding, ambulation, or range-of-motion (ROM) exercises; care of the resident unit; and transfer of residents from bed to chair. Patient care assistants are the core caregivers of the long-term care facility. A skillful LPN/LVN will establish rapport, harmony, and respect among the work team by valuing these workers, appreciating their contributions, and listening to their concerns.

Assignment Considerations

Appropriate Assignments

When assigning tasks to unlicensed assistants ([CNAs], patient care assistants, restorative aides), you must know that the UAP has shown competence at performing the task. Competencies of assistive personnel should be documented in their personnel files. Evaluation of task competence must be done at least annually. Give specific directions about what you want the person to do, how it is to be done, and what needs to be reported to you. You are responsible for the care of any resident or patient assigned to you. Do not assign unlicensed personnel to perform tasks for unstable patients.

In 1987, the Omnibus Budget Reconciliation Act (OBRA) was signed into effect by then President Ronald Reagan. This was the first revision of the standards for Medicare and Medicaid since they were originally created in 1965. OBRA was enacted so that long-term care facilities must provide the type of care to nursing home residents that promotes and results in the highest level of wellness possible for each individual recipient ([Hawes et al, 1997](#)). This act requires that all skilled nursing facilities and nursing facilities use only CNAs.

When planning care for residents in a long-term care facility, the LPN/LVN must keep in mind that the overall goals of care for the facility are to provide a safe environment, assist the resident to maintain or attain as much function as possible, promote individual independence, and **allow the resident to maintain or achieve as much autonomy as possible**.

Safety.

One of the six priorities of the Affordable Care Act (ACA) is to make care safer by reducing harm caused in the delivery of care ([Camicia et al, 2013](#)). Providing a safe environment for a group of residents, who may not be totally mentally competent, while allowing autonomy and independence is a great challenge. Two of the greatest safety concerns are to keep confused residents within the boundaries of the facility and to prevent falls. Those with physical disabilities need extra measures to ensure safety. Those with chronic physical conditions are more likely to experience mental illness. National Patient Safety Goals (The [Joint Commission \[TJC\], 2014](#)) have been developed specifically for long-term care and rehabilitation facilities (Box 9-2).

Box 9-2

The Joint Commission's National Patient Safety Goals

The 2014 National Patient Safety Goals that specifically pertain to long-term care and rehabilitation facilities include the following:

- **Identify residents correctly.** Use at least two ways to identify residents. For example, use the resident's name and date of birth. This is done to make sure that each resident gets the correct medicine and treatment.
- **Use medicines safely.** Take extra care with residents who take medicines to thin their blood. Record and pass along correct information about a resident's medicines. Find out what medicines the resident is taking. Compare those medicines to new medicines given to the resident. Make sure the resident knows which medicines to take when they are at home. Tell the resident it is important to bring their up-to-date list of medicines every time they visit a doctor.
- **Use alarms safely.** Make improvements to ensure that alarms are heard and responded to promptly.
- **Prevent infection.** Use the hand cleaning guidelines from the Centers for Disease Control and Prevention or the World Health Organization. Use proven guidelines to prevent infection of the blood from central lines.
- **Prevent residents from falling.** Find out which residents are most likely to fall. For example, is the resident taking any medicines that might make him weak, dizzy, or sleepy? Take action to prevent falls for these residents.
- **Prevent bed sores.** Find out which residents are most likely to have bedsores. Take action to prevent bedsores in these patients. From time to time, recheck residents for bedsores.

From The Joint Commission: *National Patient Safety Goals: Long term care*, 2015. Retrieved from www.jointcommission.org/standards_information/npsgs.aspx.

Fall prevention.

The first step in the prevention of falls is to recognize which residents are at greatest risk (Box 9-3). All residents are assessed for the risk of a fall on admission and whenever their condition changes (Box 9-4). The next step to prevent a fall is to recognize hazards in the environment that could precipitate a fall (Box 9-5).

Box 9-3

Problems and Disorders That Increase the Risk of Falls

- Musculoskeletal disorders that impair normal ambulation or balance
- Neurologic problems, such as peripheral neuropathy, affecting the feet
- Balance or gait problems resulting from stroke or inner ear problems
- Postural hypotension or dizziness caused by medications
- Impaired vision
- Impaired hearing
- Extreme weakness
- Oxygen deficit that may cause dizziness and loss of balance
- A history of previous falls

Box 9-4

Fall Risk Assessment

Place a check mark in front of the items that apply to the patient.

General Information

- ___ Age over 70 years
- ___ History of falls*
- ___ Confusion at times
- ___ Confused most of the time*
- ___ Impaired memory or judgment
- ___ Unable to follow directions*
- ___ Needs assistance with elimination
- ___ Visual impairment
- ___ Feels physically weak*

Medications

- ___ Central nervous system suppressants (opioid, sedative, tranquilizer, hypnotic, antidepressant, psychotropic, anticonvulsant)
- ___ Medication that causes orthostatic hypotension (antihypertensive, diuretic)*
- ___ Medication that may cause diarrhea (cathartic)
- ___ Medication that may alter blood glucose levels (insulin, hypoglycemics)

Gait and Balance

- ___ Poor balance when standing*
- ___ Balance problems when walking*
- ___ Swaying, lurching, or slapping gait*
- ___ Unstable when making turns*
- ___ Needs assistive device (walker, cane, holds on to furniture)*

*A check mark on any starred item indicates a risk for falls. A combination of four or more of the unstarred items indicates a risk for falls.

From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, St. Louis, 2014, Saunders.

Box 9-5

Interventions to Help Prevent Falls

- Keep pathways free of objects.
- Remove loose rugs or secure with a nonslip pad.
- Place shoes and slippers underneath the bed or chair rather than in the pathway.
- Provide lighting without glare or deep shadows.

- Provide adequate night lighting for the pathway from the bed to the bathroom.
- Wipe up spilled liquids immediately.
- Keep wheels locked on all equipment when stationary.
- Place belongings within easy reach to prevent leaning from the bed or chair.
- Check to see that the call bell is within reach before leaving the room.
- Promptly answer call light to prevent the resident from arising without assistance.
- Encourage the use of supportive, sturdy footwear with nonslip soles for ambulation.
- Floor covering should not be slippery or highly patterned, and should be easily navigated when ambulating in common footwear or with assistive devices.
- Encourage residents to crouch down rather than bending over to pick up something, and to sit to dry the feet and pull on underwear and pants.
- Place grab bars by the toilet, in the bath or shower, along each set of stairs, and in the hallways.
- Provide chairs that are the proper height and depth to prevent “falling” into the chair or leaning far forward to arise from the chair.

Restorative programs focus on muscle strengthening and balance. Residents who are at risk for **orthostatic hypotension** (blood pressure that falls with position change from supine to sitting or standing) are taught ways to decrease the risk of falling. Be alert to the fact that a resident who was previously ambulating safely may be weakened if he has been recently sick with fever, urinary tract infection, flu, a cold, vomiting, or diarrhea. A resident who is receiving diuretic therapy must be assessed frequently for fluid and electrolyte imbalance that could cause weakness, dizziness, or confusion. Residents on diuretic therapy must receive prompt assistance for toileting when assistance is requested. A resident who needs opioid therapy for pain or sedatives to sleep must be safeguarded. Instruct the resident to ring for assistance should the need to arise from the bed or chair occur. The bed should be kept in the low position.

Safety Alert

Medication Assessment

Assess all medications a resident is taking to determine the risk of medication-induced postural hypotension or dizziness. Medications that cause dizziness are a common contributor to falls. Over-the-counter medications should be considered as well as prescription medications.

Think Critically

Can you describe how you would determine a new resident's risk for falls? Can you identify points that should be included in the assessment of a high risk for a fall?

Use of security devices and alternative measures.

When a resident frequently forgets instructions to call for assistance, repeatedly attempts to get up and falls, or interferes with medical treatment by pulling out ordered tubes or scratching at wounds, the use of security devices may be necessary. However, these devices should only be used when all else has failed. Research has provided strong evidence that restraints increase rather than decrease the risk for injury ([Hollins and Stubbs, 2011](#)). Chemical restraints are tranquilizers or sedatives that calm a resident and alter behavior. Physical and chemical restraint use is restricted by law and is applied only as a last resort for safety when a resident is a proven threat to self or others.

Legal and Ethical Considerations

Considering Restraints

Patient deaths have occurred from improperly applied restraints. Laws require that they be used only after all other measures have been tried—such as sitters, family at the bedside, alarms, or distractions—and these other measures have failed. Documentation must be thorough, indicating specific alternative measures that have been tried and have failed. Document the time the restraint is applied, the condition of the patient at that time, interim assessments, the time the restraint is removed, and the condition of the patient at the time when the restraint is removed.

The purpose of such statutes is to ensure that restraints are used to protect residents, not to hinder their movements for the staff's convenience. Alternative measures are always tried first (Box 9-6). When a security device is used, the least restrictive device is chosen. A variety of techniques help provide a restraint-free, yet safe, environment. **All security devices must only be used as a last resort and must be ordered by a provider.** If a qualified, licensed nurse determines the need for a chemical or physical security device in an emergency, the need is specifically documented when the security device is applied. A provider's order for the security device must be written within 24 to 48 hours. Box 9-7 presents the principles related to the use of security and safety devices.

Box 9-6

Measures Helpful to Prevent the Need for Security Devices

- Explore what may be upsetting the resident and causing agitation.
- Place a restless or high-risk resident in a room or location close to the nurses' station where he can be checked frequently and attempts to get up will be most likely observed.
- Reorient an acutely confused resident as frequently as possible.
- Use validation to reaffirm the feelings and concerns of a resident with dementia.
- Provide distraction activities that keep the resident busy; give the person a "job" to do.
- If a resident is agitated, turn off the television and provide soft, soothing music.
- Provide familiar and cherished items that the resident can handle.
- Ask a family member to stay with the resident.
- Use a bed or chair alarm to alert nursing staff that the resident is attempting to get out of bed or chair unassisted.
- Remain with unsteady, agitated, or confused residents when they are up and about.
- Leave another person in charge of your residents when leaving the unit for a meal break or other reason; specifically mention which residents need to be visually checked frequently.
- If a resident needs to get up at night frequently to urinate and does not call for assistance, restrict fluid intake after 6 P.M. if appropriate.
- Provide social and diversional activities to a resident confined to a wheelchair or bed so that boredom does not cause the person to try to get up and seek activity.
- Move the mattress onto a low platform or the floor so that it is easier for the resident to get in and

out of bed without the risk of a fall.

Box 9-7

Principles Related to the Use of Security and Safety Devices

- The use of safety or security devices must help the resident or be needed for the continuation of medical therapy.
- All devices that limit movement or immobilize must be ordered by a provider.
- Use the least amount of immobilization needed for the situation. For example, use mitts rather than wrist restraints if the resident cannot otherwise be prevented from pulling out tubes or lines.
- Apply the device snugly but not so tightly as to interfere with blood circulation or nerve function.
- If a security device is applied, check on the resident at least every 30 minutes. Assess for breathing, circulation, and possible nerve or skin impairment.
- An immobilization device must be removed and the resident's position changed at least every 2 hours. Active or passive exercises are performed for immobilized joints and muscles.
- Reassess need for the security measure every 4 to 8 hours.
- Meet needs for food, fluids, and toileting and assess these needs every 2 hours.
- Assess pain and comfort level and provide interventions as necessary.
- Document alternative measures taken and their success or failure. Document all pertinent data related to assessments when security devices are in place, when they were applied, and when removed.
- The provider should be notified as soon as the security device is deemed no longer necessary.

A resident who is immobilized with a security device must be checked visually at least every 30 minutes to ensure that the resident's body is in good alignment and that there are no problems. These checks must be documented. Whenever you are in the patient's room, check skin color for circulation in the affected body parts. Residents must be turned or repositioned every 2 hours. Thorough assessment of skin and circulation is done at that time. The restraint should be removed immediately after the risk has been reduced.

Managing confusion and disorientation.

For residents with mild confusion and disorientation, various techniques and measures are used to help maintain orientation. Reality orientation involves both the environment and the people who interact with the resident and should be an ongoing process. The environment is structured so that the resident has concrete and continual reminders of the year, day, and time of day. Environmental aids include a readable, up-to-date calendar, a clock, and the daily newspaper or local television or radio news ([Figure 9-1](#)).

FIGURE 9-1 Promoting reality orientation in the long-term care environment.

Consistency in mealtimes, scheduled activities, treatments, and daily personal care routine also can be helpful. Limit the number of choices to be made during these activities. A time schedule for activities and events within the facility should be posted in large type where the resident can refer to it frequently. Decorations for the next upcoming holiday give clues as to the current season of the year. Try to assign caregivers who are familiar to the resident, avoid placing the resident in unfamiliar situations, and limit visitors to one or two people at a time.

A positive and helpful approach is to respond continuously to the resident's confusion with honest and real information. Remember to assess the possibility of a physical cause for the confusion, such as urinary tract infection, constipation, dehydration, reduced oxygenation, or suboptimal pain control.

Nocturnal confusion (**sundowning**) occurs often among some older adult residents. Sensory deficits, such as impaired sight and hearing, add to the resident's confusion and anxiety at night when the environment becomes different because of darkness. A night-light that gives illumination without shining in the resident's eyes or causing frightening shadows can be used. Keep the call bell within reach and visit the resident frequently to calm and reassure. Moving the resident closer to the nurses' station, touching, and other signs of caring are all ways to intervene to minimize nocturnal confusion. A bed alarm that alerts staff when the resident attempts to get out of bed is helpful. Door alarms that announce when the resident has left his room or designated area may be used in place of security devices and prevent patients from wandering in unsafe areas. Keeping the resident active during the day and encouraging physical exercise helps promote sleep at night. **Listening to the resident to try to determine any possible cause of unrest or fear can often help solve the problem.**

Promoting independence.

The move to a long-term care facility is a major upheaval, particularly when it is for the remainder of the person's lifetime. Specific goals should be set with the resident to encourage independence in activities of daily living (ADLs) and in recreational activity. Perhaps a resident can pursue a former hobby, such as knitting or playing the piano, if such activities are available. Adaptive devices and a consultation with the dietitian may provide all the assistance that is necessary for self-feeding once again. Other adaptive devices can make daily living considerably easier (Table 9-2). To promote a resident's independence, staff members should refrain from doing tasks that the resident is capable of doing himself. For the resident who has had a stroke or suffers from debilitating arthritis or other musculoskeletal problem, use of adaptive devices can assist in the promotion of independence, provide some autonomy, and help to maintain function (Figure 9-2).

Clinical Cues

When residents understand that they have control of what happens, they maintain good adaptive skills. They are resilient and have the power to adjust and reduce stress. This helps resist adverse effects of chronic disease. **Activity theory** states that people will be happiest in direct proportion to how much activity they are able to maintain as they grow older. **Continuity theory** proposes that participation in activities and relationships that have been maintained over a long period of time contributes to a sense of well-being and allows a sense of integrity and continuity with the past. Finding out what activities have significant meaning for the resident, and seeing how those might be continued by making adaptations so that enjoyment in the activities is possible, can greatly enhance the quality of the resident's life and reduce the negative effects of chronic conditions.

Think Critically

Can you think of three ways to foster independence in a new, right-handed resident who is still quite weak, has suffered a stroke, and has right-sided **hemiparesis** (weakness)?

Table 9-2
Uses of Common Assistive-Adaptive Devices

DEVICE	USE
Buttonhook	Threaded through the buttonhole to enable patients with weak finger mobility to button shirts. Alternative uses include serving as a pencil holder.
Sock puller	Assists in putting on socks and compression stockings. Is placed in sock; then pulling on the strings pulls up the sock.
Extended shoe horn	Assists in putting on shoes for patients with decreased mobility. Alternative uses include turning light switches off or on while the patient is in a wheelchair.
Plate guard	Applied to a plate to assist patients with weak hand and arm mobility to feed themselves.
Gel pad	Placed under a plate or a glass to prevent dishes from slipping and moving. Alternative uses include placement under bathing and grooming items to prevent their movement.
Foam buildups	Applied to eating utensils to assist patients with weak hands to grasp and help feed themselves. Alternative uses include the application to pens and pencils to assist with writing, or over a buttonhook to assist with grasping the device.
Hook and loop fastener (Velcro) straps	Applied to utensils, a buttonhook, or a pencil to slip over the hand and provide a method of stabilizing the device when the patient's hand grasp is weak.
Long-handled reacher	Assists in obtaining items located on high shelves or at ground level for patients who are not able to change positions easily.
Elastic shoelaces or Velcro shoe closure	Prevents the need for tying shoes.

Adapted from Ignatavicius DD, Workman ML: *Medical-surgical nursing: Critical thinking for collaborative care*, ed. 6, St. Louis, 2010, Saunders.

FIGURE 9-2 Adaptive devices to promote independence in eating.

Maintaining function.

Once a functional assessment has been completed, specific goals should be written to maintain the highest level of function possible for the resident. If the resident is ambulatory, exercise should be planned and encouraged on a daily basis. If the resident is not ambulatory, ROM exercises should be performed several times a day. Measures to promote continued bowel and bladder continence are essential. Assessing patterns of elimination and providing assistance for toileting as needed is a basic part of promoting continued function and protecting the resident's dignity. If the resident has been temporarily incontinent because of illness or surgery, a bowel or bladder retraining program is appropriate. Chapters 28 and 33 discuss such programs.

Mental stimulation is essential to maintaining a high level of cognitive functioning. Although resident preference and values should be considered in group television viewing areas, the staff should consider working with the residents to plan segments of time to turn on informational programs that are interesting. Scientific shows, travel shows, public television specials, and similar programs can stimulate thinking and encourage the sharing of thoughts on a variety of subjects. Assisting residents to work crossword puzzles is another way to help them keep an active mind. When a resident cannot write or read because of poor vision, group work on a puzzle is an option. Card games promote mental stimulation as well as social interaction. Group activities such as bingo, group singing, holiday celebrations, and entertainment acts provide socialization and stimulation. Continuing interest in lifelong activities is a factor in successful aging for many.

Documentation.

Documentation in a long-term care facility is somewhat different from documentation in the hospital or in home care. For long-term care documentation, an admission assessment and an extensive 38-page Minimum^E Data Set (MDS) form that is required by the federal government are filled out. Bowel and bladder training assessment forms and training program forms, weekly pressure ulcer reports, and 24-hour intake and output records are some of the other documentation forms used in the long-term care facility.

Rehabilitation

Rehabilitation is the process whereby a disabled person is helped to achieve optimal function. A primary goal of rehabilitation is to minimize the deficit from the condition and maximize the abilities that are intact. It involves measures to achieve the highest possible levels of physical, emotional, psychological, and social function and well-being. Vocational rehabilitation is job retraining for the disabled under the Americans with Disabilities Act (ADA) to provide a means of contributing to self-support. Rehabilitation is concerned with achieving a better quality of life. Most patients who require rehabilitation services are disabled as a result of a chronic illness. Others have become disabled from trauma incurred during an accident. Several of the objectives for *Healthy People 2020* are rehabilitation oriented. 

Each year about 8000 spinal cord injuries occur in the United States, and nearly 1 in 50 Americans live with paralysis ([Christopher & Dana Reeve Foundation, 2014](#)). One out of four of the more than 2 million people who suffer head injuries annually have residual deficits. Another objective of *Healthy People 2020* is to reduce the incidence of secondary disabilities associated with injuries of the head and spinal cord. The average age of those who report being paralyzed from spinal cord injury is 42 years. As the population ages, more people suffer heart attacks and strokes, which often leaves them with residual deficits. The need for rehabilitation services will continue to grow rapidly.

Rehabilitation Programs

Rehabilitation services are offered in freestanding rehabilitation hospitals, in general hospitals, and in skilled nursing homes where the patients stay for a few weeks.

Patients who have had a hip replacement often are placed in a skilled nursing facility for rehabilitation before returning home. Many communities have a hospital with an outpatient rehabilitation program for patients with cardiac and respiratory problems. Rehabilitation services are scarce in rural areas, and patients who have suffered neurologic injury or loss of musculoskeletal function as a result of amputation, trauma, or disease often have to go to a rehabilitation center far from home. Programs within large cities are often available for vision or hearing rehabilitation. Community centers often have rehabilitation programs with water exercise for patients with severe arthritis. Most burn centers have comprehensive rehabilitation programs available for burn patients. Rehabilitation programs have a philosophy that is based on three beliefs:

1. Each person is unique, whole within himself, and interdependent with his own environment.
2. Independence can be achieved within the limits of disability when the person is a full participant in managing his own life.
3. The goal is to enable patients to mobilize their own resources, choose goals, and attain them through their own efforts.

Rehabilitation involves a team effort directed at holistic care and involves a variety of disciplines.

Older Adult Care Points

An older adult patient who has suffered a major loss of body function may not be initially receptive to rehabilitation efforts. It takes a skillful nurse to help motivate the patient to want to improve his functional ability. Sometimes introducing the patient to someone close to his own age who has been through a similar illness and has managed to regain some functions is the best "medicine." Gentle encouragement with praise for small efforts and accomplishments is better than trying to force the patient to perform exercises or practice tasks.

A pulmonary (respiratory) rehabilitation program, or PR, teaches self-care techniques to the patient that will help him attain a better quality of life. There are generally three components to a PR program:

1. Breathing exercises
2. Paced walking exercise
3. Correct use of inhaled medications

These components are usually mixed with medical therapy and may also include nutritional counseling, energy conserving techniques, and psychological counseling or group support. Patients are enrolled in the program for a number of weeks and interact with other patients who have the same problems. A nurse or respiratory therapist teaches the various breathing techniques, paced walking, and use of inhalers. The nurse conducts motivational group activities to increase the desire to participate in an exercise program and to display the benefits of following the program. Teaching how to avoid respiratory infections is reinforced. The nurse or respiratory therapist is available to encourage the patient and, while he is exercising, to evaluate the patient's progress in using the techniques taught. Vital signs are monitored periodically to determine the effect of exercise on cardiac and respiratory function. Some rehabilitation centers provide respiratory services that wean the patient from the ventilator and then work with him to improve respiratory function and functional capacity for ADLs.

Cardiac rehabilitation programs are usually outpatient based and consist of several components:

- Monitored exercise to increase strength and endurance and build collateral circulation to the heart
- Diet counseling and education to lower cholesterol, triglycerides, and body fat
- Medication counseling regarding the purpose, administration, and side effects of the prescribed medications
- Vital sign monitoring to determine the effect of exercise on the cardiovascular system
- Group sessions on stress reduction techniques
- Support group sessions for those experiencing depression or anxiety after surgery or a myocardial infarction

Such cardiac rehabilitation programs usually have a physician, nurses, physical therapist, dietitian, and psychologist or social worker on staff.

Rehabilitation after knee surgery and other musculoskeletal injuries is often performed on an outpatient basis. Either the physical therapist goes to the home or the patient travels to the physical therapy facility. Supervised exercise is performed to increase ROM, decrease pain, strengthen muscles, promote ambulation, and improve balance.

Patients with neurologic damage from a spinal cord or head injury may need to spend several months in a rehabilitation facility. Because of insurance limitations, inpatient treatment is not always possible. Rehabilitation efforts then need to be continued at home.

The Rehabilitation Team

Nurses who work with rehabilitation patients must be flexible and creative and recognize that the patient is the "captain" of the rehabilitation team. The nurse's function is to assist the patient to achieve an optimal state of wellness as **defined by the patient**. It is very important that nurses be nonjudgmental and not impose their own values and attitudes on their patients.

The rehabilitation nurse must be able to work collaboratively with other health team members. Besides the provider, occupational, physical, speech, cognitive, and recreational therapists; vocational counselors; and social workers are part of the team. The nurse assists in ensuring that the patient correctly performs exercises and activities as instructed by each therapist and reinforces their teaching. A collaborative or interdisciplinary care plan is followed so that each member of the team is aware of what treatment and education the patient is receiving. Both short- and long-term goals are set. This provides for continuity of interdisciplinary care, recognizing the critical importance of each discipline in promoting positive outcomes for the patient. Team conferences are scheduled regularly for members to collaborate on the patient's care and evaluate rehabilitation progress ([Figure 9-3](#)).

FIGURE 9-3 The rehabilitation team conferring about the patient's care.

The patient and family both undergo considerable stress during the rehabilitation period. Caregivers should assist the patient and family in developing positive coping techniques. A good sense of humor; gentle, firm people skills; patience; and the ability to provide solid encouragement are good tools for working with rehabilitation patients.

The philosophy of rehabilitation nursing is based on the recognition of the patient's need for independence. Learn to judge when the patient should be allowed to struggle to do something on his own, and learn to recognize when the patient's frustration is reaching a level at which assistance is needed.

Roles of the LPN/LVN in Rehabilitation

There are often two levels of LPN/LVNs employed in rehabilitation facilities depending on the individual state practice act and facility protocols. One is the LPN/LVN I, and the other is the LPN/LVN II with intravenous (IV) therapy and Functional Independence Measure (FIM) certification. The LPN/LVN I does all nursing activities except for assessments and IV infusion therapy. The LPN/LVN II performs the same functions as the LPN/LVN I plus the tasks involved with IV infusions. At least a year of medical-surgical experience is required for employment as a nurse in a rehabilitation facility. The LPN/LVN initiates and participates in updating the team plan of care in collaboration with the RN to meet the patient's needs. The LPN/LVN assists with patient and family education by supporting the outlined teaching plan and reinforcing teaching. Any barriers to patient or caregiver readiness to learn are reported by the LPN/LVN to the supervisor. Recommendations are made by the nurses to team members on how to facilitate patient and caregiver learning. Learning outcomes are evaluated and documented. The LPN/LVN is an active participant and facilitator of both structured and nonstructured learning experiences. Leadership functions of the LPN/LVN are to supervise the patient care assistants, the CNAs, and the nursing rehabilitation technicians. The LPN/LVN acts as a preceptor for unlicensed personnel as needed and appropriate. As a member of the team, the LPN/LVN carries out all normal patient care nursing duties and provides input and feedback to the team. When assigned to do so, the LPN/LVN carries out quality improvement activities.

❖Nursing Management

■ Assessment (Data Collection)

After obtaining a thorough history, a physical and psychosocial assessment are performed for each patient to establish a baseline; to determine physical limitations, ability to perform ADLs, and amount of assistance needed; and to identify present psychosocial difficulties.

A skin risk assessment and fall risk assessment are performed (see [Chapter 42](#) for the pressure ulcer risk assessment tool). Patients covered by Medicare will have data filled in on the section of the MDS pertinent to rehabilitation[®]. The patient's home environment is examined before discharge to determine whether physical features of the home, such as stairs, narrow doorways, or access to bathroom facilities, will present a problem. Questions about the neighborhood, such as the location

of shopping centers and types of transportation available, are asked. Inquiries about who does the grocery shopping, cooking, errands, and housework for the patient are made.

The patient's usual daily schedule and habits of everyday living are examined, including sleeping, waking, eating, elimination patterns, hygiene, grooming, sexual activity, working, and leisure activities. A **functional assessment** of how the patient's disability has affected his former usual patterns (Box 9-8) focuses on the patient's present ability to perform ADLs, such as toileting, bathing, dressing, grooming, and ambulating, as well as his ability to use the telephone, shop, prepare food, and perform housekeeping chores. Various assessment tools are used to determine the patient's ability to function. A common one, the Katz Index of Independence in Activities of Daily Living, helps evaluate how much assistance the patient needs for various activities. [e](#)

Focused Assessment

For the Rehabilitation Patient

After reviewing the patient's history, the following data are collected by asking pertinent questions regarding the function of each body system.

Cardiovascular

- Fatigue
- Chest pain
- Arrhythmia
- Fear of cardiac event

Respiratory

- Activity tolerance
- Shortness of breath
- Fear of not being able to breathe

Gastrointestinal/Nutrition

- Dysphagia
- Anorexia, nausea, vomiting
- Eating pattern; amount of oral intake
- Weight loss or gain
- Bowel status; change in stool
- Serum albumin levels

Urinary

- Urinary pattern
- Fluid intake
- Retention
- Self-catheterization status

- Urinalysis and/or culture

Neurologic

- Motor function
- Sensation
- Cognitive abilities
- Assistive devices

Musculoskeletal

- Muscle strength
- Range of motion
- Endurance
- Fall risk assessment
- Assistive devices
- Safety measures

Integumentary

- Skin condition
- Skin risk of breakdown
- Presence of lesions
- Measures to decrease risk of breakdown

Degree of Independence

- Functional Independence Measure (FIM) scores per certified personnel assessment
- Ability for ADLs (Katz assessment of Independence in Daily Living)

Psychosocial

- Alteration in roles
- Financial concerns
- Support people
- Self-concept status
- Coping mechanisms
- Sexual concerns
- Employment/educational concerns
- Family strain
- Home environment alterations needed

Medications

- Scheduled medications
- PRN (as-needed) medications

Safety

- All equipment in use checked for safety
- Risk assessments for falls and skin
- Prostheses applied correctly
- Adaptive equipment obtained

Box 9-8

Functional Independence Measure Scoring Categories

- Self-care
- Sphincter control
- Transfers
- Locomotion
- Communication
- Social cognition

A score of 0 or 1 is given in each category. Totaled scores indicate independent (6-7), modified dependence (3-5), or complete dependence (1-2).

The Baird Body Image Assessment Tool is often used to perform a psychosocial assessment, which includes evaluating self-esteem and body image. Use of defense mechanisms, level of anxiety, and usual coping techniques are explored. To ascertain the patient's response to loss, ask the patient to describe feelings related to the loss of a body part or body function. The patient's support systems and the family's coping abilities also are determined. As rehabilitation progresses, perform a vocational assessment so that the vocational counselor can assist the patient in finding appropriate training, education, or employment after discharge from the rehabilitation program.

Patients with life-changing illness or injury, those who have suffered major loss of body function or former roles, and those who have lost most of their independence and social contacts may suffer from anger and depression. Assessing mental outlook is an ongoing nursing function. Should several signs of severe depression become evident, consult with the provider. The patient must be kept safe. Determining suicide potential in the depressed patient is important. [Chapter 45](#) discusses assessment and intervention for depression and suicidal thought.

Sexual concerns should be addressed during the rehabilitation period. Help the patient identify problems and concerns and work to assist him in finding means for sexual expression and gratification. If you are not comfortable or knowledgeable in this role, an appropriate referral to a psychologist or sex therapist should be made.

Think Critically

Can you explain the difference between a physical assessment and a functional assessment?

Nursing Diagnosis

Problem statements appropriate for the patient undergoing rehabilitation are listed in [Box 9-9](#).

Individual nursing diagnoses may be chosen from the NANDA-I list (see inside back cover) based on the data collected.

Box 9-9

Problem Statements Common for Patients in Rehabilitation

- Altered physical mobility due to neuromuscular impairment, sensory-perceptual impairment, and/or pain
- Altered self-care due Self-Care Deficit specify to perceptual or cognitive impairment and/or neuromuscular impairment
- Potential for altered skin integrity due to alteration in sensation, mobility, or nutritional status
- Potential for injury due to musculoskeletal weakness or perceptual or cognitive impairment
- Altered urinary elimination due to neurologic dysfunction or trauma or disease affecting spinal nerves
- Constipation due to neurologic impairment or immobility
- Altered coping ability due to added stressors or situational crisis
- Altered family coping due to situational crisis and/or added stressors
- Altered home maintenance ability due to neuromuscular impairment or perceptual or cognitive impairment
- Insufficient knowledge for self-care and techniques for rehabilitation
- Altered body image due to loss of normal function or traumatic injury and/or scarring
- Altered sexual function due to neuromuscular impairment, pain, or impaired mobility

■ Planning

An interdisciplinary[®] plan of care is devised for each rehabilitation patient (see Evolve). Often there will be five or more health professionals involved. Periodic care conferences are essential for the members of the health care team to evaluate the progress of the patient, to share perceptions and ideas, and to revise the plan of care if it is not helping the patient to meet established expected outcomes. Depending on the situation, care conferences may occur once every 1 or 2 weeks or once a month. Both long-term and short-term goals will be set. Expected outcomes are written for each problem.

■ Implementation and Evaluation

Interventions are carried out in a manner that encourages the patient to do as much for himself as possible. Praise is given for even small accomplishments or attempts at self-care. When working with the patient, observe for excessive fatigue. Pace activities according to the patient's fatigue level. Physical and occupational therapists work closely with rehabilitation patients to help them adapt so they can perform ADLs ([Figure 9-4](#)). Speech therapists, activity therapists, and others will be involved in the implementation of the care plan. The patient will be kept very busy during rehabilitation.

FIGURE 9-4 Physical therapist working with a patient on ambulation and muscle strengthening.

Discharge planning is implemented from the time the patient enters rehabilitation. The family and patient will need resources within the community. Evaluation^② is performed by gathering data that show whether the goals and expected outcomes have been met.

Home Care

Most care in the community setting is given by home health and hospice agencies. Home health care is the preferred and most cost-effective method of health care delivery. Recent innovations in medical equipment have allowed more complex, high-technology care to be given at home. For the patient there are many benefits, both physically and psychologically. **The goal of home care is to keep the patient as well and independent as possible and enable him to live at home.** The LPN/LVN must have 1 year of experience working in an acute care facility before working in home care in most states.

For home care, the RN acts as case manager and coordinates the care of all of the health care providers involved in the patient's care. The RN is responsible for the plan of care and for seeing that care is delivered in an uninterrupted manner. This nurse must act as a liaison with the other care providers to see to it that all efforts effectively complement one another. The LPN/LVN may perform treatments, perform appropriate delegated duties of the RN, or provide care in the home on a daily shift basis.

Home care nursing can prevent a patient's expensive readmission to a hospital or entry into a long-term care facility. Home health care is family centered, and the family members are also responsible for the ongoing care of the patient. Home visits are made to intervene and see that the patient is provided comfort, that complications are prevented and health is improved, and to assist with rehabilitation (Figure 9-5). Because home health care is family centered, **the philosophy of the nurse must have a different focus. In the home care setting, the patient and family are in charge. The nurse is a guest in the home and acts as a consultant, coordinator of care, provider of skilled care, teacher, and advocate.**

FIGURE 9-5 Home health nurse changing a dressing.

In home care, the patient and family are seeking the nurse's services and must be treated as valued customers. You must learn to be nonjudgmental of the patient, the family, and the living arrangements. Together, the nurse, patient, and family set goals for care, and then establish the boundaries of the nurse's role. Should the living situation not be ideal, furnishings and equipment lacking, or the home dirty, establish trust with the patient and family before trying to accomplish major changes. Be sensitive to the patient and family's cultural values, financial resources, and specific ways of doing things and try not to impose your own views. Work together with the patient and family to improve home safety, and share knowledge of available resources. **A home care nurse must be very flexible and creative in teaching patients and families ways to accomplish care of the patient while abiding by the principles of asepsis and safety.**

Think Critically

You visit a patient in his home for the first time. The sink is full of dirty dishes and there are throw

rugs throughout the home. You recognize that the sink may be a reservoir for infection and the throw rugs are a risk for patient falls. What measures can you take without making the patient feel criticized?

A large percentage of the home care nurse's time with the patient is spent evaluating physical and psychosocial status, signs of complications, side effects of medications, and effects of therapy. Both the safety of the home and the quality of nutritional and basic care are evaluated. The nurse is able to gather considerable useful data for the provider. Much time is spent consulting with providers by phone, providing updates on the patient's condition, seeking new orders, and collaborating about care needs. Each visit includes a physical assessment of the identified problems and of nutritional, home safety, elimination, skin, and psychosocial status. All findings are documented, as are data indicating that home health nursing care is still needed. Between visits, the nurse may contact the patient or family to check on various aspects of care or to see whether there are any concerns. The patient and family may contact the agency or the nurse at any time, and such phone calls are encouraged.

Other functions of the home health nurse include performing wound care and dressing changes, organizing medications for scheduled administration, monitoring blood sugar levels, drawing blood samples for laboratory testing, giving injections or teaching injection technique, monitoring pain control, and monitoring enteral feedings. Teaching self-care and rehabilitation techniques and monitoring progress and compliance with treatment are primary nursing functions that help control health care costs and keep the patient from needing hospitalization. The home care nurse needs to be a strong advocate for the patient's needs and treatment.

The home care nurse provides considerable psychosocial care for the patient and family. Sometimes, the nurse is the only visitor the patient has. In this instance the nurse becomes a sort of friend, providing social interaction as well as needed health care. The nurse must become knowledgeable about negotiating the complex medical care system and obtaining supplies, medications, or services when the patient does not have money for them. A full knowledge of the community resources available to the patient is essential. Most home health agencies have lists of resources available. A medical social worker who has a liaison with the agency also can be of help. The hospital nurse stays out of financial concerns (except for referrals to the social worker) but must try to help the patient find remedies to financial problems so that stress will be reduced and energies can be directed at healing and techniques of self-care.

Think Critically

Can you explain how you would go about trying to obtain a shower chair for a patient who cannot afford to buy or rent one?

The LPN/LVN in Home Care

Generally an LPN/LVN working in home care is under the supervision of an RN case manager. The LPN/LVN may be providing "private-duty" services for an unconscious patient who needs skilled care such as tracheal suctioning or tube feedings, performing home visits to change dressings or monitor blood sugar levels, or possibly acting as an in-agency supervisor by coordinating home health aide visits and supervising their work. The role of the LPN/LVN in home care is growing. The family provides assistance with personal care, and a home health aide may visit a few times a week to bathe the patient and shampoo hair. Homemaking is provided by family members or by a homemaker aide. "Sitters" may be hired to attend to the patient's needs at night if the family is not able to provide this service.

Nursing care plans are formulated, considering 24-hour needs, in collaboration with the patient, the family or relatives, and all other health care providers. Case conferences are conducted regularly, even if the case manager does them on the telephone with the others involved in the patient's care. Medicare requires a case conference every 60 days when more than one discipline is involved in the patient's care.

The Family Caregiver

When a patient has considerable disability and cannot function independently, a family member

often becomes the main caregiver. Depending on the degree of dependence of the patient, the caregiver may have an overwhelming task in caring for the patient, maintaining the house, obtaining food and supplies, cooking, and coordinating therapy or provider appointments. The caregiver's usual life is disrupted, and social contacts are limited because of time constraints and fatigue. You must assess the caregiver's stress levels regularly.

Focused Assessment

Assessing Caregiver Stress

- What help do you have in caring for your spouse or relative?
- Are there more family members who might help out?
- What are your cultural values related to caregiving?
- Is your sleep often disturbed because you have to meet your spouse's or relative's needs?
- Do you feel strained with all your family and caregiving responsibilities?
- Have you been feeling edgy or irritable lately?
- Are you feeling overwhelmed?
- Do you feel you cannot leave your relative alone?
- Have you been having crying spells?
- Are you having difficulty making decisions?
- Do you find you have trouble keeping your mind on what you are doing?
- Are you having frequent headaches, backaches, or muscle or stomach pain?
- Do you have any social contact?

Some home care agencies have an assessment tool for this purpose. When caregiver stress is high, calling the agency social worker for a consultation can provide either more help for the caregiver, or a respite program that might provide the caregiver a few days of needed rest and relaxation. A respite program provides room, meals, and care for a patient while the caregiver is relieved of all responsibility.

Get Ready for the NCLEX® Examination!

Key Points

- Chronic illness interferes with normal function for about 43 million people in the United States.
- Hazards of immobility are numerous and can occur within just a few days for immobile patients.
- It is a nursing responsibility to prevent hazards of immobility.
- Older adults are especially prone to develop problems of immobility.
- LPN/LVNs often work as charge nurses in long-term care facilities.
- The LPN/LVN supervises the nursing assistants in long-term care facilities.
- Safety of residents is a primary goal in long-term care facilities.
- Much attention is directed to preventing resident falls.
- Security devices are only used to protect the resident, or others, and only as a last resort.
- Frequent assessment is essential when a security device is applied to a resident.
- Techniques to minimize confusion and disorientation are used consistently.
- Keeping the resident active during the day helps decrease nocturnal confusion.
- A goal of long-term care is to promote as much independence as possible for the resident.
- Long-term care facilities must help residents to maintain or regain function.
- Rehabilitation helps a disabled person to achieve optimal function.
- There are rehabilitation programs for patients with respiratory, heart, and musculoskeletal problems.
- Rehabilitation is a team effort of the patient and many health professionals.
- The nurse assists with determining rehabilitation needs.
- Rehabilitation is carried out with a collaborative plan of care.
- Home care agencies provide continuing care in the community.
- LPN/LVNs are supervised by the provider or an RN in the home care environment.
- In the home care setting, the patient and family are in charge; the nurse is a guest in the home.
- Home care nurses must be flexible and creative to accomplish needed care of the patient in the home.

Review Questions for the NCLEX® Examination

1. An 85-year-old diabetic man with a fractured hip has begun ambulating with a walker. He likes his independence, and the nurse is concerned that he may fall after having been immobile. The nurse instructs him to please call for assistance when he gets out of bed. What can the nurse do to help decrease his fall risk?

1. Make sure the patient knows how to use the call system and that

the call bell is within reach.

2. Place a bed alarm on the bed.
3. Instruct him that he can only walk during the day and must use a bed pan at night.
4. Place the patient in restraints when the nurse is not available.

NCLEX Client Need: Safe and Effective Care Environment

2. A 33-year-old man is admitted to the rehabilitation unit after a spinal cord injury from a motorcycle accident. What interventions can the nurse perform to optimize the man's resilience? (Select all that apply.)

1. Assist the patient in identifying strategies that he has used to problem-solve in the past.
2. Choose the patient's meals for him.
3. Refer the patient to a support group.
4. Help the patient bathe and dress.

NCLEX Client Need: Health Promotion and Maintenance

3. The nurse gives discharge instructions to an 80-year-old Asian woman who had open heart surgery. After detailing the importance of increasing activity, the patient smiles and nods her head. The nurse understands that the patient:

1. understood the instructions.
2. acknowledged the efforts of the nurse.
3. demonstrated enthusiasm with increasing activity.
4. may not understand the instructions.

NCLEX Client Need: Psychosocial Integrity

4. The nurse admits a 70-year-old woman who has diminished hearing and has bilateral cataracts. The patient is taking antihypertensive medications. A priority nursing problem would be:

1. *Potential for injury.*

2. Altered communication ability.

3. Insufficient Knowledge.

4. Altered Activity Tolerance.

NCLEX Client Need: Safety and Infection Control

5. The nurse provides discharge instructions regarding home safety to a 78-year-old woman. Which patient statement indicates a need for further teaching?

1. "Scatter rugs would be useful in decreasing glare from shiny floors."

2. "My favorite slippers can be stored underneath my bed."

3. "I need to have a handyman install grab bars in the bathroom."

4. "I need to be really careful when picking up something."

NCLEX Client Need: Safety and Infection Control

6. A 78-year-old woman is admitted with sudden onset of confusion and disorientation during the early evenings. Her family indicates that she is generally alert and oriented during the day. The nurse would likely recommend:

1. keeping soft lighting without shadows on during the evening.

2. promoting activity and physical exercise during the day.

3. encouraging napping during the day.

4. medicating with sleeping pills.

NCLEX Client Need: Health Promotion and Maintenance

7. After failure of less restrictive measures, the nurse decides to apply physical restraints to a confused older adult man. Which measure(s) must the nurse include to ensure safe use of physical restraints? (*Select all that apply.*)

1. Promptly attend to the toileting needs of the patient.

2. Reevaluate use of the restraints every shift.

3. Ensure adequate nutrition and hydration.

4. Administer scheduled doses of sedative-hypnotics.
5. Provide frequent range-of-motion exercises.

NCLEX Client Need: Safety and Infection Control

8. During a home visit, the nurse finds scatter rugs all over the house, the kitchen sink full of dirty dishes, a strong odor from the toilet, and several outdated food items in the pantry and refrigerator. The 76-year-old patient is coherent with occasional forgetfulness, disheveled with stained clothing, and generally ungroomed. A possible nursing problem would be:

1. *Moral ambiguity.*
2. *Powerlessness.*
3. *Altered self-care ability.*
4. *Altered nutrition.*

NCLEX Client Need: Safe and Effective Care Environment

9. The nurse suspects early complications of immobility in a 45-year-old patient admitted for multiple stab wounds to the chest. What sign would the nurse most likely find? (*Select all that apply.*)

1. Increased muscle strength
2. Generalized weakness
3. Moist breath sounds
4. Limited range of motion
5. Pain with repositioning

NCLEX Client Need: Physiologic Integrity

10. The nurse reinforces the use of an incentive spirometer to a patient with a blunt chest injury. Understanding of nursing instructions is clear when the patient:

1. exhales normally.
2. takes rapid, shallow breaths.
3. seals the mouthpiece during exhalation.
4. tilts the incentive spirometer.

NCLEX Client Need: Health Promotion and Maintenance

Critical Thinking Activities

Scenario A

Mr. Porter has been discharged home and transferred to a home health nursing agency for continued care after suffering a stroke that has left him with left-sided hemiplegia and dysphagia. His wife will be taking care of him, but she has severe arthritis and cannot perform many needed tasks. You are assigned to provide “private-duty” care to him, because he requires tube feedings.

1. What assessments would you make each day?
2. How would you collaborate with the case manager and the physical therapist?
3. How would you plan care for rehabilitation?
4. What would you teach Mr. Porter's wife about taking care of the equipment for his tube feeding?

Scenario B

Mrs. Robbins is a new resident in the long-term care facility where you work. She is mentally alert but needs assistance with bathing, dressing, and toileting because of arthritis and weakness and fatigue from heart failure. She can use a walker to ambulate short distances but does not like to do so.

1. How would you promote independence and autonomy for this resident?
2. How can you promote maintenance of function for her?
3. How would you promote socialization for Mrs. Robbins?

UNIT III

Immune System

OUTLINE

Chapter 10 The Immune and Lymphatic Systems

Chapter 11 Care of Patients With Immune and Lymphatic Disorders

CHAPTER 10

The Immune and Lymphatic Systems

Trena Rich

Objectives

Theory

1. Describe the body's innate (natural) immune response.
2. Compare and contrast the characteristics of innate and acquired immunity.
3. Describe the role of the lymphatic system in the immune response.
4. Identify the various ways in which immunity to disease occurs.
5. Analyze the factors that interfere with normal immune response.
6. Explain the role of immunizations in relation to immunity.
7. Compare and contrast the responsibilities of different members of the health care team in preventing infection in immunocompromised patients.

Clinical Practice

8. Identify assessments that indicate immune system function.
9. Describe precautions to be taken for patients with an impaired immune system.
10. Evaluate your patient's risk for infection during a clinical experience.

KEY TERMS

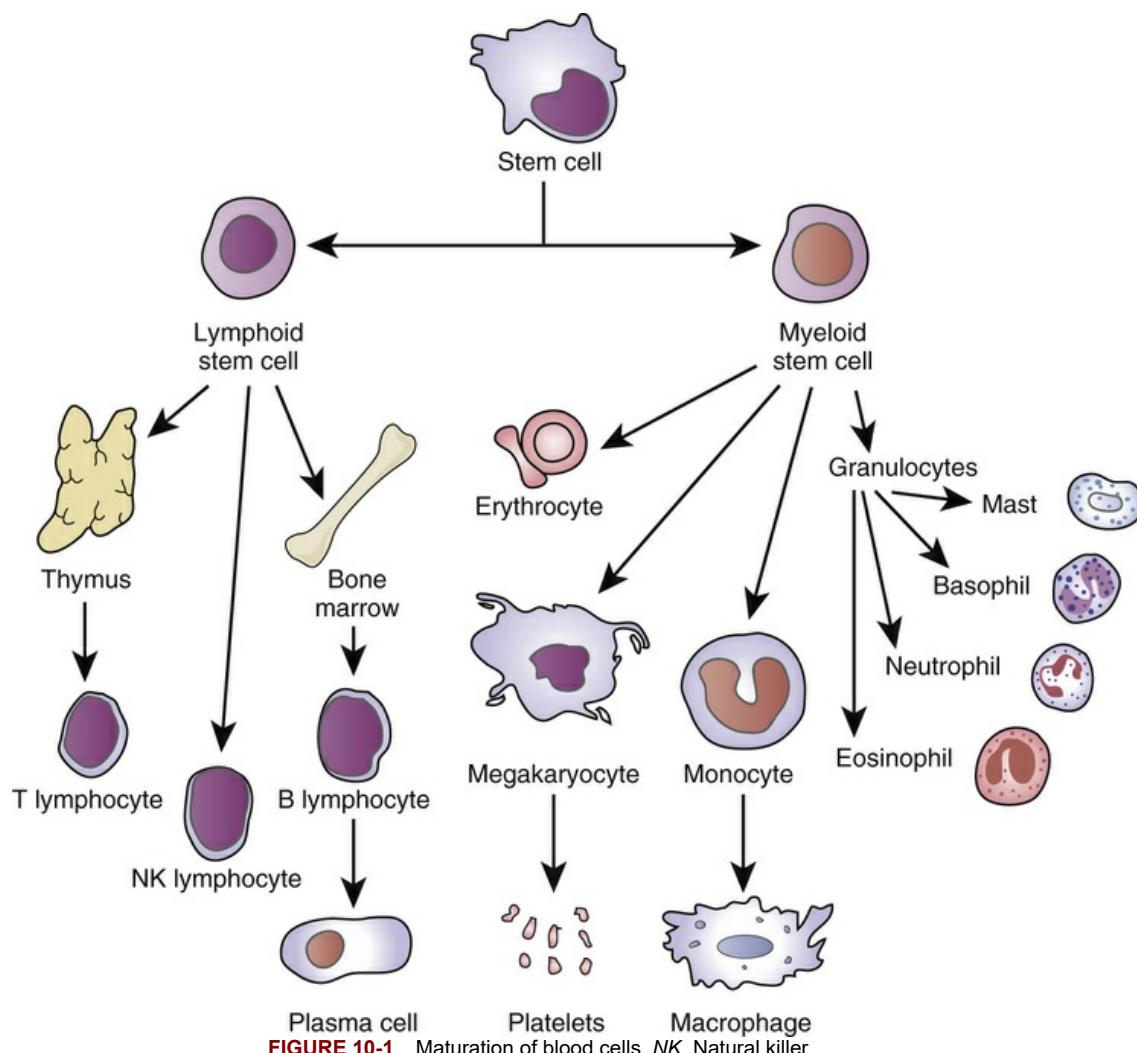

- acquired immunity (ă-KWĪRD ī-MŪ-nī-tē, p. 204)
antibodies (ĂN-tī-bō-dēz, p. 199)
antigens (ĂN-tī-jēnz, p. 200)
antigen-antibody response (ĂN-tī-jēn ĂN-tī-bō-dē rē-SPŌNS, p. 203)
antitoxin (ĂN-tī-tōk-sīn, p. 202)
autoimmune disease (ăw-tō-ă-MŪN dī-ZĒZ, p. 200)
autoimmunity (ăw-tō-ă-MŪN-ă-tē, p. 204)
cell-mediated immunity (SĒL MĒ-dē-ă-tēd ī-MŪ-nī-tē, p. 203)
complement system of proteins (PRŌ-tēnz, p. 203)
cytokines (Sī-tō-kīnz, p. 201)
homeostasis (hō-mē-ō-STĀ-sīs, p. 200)
humoral immunity (HŪ-mōr-ăl ī-MŪ-nī-tē, p. 202)
hyperpyrexia (hī-pēr-pī-RĒX-ē-ă, p. 213)
iatrogenic (ī-ăt-rō-JĒN-īk, p. 205)
immune deficiency (ī-MŪN dī-FISH-īn-sē, p. 200)

immunization (im-ū-ně-ZĀ-shūn, p. 206)
immunoglobulins (im-ū-nō-GLÖB-ū-līnz, p. 202)
immunosintigraphy (im-ū-nō-sěn-TIĞ-ră-fē, p. 211)
innate immunity (ř-NĀT ī-MŪ-ně-tē, p. 204)
lysis (Lī-sís, p. 202)
neutropenia (nū-trō-PĒ-ně-ă, p. 214)
passive immunity (PĀ-sív ī-MŪ-ně-tē, p. 204)
stromal cells (STRŌ-măl SĚLZ, p. 201)
toxin (TÖK-sěn, p. 202)

Anatomy and Physiology of the Immune and Lymphatic Systems

Organs and Structures

- Bone marrow produces a type of stem cell that is able to produce all types of blood cells (white blood cells [WBCs], red blood cells [RBCs], and platelets), which then **differentiate** (acquire individual characteristics) into the cells of the hematologic and immune systems (Figure 10-1). B lymphocytes are produced and mature in the bone marrow and play a significant role in the humoral immune response.

- The thymus gland, located behind the sternum (breastbone), is where T lymphocytes mature and are released into the bloodstream.
- Lymph nodes and vessels circulate fluid called *lymph*. It contains nutrients such as proteins, glucose, monocytes, and lymphocytes. Lymph nodes (Figure 10-2) are also where most lymphocytes are initially exposed to foreign antigens such as bacteria, fungi, and viruses.

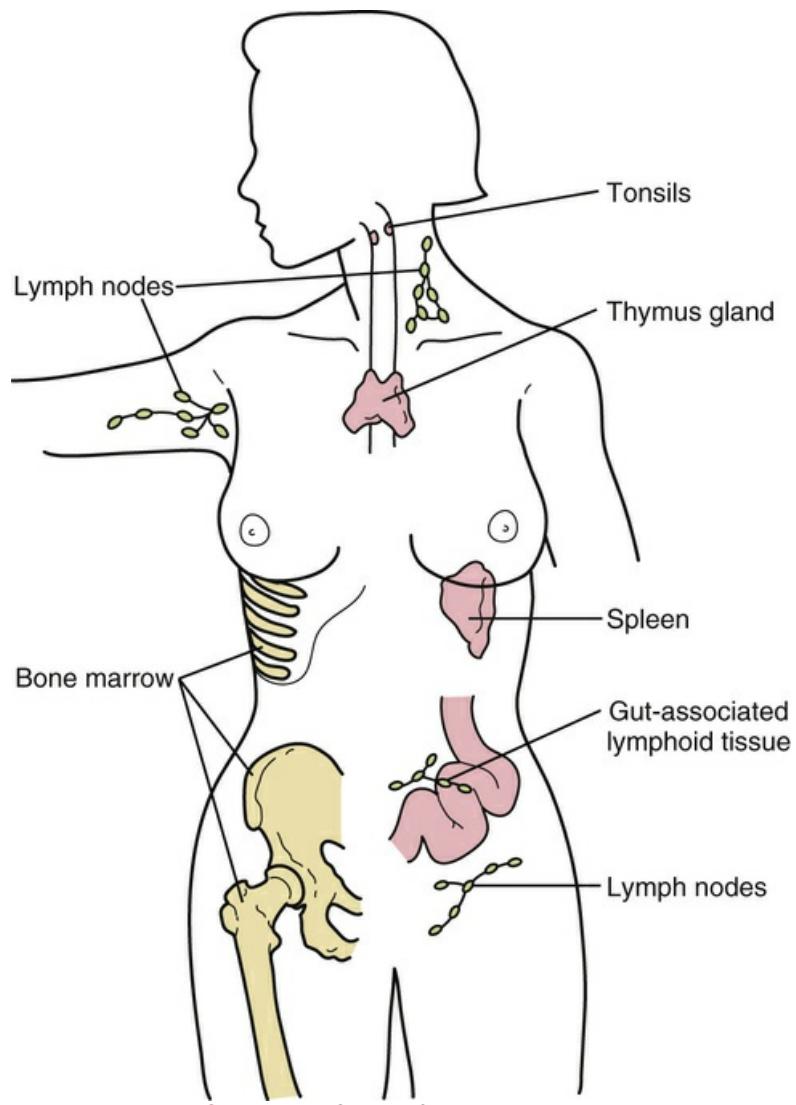

FIGURE 10-2 Organs of the immune system.

- The lymph vessels are located near the blood vessels and capillaries. The lymph system removes what is left over after the plasma has delivered nutrients to the cells.
- The lymph fluid drains into large veins, blending with the plasma circulating in the bloodstream.
- Tonsils and adenoids are lymph tissues that guard the airway from inhaled microbes.
- The spleen filters blood, which allows lymphocytes to come into contact with any circulating organism, thus activating the appropriate lymphocyte response. It also filters out damaged or old RBCs, recycling the hemoglobin in the production of bilirubin.
- Peyer patches are lymphoid tissue typically found in the ileum portion of the small bowel. These patches help defend against ingested pathogens.

Functions of the Immune and Lymphatic Systems

- The immune and lymphatic systems work together to guard the body against pathogens and to eliminate them if they manage to pass through external barriers.
- The neutrophils and macrophages of the hematologic system assist the immune system by phagocytosis when an antigen is encountered.
- Chemical mediators, plasma cells, and B and T lymphocytes play active roles in the immune response (Table 10-1).

Table 10-1

Major Components of the Immune System and Their Functions

COMPONENT	FUNCTION
Antigen	Foreign substance or component of cell that stimulates an immune response
Antibody	Specific protein produced in a humoral response to bind with an antigen
Autoantibody	Antibodies against a self antigen; attacks body's own tissues
Bone marrow	Source of stem cells, leukocytes, and maturation of B lymphocytes
Thymus	Gland located in the mediastinum, large in children, decreasing size in adults; site of maturation and proliferation of lymphocytes
Lymphatic tissue	Contains many lymphocytes; filters body fluids, removes foreign matter, part of immune response
Cells	
Neutrophils	White blood cells: for phagocytosis; nonspecific defense; active in inflammatory process
Basophils	White blood cells: bind immunoglobulin E; release histamine in anaphylaxis
Eosinophils	White blood cells: participate in allergic responses
Monocytes	White blood cells: migrate from the blood into tissues to become macrophages
Macrophages	Phagocytosis; process and present antigens to lymphocytes for the immune response
Mast cells	Release chemical mediators such as histamine in connective tissue
B lymphocytes	Humoral immunity-activating cell becomes an antibody-producing plasma cell or a B memory cell
Plasma cells	Develop from B lymphocytes and secrete specific antibodies
T lymphocytes	White blood cells: cell-mediated immunity
Cytotoxic or killer T cells	Destroy antigens, cancer cells, virus-infected cells
Memory T cells	Remember antigens and quickly stimulate immune response on re-exposure
Helper T cells	Activate B and T cells; control or limit specific immune response
Natural killer (NK) lymphocytes	Destroy foreign cells, virus-infected cells
Chemical Mediators	
Complement	Group of inactive proteins in the circulation that when activated stimulate the release of other chemical mediators, promoting inflammation, chemotaxis, and phagocytosis
Histamine	Released from mast cells and basophils, particularly in allergic reactions; causes vasodilation and increased vascular permeability or edema, contraction of bronchiolar smooth muscle, and pruritis
Kinins (e.g., bradykinin)	Cause vasodilation, increased permeability (edema), and pain
Prostaglandins	Group of lipids with varying effects; some cause inflammation, vasodilation, increased permeability, and pain
Leukotrienes	Group of lipids, derived from mast cells and basophils, that cause contraction of bronchiolar smooth muscle and have a role in development of inflammation
Cytokines (messengers)	Includes lymphokines, monokines, interferons, and interleukins; produced by macrophages and activated lymphocytes; stimulate activation and proliferation of B and T cells (communication between cells); involved in inflammation, fever, and leukocytosis
Chemotactic factors	Attract phagocytes to area of inflammation

From VanMeter KC, Hubert RJ: *Gould's pathophysiology for the health professions*, ed. 5, Philadelphia, 2013, Elsevier Saunders.

- Both humoral and cellular immunity are carried out by the lymphocytic cells, a specialized type of WBC that originates in the bone marrow.
- T lymphocytes, which provide cell-mediated immunity, pass through the thymus and migrate to the lymph tissues throughout the body.
- B lymphocytes migrate to lymphoid tissue, where they wait in readiness to form either sensitized lymphocytes or **antibodies** (immunoglobulins that identify and neutralize foreign objects).
- The lymph system, in addition to facilitating the work of lymphocytes, also drains tissue fluid and puts it back into the circulation.
- Innate (natural) immunity is nonspecific immunity that is in humans when they are born and makes them not susceptible to diseases of other species.
- Immunity can be acquired actively or passively.

Age in Relation to the Immune and Lymphatic Systems

- Neonates are susceptible to infection because they have an immature immune system.
- The thymus gland is largest during childhood and adolescence. After adolescence it begins to shrink in size, and its production of T lymphocytes decreases.
- Aging causes skin to become thin, less elastic, and more prone to injury. The skin is the first barrier encountered by pathogens.
- Decreased ciliary action in the respiratory system and gastrointestinal tract results in decreased removal of potentially harmful organisms.
- The presence of chronic diseases can decrease the immune response.

Protective Mechanisms of the Immune and Lymphatic Systems

The immune and lymphatic systems work together to defend against threats from multiple sources inside and outside of the body. Some portion of the lymphatic system is found in every part of the body with the exception of the central nervous system. The sensory nervous system interacts with the lymphatic system by helping to alert the body to outside physical threats by relaying chemical signals back to the brain. Internally, the blood and lymphatic systems are constantly protecting against microscopic threats to **homeostasis** (tendency to maintain internal stability and balance). The hematologic system interacts in the production of specialized WBCs that help fight infection and rid the body of foreign invaders. The primary job of the immune system is to protect the body from agents that can cause disease.

The human body has multiple protective mechanisms. The first line of defense begins with the skin, tears, earwax, mucous membranes, and urinary tract. They all provide external barriers to prevent foreign substances and microorganisms from entering the body. Innate immunity is present in the body even before exposure to any unknown antigen occurs. This means that the body has the ability to recognize certain microorganisms as harmful, even without prior encounters, and immediately lodge a defense. The tissue damage created by the invading microorganisms releases certain chemicals within the body. These chemical triggers, such as histamine, lead to the activation of the inflammatory response, which then causes the blood and lymphatic systems to deliver certain types of WBCs, lymphocytes, proteins, and other nutrients to the affected area.

Inflammatory Response

Trauma, pathogenic microorganisms, chemicals, or heat may cause injury to tissues inside and outside the body. The first step in the body's defense mechanisms against this invasion is inflammation or the inflammatory response (see [Chapter 6](#)). If the injury is close to the external surface of the body, there will likely be obvious redness and swelling, and the area may also be warm and tender to the touch. The delivery of select cells, proteins, and chemicals to the affected area increases blood flow to the site by dilating blood and lymphatic vessels upstream of the injury, resulting in warmth and redness. The same substances also affect downstream vessels, causing vasoconstriction and swelling. If the effects of swelling are not quickly controlled, the edema can compress nerve endings surrounding the area of injury, leading to a pain reaction.

The inflammatory response alone may be adequate in killing the invading organism by creating a hostile environment (see [Figure 6-2](#)). Protective proteins that are activated in the inflammatory response include the **complement system** of proteins. Several of these protein enzymes, when sequentially activated, form a membrane attack complex (MAC) that embeds itself into the cell membrane of the attacking microbe. This activation occurs when complement-binding sites are exposed on antibodies after they attach to antigens. This binding causes a break in the cell wall that allows ions, such as salt, to enter the cell. The salt is followed by water, which causes swelling and bursting of the microbe.

The same WBCs, lymphocytes, proteins, and chemicals respond to internal tissue injury. The results are not as readily visible but are detectable if appropriate assessments are conducted. The mechanisms of the inflammatory response combine with the immune response to eliminate foreign invaders ([Figure 10-3](#)).

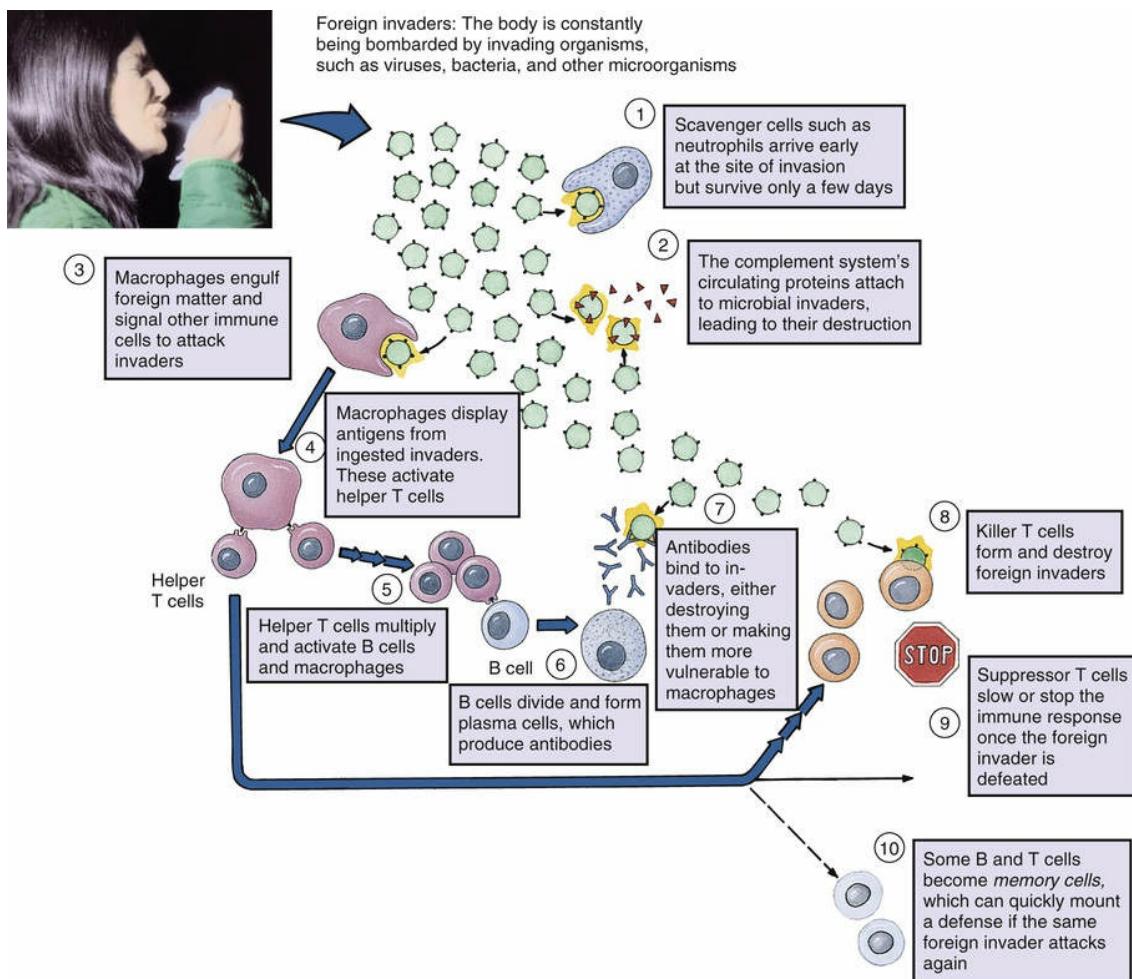

FIGURE 10-3 Action of the immune response against foreign invaders. (From Huether SE, McCance KL: *Understanding pathophysiology*, ed. 7, St. Louis, 2014, Mosby.)

Immune Response

The immune response is a remarkable series of complex chemical and mechanical activities that take place in the body. These activities involve (1) constant surveillance to detect the entry of foreign agents (**antigens**) as soon as they gain access to the body's cells, (2) immediate recognition of the agents as "nonself" (i.e., foreign or alien), and (3) the ability to distinguish one kind of foreign agent from another and to remember that particular agent if it appears in the body again at a later time. The lymphatic system, thymus, spleen, lymph nodes, bone marrow, and Peyer patches in the small intestine play a major role in the immune response (see Figure 10-2). As previously mentioned, many different cells, proteins, and chemicals assist in the body's defense against invading agents.

The immune response is usually triggered by the body's identification of something as foreign, or nonself. This recognition is essential for the body to respond to a foreign threat in an appropriate manner and to not react to tissues or cells that are typically recognized as "self." When an inappropriate response happens, one of two types of disorders occurs. If there is a lack of appropriate response, an **immune deficiency** is present. The second type of disorder occurs when the body produces an immune response to a self cell or tissue, causing an **autoimmune disease**. It is important to understand that although injury can activate a response by the immune system, massive trauma or chronic illness can also inhibit the ability of this vitally important system to respond effectively.

Types of Immunity

Once a particular kind of foreign substance has been detected and identified, the body responds in

two general ways. It immediately produces a protein (called an *antibody*) that is specifically designed to do battle with the *antigen*. The immediate response is called a *humoral response*. *Humoral* refers to any fluid or semifluid. There is also a delayed response that involves the use of sensitized lymphocytes to attack whole cells, such as those of bacteria, viruses, and malignant (cancer) cells. This second kind of response is called a *cellular* or *cell-mediated* response.

The cells that mediate the response are the T lymphocytes. Examples of antigens include bacteria, viruses, fungi, and other infectious microorganisms, as well as the toxins they produce as they invade the body. Nonliving matter such as pollen, dust, and chemicals can also be antigens. For some people, certain foods are perceived by the body as antigens and result in an adverse reaction, such as anaphylaxis, when the particular food is eaten.

T cells and B cells interact with each other in complex ways. T cells differentiate into different types of cells. For example, helper T cells stimulate B cells to produce antibodies against foreign antigens before the B cells can become plasma or memory cells. Large amounts of antibodies are secreted by plasma cells. The suppressor T cells regulate the amount of antibody that B cells produce. Both T cells and B cells are necessary for a normal immune response to occur. Acquired and inherited disorders can inhibit T- and B-cell activity.

Primary humoral response.

Lymphocytic B cells are involved in humoral immunity and the production of antibodies. They arise from stem cells in the bone marrow and undergo a maturation process that involves bone marrow **stromal cells** (cells that contribute to the development of multiple tissues and blood cells) and their **cytokines** (messenger hormones). When mature, the B cells migrate to the lymph nodes. When stimulated by an antigen, a B cell becomes a plasma cell that secretes antibody molecules into the bloodstream. B cells secrete immune globulins called antibodies in response to the specific antigen they encounter. This is antibody-mediated immunity, or **humoral immunity** (Figure 10-4). Some of the antigen-stimulated B cells become memory cells. This mechanism is the basis for acquired immunity. The memory cells reactivate the plasma cells to produce large quantities of the specific type of antibody needed to fight a particular type of antigen when the same antigen enters the body a second time. It is an immediate and potent response, and antibodies continue to be produced for many months.

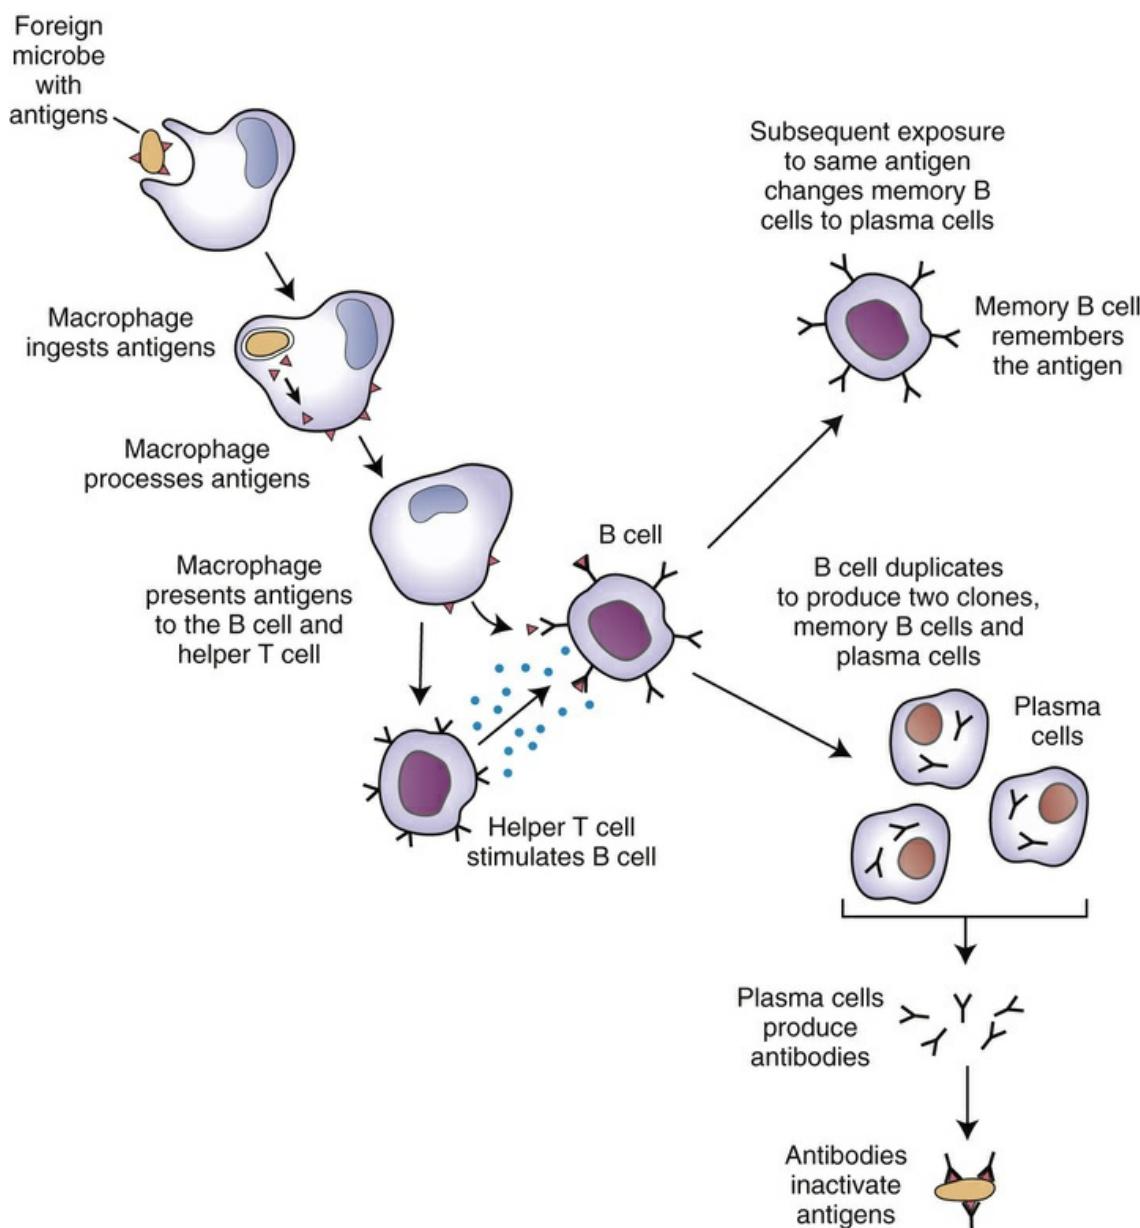

FIGURE 10-4 Humoral (antibody-mediated) immunity.

When the body is exposed to a harmful substance, the immune system produces antibodies, which are a type of protein synthesized by plasma cells. These antibodies are also called **immunoglobulins**. There are five classes of immune globulins (Ig): IgA, IgD, IgE, IgG, and IgM. Each immunoglobulin is able to attach to the kind of antigen for which it is made (Table 10-2). The antibody's ability to form a bond with its antigen is important to the destruction of the antigen, but it can sometimes result in damage to the body's own cells. Antibodies are found in the serum of blood and in other body fluids and tissues, including tears, saliva, breast milk, spinal fluid, interstitial fluid, lymph nodes, the spleen, and urine. An antibody can either destroy or inactivate its particular antigen by (1) mechanically harming it, (2) activating a complement system, or (3) causing the release of chemicals that affect the environment of the antigen.

Table 10-2
Immunoglobulins and Their Functions

CLASS	PERCENT OF TOTAL*	LOCATION	FUNCTION
IgG	75-85	Blood plasma	Major antibody in primary and secondary immune responses; activates complement system; inactivates antigen; neutralizes toxins; crosses placenta to provide immunity for newborn; responsible for Rh reactions
IgA	5-15	Tears, saliva, mucus, breast milk,	Protects mucous membranes on body surfaces; provides immunity for newborn; prevents antigens on food from

		gastrointestinal, pulmonary, prostatic, and vaginal fluids	being absorbed
IgM	5-10	Attached to B cells; released into plasma during immune response	First Ig to respond to microbial invasion; activates complement systems; causes antigens to clump together; responsible for transfusion reactions in the ABO blood typing system
IgD	0.2	Attached to B cells	Receptor sites for antigens on B cells; binding with antigen results in B-cell activation
IgE	0.5	Produced by plasma cells in mucous membranes and tonsils	Binds to mast cells and basophils, causing release of histamine; responsible for allergic reactions; helps fight off parasitic invasion

*Immunoglobulins.

From Applegate E: *The anatomy and physiology learning system*, ed. 4, Philadelphia, 2010, Elsevier Saunders.

Through a process called **lysis**, the antibody prepares the antigen for ingestion by damaging the outer membrane of the antigen's cell. The damaged cell then ruptures, making its contents accessible for digestion by phagocytes.

If the antigen is a **toxin** (poison) produced by a bacterial or viral cell, the antibody produced to fight it is called an **antitoxin**. This antitoxin is capable of neutralizing the poisonous chemical of the antigen by covering the antigenic agent. An antitoxin is therefore a specific type of antibody that acts through the process of **neutralization**.

When a bacterium or other antigen enters the body, it may encounter a B lymphocyte that is specific for that bacterium or antigen. The B lymphocyte becomes a plasma cell that secretes IgM (antibody), which attacks the bacterium or antigen. After the particular bacterium or antigen is encountered for the first time, it takes 4 to 8 days for the B lymphocyte to produce immune globulins that can attack. If the same bacterium or antigen enters the body again several months or even years later, the immune globulin response by the memory cells is much quicker and the invading cells are attacked much sooner, typically 1 to 2 days after a reexposure. The major function of the humoral **antigen-antibody response** is to provide protection against acute, rapidly developing bacterial and viral diseases. The antigen-antibody response is also involved in allergic and transfusion reactions.

Secondary cellular response.

The second type of immunologic response of the body involves various interactions with antigens by T lymphocytes. Unlike the humoral response, which takes place in the plasma, the cellular response involves whole cells called *sensitized lymphocytes* and occurs out in the tissues. They are said to be *sensitized* because they have been made sensitive to a specific antigen after their first contact with it. Subsequent exposure to the antigen to which they are sensitive triggers a host of chemical and mechanical activities, all designed to either destroy or inactivate the offending antigen.

Those lymphocytes destined to provide cellular immunity pass through the thymus and migrate to the lymph tissues throughout the body. These are called the *T lymphocytes* (the "T" is for *thymus*), and they are further divided into helper T cells, memory T cells, suppressor T cells, and sensitized T cells (killer cells). T cells provide defense against viral infections. Viruses are difficult to destroy because they inject themselves into host cells and reproduce themselves. T cells respond to foreign or abnormal molecules on the surface of cells. Host cells containing virus have small fragments of the virus slightly protruding from the cell membrane. T cells identify the virus fragment as foreign and kill the host cell. T cells and macrophages produce a variety of substances called *lymphokines* that help destroy antigens. Killer T cells attach themselves to cells bearing antigens and secrete toxic substances that kill the antigen-bearing cells. This cell-to-cell contact response is called **cell-mediated immunity** or cellular immunity (Figure 10-5).

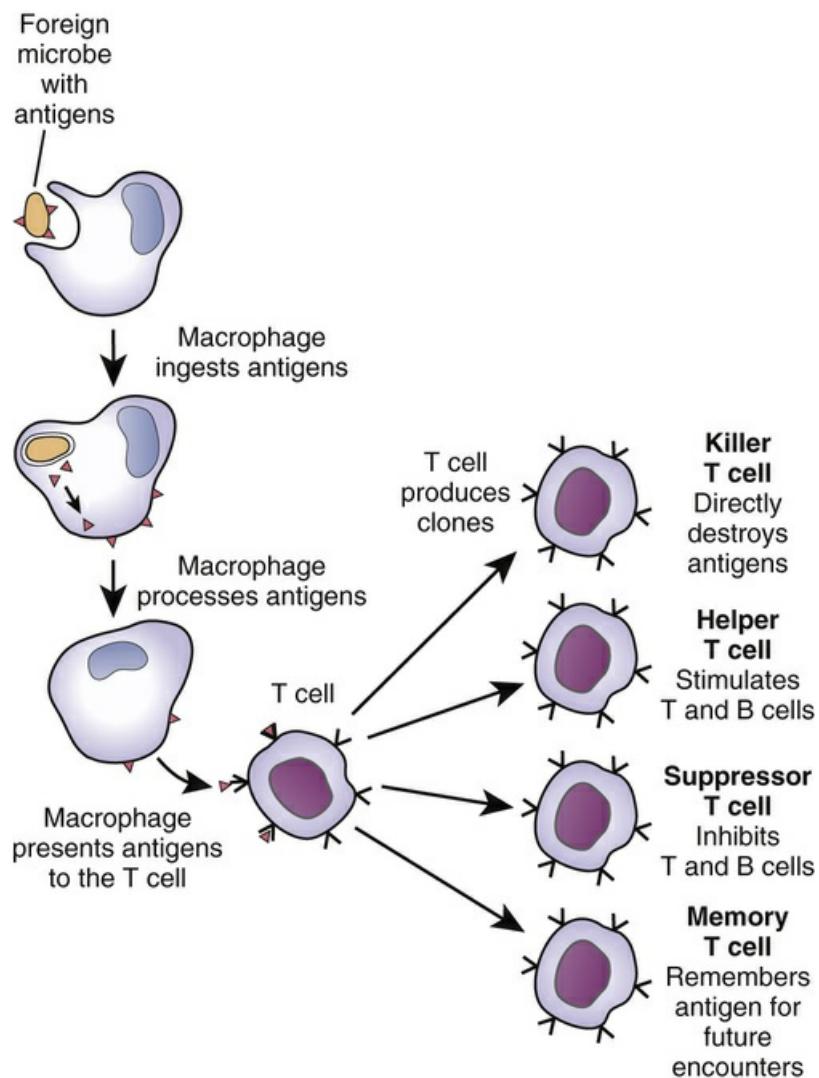

FIGURE 10-5 Cell-mediated immunity.

The T lymphocytes mediate (indirectly accomplish) the cellular response. When an antigen is complex (e.g., a bacterium or another type of living cell), T lymphocytes that are specifically reactive with the particular antigen mediate the cellular response in several ways. These specific T lymphocytes enter the circulating fluids of the body from the lymphoid tissues, migrate widely, and react anywhere in the body where they encounter the particular antigen. Destruction of the antigen may occur by release of chemicals into the membrane of the target cell, by secretion of lymphokines such as interleukin-2 or T-cell growth factor, or by other processes. This direct contact by the T lymphocytes with an antigen is called *killer activity*, and such lymphocytes are named *killer T cells*. Cellular immune response is often termed *delayed hypersensitivity*. The larger the amount of antigen present, the greater the response of sensitized T lymphocytes.

The **complement system of proteins** is a series of proteins produced in the liver that work with antibodies to destroy antigens. Similar to the inflammatory response, the complement system directly kills microbes by attaching to the cell wall and allowing salt and water into the cell, causing it to burst. The proteins of this system "complement," or assist, the immune system.

The T lymphocytes perform immune surveillance for the body by detecting cells that enter the host and have foreign antigens on their surface. T lymphocytes are also defensive cells that patrol the blood and tissues. Sensitized T lymphocytes are the cause of allergic reactions. T cells are responsible for the inflammatory response present in people with a variety of autoimmune diseases. **Autoimmunity** means that there is a defective cellular immune response, and antibodies are produced against normal parts of a person's body. These T lymphocytes, along with migrating macrophages, are responsible for rejecting transplanted organs as well. This is why transplanted tissue must have surface antigens that are very similar to those of the host (transplant recipient).

tissue to be accepted by the host body.

Immunity Against Disease

There are two major types of immunity to specific disease: innate (natural) immunity and acquired (adaptive) immunity. **Innate immunity** is present at birth. **Acquired immunity** occurs through active production of antibodies when the body is invaded by pathogens or through an immunization that causes antibodies to a specific pathogen to form.

Innate (natural) immunity.

Unique innate, or inborn, features of human cells make a person naturally immune to certain diseases. Humans are immune to some diseases simply by being human and are not susceptible to the same diseases as animals of other species. Some immunity is related to race, gender, or a particular inherited genetic makeup. Genetic factors present at birth may **predispose** individuals to immune disorders (Figure 10-6).

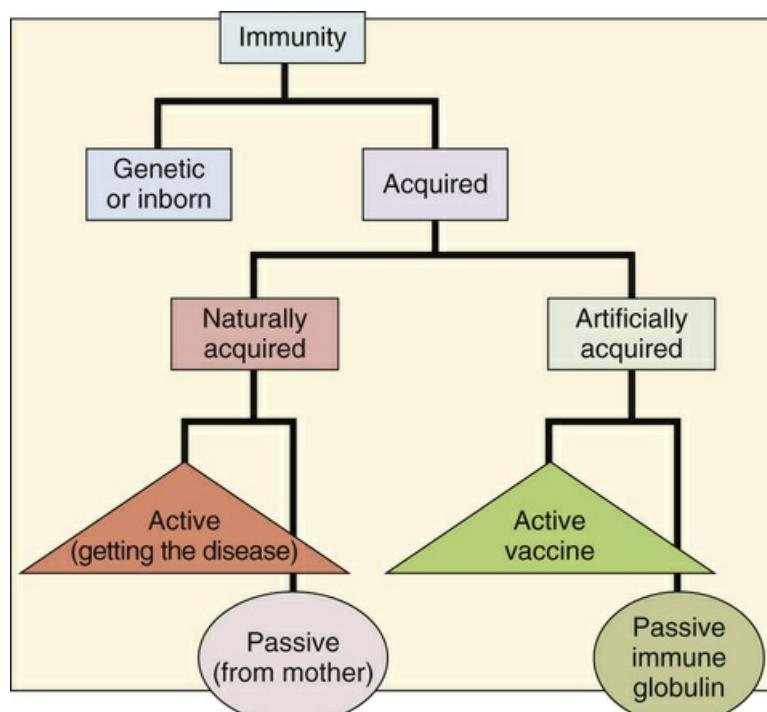

FIGURE 10-6 Types of immunity. (From Herlihy B: *The human body in health and illness*, ed. 5, Philadelphia, 2013, Saunders.)

Acquired immunity.

In acquired immunity, a person can either actively produce her own antibodies or passively receive antibodies produced by another person or animal (**passive immunity**). *Passive natural immunity* is the type that is transmitted from mother to baby. The mother passes antibodies to the fetus in utero or after birth through breast milk. When the fetus is in utero, it passively receives some natural immunity when antibodies from the mother's bloodstream pass through the placenta and mix with the blood of the fetus. Those maternal antibodies are then present in the infant's blood at birth. More immunity can be passed to the infant through breast milk. Breast-feeding is the best way to protect the newborn from infectious disease. Depressed immune function in the mother can limit the benefits typically received from breast milk to her baby.

Administration of human immune globulin to boost the immune system is an example of *passive artificial immunity*. Human immune globulin, formerly called gamma globulin, contains antibodies against not just one, but many infectious diseases. It is developed from donated blood plasma and purified to prevent the spread of additional disease. This type of immune globulin is used when a

susceptible person is exposed to or contracts a communicable disease such as hepatitis A, rubella, or varicella to help lessen the effects of the disease.

The blood serum from a horse that has been prepared with increasingly strong injections of tetanus antigen contains ready-made antibodies and antitoxins against that antigen. Antivenoms that contain antibodies against snake venoms and the poisons produced by the black widow spider are also available. Injections that provide passive immunity should be given as early as possible in the disease, because they only protect against further tissue damage. It is important to note that immune globulins, regardless of the source, cannot reverse damage already done.

Passive immunity is usually time-limited, because the antibodies provided only last for a specific period.

Think Critically

What type of immunity is provided by a “flu shot”? How does an injection of human immune globulin protect a world traveler from hepatitis A?

Active naturally acquired immunity occurs when a person contracts and survives a disease. Once survival from a particular disease has occurred, the person is considered immune and will not contract that particular disease again, for example, measles or rubeola.

Active artificially acquired immunity occurs by vaccination or immunization. To provide active immunity to diseases by artificial means, the actual pathogenic microorganisms are grown and cultured in the laboratory. They are divided into single doses under rigid controls and made into vaccines. These specially treated microorganisms are weakened (attenuated) or killed so that they will stimulate the production of antibodies but will not cause the disease itself. Vaccines from cowpox, tetanus, polio, influenza, measles, mumps, chickenpox, and hepatitis A and B viruses are examples of immunizing agents used to produce an active immunity in humans.

This method of stimulating the production of immunizing substances in the body is successful in situations in which there is time to wait for the person to build up her own defenses. This immunity does not last indefinitely. The body must be reminded of the need to produce more antibodies. To achieve this, a booster dose of an immunizing agent is given to boost the memory of the specific B cells and cause them to actively produce more antibodies. This is one reason why a yearly influenza vaccine is recommended and a booster for tetanus is recommended every 10 years.

Immune and Lymphatic System Disorders

With all of the complexity of the human immune response, there are multiple natural areas of dysfunction that occur. One of the more commonly encountered reasons for alteration in immune function not caused by pathogenic factors is **iatrogenic**—a condition caused by medical treatment. Current therapies for asthma, inflammatory disorders, autoimmune disorders, and organ transplantation are all aimed at suppressing or attenuating the body's natural immune response. Although this effect is helpful in addressing the primary disorder, it also makes the patient more vulnerable to infection or other autoimmune diseases. Many over-the-counter medications have anti-inflammatory effects and are used to decrease pain caused by inflammation. The inflammation is the initiation of the immune process. Suppression of this response can hinder the body's ability to fight infection or disease.

Older Adult Care Points

Older patients are at risk for problems with immunity because of decreased immune function. They also are more likely to have chronic illness and decreased nutritional intake. For those in long-term care or assisted living facilities, living in close proximity to others makes transmission of communicable diseases easier if the appropriate Standard Precautions are not taken (see [Chapter 6](#) and [Appendix B](#)).

Consumption of alcohol can alter the body's ability to launch an immune response. There are both long- and short-term effects of alcohol on the immune system. Two drinks can impair the ability of the B lymphocytes to produce antibodies and can affect T-cell activity. Long-term alcohol use leads to alteration in liver function and impaired nutrition, also altering immune function. Many other drugs, including cocaine, marijuana, and methamphetamines, also compromise the immune system.

Autoimmune disorders are caused by a malfunction of the body's immune system. When the body does not recognize tissues as self, defense mechanisms are launched against the body's own tissues. The trigger for this attack is largely unknown; however, some of these disorders are believed to be initiated by a systemic infectious process or by inherited factors that are still not fully understood.

Health Promotion

Maintaining a Healthy Immune System

A healthy immune system is a function of a healthy body. Eating right and getting enough rest and exercise are all important in maintaining resistance to infection and disease. Frequently skipping meals, eating unhealthy meals, sleeping too little, or not exercising weakens the immune system and makes people more susceptible to pathogens.

Clinical Cues

Treat any patient with chronic substance abuse as immunocompromised until proven otherwise.

Prevention of Immune and Lymphatic System Problems

Immunization

Before **immunization** and inoculation became commonplace, the only way an individual could acquire immunity was to contract a disease and survive. Today, immunity from immunizations is usually achieved by administering the vaccine in divided doses over weeks or months. This sets in motion the more powerful, longer lasting secondary immune responses. For example, infants are given immunizations at intervals during infancy and then periodically throughout early adolescence. To stimulate continued immunity, adults should have immunizations against tetanus

and diphtheria every 10 years. The Centers for Disease Control and Prevention (CDC) also recommends that adults receive a one-time vaccine referred to as *Tdap*, which helps fight against tetanus, diphtheria, and pertussis. Patients should also be encouraged to discuss with their health care providers whether they should receive a hepatitis B vaccine booster.

Nursing implications.

Nurses play a major role in providing education regarding the importance of immunizations. Vaccine-preventable diseases cause disabilities and deaths every year. Nurses can have significant influence by encouraging the public to participate in immunization programs recommended by public health officials and by helping to identify people in need of immunization. *Healthy People 2020 Immunization and Infectious Disease Goal 1* is to reduce, eliminate, or maintain cases of vaccine-preventable diseases.

An important aspect of health teaching is to improve the general public's awareness of the importance of immunization as a means of preventing certain diseases and their consequences. Despite the availability of vaccines against poliomyelitis, measles, rubella, mumps, and other potentially dangerous diseases, there still are many children who have not been adequately immunized. This is particularly true in areas where people do not have easy access to the health care system. Nurses have a responsibility to inform the public about the purpose and importance of immunization in terms the layperson can understand. [Figure 10-7](#) shows the secondary response and longer lasting immunity provided by a second injection of an antigen.

Legal and Ethical Considerations

Immunizations

Immunizations are a proven way to decrease illness for individuals and the spread of diseases in communities. Some religious and cultural practices forbid immunizations. How can the needs of society be balanced with the rights of individuals?

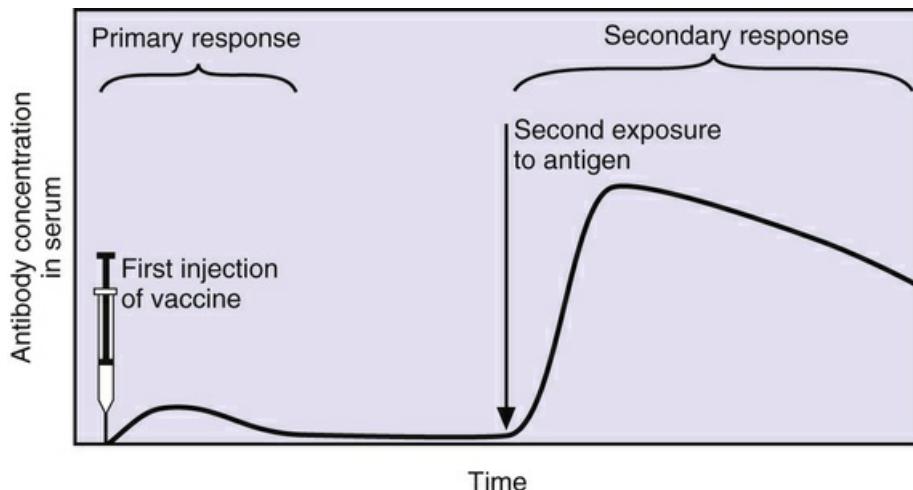

FIGURE 10-7 Comparison of primary and secondary immune response. (From Applegate E: *The anatomy and physiology learning system*, ed. 4, Philadelphia, 2010, Saunders.)

Parents should be told why immunization is important for their children and be warned of the dangers faced by children who are not adequately immunized. This information must be presented in such a way that the parents do not feel threatened or badgered. Older adults and others who are particularly susceptible to influenza and pneumococcal pneumonia should also be immunized according to the recommendations of public health officials. Health care workers should be immunized annually for influenza so they do not transmit the disease to susceptible patient populations. The [CDC \(2015\)](#) has recommended immunization schedules for all ages, including those who have never been vaccinated. The most current recommendations are available at

<http://www.cdc.gov/vaccines/schedules/index.html>.

Circumstances that require modifying or postponing immunization include fevers; immune deficiency disease; immunosuppressive therapy; and administration of human immune globulin, plasma, or whole blood transfusion 6 to 8 weeks before the immunization. Some immunizations, such as live attenuated influenza vaccine (contains weakened live flu virus), are also contraindicated immediately before and during pregnancy and when a person is taking certain drugs, such as chemotherapy; however, the inactivated (killed virus) influenza vaccine is rarely contraindicated. Information inserts accompanying these vaccines will identify restrictions prohibiting the administration of an immunizing agent. The vaccine for tuberculosis (TB), bacille Calmette-Guérin (BCG), is not routinely used in the United States because of the low incidence of TB. However, BCG is given in countries where TB is more prevalent, and individuals who have received vaccine may have a positive TB skin test for a number of years. The Mantoux tuberculin skin test (TST) administered in the United States typically does not cause a positive skin test result unless the person has been infected with *Mycobacterium tuberculosis*.

Whenever an immunizing agent is to be administered, precautions must be taken to ensure, as much as possible, that the patient is not hypersensitive to the components of the agent. Religious orientation is also important to consider, because some vaccine products are made using pork or bovine serum and are strictly forbidden by certain religious tenets. Common substances used in the manufacturing of vaccines include chicken embryos, horse serum, bovine serum, and preservative agents (CDC, 2011). These substances can produce a serious allergic reaction in people who are hypersensitive to them. Immunizing agents that are most often associated with anaphylaxis, a potentially fatal reaction, include tetanus antitoxin, botulism antitoxin, diphtheria antitoxin, rabies antitoxin, and antilymphocyte globulin.

It is imperative that a history of allergies in the patient and her family be obtained before administering an immunizing agent. It also should be determined whether the patient has an immune deficiency disorder of any kind that would prevent a normal immune response to the immunizing agent. If a patient does have a history of allergies or an immune deficiency, the health care provider should be made aware of this fact before the immunizing agent is given. If the patient has had an allergic reaction to the specific agent she is supposed to receive, the vaccine must not be given.

There are serums that require a skin sensitivity test before they may be administered to a patient. Skin testing for sensitivity should not be confused with skin testing for diagnostic purposes. Testing for sensitivity is performed to determine whether a minute amount of the immunizing agent will produce a local reaction. If it does, chances are the patient will have a severe reaction if the agent is given systemically. Botulism antitoxin is an example of a treatment for which a "scratch test" is mandated before its administration.

Despite these precautions, it is possible that a patient will suffer from hypersensitivity to an immunizing agent. To avoid serious problems, always be prepared to act quickly and effectively in such an emergency. In all patient care areas where immunizing agents are administered, emergency equipment should be readily available. As an extra precaution to ensure prompt treatment of a hypersensitivity reaction, it is advisable for people receiving immunizing agents to remain in the clinic or office for 15 to 20 minutes after an injection is given. This practice is in accordance with the National Patient Safety Goal of recognizing and quickly responding to changes in a patient's condition.

In addition to enhancing the immune system by administering immunizations, instruct the patient about other measures for maintaining a healthy immune system. Keeping the body healthy is the best way to preserve immune function. Not smoking, staying physically active, getting adequate rest, and eating a balanced diet are all measures that should be encouraged.

Complementary and Alternative Therapies

Garlic Assists Immune Action

Garlic has been used for centuries to increase resistance to the common cold and other infections. It has a variety of actions, including antilipidemic, antitriglyceride, antiplatelet, antioxidant, cancer preventive, and antimicrobial. It inhibits the growth of both gram-positive and gram-negative organisms and is effective against certain fungi, viruses, and helminths. Because garlic interacts

with many drugs, the health care provider should be consulted before administration. It should not be used by pregnant women, because it may induce labor. Patients taking anticoagulants need to know that it may extend their action.

❖Nursing Management

■ Assessment (Data Collection)

If the immune system is functioning normally but not activated, there will be an absence of physical signs and symptoms of an immune response or infection. It is when the system is activated and doing its job or is unable to mount an active defense, detectable physical signs and symptoms may become evident.

Because the function of the immune system is to guard the body against microbial invasion, it is important to assess for signs and symptoms of infection. These include fever, redness, swelling, and exudate from open skin areas. Patients who have a known infection but do not exhibit obvious signs and symptoms of infection should be evaluated for an immune deficiency. Another indicator of a depressed or inadequate immune response is recurrent infections or infections of common organisms to which individuals with normal immune systems are not susceptible. A thorough history should be gathered.

▣ Focused Assessment

Data Collection for the Lymphatic and Immune Systems

- What immunizations have you had? When were you last immunized for tetanus, diphtheria, and influenza?
- Have you had a recent infection or a recurrence of infection?
- Do you have any allergies to medications, food, or other substances?
- Do you have any chronic illnesses such as diabetes mellitus, rheumatoid arthritis, inflammatory bowel disease, Crohn's disease, lung disease, renal disease, or HIV or AIDS?
- Have you ever had cancer? Radiation therapy? Chemotherapy?
- Have you recently had surgery or a blood transfusion?
- Do you get sick frequently?
- Have you recently traveled out of the country?
- What do you usually eat in a day?
- Has your weight changed lately?
- Do you smoke, drink, or use illicit drugs?
- Have you been exposed to industrial or agricultural chemicals?
- Have you been exposed to industrial radiation?
- Are you on any medications?
- Do you take any supplements or herbal preparations?
- Do you see a health care provider regularly?
- Are you under excessive stress at home or in your job?

- Are you sexually active? Do you use protection such as latex condoms? Are you monogamous?

Previously diagnosed diseases that affect the immune system, immunizations, medications (including herbal supplements), allergies, and nutritional status are important areas to explore. The patient should also be questioned about any recent surgeries, blood transfusions, and diagnoses of chronic illnesses. Habits and lifestyle questions are also important to include in the data collection. Because diseases that affect the immune system can be transmitted through the exchange of blood and body fluids, asking about the use of illicit drugs and sexual history are very important. Information regarding smoking history and exposure to environmental and industrial radiation or pollutants should also be obtained.

Physical Assessment

The skin is a major defense against access to the body by microorganisms. It is important to do a thorough assessment of the skin to identify any potential entryways for organisms. Remember to assess those areas where catheters, tubes, and other medical devices may penetrate the skin barrier. The skin may show an excessive immune reaction, such as an allergic response resulting in hives, rash, or other skin eruptions.

Clinical Cues

Latex allergy can be another cause of redness at tube sites if the tube or the occlusive dressing contains latex.

When the immune response is activated, lymph nodes may become swollen and tender and can be evaluated by palpation. Nodes in the neck, axillae, and groin areas are those most commonly examined, because they are closer to the skin surface. Data obtained from a head-to-toe physical assessment provide important information regarding immune and lymphatic system function.

Focused Assessment

Physical Assessment of the Lymphatic and Immune Systems

- Take vital signs, noting if there is an increase in temperature or pulse rate.
- Measure height and weight.
- Inspect the skin for color, turgor, texture, and presence of lesions.
- Assess extremities for edema.
- Inspect ears, eyes, nose, and throat for drainage, redness, or exudate.
- Palpate lymph nodes in the neck to identify enlargement or tenderness.
- Auscultate lung fields and assess work of breathing.
- Analyze laboratory results such as complete blood count (CBC), C-reactive protein, and antibody screening tests.

Diagnostic Tests, Procedures, and Nursing Implications

Skin testing. Skin testing is one of the most commonly used techniques to measure immunity and to identify people who may have a dormant infectious disease. These tests include the **Schick test** to determine susceptibility to diphtheria and the **TST** (Mantoux test) to identify those who might need treatment for TB. The Mantoux test and other tests for TB are covered in [Chapter 14](#).

Several types of skin testing may also be performed to identify allergens that are causing allergic symptoms in an individual. A scratch test (also called a prick or puncture test) involves dropping extracts of allergens into scratches made on the skin. Intradermal injection of allergens is used to

detect allergies to insect venom or penicillin. Patches containing allergens that might cause contact dermatitis are placed in direct contact with the skin. Inflammation and itching identify those allergens that provoke the immune system.

Laboratory tests. Laboratory tests on blood and serum also give important information regarding the status of the immune system. A CBC gives information regarding the number of circulating WBCs. The differential indicates what percentage of the total WBC count is accounted for by the different cell types. An increased WBC count indicates that the immune system has been activated (Table 10-3). If a specific disease or condition is suspected, blood testing can determine whether antibodies to that disease or condition are present.

Table 10-3

Diagnostic Tests for Disorders of the Immune and Lymphatic Systems*

TEST AND NORMAL RANGE	PURPOSE	DESCRIPTION	NURSING IMPLICATIONS
Complete Blood Count (CBC)			
	Determines whether abnormalities are present in the numbers of blood cells or types of blood cells; assesses the amount of hemoglobin present Useful to diagnose anemia	Fill a lavender-top tube containing EDTA with a venous sample of blood. Use a site where there is little chance of dilution from intravenous solution. Mix the blood and the EDTA by gently rotating the tube.	Warn the patient that a "stick" is about to occur, but that the pain will be short lived. Apply pressure directly to the puncture site after withdrawing the needle; at the antecubital space, do not have the patient flex the arm, because this tends to cause a hematoma.
Erythrocytes			
Hemoglobin: females, 12.0-16.0 g/dL; males, 13.0-18.0 g/dL Red blood cell count: females, 4.2-5.4 million/mm ³ ; males, 4.6-6.2 million/mm ³ Hematocrit: females, 37%-47%; males, 40%-54%			
Leukocytes			
White blood cell (WBC) count: 4500-11,000/mm ³			
Differential Count			
Granulocytes Neutrophils: 54%-62% of WBCs Eosinophils: 1%-3% of WBCs Basophils: 0%-1% of WBCs Agranulocytes Lymphocytes: 25%-33% of WBCs Monocytes: 3%-7% of WBCs Thrombocytes (platelets): 150,000-400,000/mm ³ of blood Mean corpuscular hemoglobin (Hgb) (MCH): 26-34 pg/cell Mean corpuscular Hgb concentration (MCHC): 32-36 mg/dL Mean corpuscular volume (MCV): 80-96 µm ³			
Lymphangiogram			
Normal-size vessels and nodes without filling defects	Detects abnormalities in the lymphatic system, especially cancer	Dye is injected intradermally between the first three toes of each foot while the patient is supine. Local anesthesia is injected, and an incision is made in the dorsum of the foot to inject iodine contrast material directly into a lymphatic vessel over 1.5 hr. X-rays are taken of the abdomen, pelvis, and upper body.	Repeat films are taken in 24 hr. Obtain written consent. Assess for allergy to iodine or shellfish. Explain procedure. After the procedure, elevate the legs for 24 hr to decrease swelling. Assess for signs of infection and oil embolism q4h for 24 hr.
Spleen Sonogram			
Proper size, shape, and position	Detects structural abnormalities of the spleen	An ultrasound wand is moved over the abdomen in the area of the spleen with the patient supine on the examining table.	Explain that the test typically takes about 30 min.
Spleen Scan			
Looks at the distribution of radioactive erythrocytes throughout the spleen	Detects anatomic changes in the spleen; determines invasion of Hodgkin or metastatic disease Usually done in conjunction with a liver scan	A radioactive nuclide colloid is injected intravenously. After about 20 min, a minimum of three views are obtained. Radiation exposure is about 0.5 rad (equal to about 1 yr of natural radiation exposure to the body). Schedule scan before tests using barium.	Explain that a substance will be injected and scanning will begin after about 20 min. Radiation exposure is minimal. The test takes about 60 min.
Immunoglobulins (Ig), Serum			
IgG: 564-1765 mg/dL IgA: 85-385 mg/dL IgM: 53-375 mg/dL IgD: 0-14 mg/dL IgE: 0 <100 International Units/mL	Detects and monitors quantities of antibodies circulating in the blood Useful for monitoring hypersensitivity diseases, immune deficiencies, autoimmune diseases, and chronic infections	Serum is placed on a slide containing agar gel, and an electrical current is passed through the gel. The immune globulins are separated out and electrophoresed according to the quantity and difference in electrical charge.	No fasting or special preparation is required. Requires drawing 7-10 mL of blood.
Complement Assays			
Total serum complement (CH ₅₀): 40-1000 units/mL C3 (mature T cells): 1200-1500 mcg/mL C4 (helper T cells): 350-600 mcg/mL	Monitors immune disorders, genetic complement deficiencies, and treatment response	In the presence of antibody/antigen complexes, the complement system is overly activated, and the complement components are "consumed" or used up.	No fasting or special preparation is required. Requires drawing 7-10 mL of blood.
C-reactive protein (CRP) <8 mcg/mL	Detects the presence of an inflammatory process	CRP is initiated by antigen-immune complexes, bacteria, fungi, and trauma. It interacts with the complement system.	Explain that fasting may be required for 4-12 hr. Water is permitted. Requires drawing a blood sample. Cigarette smoking can cause increased levels. Alcohol consumption can decrease levels. Estrogens and progesterones may cause increased levels. Statins, fibrins, and niacin may cause decreased levels.
Lymph Node Biopsy			
Negative for abnormal cells or infectious agents	Detects changes in tissue; identifies autoimmune disease or detects the spread of malignancy	Tissue is obtained by needle aspiration, excision, or needle punch using aseptic technique.	Fasting may be required. Sedation and/or local anesthesia will be administered. Biopsied material is placed in formaldehyde. Label and transport to the laboratory immediately. A dry sterile dressing is applied to the biopsy site. Instruct the patient to watch for signs of infection: increasing pain, redness, swelling, purulent drainage, or fever >101° F (38.3° C).
Culture			
	Determines organism responsible for infection	A sample of exudate, fluid, or tissue is taken from the suspected infected area.	The procedures for collecting bacterial, viral, and fungal samples are different. Consult agency protocol.

		Gather the correct culture tubes and culture media. Label all containers before collecting the specimen(s). Transport the specimen(s) to the laboratory immediately.
--	--	--

¹Diagnostic tests for human immunodeficiency virus are presented in Chapter 11. Bone marrow aspiration is covered in Chapter 16.

EDTA, Ethylenediaminetetraacetic acid.

Imaging studies. **Immunoscintigraphy** is a nuclear medicine imaging procedure in which antibodies labeled with radioactive isotope are injected into the bloodstream. The isotope emits gamma rays that can be detected by the imaging equipment. Computers construct a picture of sites in the body where the antibody accumulates. The primary use of this technique is for identification of neoplasms, as well as in locating and confirming areas of infection, such as in osteomyelitis. Current research is investigating techniques for “tagging” other cellular components of the immune system with radioactive substances that can then be visualized with nuclear medicine equipment.

Computed tomography (CT), magnetic resonance imaging (MRI), and positron emission tomography (PET) can all be used to evaluate the thymus gland and other tissue structures of the immune system.

Nursing Diagnosis

Problems of the immune and lymphatic system involve body systems and cause psychosocial problems as well and are identified from the assessment and data collection. Table 10-4 lists the most common problems. Numerous nursing diagnoses for patients with immune and lymphatic disorders are available on the NANDA-I list (see inside back cover).

Table 10-4
Common Problem Statements and Interventions for Patients With Alteration in Immune and Lymphatic Function

PROBLEM STATEMENT	GOALS/EXPECTED OUTCOMES	NURSING INTERVENTIONS
Excessive Immune Response		
Altered breathing pattern due to excessive immune response	Patient will maintain a patent airway and adequate oxygenation.	Maintain patent airway. Assess respiratory function q2-4h. Provide supplemental oxygen as needed and ordered.
Altered thermoregulation due to inflammatory response	Patient will maintain core temperature within normal range.	Monitor temperature. Administer antipyretics as indicated. Initiate cooling measures if indicated. Monitor intake and output. Encourage fluid intake.
Potential for altered skin integrity due to allergens	Patient's skin will be intact and without redness or rash or hives.	Assess for rash or hives. Administer topical and systemic medications as ordered. Keep skin clean and dry; use lotions for lubrication. Refrain from bathing in hot water. Suggest use of ice to decrease itching. Keep nails short to reduce risk of injury from scratching. Provide distraction activities to shift focus from itching.
Anxiety due to threatened health status	Patient will assist with relieving symptoms through various techniques. Patient's anxiety will decrease by discharge.	Assess level of anxiety. If patient is having respiratory difficulty, stay with the patient. Explain to the patient what is being done to help her and what she can do to lessen the symptoms. Teach relaxation exercises.
Deficient Immune Response		
Potential for infection due to decreased resistance	Patient will remain free of infection or, if infection occurs, it will be promptly identified and treated.	Maintain infection control standards to prevent health care-associated infections. Assess for signs and symptoms of infection. Aggressively treat infection if it occurs. Instruct patient in techniques to prevent acquisition of infection.
Altered social activity resulting in social isolation	Patient will participate in social activities within ability.	Encourage interaction using technology to maintain relationships and prevent infections. Provide positive reinforcement when the patient participates socially. Provide education regarding modes of transmission so that social interactions can be safely undertaken.
Potential for altered thermoregulation due to illness	Maintain body temperature within normal range.	Monitor core body temperature. Maintain a comfortable ambient temperature. Restore/maintain temperature within patient's normal range.
Altered nutrition due to loss of appetite	Maintain stable weight.	Assess presence and degree of nausea or loss of appetite. Assist patient to make a dietary plan including favorite foods. Consult with dietitian and health care team. Offer frequent small meals. Promote an odor-free, relaxing atmosphere for meals.
Insufficient knowledge regarding disease process and prevention of infection transmission	Patient and family will verbalize understanding of disease process, treatment, and necessary precautions.	Assess readiness to learn. Provide information in multiple formats: verbal, visual media, written. Teach necessary precautions to prevent infection. Provide positive reinforcement. Use team and group teaching as appropriate. Provide access to other information sources. Refer to community agencies and support groups.
Lymph System Disorders		
Acute pain due to disease process	Patient's pain will be reduced and kept within range acceptable to patient.	Teach patient use of pain scale for reporting of pain. Accept patient's report of pain. Monitor vital signs. Provide comfort measures. Instruct and encourage relaxation, imagery, and diversional activities. Administer analgesics as needed to maintain acceptable comfort level. Encourage adequate rest periods. Work with patient and family to identify effective strategies for

Altered nutrition due to disease process	Patient will maintain present or ideal body weight.	pain management. Determine ability to chew and swallow. Identify patient food preferences. Offer frequent small meals. Weigh daily. Promote relaxing meal environment. Provide oral care before and after meals.
Lack of power due to disease process	Patient will become actively involved in care and will make choices related to care.	Asses patient's knowledge and perception of condition. Identify patient support systems. Listen to patient's expressions of feelings. Show concern for patient as an individual. Treat patient's decisions with respect. Encourage realistic goal setting. Provide opportunities for the patient to control as many events as restrictions allow.
Altered body image due to lymphedema	Patient will verbalize understanding of body changes.	Teach patient and family about pathophysiology of lymphedema. Institute measures to reduce lymphedema: elevation of extremity and use of pressure sleeve as ordered. Teach measures to prevent lymphedema recurrence. Support patient decision making. Refer to appropriate support groups.

■ Planning

Planning is based on the particular problems identified for the individual patient (see [Table 10-4](#)). General nursing goals include the following:

- Protect from infection
- Improve health status
- Maintain a high degree of wellness to promote optimal immune function

■ Implementation

Nursing interventions include all methods to prevent the spread of infection. Meticulous adherence to Standard Precautions, including appropriate hand hygiene, is essential. Additional protection from infection may include implementation of protective isolation. Promotion of balanced, adequate nutrition is essential in maintaining or regaining optimal immune function.

■ Assignment Considerations

Instructing CNAs and UAP

When assigning patients or tasks to CNAs or UAP, remember to share that a patient is immunocompromised (very susceptible to infection) and that it is important to be extra diligent about complying with hand hygiene. Ask them to adhere to transmission-based isolation precautions, including restricting people who have an infection from entering the patient's room. Remind them that it is important that the patient obtain sufficient rest and not be continually disturbed. Ask the CNA/UAP to report any new skin lesion, irritation, or redness that is noticed during bathing, toileting, or repositioning. State that you want to know if the urine has a foul odor. Remember at the end of the shift to thank the person for the help provided.

Psychosocial care to decrease fear, help deal with lifestyle or role changes, and reduce stress is important in caring for the whole person. Patient teaching regarding the disorder, treatment, signs of complications, and self-care is an effective way to reduce stress and fear. Nursing care for specific disorders of the immune and lymphatic system is presented in [Chapter 11](#).

■ Evaluation

Determining whether expected outcomes are being met includes assessing for signs and symptoms of immune function. This includes gathering physical data, as well as monitoring laboratory and diagnostic study results for improvement. Temperature and other vital signs are also good indicators of immune function. General well-being and side effects of medications should also be monitored in evaluating the effectiveness of nursing and medical interventions.

Common Problems Related to the Immune and Lymphatic Systems

Fever

A rise in body temperature typically signals a normal immune system response to infection. The rise in temperature is only one component for fighting off the invaders by promoting a hostile environment. There is a significant amount of evidence-based research that shows how fever is helpful to the immune system. However, there is continued controversy about when to treat an elevation in body temperature. **Hyperthermia** or fever related to infections can cause discomfort, and excessive fever can lead to complications such as seizures. Decreasing body temperature by physical or pharmaceutical means promotes comfort for the individual but may decrease the effectiveness of the body's efforts to eliminate pathogenic microorganisms. Excessive fever (**hyperpyrexia**) is usually treated with antipyretics and cooling measures.

Nursing Management

Cooling measures can be as simple as removing excess coverings or as complex as using mechanical cooling blankets and cooled intravenous fluids. Usual nursing measures for decreasing body temperature include sponging with tepid water. Cold water is contraindicated because rapid cooling can induce shivering, which can drive the temperature back up.

Clinical Cues

Sometimes body temperature can be lowered by placing ice bags in the axillae and groin area. Be sure to insulate the packs with a cloth before placing them on the body. These areas have good blood circulation and can help with cooling the core body temperature.

The ideal treatment for fever is to address the cause. Appropriate antibiotic therapy can reduce fever by fighting the infection, if it is bacterial in origin. Allergic inflammatory responses can be treated with corticosteroids. Anti-inflammatory medications such as aspirin, ibuprofen, or naproxen may also be administered to lower the temperature.

Nutrition

Anorexia (decreased desire for food) often accompanies fever, infection, and use of some antimicrobial agents. Adequate amounts of fluid, calories, vitamins, and protein are essential in rebuilding tissues affected by infection and maintaining the immune system. Increased body temperature causes an increased metabolic rate. This increase in cellular metabolism uses more oxygen and water than under normal circumstances. Respiratory and heart rates increase with the core body temperature; therefore if a high temperature is not lowered and fluids replenished, the body ceases to function at an optimum level, which could lead to shock or even death.

Nursing Management

Offering favorite fluids and foods in small portions can sometimes tempt the appetite. When febrile, individuals often prefer cold or frozen items. Easily digested food items are usually more tempting, such as soup, ices, pops, and clear (nonpulp) juices.

Immunosuppression

Patients can be immunosuppressed either from the disease process or from medical treatment. This makes the person highly susceptible to common microorganisms. Patients who have to take daily corticosteroids for any reason, such as those with chronic asthma, post-organ transplantation patients, or patients who are receiving chemotherapy, are immunosuppressed. Individuals with diabetes mellitus may also have a depressed immune system.

Nursing Management

Hospital settings are known for having a high concentration of pathogens simply because of the variety of patient illnesses. In the hospital environment, **it is critical that all standard infection prevention and control protocols be implemented and followed by everyone without fail.**

Patients with **neutropenia** (less than normal amount of WBCs) may need additional precautions. *Transmission-based isolation precautions* refer to procedures that may be implemented to protect immunosuppressed patients from exposure to infectious microorganisms (see [Chapter 6](#)). In some cases, the precautions may also include restrictions on fresh fruits, vegetables, and flowers. Visitors who may have an infectious disorder may also be restricted from walking in the halls or going into populated areas such as a gift shop or cafeteria. Regardless of what is implemented, the principle is the same—preventing the transmission of potentially infective microorganisms to other patients, regardless of their immune status. These measures may include specially constructed rooms with positive airflow, monitoring of water purity, and monitoring of air vents for the presence of pathogenic microorganisms. The degree to which these measures are implemented is determined by the degree of immunosuppression. Any patient who is ill and hospitalized has an immune system under stress. Health care staff meticulously adhering to Standard Precautions and, if needed, Transmission-Based Precautions will help protect patients. [Chapter 15](#) presents more on the care of neutropenic patients.

Think Critically

What devices, tools, equipment, or other objects are routinely carried from patient to patient without disinfection? Where do they fit in the chain of infection? What can you, as a health care provider, do about reducing transmission of microorganisms?

Get Ready for the NCLEX® Examination!

Key Points

- The immune and lymphatic systems protect the body against microscopic threats to homeostasis.
- The inflammatory response is the first step in the immune response.
- Antibodies are proteins that fight antigens.
- B and T lymphocytes are major forces in fighting infection.
- The body produces a humoral (immediate) and cellular (delayed) response to antigens.
- Chronic consumption of alcohol can alter the body's ability to launch an immune response.
- Active artificially acquired immunity occurs by vaccination or immunization.
- Immunizations introduce pathogens to the body in a controlled way, allowing the body to produce antibodies to prevent future illness.
- The nurse plays a major role in providing patient education regarding the importance of immunizations to public health.
- Decreased immune response puts the patient at risk for infection.
- Measures such as hand hygiene and strict adherence to Standard Precautions should always be implemented, regardless of immune status, to prevent health care-associated infections.
- Good nutrition and healthy lifestyle choices are important for a healthy immune system.
- Immunosuppression can be caused by treatment for conditions such as asthma, autoimmune disorders, and cancer.

Review Questions for the NCLEX® Examination

1. _____ is the administration of weak or attenuated microorganisms to stimulate the production of antibodies without causing a full-blown disease.

NCLEX Client Need: Health Promotion and Maintenance: Disease Prevention

2. The nurse demonstrates understanding of passive natural immunity when he makes which statement?

1. “Breast-feeding is the best way to enhance the infant's immunity.”
2. “Timely vaccination could easily provide protection from hepatitis.”
3. “The skin provides passive natural immunity for warding off diseases.”
4. “Administration of human immune globulins boosts the immunity.”

NCLEX Client Need: Physiological Adaptation: Basic Pathophysiology

3. Testing for antibodies is indicated for which immunization? (*Select all that apply.*)

1. Rabies
2. Botulism
3. Mantoux
4. Tetanus

NCLEX Client Need: Physiological Adaptation: Basic Pathophysiology

4. During a health promotion outreach for older adults, the nurse discusses the physiologic changes in aging that increase susceptibility to infection. Which statement is true?

1. "With advanced age, the skin becomes tough and leathery."
2. "Decreased cilia in the lungs provide a more hospitable environment to harmful organisms."
3. "Decreased normal flora in the intestines causes the harboring of pathogens."
4. "Repeated infections build up immune responses."

NCLEX Client Need: Physiological Adaptation: Alterations in Body Systems

5. A patient is newly diagnosed with an autoimmune thyroid disease. When the nurse discusses the patient's questions and concerns, the patient asks, "What did the provider mean by autoimmune disease?" What is the most appropriate response?

1. "The body's immune defenses fail to respond to the pathogenic agents."
2. "Immune defenses are attacking the normal body cells."
3. "There is a break in the body's defenses."
4. "The provider was able to identify the underlying cause of the disorder."

NCLEX Client Need: Psychosocial Integrity: Therapeutic Communication

6. A nurse is assessing the condition of a sacral pressure ulcer on an immobilized patient. Which sign or symptom indicates the presence of infection?

1. Warm to touch
2. Pink wound surface
3. Wound culture <10,000 colonies
4. Purulent drainage

NCLEX Client Need: Physiological Integrity: Physiological Adaptation

7. While caring for an immunocompromised patient, which action by a nursing assistant indicates a need for instruction and supervision by a licensed nurse?

1. Reporting changes in the physical characteristics of the urine
2. Allowing all family members in the patient's room at all times
3. Meticulous hand hygiene before entering the patient's room
4. Turning the patient while bathing her

NCLEX Client Need: Safe and Effective Care Environment: Coordinated Care

8. During the data collection process, a patient indicates, "I take garlic pills to reduce my risk for cancer." What is an appropriate nursing response?

1. "How much and how often do you take your garlic pills?"
2. "Have you been screened for cancer?"
3. "What other herbal medications are you taking?"
4. "You sound worried. Could you talk more about it?"

NCLEX Client Need: Health Promotion and Maintenance: Data Collection Techniques

9. The patient needs to have blood drawn for C-reactive protein. What is an important preprocedure instruction?

1. Hormone replacement therapy can increase the level of C-reactive protein.
2. Cigarette smoking is never advised but will not affect the level of C-reactive protein.

3. Your morning dose of niacin and simvastatin will not affect the outcomes of the test.
4. The procedure requires a 4- to 12-hour fast with no water intake.

NCLEX Client Need: Reduction of Risk Potential: Diagnostic Tests

10. Before receiving antivenom, a patient asks, "How does the antivenom work?" Which statement demonstrates that the nurse has knowledge of the medication?

1. "The antivenom provides a lifelong protection from any snake bite."
2. "The antivenom must be given as early as possible to afford immediate reversal of the subsequent effects of the venom."
3. "The antivenom reverses the effects of the poisonous snake bite."
4. "The antivenom cannot be given to patients who are allergic to eggs."

NCLEX Client Need: Physiological Integrity: Basic Pathophysiology

Critical Thinking Questions

Scenario A

Mr. Green, an 80-year-old farmer, is admitted with pneumonia. His vital signs are: temperature 103° F (39.4° C) (oral), blood pressure 136/78 mm Hg, heart rate 100 bpm, respirations 28 breaths/min, and no complaint of pain.

1. What assessment data indicate that the immune system is active?
2. Describe how the body is reacting to the lung infection. Which type of immunity will help fight the infection?
3. List appropriate nursing interventions for Mr. Green.

Scenario B

Mrs. Hope brings her newborn into the pediatrician's office. She is seeking information.

1. Mrs. Hope asks when she should bring her baby in for immunizations. What will you tell her?
2. Explain how immunizations help protect the body.
3. Discuss what information should be given so that Mrs. Hope could identify if her baby has had a reaction to an immunization.

CHAPTER 11

Care of Patients With Immune and Lymphatic Disorders

Trena Rich

Objectives

Theory

1. Discuss the key differences between primary and acquired immune deficiency disorders.
2. Summarize the ideal actions of therapeutic immunosuppressive drugs.
3. Illustrate the modes of transmission for HIV.
4. Discuss how pre-exposure prophylaxis reduces the risk of contracting HIV.
5. List diagnostic tests for HIV and those used to monitor the immune status of individuals who are HIV positive.
6. Explain opportunistic infections (viral, bacterial, fungal, parasitic) that occur in HIV patients.
7. Give examples of each of the three categories of autoimmune disorders and diseases.
8. Compare and contrast the two types of lymphoma, including how they are diagnosed.
9. Explain why the process of diagnosis and treatment for fibromyalgia would be difficult or frustrating for the patient.
10. Construct how an allergic reaction occurs during an excessive immune response.
11. Relate the nurse's role in helping a patient to control allergies.

Clinical Practice

12. During a clinical rotation, review the facility's policy for exposure to blood or body fluids from an HIV-positive patient.
13. List nursing measures for the prevention of infection for an immunocompromised patient.
14. Perform data collection on a patient in whom an immune-suppressant disorder is suspected.
15. Review a nursing care plan for a patient who has low immunity.
16. Write nursing interventions for a patient with fibromyalgia.
17. List the usual measures for treating an anaphylactic reaction and locate the necessary emergency equipment on your clinical unit.

- wasting syndrome (p. 224)

Immune Function and Dysfunction

An immune system that functions properly creates immunocompetence. With **immunocompetence**, when a threat to the immune system occurs, it stimulates certain physiologic responses (i.e., the vascular system, initiation of chemical responses, and the release of white blood cells) to protect the body against invasion from microorganisms or toxins. Abnormal responses of the immune system are typically the result of an infection, medical therapy, or exposure to select toxins. These abnormal responses are divided into two basic categories: immune deficiency disorders and autoimmune diseases.

In **immune deficiency** disorders, there is an insufficient production of antibodies, immune cells, or both; the disorders may be congenital or acquired. A deficiency in the immune system leaves the body unable to resist foreign microbes or toxins. Common viral infections, such as influenza or infectious mononucleosis, can cause a short-term weakened immune response.

Autoimmune disorders involve the overreaction or hypersensitivity to antigens from the external environment that cause the immune system to be unable to tell the difference between "self" (the body's own cells) and "nonself" (foreign cells). Autoimmunity can be organ specific, such as in type 1 diabetes mellitus in which the body attacks the pancreatic cells that produce insulin, or it can be like systemic lupus erythematosus (SLE), in which antibodies are produced that assault healthy cells throughout the body.

Immune Deficiency Disorders

There are two forms of immune deficiency: primary and acquired. In **primary immune deficiency disorders (PIDDs)**, the cause is an inherited genetic mutation, and some PIDDs are detected during infancy or early childhood. Approximately 500,000 Americans have some form of PIDD, and approximately 15% of those are severely affected. Patients with this type of disorder experience repeated infections that clearly increase their risk of morbidity and mortality as well as the cost of health care. Refer to [Box 11-1](#) for a modified list of PIDDs.

Box 11-1

Primary Immune Deficiency Disorders

Autoimmune lymphoproliferative syndrome (ALPS)

Chronic granulomatous disease (CGD)

Common variable immunodeficiency (CVID)

Severe combined immunodeficiency (SCID)

Adapted from National Institute of Allergy and Infectious Diseases. Retrieved from
<http://www.niaid.nih.gov/topics/immunodeficiency/Pages/Default.aspx>.

Acquired immune deficiency disorder can result from medications such as immunosuppressants that are used to prevent tissue/organ transplant rejection or chemotherapeutic agents to treat cancer that temporarily reduce the ability of the bone marrow to produce white blood cells (WBCs). **Acquired immunodeficiency syndrome (AIDS)** is perhaps the most commonly known disorder that is caused by the **human immunodeficiency virus (HIV)**. This virus affects the body's ability to fight off an array of infections and diseases if recommended treatments are not followed.

Therapeutic Immunosuppression

A variety of disorders or conditions can be treated or controlled by medications or therapies such as corticosteroids, hemodialysis, organ transplantation, or radiation. However, some of these treatments can lead to chronic medical conditions or **iatrogenic** (a side effect of medical treatment) complications such as diabetes mellitus, osteoporosis, chronic infections, and significant weight gain. Drug-induced **immunosuppression**, often referred to as *therapeutically induced immunosuppression*, requires a delicate balance between the control of the body's immune response and the side effects. The ideal balance of therapeutic immunosuppressive drugs would inhibit the normal immune system response; defend against invasion from assorted pathogenic agents; and control the occurrence of the usual side effects, such as stomach ulcers and tremors (Box 11-2).

Box 11-2

Ideal Actions of Immunosuppressive Drug Therapy

- Offer a wide margin of safety between therapeutic and toxic dosing
- Produce selective effects on lymphoid cells without harming the rest of the body
- Suppress only the specific immune processes on the cells involved in causing the disease
- Require drug administration for a limited amount of time so the body's immune response becomes familiar with the foreign antigen and sees it as a part of the self
- Once the new immune response has been developed, be effective against the immune processes of the body

An example of an iatrogenic immune suppression occurs with an organ transplant recipient. The patient must take multiple medications, such as mycophenolate mofetil (CellCept) and cyclosporine (Sandimmune), for the rest of his life (Table 11-1). Lifelong immunosuppressive therapy does not completely eliminate the danger of organ rejection or other health complications, and the drugs need to be adjusted according to the systemic and immune response of each patient and to prevent toxicity. This treatment regimen must be strictly followed or the risk of organ rejection is increased from activation of the patient's own immune system to destroy the "foreign" organ.

Table 11-1
Types of Antirejection Medications

NAME	ACTION
Antithymocyte globulin	Immunosuppressive agent that selectively destroys T lymphocytes.
Basiliximab	Binds and blocks T cells from replicating and from activating B cells, thereby decreasing the production of antibodies that can lead to rejection.
Daclizumab	Inhibits the function of interleukin-2 (IL-2) receptors on the T cells, which prevents the cells from activating and stimulating the formation of antibodies.
Lymphocyte immune globulin	Reduces the number of circulating thymus-dependent lymphocytes in the blood.
Methylprednisolone	A corticosteroid with anti-inflammatory properties.
Muramab-CD3	Blocks the function of CD3 molecules in the membrane of human T cells.
Rapamycin	An antimicrobial that demonstrates antifungal, anti-inflammatory, antitumor, and immunosuppressive properties, which inhibits IL-2 so the T and B cells are not activated.

There is significant evidence that use of antirejection medications increases the survival rate of patients with certain organ transplants. These immunosuppressive agents are also helpful in the management of autoimmune disorders such as multiple myeloma, non-Hodgkin lymphoma, rheumatoid arthritis, and certain neoplastic growths.

Diagnostic Tests and Treatment of Immune Deficiencies

In the early stages of an autoimmune disorder, definitive diagnosis may be difficult. The health care provider must look at the complete health history, current complaints or symptoms, and physical examination findings so that the appropriate diagnostic studies can be performed (Box 11-3).

Box 11-3**Examples of Diagnostic Tests to Detect an Autoimmune Disorder**

- Complete blood count with differential
- Red blood cell count
- Creatinine level
- Antinuclear antibody (ANA)
- Bone marrow studies
- Serum protein
- Protein electrophoresis
- Immunoelectrophoresis
- T-cell and B-cell assays
- Enzyme-linked immunosorbent assays (ELISAs)

Some patients' immune systems have virtually no ability to respond to antigens, because they are unable to produce lymphocytes that are sensitized, or to synthesize antibodies, whereas others have a temporary minor defect in the humoral or cell-mediated immune response. In some types of immune deficiency, passive immunity can be accomplished by transfusing specifically sensitized lymphocytes to help the patient resist infection. Immune globulin (Ig) is a blood product that is given for the treatment of primary immunodeficiency diseases and certain autoimmune and other diseases in which antibody levels are low or dysfunctional. Immune globulin is also used to remove harmful antibodies and to block damage from immune cells. Administration of immune globulin may be given on a regular basis to provide passive immunity for those who are unable to produce their own antibodies. When impaired function of the bone marrow is involved, such as in leukemia, the patient may receive a bone marrow transplant to provide the stem cells that will eventually become immune bodies. To help prevent or combat infection in immunosuppressed patients, granulocyte colony-stimulating factor (filgrastim [Neupogen]) can be used to promote the growth of neutrophils, especially in patients with significant immunodeficiency.

As soon as an infection is evident, antimicrobial agents are usually given. However, these drugs can also be immunosuppressive and can lead to the development of multidrug-resistant organisms (MDROs), leaving the patient more vulnerable to infection and other complications. (Refer to [Chapter 6](#) for more on MDRO.)

Treatment in an immunocompromised patient is aimed at controlling the disease or eliminating the condition that led to an inadequately functioning immune system. For some immune disorders, treatment consists of minimizing the effects of the illness in the immunosuppressed patient in an effort to optimize quality of life.

▣ Older Adult Care Points

After age 70 years there is a definite decline in the function of the immune system. Many of the blood-forming tissues in the bone marrow are replaced with fat (lipids). B-cell numbers usually remain the same, but T-cell circulation is diminished.

❖Nursing Management**■ Assessment (Data Collection)**

When an immune deficiency is suspected, information about the current physical status of the

patient, such as his general state of health, infections he may have recently had, how the infections affected him, and how frequently they occur is gathered. It is important to determine whether occupational or environmental exposure to assorted agents has occurred. Nutritional status should be assessed by measuring height and weight and inspecting the skin, hair, and overall appearance. If a significant decrease in weight is noted (usually greater than 10%), ask if it was intentional. If not, ask when the loss first started. It is also essential to assess for risk behaviors such as intravenous (IV) drug use, multiple sexual partners, exposure to HIV, immunosuppressive drug therapy, alcohol consumption, and family history of genetic immune disorders.

Physical assessment should include palpation of the superficial lymph nodes in the neck, axilla, and groin to detect any abnormalities, as well as assessing the body systems involved in the patient's chief complaints. For example, the patient tells the nurse that she feels a bulge around her stomach, so the nurse would palpate both upper quadrants of the abdomen.

Body temperature should be closely monitored for significant changes, **although immune-deficient patients may not have a temperature elevation even in the presence of infection**. The body may not be able to recognize that an infection is beginning until much later in the process because of the body's impaired immune response. Therefore you must assess the whole patient and not just one or two areas, because important signs or symptoms of potential complications can be easily missed if assessment is not performed correctly.

Nursing Diagnosis and Planning

Problem statements for patients with immune deficiency should always include one regarding the potential for infection, which is a major problem. Psychosocial problems often accompany physical problems. Problem statements are based on the data gathered. Specific nursing diagnoses can be chosen from the NANDA-I list. The primary nursing goals when caring for a patient who has an immune deficiency are to (1) protect the patient from infection, (2) improve her health status, and (3) promote as high a degree of wellness as possible. Expected outcomes based on the patient problems might include:

- Patient will remain free from infection.
- White blood cell counts are within normal limits.

Planning care for the patient with an immune deficiency focuses on preventing exposure to pathogens. A patient whose immune deficiency is severe will likely need to be placed in protective isolation precautions. (See [Chapter 16](#) for additional information on neutropenia.) Working with patients in this type of isolation requires more time because of the need for donning and removing the personal protective equipment (PPE) before entering and on leaving the patient's room (see [Chapter 6](#)). Integrating care of this patient along with the rest of the patient assignments for the shift needs to be carefully planned. It is also important to teach patients with immune compromise the actions that should be taken once they are discharged from the hospital to prevent the onset of infection.

Patient Teaching

The Patient With Compromised Immunity

- Perform hand hygiene frequently and particularly before eating, after toileting, after petting an animal, after touching or shaking hands, and when returning home from shopping or errands.
- Wash the armpits, groin, genitals, and anal area at least twice a day with an antimicrobial soap and dry areas thoroughly.
- Obtain adequate rest daily to allow the body to function as well as possible.
- Take the temperature at least once a day.
- Assess for signs of infection on a daily basis and report such signs immediately to the doctor.
- Take all prescribed medications per instructions.

- Refrain from mingling in crowds, especially during flu season.
- Avoid others who are displaying signs and symptoms of an infection.
- Avoid travel to areas with poor sanitation or inadequate health care facilities.
- Cook foods well and avoid eating raw, unwashed foods.
- Wash dishes in the dishwasher or with hot, soapy water.
- Cutting surfaces, knives, and food preparation areas that have come in contact with raw poultry, meat, and seafood should be cleaned thoroughly after use.
- Do not dig in the soil or work with houseplants.
- Use stress reduction techniques on a regular basis.

■ Implementation

Proteins are needed to synthesize antibodies. If a patient has a condition or is on medications that suppress appetite or cause nausea, nutritional intake can be inadequate. Nutritional supplements may be added, and multiple small meals of high-protein foods chosen by the patient may need to be scheduled throughout the day. However, if the patient is on corticosteroid therapy, controlling overeating may be a challenge, and the patient must be carefully monitored for weight gain. Providing low-calorie snacks such as cooked vegetables and fruits instead of high-calorie chips, cookies, and sodas is helpful.

? Think Critically

How would you explain to a patient why good-quality protein is important in the diet when an immune deficiency is present?

! Safety Alert

Preventing Infection Among Immune-Deficient Patients

Transmission-based isolation precautions may be indicated when providing care to immune deficient patients (see Chapter 6). It is well known that while providing nursing care, scrupulous hand hygiene is the standard of care for all patients, but for an immunocompromised patient this basic measure could mean the difference between life and death. Disinfect any object, such as your stethoscope, that may serve as a source of infection. Observe strict surgical aseptic technique when performing invasive nursing care procedures such as catheterization, dressing changes, and IV infusions.

Excessive stress can further depress immune function. Many factors related to family, employment, finances, or transportation can significantly increase the stress level for the patient or loved ones. As illness progresses, many patients may have difficulties at school or work.

Collaboration with a social worker is often indicated. Referrals to community resources can greatly assist the patient and family in dealing with the added stress. You can be instrumental in teaching the patient stress-reduction strategies, such as light exercise, meditation, relaxation techniques, and guided imagery (see Chapter 7) (See the Evolve website.). 

Providing instruction regarding the immune disorder, any therapies recommended for the patient, and follow-up care are essential nursing interventions. Teach the patient and family to assess for signs of infection and to report them immediately. If traveling, the patient may need to employ additional safeguards to ensure he remains healthy. (See the Evolve website.)

■ Evaluation

Ensure that strict hand hygiene is being performed and adhere to transmission-based isolation

precautions. Check laboratory test results to assess whether immune function is improving. B-cell and T-cell assays are particularly important to monitor. Evaluate the patient for adequate recovery from any infection that might have been present, as well as for general well-being, appetite, weight changes, and side effects of medications or other therapies.

Human Immunodeficiency Virus and Acquired Immunodeficiency Syndrome

HIV/AIDS is one of the most commonly known immune deficiency disorders. When first identified in 1981, HIV/AIDS was a fatal disease, and the only treatments available were comfort measures and hospice care for several years. Today, there is still no cure, but there are now close to 40 U.S. Food and Drug Administration (FDA)-approved medications for treating HIV/AIDS. If HIV-positive patients are compliant with their HIV treatment, including routine testing to monitor overall health status and managing the effects of this chronic disease, it can be controlled and a good quality of life can be maintained ([Figure 11-1](#)).

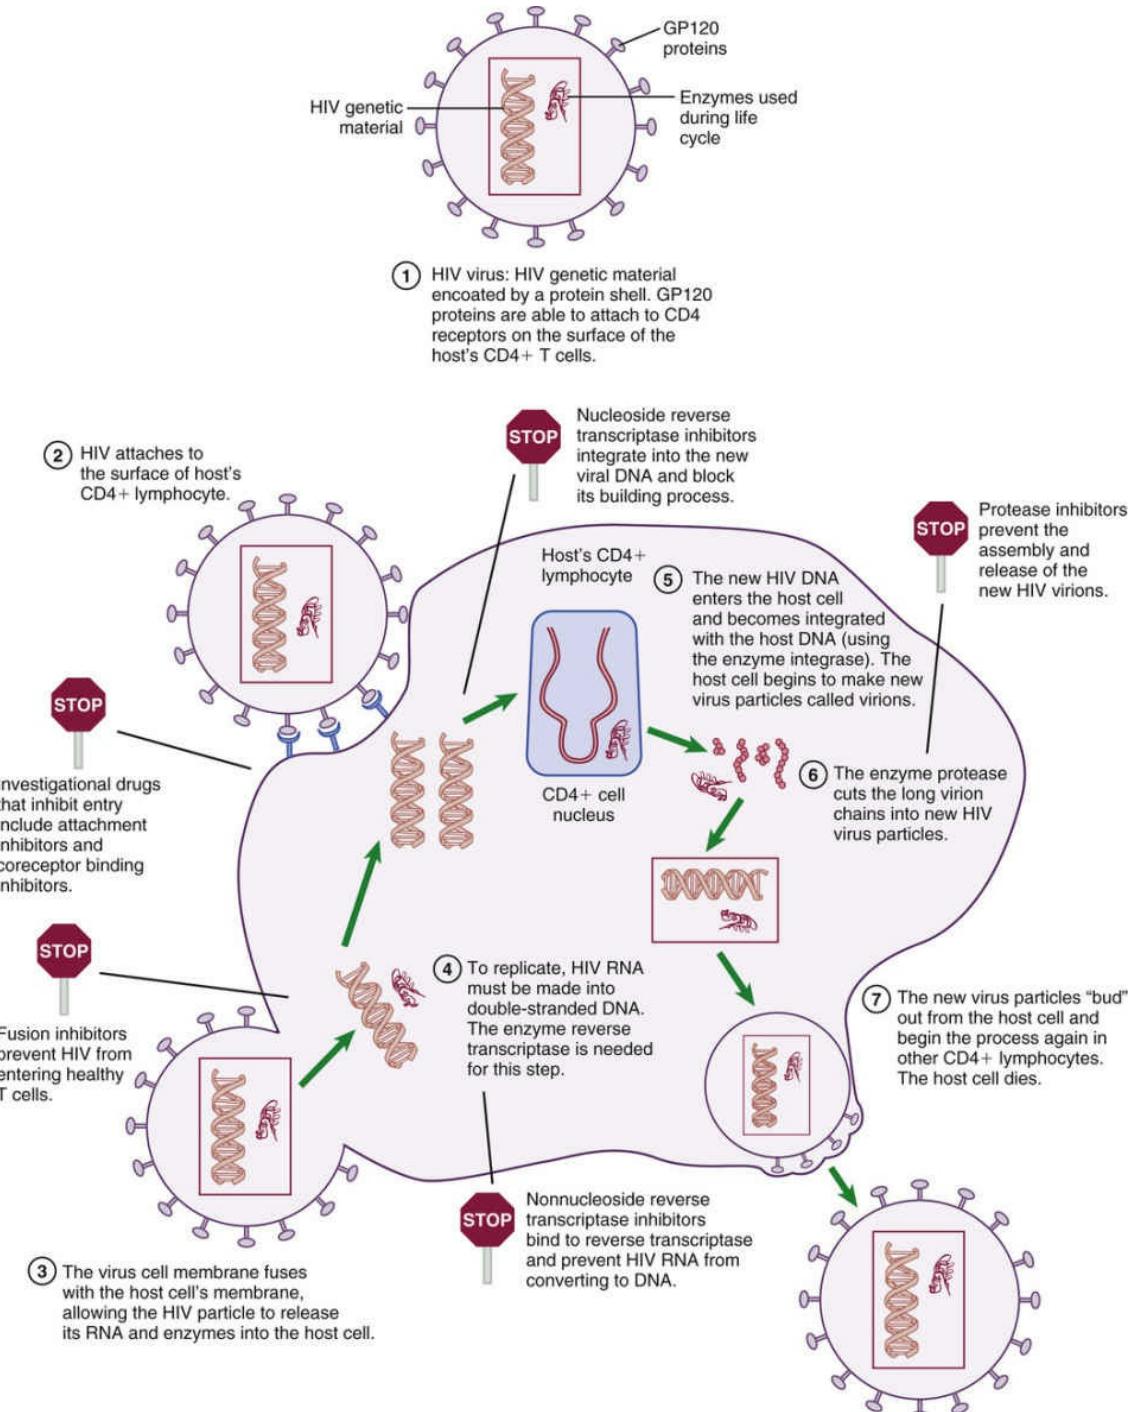

FIGURE 11-1 The steps in the life cycle of HIV and the effects of medications. (From Black JM, Hawks JH: *Medical-surgical nursing: Clinical management for positive outcomes*, ed. 8, Philadelphia, 2009, Elsevier Saunders.)

There are two forms of HIV infection. HIV-1 is the most common cause in the United States, Europe, and Asia. HIV-2 is widespread in western Africa. Research shows that HIV-2 spreads at a lower rate, has a lower plasma viral load, and takes longer to incubate, and individuals with this strain have a lesser risk of developing AIDS (AIDS Education and Training Center). Laboratory criteria can recognize recent (occurring within the past 5 months) or long-standing HIV infection (CDC, 2015). (See Evolve for the classification system for HIV.)

Clinical Cues

A person with AIDS also has HIV; however, a person with HIV does not necessarily have AIDS.

Pathophysiology

HIV-1 and HIV-2 are retroviruses that have only ribonucleic acid (RNA) as their genetic material. A **retrovirus** differs from other viruses because of an enzyme called **reverse transcriptase**, which helps the virus **replicate** (reproduce) and place its genetic material in the deoxyribonucleic acid (DNA) of the host cell. The resulting new DNA continues the process of replication and produces as many as 2 billion viral particles a day that are released from the host cell into the circulatory system, infecting other cells in the body.

In a healthy immune system, the T cells that have the protein CD4 on their surface are known as *CD4 positive (CD4+)* and as *T-helper cells*. Normally CD4+ T cells activate B cells, natural killer cells, and phagocytes. These cells participate in both cellular and humoral immunity. HIV primarily attaches to the CD4 cell wall receptors found on lymphocytes and some monocytes. The virus must go through several stages (**Table 11-2**) before it can effectively infect a host cell. Once infected with HIV, the host cell and the ability of the cell-mediated immune response is seriously impaired. Once the infection occurs in the CD4 lymphocytes and produces HIV, the CD4 cell itself dies. Overall, detection in the infected person's blood takes around 10 days for HIV-RNA and 25 days for HIV antibodies.

Table 11-2

Life Cycle of Human Immunodeficiency Virus

STAGE	ACTION
Viral attachment	Virus binds to envelope protein of T cells or CD4 molecules, causing virus to fuse to host cell. HIV-1 injects proteins into the target T-cell cytoplasm.
Uncoating	Protective coating surrounding cell is dissolved, and genetic material is used to reproduce the virus.
Reverse transcription	Single-stranded RNA is transcribed into double-stranded DNA with the help of the enzyme reverse transcriptase. This phase is very error-prone and can lead to mutations.
Integration	The new DNA inserts into the cell nucleus.
Viral latency	Virus has to wait for more protein building blocks to be formed by the cells to complete the reproductive process.
Final assembly	Viral protein production is activated, and T cells are modified by HIV-1 protease.
Budding	With its genetic material tucked away and a new outer coat made from the host CD4 cell's membrane, the newly formed HIV pinches off and enters into circulation, ready to start the whole process again.

An individual infected with HIV becomes more prone to **opportunistic infections (OIs)**, including those derived from normal flora found in the body (see **Chapter 6**). **Suppression** or inhibition of the immune response as a result of HIV infection is the cause of AIDS. The diagnosis of AIDS is usually made when an HIV-infected patient's CD4 T-lymphocyte count is less than 200 cells/ μ L or when a specific OI is diagnosed.

Transmission

Research has shown that HIV cannot be transmitted by casual contact, routine nursing care (which includes following Standard Precautions), or by household contact. The **only** mode of transmission is by exposure to HIV-infected blood, body fluids, or tissue (**Box 11-4**). Any break in skin or mucous membranes is an entry portal for HIV. The highest risks for becoming infected with HIV are having unprotected sex (oral, vaginal, or anal), sharing needles and syringes with an HIV-infected person, and maternal-fetal exposure.

Box 11-4

Additional Modes of Human Immunodeficiency Virus Exposure

- Percutaneous exposure through an open-bore needle stick with an HIV-contaminated needle
- Not using a latex condom or dental dam during sexual intercourse or activity
- Maternal transmission, referred to as vertical transmission, to an infant through vaginal delivery or breast milk
- Receiving a transfusion of HIV-infected blood or blood products
- Receiving an organ transplant from an HIV-positive person

A CDC report in 2012 stated that more than 1.1 million people in the United States are living with HIV infection and that 1 in 6 are unaware they are infected. Over the past decade, an increasing number of people are surviving with HIV, and the annual number of newly diagnosed cases has remained at around 50,000. In a CDC report looking at data for 2010, the largest proportion of new cases (78%) was found in men who have sex with men (known as MSM). The second highest rate (25%) of new HIV-positive cases was found in the heterosexual population, especially among those involved in the high-risk behaviors (CDC, 2012). The increased numbers of heterosexual cases may be from bisexual MSM engaging in unprotected sex with female partners. Participating in anal intercourse unprotected (no form of barrier precaution such as a latex condom) with an HIV-positive partner increases the risk of exposure because of the microscopic tears that occur in the lining of the anus (a lining that is thinner than the vaginal walls) during sex.

Exposure Prophylaxis

Pre-Exposure

In 2012, the FDA approved the use of Truvada (tenofovir disoproxil fumarate [TDF] 300 mg) and emtricitabine (FTC 200 mg) in combination with safer sex practices for pre-exposure prophylaxis (PrEP). Daily oral PrEP has been shown to be safe and effective in reducing the risk of acquisition for HIV-1. Reducing the possibility of HIV infection with its resulting morbidity, mortality, and cost to individuals and society is the primary goal of PrEP. Therefore PrEP is recommended for at-risk individuals such as sexually active adult MSM, a non-HIV-infected sexual partner, and illicit drug injection users (IDU). Before starting PrEP, acute and chronic HIV infection must be excluded by symptom history and HIV testing (Box 11-5). HIV status should be assessed every 3 months while taking PrEP to determine the feasibility of continuing this form of preventive therapy. Patients should be taught that a prescription of oral PrEP is to be taken daily and not just coitally timed or taken intermittently.

Box 11-5

Tests for Human Immunodeficiency Virus

- Rapid HIV antibody test
- Can use blood, saliva, or urine.
- Results available within 10 to 20 minutes.
- If positive, must be confirmed by Western blot (WB) test.
- Enzyme-linked immunosorbent assay (ELISA), a type of enzyme immunoassay (EIA)*
- Can use blood, saliva, or urine.
- If positive, must be confirmed by WB test.
- Antibody assays do not detect HIV antibody in the earliest stages of the infection. (HIV antibody may be detected normally from 2 weeks to 6 months after the acute infection.)
- False-positive ELISA may be seen in the presence of maternal antibodies.

- Sensitivity: 98%.
- WB test*
- Normal value: Negative.
- HIV-antibody test used to confirm a positive rapid HIV and ELISA.
- Can take up to 2 weeks to obtain results.
- False-positive WB may be seen in the presence of maternal antibodies.
- Polymerase chain reaction (PCR)
 - Can detect HIV in blood within 2 to 3 weeks of infection
 - Also used to determine viral load
 - Used to confirm whether an infant born to an HIV-positive mother is also positive for HIV.
- Sensitivity: 100%.
- Immunofluorescent antibody assay (IFA)
- Normal value: Negative.
- Sensitivity: 99.8%.
- CD4 cell count†
 - Normal value: 500 to 1500 cells/ μL .
 - Values below 350 cells/ μL prompt treatment.
 - Values below 200 cells/ μL , if accompanied by opportunistic infection, confirm diagnosis of AIDS.

*Test is not able to differentiate between HIV-1 or HIV-2.

†Not an HIV test; used to monitor immune system function.

Postexposure

Research has also found that postexposure prophylaxis (PEP) is more likely to be effective when the exposure is a single episode, such as unprotected sex (not using a latex condom) with an HIV-

positive partner, and the PEP is initiated less than 72 hours after exposure. PEP is not appropriate for cases of multiple unprotected sexual exposures or frequent IDU.

Health Promotion

People who take antiretroviral medications and have unprotected sex or who share needles and syringes with IDUs increase the risk of spreading the drug-resistant strains of HIV. Different factors can increase or decrease transmission risk. For example, taking antiretroviral therapy (i.e., medicines for HIV infection) can reduce the risk of an HIV-infected person transmitting the infection to another by as much as 96%, and consistent use of condoms reduces the risk of getting or transmitting HIV by about 80%. Using both condoms and antiretroviral therapy reduces the risk of HIV acquisition from sexual exposure by 99.2% ([Cohen et al, 2011](#)).

Safe Sexual Practices

Barrier protection must be practiced with every sexual encounter to prevent transmission of HIV or other infectious diseases. Latex condoms are more impermeable than other types of condoms. Polyurethane and deproteinized latex condoms are available for those allergic to latex. Condoms should not be stored in wallets, glove compartments, or hot or sunny areas, because the temperature will degrade the integrity of the condom material. Lambskin condoms help prevent pregnancy but may allow the virus to seep through; therefore they do not prevent transmission of HIV. Spermicides may help in preventing pregnancy, but they may cause tissue irritation and thereby increase the risk of injury to the mucous membranes. **The only guaranteed way to prevent sexual transmission of HIV is through abstinence.**

Another unsafe practice is orogenital (fellatio or cunnilingus) or oroanal (rimming) stimulation without a barrier (dental dam). Direct contact with any body fluids, such as semen or vaginal secretions and blood, must be avoided when the partner has HIV. There is no reason for HIV-infected individuals to completely discontinue sexual activity. Touch and various forms of intimacy are important parts of any relationship. However, there is a need to reduce the risk of transmitting the virus to others and to prevent exposure to other sexually transmitted infections, because additional infection is more difficult to treat when the immune system is compromised by HIV. It is important to note that if two people with HIV have sex with each other, condoms should still be used, because one partner may have a drug-resistant strain of HIV and can transmit that resistance to his or her partner, thereby increasing the risk of failed drug therapy for the partner's HIV infection.

Blood Products

For more than 30 years, all blood, blood products, and prospective organ donors have been screened for blood-borne pathogens such as hepatitis and HIV. According to the [CDC \(2010\)](#), the current risk of contracting HIV from receiving a blood transfusion, blood products, or a donated organ or tissue is extremely small, about 1 in 1.5 million.

Vaccine Development

HIV mutates rapidly, and countless mutations have been found, making it difficult to develop an effective vaccine against HIV ([CDC, 2010](#)). Mutations are found in newly infected as well as chronically infected individuals.

Prevention Through Education

Providing basic understandable information helps to dispel the myths and fears associated with HIV/AIDS, and assessing for high-risk behaviors helps develop and implement individualized education. A nurse can contribute to the prevention of HIV/AIDS by obtaining accurate facts and by educating others—patients, colleagues, and the community—about individual roles in helping to prevent the spread of HIV as stated in the *Healthy People 2020* objectives (<https://www.healthypeople.gov>).

Cultural Considerations

Human Immunodeficiency Virus and Minorities in the United States

HIV reporting in the United States indicates that more than 74% of new HIV infections occur among minorities, specifically African Americans and Hispanics (CDC, 2012). Several factors may contribute to the increased incidence of HIV/AIDS among minority groups:

- Lack of culturally sensitive and high-quality information about HIV risk and prevention
- Socioeconomic status and limited access to health care
- Health beliefs concerning sexual practices, roles of women, the value of children, and HIV treatment
- The cost of highly active antiretroviral therapy (HAART)

Data from <http://www.cdc.gov/hiv/basics/index.html>.

Signs and Symptoms

A person's preexisting health status influences the length of time needed for the humoral (antibody-mediated) and cellular (cell-mediated) immune responses to lodge a defense against HIV. HIV has variable clinical presentations and latent periods without obvious symptoms. Often, the initial signs and symptoms of infection are similar to flu: fever, fatigue, diarrhea, and loss of appetite. These symptoms may be ignored until the immune system begins to fail, as evidenced by the appearance of symptoms related to **sentinel infections** (opportunistic infections that indicate immunosuppression), such as oral thrush, recurrent infections, skin disorders, night sweats, swollen lymph glands, and significant unintended weight loss. It is typically at this point that the person seeks health care.

Diagnosis

Testing is available through a health care provider, local public health clinic, community agency, or by home test kit (Box 11-5). Currently, only two FDA-approved home testing kits are available in the United States. They are the Home Access HIV-1 Test System and OraQuick In-Home HIV. These kits allow a person to anonymously perform the test and obtain the results in their own home. Follow-up with a health care provider is strongly recommended, **regardless** of the test result.

The most common confirmatory test used in a clinical laboratory setting for any positive rapid HIV test is the enzyme-linked immunosorbent assay (ELISA). A positive HIV ELISA test is usually confirmed by performing a Western blot (WB) HIV gene sequence test. The patient may also require other tests for concurrent hepatitis or sexually transmitted infections.

It is estimated that 25% of HIV-infected patients are unaware of their infection and thus may be unintentionally infecting others (CDC, 2013). This is why it is recommended that any sexually active person between ages 13 and 64 be offered HIV testing at the time of a complete physical examination. It is no longer necessary to get specific consent for HIV testing or perform pretest and post-test HIV counseling in most states; however, it is important for the nurse to be familiar with state or local HIV testing requirements. The results of HIV antibody tests are confidential patient information and are HIPAA protected. If the patient elects to "opt out" of HIV testing, a note about the declination should be documented in the clinical record.

Management of Human Immunodeficiency Virus Infection

When an individual is confirmed to have HIV, a comprehensive history and physical examination for health status should be conducted, including additional baseline laboratory and diagnostic studies (Table 11-3). A CD4 lymphocyte count should be performed. If the count is less than 350 cells/mm³, it is recommended that the patient initiate antiretroviral therapy (ART) and prophylaxis for OIs.

Table 11-3

Additional Laboratory and Diagnostic Studies for Patients Newly Diagnosed With Human Immunodeficiency Virus*

LABORATORY/DIAGNOSTIC STUDY	PURPOSE
HIV antibody confirmatory study	Confirms diagnosis of HIV
CD4 count (reported as cells/ μ L)	Identifies what stage of HIV infection patient may be in; determines when to start antiretroviral therapy (ART) and prophylactic therapy for OIs; should be obtained every few months to assess immune and/or therapeutic response and evaluate need for starting ART
Quantitative plasma HIV-RNA level (viral load, reported as copies/mL)	Estimates level of HIV replication; helps determine need for starting or effect of ART and whether it needs adjustment
Drug resistance test (genotype: mutations; phenotype: viral replication)	Determines which ART will be most effective; prevents further development of drug-resistant strains of HIV; should be done as early as possible
Complete blood cell (CBC) count	Assesses for anemia, leukopenia, and thrombocytopenia; certain ARTs may be less effective if any of these are present
Comprehensive chemistry panel (includes electrolytes, BUN/creatinine, liver enzymes, cholesterol, triglycerides, glucose)	Determines baseline kidney and liver function, as well as lipid profile; results can be used to determine potential for complications with proposed ART
Sexually transmitted infections	Establishes whether treatment is needed
<i>Toxoplasma gondii</i> IgG	Detects prior exposure; if positive in the newly diagnosed, patient is at increased risk of developing CNS difficulties when CD level is <100 μ L
Hepatitis A, B, C	Determines prior exposure to hepatitis and also indicates need for vaccination against hepatitis A and B

*Additional testing may also include tuberculosis, PAP and pregnancy tests for women and prostate-specific antigen level and prostate examination for men, cytomegalovirus antibody screening, varicella IgG test, and eye examination along with routine health maintenance examinations based on the age of the patient.

BUN, Blood urea nitrogen; CNS, central nervous system; IgG, immunoglobulin G; OIs, opportunistic infections.

Adapted from UDHHS/HRSA: HIV/AIDS Bureau: *Guide for HIV/AIDS clinical care*, 2014.

Choice of optimal therapy is based on clinical data and individual factors, such as past health status, medication history, quality-of-life issues, and patient expectations of therapy. The World Health Organization (WHO) has established standard criteria for staging HIV infection (see Evolve).⑩ Genotyping or phenotyping blood tests to detect a drug-resistant strain of HIV are strongly recommended before starting drug therapy. Certain viral subtypes have a higher likelihood of developing drug resistance than others, and patients with these types may require closer monitoring.

The most effective current treatment is highly active antiretroviral therapy (HAART), a combination of available drugs recommended for HIV. This therapy is also effective against other conditions common to HIV/AIDS. OIs are treated with drugs specific to their cause, and sometimes antimicrobials are given to prevent infection. Table 11-4 presents the current classes of antiretroviral medications with select nursing implications and side effects. Regardless of the medications prescribed, it must be stressed that the more compliant the patient is with the proposed treatment regimen, the less likely he is to experience OIs.

Table 11-4

Antiretroviral Drugs Commonly Used to Treat HIV/AIDS

CLASSIFICATION	ACTION	NURSING IMPLICATIONS AND SIDE EFFECTS*
Nucleoside reverse transcriptase inhibitors (NRTIs)	Block conversion from RNA to DNA, thus preventing HIV genetic material from entering host cells	Monitor hepatic and renal function, complete blood cell count. Assess for signs of abdominal pain, nausea, vomiting, dizziness, neuropathy, difficulty in vision, hearing, touch, and balance. If sore throat, fatigue, shortness of breath, or flulike symptoms occur, drug class may need to be modified or discontinued completely.
Nonnucleoside reverse transcriptase inhibitors (NNRTIs)	Act by binding to and disabling reverse transcriptase, a protein that is needed for replication of HIV	Monitor renal and hepatic function and, if on anticoagulants, coagulation levels. Monitor for headaches, dysphoria, dizziness, insomnia, and nightmares. Diarrhea occurs in some patients. Contraindicated in pregnancy.
Protease inhibitors (PIs)	Work at the last stage of the viral reproduction cycle by preventing the virus from maturing and causing the release of immature viruses, which are then unable to infect other host cells	Monitor serum lipid levels, glucose, bilirubin levels. Cause a higher incidence of nephrolithiasis. Most must be given with food, and adequate hydration is required.
Fusion inhibitors	Block HIV from entering the CD4 cells of immune system	Must rotate injection sites because of local irritation. Associated with a higher risk of pneumonia.
Entry Inhibitors	Block proteins on CD4 cells	Associated with a higher incidence of hepatotoxicity, severe rash, and systemic allergic reaction.
Integrase inhibitor	Block the integrase enzyme needed for HIV to make copies of itself	Monitor hepatic function. Can cause life-threatening and fatal skin reactions.
Combination HIV medications	Block virus from binding, fusing, and entering into CD4 cells	Usually given to patients with a higher risk of drug resistance.
Coreceptor antagonist		Assess for headaches, nausea, vomiting, and skin rash.

*Refer to current drug reference materials for drugs prescribed and review side effects and patient teaching recommendations.

Adapted from UDHHS: HIV/AIDS Bureau: *Guide for HIV/AIDS clinical care*, 2014. For the most current recommendations, visit the AIDS Education Training Center (AETC) website: <http://www.aidsetc.org/resource/hrsa-guide-hiv-aids-clinical-care>.

As the disease progresses, many patients with HIV/AIDS and/or chronic conditions become too ill to work. It is estimated that drug therapy and laboratory testing for HIV/AIDS combined costs at least \$25,000 a year per patient and well over \$367,134 if a patient lives with HIV/AIDS for 20 years or more. The cost savings in 2009 from prevention programs were \$129.9 million, with at least 361,878 HIV infections averted (CDC, 2013a).

Think Critically

How would you go about helping a patient who has HIV find a way to afford the medications needed to control the disease?

Complications

Opportunistic Infections

OIs are diseases caused by microorganisms commonly present in the environment or the body that only cause disease when there is a weakening or suppression of the immune system. They are caused by many types of organisms: virus, bacteria, fungi, parasites, and even protozoa. OIs are often the hallmark of a transition from HIV infection to AIDS (Table 11-5). Each OI is treated with specific medication. With the increased effectiveness of HAART therapy for HIV patients, the incidence of OIs has decreased (Masur, 2012).

Table 11-5

Opportunistic Infections that Occur With Human Immunodeficiency Virus Infection

ORGANISM OR DISEASE	MANIFESTATIONS
Herpes simplex types 1 and 2	Type 1: vesicles and ulcerations on lips, oral membranes, and eye and possible meningitis; type 2: genital and/or perianal vesicles and ulcerations
Varicella-zoster (chickenpox virus)	Vesicles along dermatomes (nerve tracts); "shingles" with itching and burning pain, low-grade fever
Cytomegalovirus	Retinitis; esophagitis; stomatitis; gastritis with diarrhea, cramps, anorexia, and weight loss
Hepatitis B and C	Often no symptoms; jaundice, dark urine, abdominal pain, loss of appetite, nausea, vomiting, joint pain
Mycobacterium tuberculosis	Respiratory and CNS, bone, skin, GI tract, liver, and spleen; productive cough, fever, night sweats, weight loss
Mycobacterium avian complex (MAC)	Respiratory and GI tract; other systems may be affected; nonproductive cough, fever, malaise, fatigue
Cryptococcosis	Fungal meningitis, fever, headache, seizures, motor dysfunction, altered mental status
Histoplasmosis	Fever, pneumonia, lymphadenopathy, weight loss, CNS symptoms
Coccidiomycosis (Valley fever)	Pulmonary infection, fever, purulent sputum, rash
Candidiasis	Thrush; esophagitis; vaginitis; yellow patches in mouth, GI tract, and vagina
<i>Pneumocystis jiroveci</i> (formerly <i>P. carinii</i> , PCP)	Nonproductive cough, shortness of breath, fever, malaise, night sweats, fatigue, weight loss
Toxoplasmosis	Flulike symptoms, inflammatory response
Cryptosporidiosis	Gastroenteritis, dehydration, malnutrition, debilitation

CNS, Central nervous system; GI, gastrointestinal.

Wasting Syndrome

Wasting syndrome is defined as losing more than 10% of weight along with at least 30 days of either diarrhea or weakness accompanied by fever. There is loss of body fat and muscle mass. This syndrome has a strong correlation to progression of AIDS and typically leads to death. Contributing factors include decreased appetite, the inability to absorb nutrients through the small intestines because of diarrhea, and an altered metabolism that may be associated with hormone levels.

Neoplasms

Kaposi sarcoma.

Kaposi sarcoma (KS) is one of the most common causes of malignancy in HIV-positive people and is more common in HIV-infected men than women and in African American men than in whites (American Cancer Society, 2013). KS is caused by the human herpesvirus type 8. KS does not usually cause death. KS appears as discolored areas on the skin but can also form inside the mouth, lungs, and intestines (Figure 11-2). The skin discoloration may range from pink to red or purple. The lesions tend to darken over time. In people with olive or black skin, the lesions may appear dark brown or black. The discoloration is caused by the formation of many tiny blood vessels and cancer cells under the skin.

FIGURE 11-2 Kaposi sarcoma. (From Van Meter KC, Hubert RJ: *Gould's pathophysiology for health professions*, ed. 5, Philadelphia, 2015, Elsevier Saunders.)

HAART has been shown to halt or even eliminate the progression of skin lesions in some individuals and has decreased the incidence of KS. Skin lesions can be concurrently treated with liquid nitrogen, surgical removal, or injection with anticancer drugs. Low-dose radiation therapy is used for small skin lesions. Larger doses are required for internal organs and lymph node involvement. Radiation treatment can reduce the size of tumors near lymph nodes; this improves lymph flow and decreases lymphedema (see Chapter 38). If KS has spread into internal organs and HAART treatment is insufficient, chemotherapy or immunotherapy is used.

Lymphomas.

Lymphomas are tumors of the tissues and cells of the lymphatic system. Non-Hodgkin lymphoma (NHL) is the most common lymphoma in people with HIV/AIDS. Most cases of NHL in these patients are large B-cell lymphomas and have an approximate 2-year mortality rate. HAART therapy appears to slow its progression; however, death is the outcome in a large percentage of cases (Quinn, 2011).

Neurologic Complications

HIV encephalopathy and AIDS dementia may occur at any point in the disease process. In some individuals it may be the only symptom. The neurologic signs and symptoms displayed could arise from the progression of the virus or they could be a result of opportunistic infections, tumors, or drug-related complications. The symptoms have a very subtle beginning and are difficult to differentiate from depression, Parkinson disease, and Alzheimer disease.

Treatment with HAART appears to be the most effective intervention by targeting the primary cause of the problem. Nursing interventions focus on preventing the individual from doing harm to self or to others and ensuring that daily needs are being met.

❖Nursing Management

■ Assessment (Data Collection)

The assessment should include a review of signs and symptoms; functional level (ability to perform activities of daily living [ADLs]); safety; self-care abilities; support systems; financial status; risk behaviors; living environment; and understanding of disease process, transmission, and therapeutic regimen. The assessment of the functional level is an ongoing assessment using a tool such as the Karnofsky Performance Scale (see the Evolve website). 

History and Physical Assessment

The history should include a general assessment of the patient's past and present status. Previous history of HIV testing, such as blood donations or military service, might be important for determining the timing of HIV infection. Current prescription medications and treatments should be documented, and documentation should include whether the patient is on any experimental, herbal, immune complex boosting agents or other complementary and alternative therapies. If the patient has been HIV positive for some time, it is important to obtain a history of OIs. Ask if there is any history of respiratory illnesses that increase risk for current problems, such as bacterial or opportunistic pneumonia, chronic obstructive pulmonary disease, or asthma. Assess for smoking

history. Determine whether the patient has been tested for *Mycobacterium tuberculosis* (MTb)—if so, when, and what were the results? The neurologic history should include questions about pain or numbness in the extremities and changes in mental status (because HIV/AIDS can cause serious neurologic changes as the disease progresses). A sexual history is needed to ascertain risk behaviors such as multiple sexual partners, possible exposure to other sexually transmitted infections, and a history of substance use to determine the risk of transmission. Discussing notification of sexual or needle-sharing partners is essential.

A complete head-to-toe physical assessment should be performed.

Focused Assessment

Data Collection for Patient With Human Immunodeficiency Virus

First gather a general health history, then:

- Obtain height and weight; note any loss from usual weight.
- Obtain vital signs. Assess for hypotension, orthostatic hypotension, and fever.
- Determine level of consciousness, orientation to time and place, cognition, and concentration ability.
- Assess for visual changes.
- Assess mouth condition and presence of any lesions.
- Determine whether there has been a change in eating pattern.
- Evaluate ability to swallow.
- Determine presence of nausea, vomiting, or diarrhea. If diarrhea is present, note the volume, quantity, and duration.
- Check lymph nodes for any swelling or hardness.
- Assess for dehydration and electrolyte imbalances.
- Auscultate the heart.
- Assess quality of respirations; auscultate breath sounds.
- Determine character of the cough and sputum if cough is present.
- Assess condition of skin and mucous membranes.
- Assess for peripheral and periorbital edema and lymphedema.
- Identify any psychosocial issues that may complicate or enhance care.

When there is considerable weight loss, referral to a nutritionist or dietitian and providing written materials, such as how to plan a nutritious balanced diet using the USDA Choose My Plate (available at <http://www.choosemyplate.gov/>), can also be helpful. Changes in nutritional status could be caused by nausea, vomiting, or diarrhea related to the HAART regimen.

Psychosocial History

The psychosocial assessment should include a history of interpersonal relationships, educational level, and career information. It is important to determine whether the patient has told his family of his HIV status. Examples of questions to ask include: Have you experienced multiple losses, such as your job, house, or partner? What is your living situation? Do you live with someone who is

helpful? Referrals (such as community-based AIDS organizations) are needed if the patient does not have a support network.

Think Critically

A diagnosis of HIV affects a person's self-concept. How could you help a patient to voice his feelings about the diagnosis and find an effective means to cope with the disease?

Table 11-6 identifies common patient nursing problems, expected outcomes, and interventions that may be associated with systemic, psychosocial, or specific body system responses to HIV/AIDS.

Table 11-6

Problem Statements and Interventions for a Patient With Immune Deficiency or Autoimmune Disorder

PROBLEM STATEMENT	EXPECTED OUTCOMES	NURSING INTERVENTIONS
Potential for infection due to depressed immune function	Patient will exhibit no signs of infection; normal temperature.	Monitor body temperature daily. Monitor for outward signs of infections and for symptoms of opportunistic infection. Assess for signs of dehydration and altered mental status.
Altered gas exchange due to excessive lung secretions and shallow breathing	Patient's oxygenation will improve to within baseline levels within 3 wk of beginning treatment.	Encourage deep breathing and coughing as indicated. Conserve strength and oxygen by assisting with activities of daily living. Position patient to allow for maximum chest expansion. Monitor breathing patterns and breath sounds q4h. Provide supplemental oxygen as ordered. Monitor blood gases as ordered. Suction airway PRN as ordered.
Altered skin integrity due to multiple areas of skin abrasion and dehydration	No further areas of skin breakdown will occur. Areas of abrasion will heal within 2 wk.	Assess skin status q4h; assess for areas of excoriation, lesions, rashes, and discoloration. Report changes from baseline findings. Change linens as needed if diaphoresis or incontinence is present to keep skin clean and dry. Use elbow and heel protectors and special mattress if patient is bedridden. Encourage adequate fluid intake per physical status. Monitor intake and output. Assess for signs of dehydration or fluid overload/edema q4h.
Altered nutrition due to eating and swallowing difficulties	Patient will not experience further weight loss.	Assess patient's ability to take in food, chew, and swallow. Monitor weight twice a week. Record input and output. Administer antiemetics as ordered. Assess the availability of food within living situation. Assess ability of caregiver to meet patient's nutritional needs. Administer dietary supplements if required.
Pain due to pressure on nerves and discomfort from peripheral neuropathy	Pain will be controlled within tolerable levels within 4 days.	Assess pain level and patient's methods to relieve it. Relieve causes of pain by correcting underlying condition if possible. Administer pain medications as ordered; assess amount of relief provided by medication; if relief is not adequate, consult with provider for more effective protocol for pain relief; explore use of NSAIDs and antidepressant medications for pain relief in conjunction with other analgesics. Implement adjunctive therapies to assist with pain relief: massage, cold or hot applications, repositioning, distraction, meditation, imagery. Teach relaxation techniques.
Altered activity tolerance	Level of activity intolerance will improve within 1 mo.	Encourage periods of rest alternated with periods of activity; plan activities according to usual stamina levels; change schedule of activities as degree of fatigue indicates need; assist with activities of daily living as needed to conserve energy.
Limited coping ability due to diagnosis of life-threatening illness, fatigue, and anxiety	Patient will exhibit usual effective coping techniques to meet challenges of the illness.	Establish rapport with the patient, the partner, and family. Assess past methods of effective coping. Assess patient's strengths. Schedule activities that may cause stress when the patient is most rested or has support person available. Review effective methods for problem solving.
Inability for self-care due to fatigue, deterioration of physical condition, mental changes, and neurologic impairment	Patient will accomplish as many activities of daily living as possible without undue fatigue. Patient will accept assistance with activities of daily living within 2 wk.	Assess ability to perform own activities of daily living. Provide assistance for activities the patient is unable to perform. Refer to occupational and physical therapy for assistive devices and home equipment needed. Instruct significant other and family members how to assist with activities of daily living.

NSAIDs, Nonsteroidal anti-inflammatory drugs; PRN, as needed.

Planning

An HIV-positive patient can have significant issues related to finance, employment, housing, mental health, substance abuse, or other medical problems. HIV care is usually performed in an outpatient clinical setting, and the health care team may include the patient, nurses, health care providers, dietitian, pharmacist, case manager, and primary caregiver at home. Information related to the patient's social and economic status is critical for the team to develop and implement a successful treatment plan. The patient's ability to participate in the delivery of the plan of care must be periodically reassessed. If the patient is able to have a role in decisions and adjustments to the treatment plan, it increases the likelihood of compliance. The major nursing goals are listed in Box 11-6.

Box 11-6

Major Nursing Goals for Adults With Human

Immunodeficiency Virus/Acquired Immunodeficiency Syndrome

- Prevent secondary bacterial, viral, and fungal infections.
- Prevent wasting resulting from malnutrition.
- Maintain or improve the present level of immune function.
- Maintain adequate social functioning.
- Maintain or improve current mental status.

Instruct the patient on how to take the medication and which medications should be taken with or without food. By consistently taking antimicrobials and antiretroviral medications as ordered, less resistance to the drugs occurs, and the effectiveness of the drugs is thus prolonged.

Encourage social interaction and independence in activities as tolerated. Support groups can boost feelings of self-esteem and self-worth. Social interaction may reduce situational depression and can empower the patient. Promoting a positive attitude may reduce feelings of powerlessness. Referral to community-based AIDS organizations is appropriate, with the patient's consent.

■ Nutrition Considerations

Improving Food Intake for a Patient With Acquired Immunodeficiency Syndrome

Encourage the following measures:

- Eat small amounts frequently.
- Eat high-calorie snacks or commercially available liquid supplements or "power" bars.
- Eat foods at room temperature.
- Soften dry grain foods such as breads, crackers, and cookies in milk before eating them.
- Eat nonabrasive foods that are easy to swallow such as pasta, well-cooked eggs, baked fish, soft cheese, pudding, and ice cream.
- Suck on ice pops to numb or soothe mouth pain.

The patient should avoid:

- Raw fruits and vegetables, unless they are thoroughly washed.
- Spicy, acidic, or salty foods.
- Alcoholic and carbonated beverages.
- Excessively hot food.

■ Implementation

In accordance with the CDC, Standard Precautions must be consistently used when caring for all patients (see [Chapter 6](#) and [Appendix B](#)). Hand hygiene is critical for health care providers, the patient, and the family to prevent secondary infections. Role modeling and teaching about the importance of hand hygiene happens during routine care. You must also teach about decreasing infection risk in the home setting.

■ Evaluation

A patient's expectations may not be the same as those of the health care team or the primary caregivers, so when outcomes are evaluated, variations in expectations should be addressed by all of those involved. Monitoring laboratory tests to determine immune status, viral load, blood cell status, and effects of medications is a large part of the evaluation process.

Human Immunodeficiency Virus Risk in Patients Older than 50 Years

The life expectancy in the United States has increased to greater than 78.74 years ([CDC, National Center for Health Statistics, 2013](#)). By 2015, it is estimated that more than half of the people with HIV in the United States will be older than 50 years and 17% of all new HIV/AIDS cases are in this population ([CDC, 2013b](#)). The media tend to report more on younger populations with HIV/AIDS, including MSM, transgendered individuals, the homeless, and IV drug users. Many older adults are single because of divorce or death of a spouse or partner. A persistent myth is that older adults are no longer interested in sex. Because pregnancy is not a consideration, condoms are typically not used as they should be. Also, erectile dysfunction medications allow sexual activity for longer periods in many men.

Many older adults are not aware of the risks, but old age is no barrier to becoming infected with HIV. The primary modes of transmission in adults older than 50 years are through heterosexual contact and sharing of contaminated needles among IV drug users. An older adult may ignore symptoms because of a belief that they are a normal part of aging. By the time an older at-risk adult is actually diagnosed, the survival rate is markedly less than that of a younger person. This is probably because of comorbidities (simultaneous presence of two chronic diseases or conditions in a patient) common to the older population. Skin and mucous membranes are more fragile in the older adult, possibly making transmission easier. Menopausal women are more vulnerable to HIV infection from sexual transmission, because decreased estrogen levels cause thinning and decreased lubrication in the vagina. In the older population, the virus is also spread more easily because of the thinning and microscopic tearing of the anal mucosa. Educate and encourage this age group about the need for HIV testing in **both** partners before entering into a new sexual relationship, along with recommendations to use barrier techniques.

Older Adult Care Points

New diagnoses of HIV infection are growing faster among adults older than 50 than among those younger than 50 years. All sexually active adults should be assessed for at-risk behaviors, regardless of their age. Age-specific referrals to a geriatric nurse practitioner or counselor with experience working with older adults may also be appropriate.

Community Education and Care

All nurses should be alert to the possibility of transmission of HIV and the methods of prevention and should share this information with at-risk populations. Patients and their partners, families, and friends should all be included in the educational opportunities.

Human Immunodeficiency Virus Confidentiality and Disclosure Issues

When a patient signs a form to release medical information, the form must also state whether the patient wants his HIV/AIDS diagnosis and treatment information released. If protected health information (PHI) is released without following Health Insurance Portability and Accountability Act (HIPAA) guidelines, a lawsuit and even loss of the nursing license may be the penalty for a nurse who is indiscreet and discloses PHI without specific patient authorization. For the patient, the consequences may be the loss of a job, housing, or insurance benefits and possible discrimination and rejection by families and friends.

■ Legal and Ethical Considerations

Confidentiality and Human Immunodeficiency Virus/Acquired Immunodeficiency Syndrome

The diagnosis of HIV/AIDS is a medical diagnosis and can be discussed among health care personnel like any other medical diagnosis for the purpose of rendering care to the patient and does not require a patient's consent. The right to disclose HIV status is regulated by the state in which you are working, but all states do require the reporting of new HIV/AIDS cases for public health statistical tracking. It is important for every licensed nurse to be aware of the state regulations and institutional policies. It is always preferable for the patient to disclose diagnostic information and HIV status to the family. If the patient has given permission (preferably in writing), the family can be informed about the health status and what progress or lack of progress is occurring.

■ Legal and Ethical Considerations

When a Nurse Has Human Immunodeficiency Virus

If a health care worker is HIV positive, there is a risk of transmitting the virus to others. What are the ethical, moral, and legal responsibilities to patients in such a situation?

Blood-Borne Pathogen Exposure and Health Care Workers

The CDC and the Occupational Safety and Health Administration (OSHA), along with other health care agencies, have developed evidence-based guidelines to prevent exposure to blood, body fluids, and other potentially infectious microorganisms (OPIM) (see [Box 6-4](#)). If the health care worker correctly follows these guidelines, the risk of being exposed is markedly reduced.

■ Safety Alert

Possible Exposure to Human Immunodeficiency Virus

After an unintended exposure to the blood or body fluids of a person who either is HIV positive or whose HIV status is unknown, the need for PEP must be assessed within 2 hours. Exposure can be from a large-bore needle stick, significant mucosal contact with body fluids, or contact with body fluids via a break in the skin. The facility's Infection Preventionist or employee health office should

be notified of the exposure. Two- or three-drug therapy, depending on the degree of determined risk, may be initiated as soon as possible after the exposure event. The drugs used are from different drug classes (nucleoside reverse transcriptase inhibitors, nonnucleoside reverse transcriptase inhibitors, or protease inhibitors). The medications may need to be taken until HIV status from the source patient has been determined; if the patient is known to be HIV positive, the drugs should be taken for 4 to 6 weeks. If PEP is indicated, the nurse may be unable to work for the first few weeks while taking the medications because of the significant side effects (i.e., headaches, nausea, vomiting, and diarrhea).

Autoimmune Disorders

Autoimmune disorders are caused by the immune system reacting against the body's own cells. The three categories of autoimmune disorders are classified according to how extensively the disorder affects body tissues: (1) **local**, which affects only a single organ or tissue; (2) **systemic**, which affect many organs or tissues; and (3) **mixed localized and systemic**, which can cause problems both in a localized area and systemically.

Signs and Symptoms

Table 11-7 gives a partial list of diseases, with signs and symptoms, possibly caused by autoimmunity. Not all experts agree, but at this time more than 80 diseases are thought to be triggered by an alteration in immune function. Some of the diseases have other causes in addition to autoimmunity, and some may be primarily a disorder of the immune system.

Table 11-7
Autoimmune Disorders and Body Systems Affected

DISORDER	AREA AFFECTED	SIGNS AND SYMPTOMS
Systemic Autoimmune Disease		
Autoimmune hemolytic anemia	Red blood cells	Anemia, splenomegaly, hyperbilirubinemia, fatigue
Bullous pemphigoid	Skin, more typically on arms, legs, and trunk	Large fluid-filled vesicles on a swollen erythematous base
Goodpasture syndrome	Lungs and kidneys	Shortness of breath, hemoptysis, fatigue, edema, pruritis
Polymyalgia rheumatica	Large muscle groups, primarily neck, shoulders, upper arms, thighs, and hips	Moderate to severe aching and stiffness, fatigue, unintentional weight loss, anemia Can literally appear overnight; usually goes away on its own
Rheumatoid arthritis	Heart, lungs, joints, nerves, and skin	Variety of symptoms depending on what is most affected: fever, fatigue, joint pain and stiffness, deformity of the joints, shortness of breath, chest pain, edema, loss of sensation, rashes
Systemic lupus erythematosus (lupus)	Brain, heart, lungs, kidneys, joints, blood cells, and skin	Fatigue, weakness and light-headedness, shortness of breath, chest pain, edema, rash, butterfly rash on the face in some cases
Temporal arteritis/giant cell arteritis	Arteries of the head and neck	Can affect all vessels within the body Symptoms vary depending on location
		Can have headache, loss of vision, chest pain, dyspnea, kidney failure, abdominal pain, weight loss, skin rash
Wegener granulomatosis (a form of vasculitis)	Nasal sinuses, lungs, and kidneys	Causes end organ damage and can be life threatening if not treated
		Rhinitis is generally first sign in most patients
Localized Autoimmune Diseases		
Addison disease	Adrenal glands	Slow progression Fatigue, dizziness, muscle weakness, diarrhea, diaphoresis, orthostatic hypotension, hyperpigmentation of the skin
Celiac disease	Gastrointestinal tract	Intolerance of gluten products; impaired nutrient absorption, abdominal pain, chronic diarrhea, vomiting, weight loss, pale, foul-smelling or fatty stools
Crohn disease	Ileum and beginning of large colon	Persistent diarrhea, rectal bleeding, fever, loss of appetite, bloody stools
Graves disease (hyperthyroidism)	Thyroid gland	Tachycardia, tremors, nervousness, weight loss, intolerance to heat
Guillain-Barré syndrome	Peripheral nervous system	Ascending paralysis, starting in legs, then arms, then face Deep tendon reflexes disappear Some patients require mechanical ventilation until recovery occurs
Hashimoto thyroiditis (hypothyroidism)	Thyroid gland	Weight gain, coarse skin, drowsiness, intolerance to cold
Multiple sclerosis	Brain and spinal cord	Abnormal sensations, weakness, vertigo, vision problems, muscle spasms
Myasthenia gravis	Connection between nerves and muscles (neuromuscular junction)	Muscles weaken and tire easily, especially the eyes
Pernicious anemia (vitamin B ₁₂ deficiency)	Select cells in stomach	Anemia results in inadequate production of mature blood cells and maintenance of nerve cells and leads to fatigue and weakness; nerves can be damaged with resulting loss of sensation
Primary biliary sclerosis, primary sclerosing cholangitis, autoimmune hepatitis	Liver	Occurs more commonly in women Chronic cholestasis, which leads to destruction of the smaller bile ducts Fatigue, pruritus, hepatomegaly, jaundice, hyperpigmentation
Raynaud disease (isolated)	Fingers, toes, nose, ears	Can be triggered by changes in temperature
Raynaud phenomenon (accompanied by other autoimmune disorders [scleroderma, lupus])		Numbness and tingling in digits, which then become pale and turn blue because of lack of oxygen; as digits warm up, they turn red because of influx of blood Restricts blood flow of the microvascular system, can cause pitting ulcerations In some cases, gangrene requiring amputation
Type 1 diabetes mellitus	Islet (beta) cells of pancreas (insulin production)	Excessive thirst, appetite, and urination (initial symptoms) Can lead to significant multisystem disease (blindness, kidney failure, impaired circulation, amputations, especially of lower extremities)
Mixed Localized and Systemic Autoimmune Disorders		
Scleroderma	Localized: skin	Skin and connective tissue tightens and hardens
	Systemic: heart, lungs, kidneys, and intestines	Skin will have patches that are thick, white, or pale in the center surrounded by a purple border Heart may develop dysrhythmias; congestive heart failure and pericarditis can also occur Lungs become scarred (pulmonary fibrosis); pulmonary hypertension may develop Kidneys will release more protein into the urine; can trigger hypertension
Sjögren syndrome	Salivary glands, lacrimal glands, joints	Dry eyes and mouth, gum disease, dental caries
	Can also affect lungs, lymphatic system, kidneys, and muscles	

Data from Cooper K, Gosnell K: *Adult health nursing*, ed. 7, St. Louis, 2014, Elsevier; Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 7, Philadelphia, 2012, Elsevier Saunders.

Diagnosis

Diagnosing autoimmune disorders can be difficult. A detailed health history and complete physical examination must be conducted. Symptoms may be vague and intermittent and may occur over a period of years. Some health care providers may hesitate to initiate diagnostic studies based on a

patient's self-report, because results are inconclusive in the earlier phase of the disease process. This can be frustrating for patients who "just have not felt well for some time" and are looking for an explanation or diagnosis. There are many tests that can be performed to rule out conditions, but they can be costly and inappropriate in earlier phases of the disorder.

Blood tests, such as a complete blood count with differential, will typically be performed (see Box 11-3). Some immune disorders are associated with a specific antibody that can be detected in the blood. Other laboratory tests evaluating inflammation, such as an erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels, are not specific to immune disorders but may help confirm the diagnosis when used with other information. For disorders that are organ specific, a biopsy of the affected tissue may be used to confirm or exclude the diagnosis.

Treatment and Nursing Management

Treatment falls into two categories: (1) replacement or support of lost or ineffective body function and (2) therapies targeted to halt the destructive process. The goal of physical, occupational, speech, or even psychological therapeutic interventions is to help the patient learn how to effectively deal with the disorder and be able to function at the highest achievable level for as long as possible. In medication therapy for autoimmune disorders, the chemical treatment is aimed at altering cell function to prevent further harmful effects, not kill the cells. However, some medications are able to minimize side effects, whereas others can cause additional medical complications. Other autoimmune disorders are discussed in relevant chapters (multiple sclerosis, Chapter 24; rheumatoid arthritis, Chapter 32; and psoriasis, Chapter 42).

Assignment Considerations

Protecting the Patient

Any health care team member that has a potentially infectious condition, such as a cold or the flu, should not be assigned to care for patients with alterations in immune function. If symptoms develop in the middle of the shift, the staff member should wear a mask and use gloves until the assignments are reorganized.

Systemic Lupus Erythematosus

Systemic lupus erythematosus (SLE), also known as lupus, is an autoimmune disease. The term *erythematosus* refers to the **erythema** (patchy congestion of capillaries of the skin with blood) that often accompanies the disease. As with most autoimmune disorders, the cause is largely unknown. Genetics, hormones, immunologic response, and environmental influences may play a role in the development of this disease; however, no specific link has been established. In SLE, the body begins to produce abnormal antibodies that attack the target tissues or cells instead of foreign agents such as bacteria, fungi, and viruses. This assault can go on for years before onset of symptoms become evident and health care is sought.

SLE has a discoid form (skin is affected but internal organs are not), a systemic form (involves internal organs and is the most common type), and a drug-induced form (tends to be milder and less damaging to the body). Although SLE is incurable, symptoms can be treated.

Individuals of all ages have been diagnosed with SLE, but the typical age of onset appears to occur after puberty and peaks between 15 and 40 years of age. It occurs more often in women than men (a ratio of 11 : 1). The overall rate is 5 new cases per 100,000 individuals in the United States (CDC, 2012). Of note, African Americans and Hispanic women of childbearing age in the United States are affected more often than other ethnicities. In 2006 the 5-year survival rate was around 97% at 5 years; now the 10-year survival rate is 90%, and many affected individuals live out a normal life span (Schur, 2014).

Etiology and Pathophysiology

SLE occurs from an abnormal reaction of the body's immune system, especially against proteins found in the nucleus of body cells. Inflammation of the muscles, blood vessel abnormalities, and immune complex deposition in tissues occur throughout the body. SLE usually waxes and wanes

throughout the course of the disease. Some individuals have a very mild form of the disorder and have infrequent flare-ups with minimal symptoms. Others have severe, debilitating symptoms that, if left untreated, can lead to death.

Prolonged exposure to sunlight can initiate a flare-up of SLE, so use of sunblock and covering of the skin are important. A variety of drugs exacerbate lupus, such as oral contraceptives (especially in women who test positive for the presence of antiphospholipid antibodies), sulfa-based antimicrobials, and penicillin. In addition, hydralazine, procainamide, and minocycline are known to produce a lupuslike syndrome.

Signs and Symptoms

Signs and symptoms tend to come and go and include painful or swollen joints and muscle pain, extreme fatigue, unexplained fever, red rash usually on the face ([Figure 11-3](#)), unusual loss of hair, sensitivity to the sun, weakness and profound fatigue, mouth ulcers, poor appetite, weight loss, abnormal menses, edema, and swollen glands. All body systems can be affected ([Figure 11-4](#)). Weakness is a hallmark of the SLE disease process. It is not unusual to see skeletal abnormalities such as asymmetrical arthritis, especially in the fingers, hands, wrists, and knees. Azotemia, hematuria, proteinuria, and pyuria indicate renal involvement, such as nephrotic syndrome or acute or chronic renal failure (see [Chapter 34](#)). Neurologic symptoms may include headaches, seizures, psychosis, and other cognitive disorders. Pleurisy may develop in the lining of the lungs and can lead to chest pain, shortness of breath, and pulmonary hypertension. Heart failure, pericarditis, and coronary disease may also be symptomatic of SLE (see [Chapters 19](#) and [20](#)).

FIGURE 11-3 The characteristic “butterfly” rash of systemic lupus erythematosus. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 7, Philadelphia, 2013, Elsevier Saunders.)

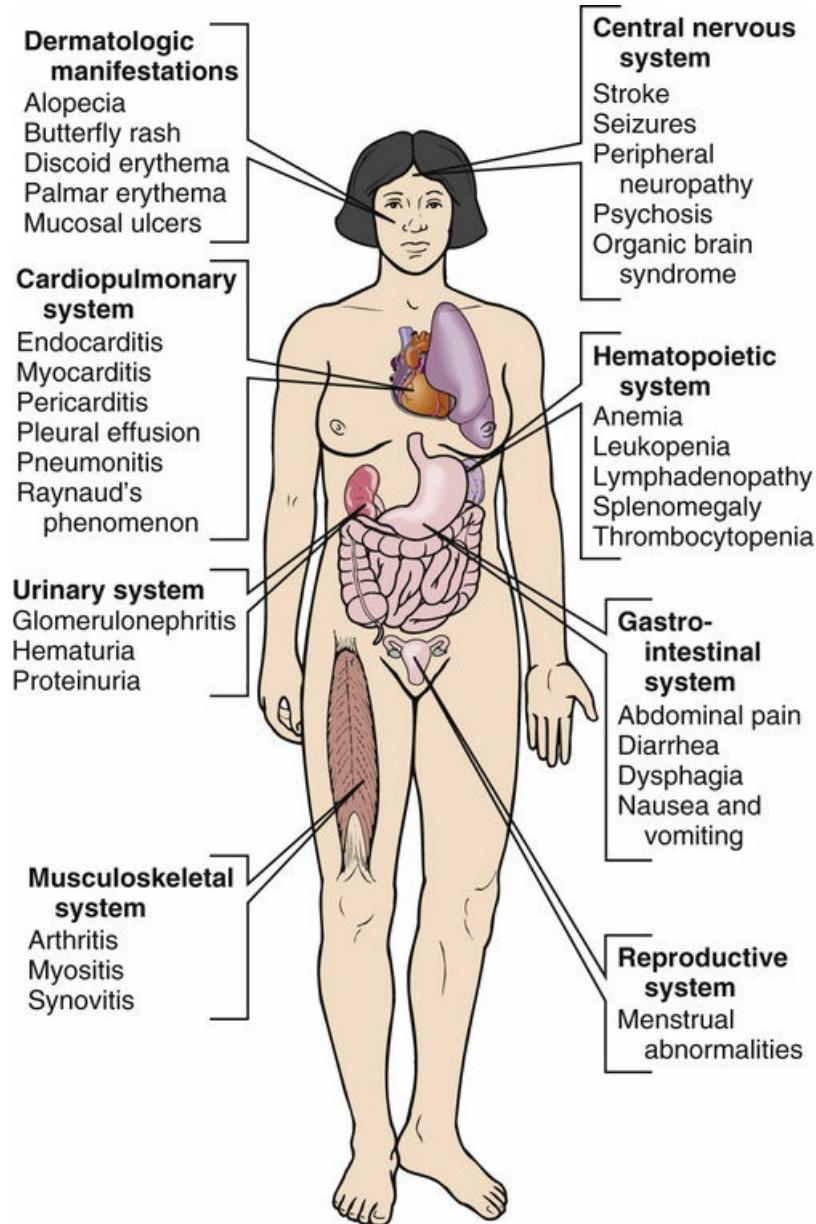

FIGURE 11-4 Multisystem involvement in systemic lupus erythematosus. (From Lewis SL, Dirksen SR, Heitkemper MM, Bucher L: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2014, Mosby.)

Diagnosis

Currently, no single test can confirm a diagnosis of SLE. A complete medical history is necessary to guide the diagnostic studies. To confirm SLE, a patient must have at least 4 of the 11 clinical presentations or laboratory test results performed for SLE (see the Evolve website).¹⁰ Typically the patient shows evidence of a multiorgan disorder. Initially serum blood studies, along with a urinalysis and tests for renal and liver function, are performed. Levels are obtained for anticardiolipin antibody (ACA), antinuclear antibody (ANA), antiphospholipid antibody (APA), autoantibodies (anti-dsDNA), anti-Smith (anti-SM), anti-U1RNP, anti-Ro/SSA, and anti-La/SSB, and kidney and skin biopsies are performed.

A syphilis test measures antiphospholipid antibodies in the blood, which are known to be present in lupus, so a false-positive syphilis test is another indicator of SLE. Tests for signs of inflammation include obtaining an ESR and CRP level. Current research is focusing on identifying biomarkers that would indicate the presence of SLE.

Treatment

There is no cure for SLE. Current treatments are targeted toward symptom control or management to prevent exacerbations, treat flare-ups when they occur, and minimize organ damage and long-term complications. Hydroxychloroquine, an antimalarial drug, aids in long-term control of SLE. Glucocorticoids, such as prednisone, are taken to reduce symptoms experienced during major flare-ups. Nonsteroidal anti-inflammatory drugs (NSAIDs) are used to reduce inflammation and control pain. Dehydroepiandrosterone (DHEA), a mild male hormone, is given to treat hair loss, joint pain, fatigue, and memory issues. Immunosuppressant agents are given to suppress the immune system, thereby reducing the risk of a systemic attack. Immunosuppressive agents, such as azathioprine (Imuran), are used to interfere with immune function by damaging autoantibody-producing cells. Belimumab (Benlysta), an IV medication that targets B-lymphocyte stimulator (BLyS) protein, may reduce the number of abnormal B cells, which are believed to be a contributing factor in lupus. Rest, balanced diet, and exercise are also primary treatments for patients with SLE. Women with lupus are at higher risk for pregnancy complications, and those with antiphospholipid antibodies have an increased risk of miscarriage and preeclampsia. Oral contraceptives are not contraindicated in women with mild lupus or who have a low risk of clotting.

Complementary and Alternative Therapies

Use of Alternative Therapies by Patients With an Immune System Disorder

Relaxation, meditation, Reiki, and imagery can help decrease stress. Acupressure and acupuncture may help control pain. There is controversy regarding using herbal and other substances to boost the immune system, because some can interfere with prescription medication. The health care provider should be consulted before starting use of complementary and alternative therapies.

Nursing Management

Assessment of the patient's ability to participate in activities of daily living (ADLs) is important. Joint pain is also common; thus management of pain and assisting with mobility are priorities. Ongoing assessment of body systems is important to determine whether the disease process is affecting additional systems. [Nursing Care Plan 11-1](#) presents interventions for the more common problems experienced by most patients with SLE.

Nursing Care Plan 11-1

Care of a Patient With Low Immune Response

Scenario

Julie Hansen, age 37, has just been diagnosed with systemic lupus erythematosus (SLE). She has flat erythema in a butterfly pattern over the face, is complaining of joint pain in her knees and elbows, and has experienced constant fatigue and weakness for the past 6 months. Her erythrocyte sedimentation rate (ESR) is elevated and she has a positive antinuclear antibody (ANA) test. Other tests helped confirm the provider's diagnosis. She lives with her husband, 12-year-old son, and 14-year-old daughter.

Problem Statement/Nursing Diagnosis

Altered activity tolerance/*Activity intolerance related to inflammatory nature of the disease as evidenced by need for increased rest and sleep and inability to keep up with household chores along with work.*

Supporting Assessment Data

Subjective: States she cannot keep the laundry done or the house clean because she is so tired when she comes home from work; has been using more and more "fast food" for family dinners.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will manage household along with work with help within 6 wk.	Explore chores that other family members may be able to take over. Assist to work out a schedule for rest periods at lunchtime, after work, and on the weekends.	Husband and children could help with cleaning, laundry, errands, and meal preparation. Resting for 30 min at lunchtime eases fatigue.	Daughter will wash the clothes and son will fold and put them away. Husband will do errands. All members will assist with meal preparation and cleanup. Will try to find a place at or near her workplace where she can rest at lunchtime. Continue plan.

	Assist to plan meals for the week and to cook large quantities of items on the weekend that can be divided into individual meals and frozen for family dinners.	It is less fatiguing to cook large quantities of entrees once a week and to freeze portions than to prepare a dinner every day.	Will consider what meals might be cooked on the weekends and frozen. Continue plan.
--	---	---	---

Problem Statement/Nursing Diagnosis

Pain/Chronic pain related to inflammation from disease process.

Supporting Assessment Data

Subjective: "My knees and elbows ache whenever I have walked for more than a block or used my arms to lift things frequently during the day."

Objective: Tenderness around elbow and knee joints.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will experience fewer days of pain with regular use of anti-inflammatory medication.	Instruct to take 400 mg of ibuprofen tid on a regular basis.	Keeping a steady blood level of the drug will help decrease and prevent inflammation.	States will begin taking the prescribed regimen of ibuprofen. Continue plan.
	Advise to let family lift heavy items and do chores requiring repetitive elbow motion or squatting.	Refraining from lifting, repetitive joint motion, and squatting helps prevent joint strain and added inflammation.	States will let family bring in groceries and put them away. Will remind family to pick up around the house every other day. Will refrain from gardening while bending down on her knees. Continue plan.

Problem Statement/Nursing Diagnosis

Potential for altered skin integrity/Risk for impaired skin integrity related to "butterfly" rash and sun sensitivity from disease process.

Supporting Assessment Data

Subjective: States sunburns very easily.

Objective: Inflamed rash in butterfly pattern over large part of face.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient's skin will remain intact.	Instruct in proper skin care with mild soap and alcohol- and astringent-free products.	Avoiding harsh skin care products will help prevent excoriation and breaks in the skin.	States will check her skin-care products for alcohol and astringents.
	Instruct to moisturize the skin twice daily.	Moisturizing products will help keep skin supple and prevent breaks.	Will begin moisturizing a second time a day before bedtime. Continue plan.
	Instruct to inspect the skin closely for any breaks or new lesions.	Finding breaks in the skin promptly and caring for them properly will help prevent infection.	Will begin to inspect skin after shower daily. Continue plan.
	Instruct to cover skin when out in the sun and to avoid ultraviolet rays as much as possible.	Protecting the skin from sunlight will help prevent flare-ups of the disease and will protect the skin from further damage.	Will wear suggested clothing of long sleeves, long pants, and a wide-brimmed hat when out in the sun.
	Instruct to use a sunblock product with an SPF of 30 or more when outdoors.	Sunblock helps prevent the damage that can occur from ultraviolet rays.	States will use sunblock on a daily basis on exposed parts of skin.
	Instruct to stop going to the tanning salon.	Ultraviolet light damages the skin and can cause a flare-up or progression of SLE symptoms.	States that she hates to give it up, but will refrain from going to tanning salon.

SPF, Sun protection factor.

Critical Thinking Questions

- What types of entrees could you suggest that could be fixed ahead in large quantities and then frozen in family-sized portions?
- What might you suggest as ways to rest at lunchtime when the patient is at work on weekdays?

Educate the patient about the disease and how to prevent possible complications. For example, any flulike illness lasting more than a few days should be reported to the health care provider. Review appropriate skin care, including the correct method of applying and reapplying sunblock with a sun protection factor (SPF) of 30 or higher. Infections can also exacerbate the symptoms, so the patient should avoid being around anyone who is showing signs or symptoms of a communicable disease.

Patient Teaching

Skin Protection for Patients With Systemic Lupus Erythematosus

- Avoid direct sunlight and any other type of ultraviolet lighting, including tanning beds.

- Use an SPF 30 or higher sunblock when outdoors.
- Wear long pants, a long-sleeved shirt, and a wide-brimmed hat when in the sun.
- Cleanse the skin only with a mild soap that has a glycerin base.
- Dry the skin thoroughly by patting rather than rubbing it.
- Apply nonperfumed lotion liberally to dry skin areas at least twice a day.
- Avoid using alcohol-based skin care products, face powder, or other astringent agents.
- Use cosmetics that contain moisturizers.
- Inspect the skin daily for rashes and open areas.

Disorders of the Lymphatic System

Lymphoma

Lymphoma is a form of lymphatic cancer that starts in the lymphocytes. These cells become malignant and multiply, crowding out the normal cells, which leads to the creation of solid tumors in the lymph nodes. The two main types of lymphoma are Hodgkin lymphoma (HL) and NHL. The primary differences between the two are the types of lymphocytes involved in the disease. If, under microscopic examination of tissue, Reed-Sternberg (R-S) cells are present, the patient has HL. If the R-S cells are not present, the patient has NHL, which is further identified as B-cell and T-cell lymphoma and has around 30 subtypes. There are two main types of HL—classical HL and lymphocyte-predominant HL.

Classification and staging of these two diseases is complicated. It relies heavily on microscopic examination of tissues and diagnostic studies, including serum blood testing and select types of scans to determine the type and true extent of the disease. Many of the NHL subtypes look similar, but they are quite different and respond to different therapies with varying degrees of success.

Hodgkin Lymphoma

Etiology.

HL, also known as *Hodgkin disease*, is one of the more curable forms of cancer when diagnosed and treated early. It accounts for less than 1% of all cancers. HL primarily affects young adults, but it can occur in those older than 55 years of age. Incidence rates are higher in whites than African Americans. Because of the advent of radiation and chemotherapy, the cure rate has more than tripled over the past 40 years, and the overall survival rates are 85% at 5 years and 80% at 10 years ([American Cancer Society, 2015](#)).

The cause of HL is not known, but there is a possible genetic as well as environmental component that, in combination, can initiate the onset of this disease. Studies have shown that there is a 10 times higher risk of developing the disease in same-sex siblings of patients with HL. An association has been found among patients with HL who had few or no siblings, lived in a single-family house, were early in the family's birth order, and had few playmates. This form of life environment tends to decrease exposure to infectious agents at an early age, so the immune system is not exposed to as many microorganisms, and therefore less antibodies are produced. Other possible triggers are viral infections, such as Epstein-Barr and HIV. Previous exposure to various chemical agents has also been implicated.

Pathophysiology.

The B cells in the immune system begin to develop atypical cells. The abnormal R-S cells have two unique features: (1) they rapidly replicate more defective B cells and (2) they do not die off as normal cells do. These R-S cells replace normal cells in the nodes and lymph tissue. The disease spreads from one area to another via the lymphatic system and can invade other body systems. As it progresses, the ability of the body to fight off infection can become severely impaired.

Signs and symptoms.

More than 80% of cases present with **lymphadenopathy** (enlarged lymph nodes) above the diaphragm. The enlarged, painless lymph nodes can be easily felt in the neck, mediastinum, and axilla and less easily in the abdomen and inguinal (groin) area. The patient may also complain of abdominal fullness, fatigue, profuse night sweats, unintentional weight loss, and pruritus. High suspicion for HL exists when the patient has complaints of swollen lymph glands lasting for several weeks and no recent history of any type of infection. The patient will likely require a series of diagnostic studies. If there is a mediastinal mass of involved lymph tissue, the patient may have a nonproductive cough because of the narrowed airways from the swollen lymph glands. Many other organs can become affected, as displayed in [Figure 11-5](#).

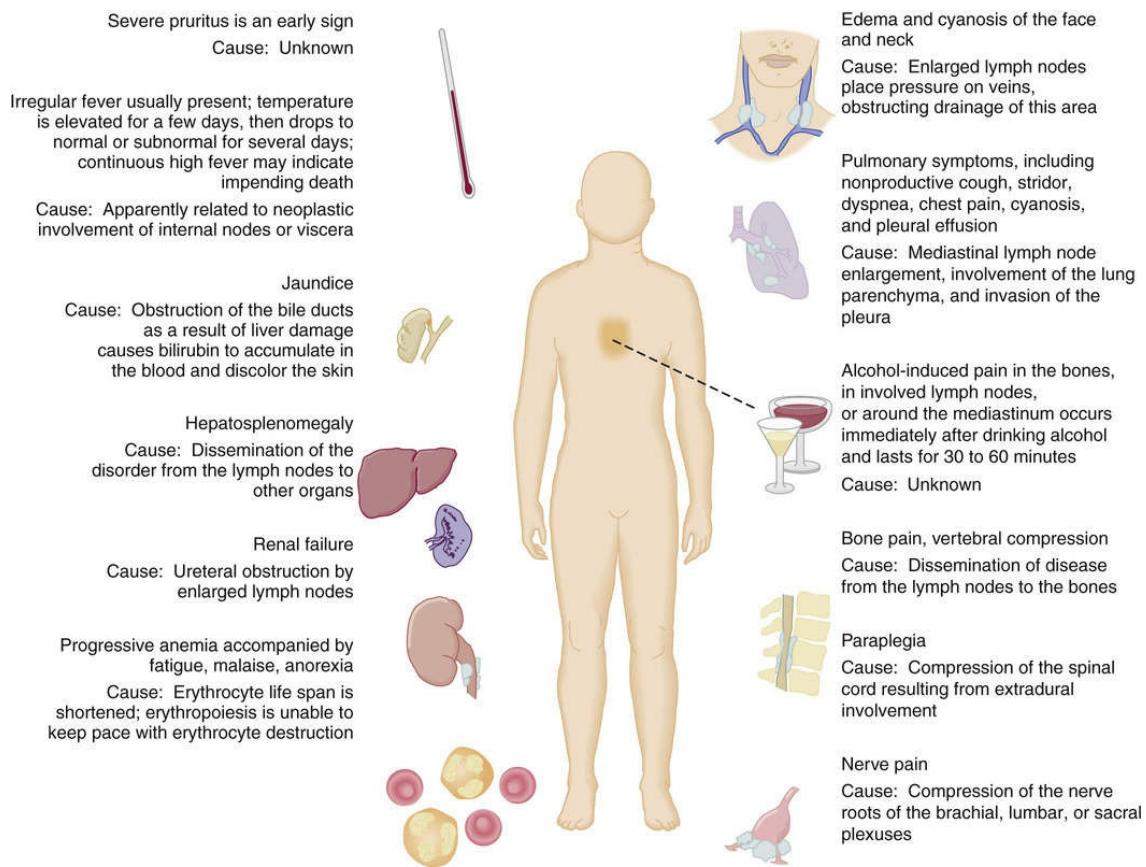

FIGURE 11-5 Clinical manifestations and pathophysiologic basis of Hodgkin lymphoma. (From Black JM, Hawks JH: *Medical-surgical nursing: Clinical management for positive outcomes*, ed. 8, Philadelphia, 2009, Elsevier Saunders.)

Diagnosis, treatment, and nursing management.

A definitive diagnosis for HL is confirmed by the presence of R-S cells in the tissues obtained by biopsy of the lymph nodes. Radiographs, computed tomography (CT) scans, positron emission tomography (PET) scans, and bone marrow biopsy can also be used to help determine the extent or stage of the disease.

Treatment depends on the stage of the disease and whether involvement is above or below the diaphragm or both. (See the figure on staging classifications on the Evolve website.) Once the stage is known, the absence or the presence of one or more of the following symptoms is noted: unintentional weight loss of more than 10% of body weight over the previous 6 months; an unexplained fever greater than 100° F (38.5° C) for 3 days or longer; and profuse night sweats not related to weather conditions. In patients with four or more involved nodal areas, who are older than 50 years, and have an ESR greater than 30, the outlook is less favorable.

Chemotherapy can be given in all stages of the disease. Once it is completed, a more precise form of radiation therapy called *involved-node radiotherapy (INRT)* may be considered. Typically, INRT is delivered only to the affected areas of the body, so less damage occurs to the surrounding tissue. For stages I and II, administration of doxorubicin (Adriamycin), bleomycin, vinblastine, and dacarbazine (ABVD therapy), followed by INRT, has proven to be the most successful treatment. Stages III and IV disease show better improvement with mechlorethamine, vincristine (Oncovin), procarbazine, and prednisone (MOPP therapy) in combination with ABVD therapy. The number of cycles of chemotherapy depends on the stage of the disease, the response of the patient to the therapies, and whether a **relapse** (reappearance of abnormal cells) occurs. Patients may experience many complications from HL and the treatments. Examples of some of the adverse effects include permanent sterility, temporary hair loss, subclinical hypothyroidism, and an increased risk of developing cancer in other organs years after completing radiation therapy.

Nursing care should focus on symptoms the patient is currently experiencing and the side effects of the prescribed therapies. Prevention of health care-associated infections is essential. The problems/nursing diagnoses, expected outcomes, and interventions for patients with HL are the

same as those for patients with leukemia (see [Chapter 16](#)).

Non-Hodgkin Lymphoma

Etiology and pathophysiology.

The United States has the highest rate of NHL, the sixth most common cancer in men and the fifth most common cancer in women ([ACS, 2015](#)). The overall incidence is higher in men than women. The National Cancer Institute estimated that in 2015, 71,850 new cases of NHL will be diagnosed and that at least 19,790 people will die of NHL ([American Cancer Society, 2015](#)). Part of the increase has been linked to the increased number of patients with HIV and hepatitis C patients and those who have contracted an Epstein-Barr virus infection. The median age of diagnosis of NHL is 50 years of age. The overall rise in incidence is believed to be related to the continued advances in the successful diagnosis and treatment of a variety of diseases.

NHL is similar to HL, but NHL is less predictable and tends to spread to other body sites much more rapidly. There is also an abnormal proliferation of defective B cells or T cells in NHL. Only biopsy of pathologic lymph nodes and tumor tissue can provide a definitive diagnosis of NHL. There are several types of NHL. One type of NHL is an indolent, slow-growing form in which symptoms are usually not present until the advanced stages of the disease. Bone marrow involvement and intra-abdominal adenopathy may occur with this form of NHL, and it has a better prognosis if treatment is given in stage I or II of the disease. Usually radiation therapy is used, because most indolent forms of NHL are nodular in shape.

The other forms of NHL are more aggressive; if treated with intensive chemotherapy, there is a survival/cure rate of 67% at 5 years and 55% at 10 years ([Simon, 2013](#)). The symptoms manifest early in the aggressive forms, and with vigorous therapy, there is a potential for cure. The rate of cure is reduced if NHL is diagnosed in a late phase. Five risk factors for **disseminated** (widely spread) tumors, elevated levels of lactate dehydrogenase, poor functional ability of the patient, age older than 60 years, and spread beyond lymph nodes), are used to predict the outcome of patients with the more aggressive forms of B-cell lymphoma, which is the most common type. Having none or one of the risk factors suggests a good outcome, but having four or five indicates a poor prognosis. When relapses occur, they typically do so within the first 2 years after treatment.

Signs and symptoms.

NHL tends to have more widespread involvement of lymphoid tissue than is found in HL. Unlike HL, NHL typically shows up in one node, then one or more nodes are skipped, and then another node is affected (referred to as *noncontiguous*). NHL usually manifests as a unilateral, painless enlargement of a lymph node that may progress to generalized, painless lymphadenopathy. NHL tumors can occur in the brain, respiratory system, spleen, GI tract, bone, or other parts of the body. As the disease progresses, the patient notices more symptoms, probably because of the increasing size of the affected lymph nodes. Symptoms related to other organs are site specific and can include complaints of high fevers, chills, drenching night sweats, unexplained weight loss, cough, dyspnea, chest pain, nausea, vomiting, a sense of fullness in the abdomen, and constipation. Hepatomegaly or splenomegaly occurs in about one third of patients. The nodes closer to the skin tend to be more easily palpated, are very pruritic, and may be either red or purple in hue. Laboratory tests may show elevated liver enzymes. Physical examination may reveal a change in level of consciousness related to an elevation in intracranial pressure, especially in patients with aggressive NHL.

Diagnosis and treatment.

The effectiveness of treatment depends on the stage of the tumor at the time of diagnosis and the type of lymphoma (indolent or aggressive). Staging considers the number and location of affected lymph nodes, whether the nodes are on one or both sides of the diaphragm, and whether the disease has spread to other tissues. To aid in staging, CT, magnetic resonance imaging (MRI), PET, or ultrasound can be used to determine the extent of tissue involvement and to assess therapeutic response after therapy has been completed. Biopsy of various body tissues may also be performed in one of three ways to determine the type of NHL: (1) an excisional biopsy, in which an entire node is removed; (2) an incisional biopsy, in which only a piece of the node is removed; or (3) fine-needle aspiration (FNA), in which a needle is used to aspirate tissue from the mass of cells. Bone marrow biopsy is usually performed after the diagnosis has been confirmed or is done to determine whether

the disease has reached the bone marrow.

Treatment can be with chemotherapy or irradiation, depending on the stage of disease. Stage I or II or low-grade NHL may be cured with radiation therapy alone. Various combinations of drugs are used for other stages of the disease depending on the type and aggressiveness. Cyclophosphamide (Cytoxan), hydroxydaunomycin (doxorubicin), vincristine (Oncovin), and prednisone (CHOP therapy) is standard treatment and has proven particularly effective for many stages when used with rituximab (Rituxan). Several other chemotherapy combinations are also often used. Bone marrow transplantation, autologous stem cell transplantation, and immunotherapy with monoclonal antibodies are possible treatment options. There are a number of drugs that provide radiolabeled monoclonal antibody agents. Once infused, these antibodies recognize and react to kill specific tumor cells. Other experimental therapies are under study.

Surgery may be attempted if the tumor is localized or as palliative care. Vaccines for this disease are currently in clinical trials.

Nursing management.

Nursing care is directed toward supporting the patient through the diagnostic process and observing for and treating the side effects of radiation and chemotherapy. If bone marrow or stem cell transplants are performed, nursing care and patient education must focus on prevention of infection and other complications. [Chapter 8](#) provides information on specific nursing problems/diagnoses and interventions for patients with cancer. Common problems for a patient with NHL include the following:

- Potential for infection due to neutropenia
- Risk for hemorrhage from thrombocytopenia
- Fatigue
- Nutritional deficit with weight loss

Expected outcomes might include the following:

- Patient will not experience infection.
- Patient will not experience hemorrhage.
- Fatigue will lessen after 6 weeks of treatment.
- Patient will gain 1 lb per week until desired weight is reached.

Nursing interventions are similar to those for the problems of leukemia (see [Chapter 16](#)).

Lymphedema

The lymphatic system drains water, proteins, lipids, and waste from the interstitial spaces throughout the entire body and returns them to the lymph nodes, where waste materials and foreign cells, such as bacteria, are filtered out. Once "clean," the lymph fluid returns to the lymphatic vessels, and the whole process is repeated. When the lymph system is unable to circulate normally, large amounts of fluid accumulate (**lymphedema**), causing swelling. If not controlled, this swelling can lead to further damage to surrounding nerves, blood vessels, and tissues.

There are two types of lymphedema: inherited and acquired. The inherited form (primary) is a congenital condition in which there is deficient growth of the lymphatic system, especially in a lower extremity. This condition chiefly affects women and most often becomes apparent during the middle teens to early twenties.

The acquired form (secondary) typically results from an obstruction caused by trauma to the lymph vessels and nodes, such as occurs during mastectomy when lymph nodes are removed, after radiation therapy, or after a liposuction procedure where some of the lymph nodes may have been damaged. Other causes of obstruction include extensive soft-tissue injury and scar formation and, in tropical countries, parasites that enter lymph channels and block them (e.g., elephantiasis).

Patients may have a variety of symptoms, including restricted range of motion; heavy feeling; aching discomfort; recurrent infections; and thick, hard skin. To confirm the cause, an MRI of the affected body part, lymphangiography, or a lymphoscintigraphy may be performed to determine whether there are any blockages in the lymphatic system or some other form of pathology.

Regardless of the cause, treatment goals are to minimize the effect of the disease process on the individual.

Lymphedema of an extremity can often be treated conservatively through light aerobic exercise and by using simple nursing measures. For example, the patient can be taught to wrap the extremity with an elastic bandage, beginning at the most distal portion and working up the extremity. This compression bandage may help minimize the degree of lymphedema. Surgical intervention is palliative at best and is therefore controversial as a treatment option. There is no cure for this condition. Prevention and treatment of lymphedema of the arm and hand after mastectomy are covered in [Chapter 38](#).

Fibromyalgia

In the 1970s, fibromyalgia was identified as a condition of chronic systemic pain and multiple symptoms that could not be explained as caused by any other source or disease. This disorder affects 5 million people in the United States. Women are 10 times more likely than men to experience fibromyalgia symptoms, and the condition is typically seen in women ranging in age from 25 to 60 years. Researchers believe the way the brain perceives pain is changed in some way as a result of stressors such as infection, trauma (physical and psychological), family history, and autoimmune disease. The change in pain perception can trigger fibromyalgia and its related symptoms ([Box 11-7](#)). The most common feature of this disorder is musculoskeletal pain. It is typically described as diffuse or multifocal pain, with flare-ups and **remissions** (disease is under control), along with migration from one area of the body to another. Fibromyalgia interferes with a person's ability to perform ADLs and can cause significant fatigue and pain; it is considered as part of the arthritis spectrum and may accompany SLE or rheumatoid arthritis.

Box 11-7

Fibromyalgia Symptoms

- Chronic muscle pain, spasms, or tightness
- Stiffness on waking or after staying in one position for too long
- Moderate to severe fatigue and decreased energy levels
- Reduced exercise tolerance and increased muscle pain after exercise
- Tension or migraine headaches
- Jaw and facial tenderness
- Insomnia or waking up feeling just as tired as when you went to sleep
- Anxiety, depression
- Difficulty with concentration, memory recall, and performing simple mental tasks
- Abdominal pain, bloating, nausea, and constipation alternating with diarrhea (irritable bowel syndrome)
- A sensation of swelling (without actual swelling) in the hands and feet
- Increase in urinary urgency or frequency (irritable bladder)
- Sensitivity to one or more of the following: odors, noise, bright lights, medications, certain foods, and cold

Patients typically have either **hyperalgesia** (heightened response to painful stimuli) or **allodynia** (pain response to nonpainful stimuli). This disorder may also be caused by a deficiency in the neurotransmitters dependent on serotonin and norepinephrine within the central nervous system. The criteria were originally established in 1990 but were updated in 2011 and include whether

symptoms have been present for at least 3 months; whether they occur on both sides of the body; and whether there are any tender points in at least 11 of 18 sites (Figure 11-6). Other symptom diagnostic criteria are sleep problems, poor cognition, fatigue, headaches, depression, and abdominal pain (Henderson, 2014).

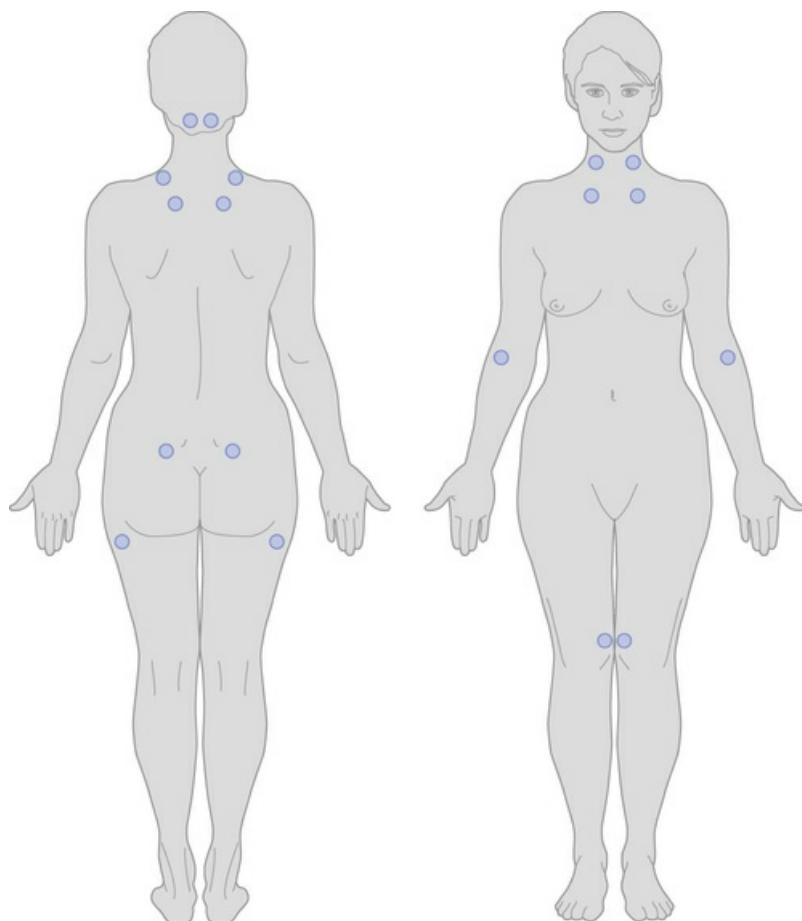

FIGURE 11-6 Tender points in fibromyalgia. (From Freundlich B, Leventhal L: Diffuse pain syndromes. In Klippel JH (Ed.): *Primer on the rheumatic diseases*, ed. 13, Atlanta, 2008, Arthritis Foundation.)

There is no specific diagnostic test that can confirm the diagnosis of fibromyalgia, so treatment focuses more on symptom relief. Currently, there are three antidepressant medications approved by the FDA that also help with pain management: pregabalin (Lyrica), duloxetine (Cymbalta), and milnacipran (Savella). Low-dose antidepressants that can also be used include tricyclics, serotonin reuptake inhibitors (SSRI), and benzodiazepines. NSAIDs and long-term use of narcotic pain relievers are not as effective in treating the pain experienced in this disorder because of the abnormal reactions of pain receptors. Additional treatment is based on the symptomatology and could include light exercise, massage therapy, guided imagery, dietary changes, and referral to a mental health provider. Nursing responsibilities include taking a detailed history of symptoms and measures the patient has tried to relieve the pain. Interventions should focus on helping the patient to manage fatigue, pain, activity intolerance, sleep disruption, and stress. Family should be included in the education process.

Disorders of Inappropriate Immune Response

Allergy and Hypersensitivity

An **allergy** is an abnormal response to certain substances; it is considered a systemic immune disorder, rather than a localized one, and the reaction can be seen or expressed in one or more body systems. **Hypersensitivity reactions**, better known as allergic reactions, are the body's excessive response to a normally harmless substance. The severity of the condition can range from a mild rash to **anaphylaxis** (an extreme allergic reaction that is life-threatening).

Etiology and Pathophysiology

As the environment has become cleaner over the past decades, there has been an increase in the development of allergies, especially among those of higher socioeconomic status, those living in an urban area versus rural, and first-born children (who have less exposure to other illnesses from siblings). Complex hereditary, environmental, and site-specific factors contribute to allergic reactions.

Allergies are divided into two major categories: (1) immediate hypersensitivity reactions that are mast-cell mediated (type I hypersensitivity) and (2) delayed-reaction allergies involving T cells (type II hypersensitivity). As with all types of normal and abnormal immune responses, a reaction will not occur until an individual's body cells have been sensitized to the specific substance that triggers the response. This means that on first contact with the antigen (allergen), the body's immune system is triggered to produce immune globulin E (IgE) antibodies to recognize the specific antigen. On the second and subsequent contacts with the allergen, the antibodies specific to the allergen are rapidly produced and released into the circulating blood or in the lymphoid tissues, in larger and larger quantities. See Evolve[®] for **mechanisms activated in hypersensitive reactions**. Because of the increased amount of antibodies, they can be quickly transported to the location of the allergen, causing a more rapid, and sometimes virulent, allergic reaction. This type of reaction is typically seen within 15 to 30 minutes from exposure to the antigen and results from the increased production of mast cells and basophils from IgE antibodies. During this reaction, **histamine** is released from a mast cell mediator. When histamine is released because of an immune response, it triggers increased mucus secretions, vascular permeability, and vasodilation, which leads to tissue edema. Dilated blood vessels transport the IgE antibodies, histamine, and other chemicals to the site of exposure to the allergen ([Figure 11-7](#)).

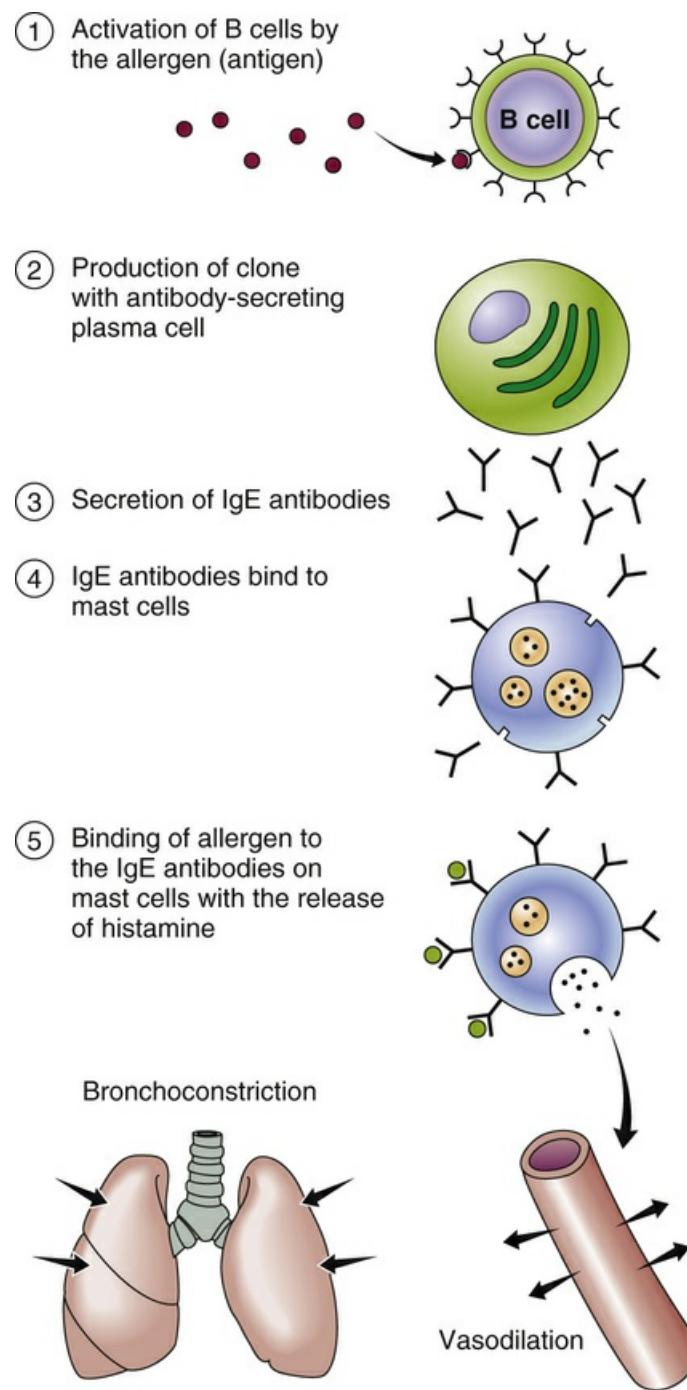

FIGURE 11-7 Immediate-reaction allergy.

If the mast cells are IgE dependent, they typically produce only a localized allergic response. Examples of this are allergic conjunctivitis or allergy-induced asthma. A person who has **atopy** (a response that affects various parts of the body without being in direct contact with the allergen), such as is seen in eczema, tends to be hypersensitive to a variety of allergens. Type II or delayed reactions result from increased production of IgG.

Signs and Symptoms

The body system most affected by the offending agent may present more specific symptoms. For example, when the nose and eyes are exposed to a contact allergen, symptoms of itchy, red, watery eyes; soft palate pruritus; clear rhinorrhea; and sneezing are common. Should the allergen be inhaled, the release of histamine can cause the contraction of smooth-muscle tissues in the bronchioles of the lungs. These internal changes also produce an allergic response, notably

erythema, edema, increased exudate, and breathing difficulties such as dyspnea and wheezing. [Table 11-8](#) presents the four broad types of allergens.

Table 11-8
Four Broad Categories of Allergens*

CATEGORY	METHOD OF EXPOSURE	TRIGGERS	EFFECTS
Contactants	Direct contact with mucosa/skin/tissue	Dust, wool fabrics, detergents, soaps, lotions, cosmetics, plants such as poison ivy, dyes, metals in jewelry, and latex	Irritation to the conjunctiva of the eyes, urticaria, rashes, hives, dermatitis, and eczema
Ingestants	Swallowed	Food: citrus fruits, tomatoes, strawberries, cow's milk, wheat, eggs, dairy products, seafood, chocolate, nuts, monosodium glutamate (MSG), other preservatives, and artificial food coloring	Abdominal pain, flatulence, nausea, vomiting, and diarrhea
		Drugs: aspirin, barbiturates, anticonvulsants, and antimicrobials; any drug may cause an allergic reaction	Can also cause atopic dermatitis, rash, and dyspnea
Inhalants	Entry through nose or mouth	Dust mites, molds, pollen, fragrances, animal dander, insect feces, and some chemicals	Edema of nasal mucosa, allergic rhinitis or sinusitis, rhinorrhea, sneezing, laryngeal edema, coughing, dyspnea, bronchoconstriction, and wheezing
Injectables	Via needle (i.e., hypodermic, intramuscular, intravenous; animal or snake bites, insect stings)	Medications, vaccines, animal saliva, and snake or insect venoms	Swelling and pain at injection site, bruising, discoloration, necrotic skin

*Any allergen can cause severe allergic reactions, including anaphylaxis and death, if not recognized and treated immediately.

Diagnosis

Identification of allergens.

Identification of allergens can be a tedious process. Many times more than one substance produces the symptoms of an allergy. Reactions to certain food products, animals, insect stings, drugs, and other substances that are out of the norm are noticeable because of the relationship between cause and effect. Ask about exposure to substances that appear to have, or are known to cause, an adverse response. Help the patient to recognize that vague symptoms, such as consistently becoming "stuffed up" only at night when in bed, could be an allergic reaction, perhaps to the pillow.

Diagnostic tests.

Two primary methods are used to test for allergies. One is performing a radioallergosorbent test, known as *RAST*. This test uses blood serum from the patient to determine whether the IgE to the suspected allergen is present. The major advantages to this type of allergy testing are that antihistamine medications can continue; it is safer for patients with serious heart and lung problems; there is no chance of an anaphylactic reaction; it is more useful to identify a true food allergy; and it can be used when severe skin conditions prevent skin testing. The disadvantages to the RAST are that it is more expensive than skin testing; it can take several days to weeks before results are known; and it is less specific, meaning this test tends to produce more false-positive and false-negative results to allergens.

The skin **scratch test** has been the most reliable method of allergy testing for more than 100 years. The skin is pricked by a needle, and a drop of the suspected allergen is applied to the area. A needle is then used to slightly scratch the skin just below the epidermis. The **patch test** is similar to the scratch test except the allergen is simply placed on the surface of the skin and covered with an airtight dressing (patch). For both of these tests, a negative reaction occurs when there is no erythema, swelling, or complaint of itching. A positive reaction to either of these tests is indicated by the appearance of a small (usually dime-size) wheal at the site of contact with the allergen and possibly by complaints of itching by the patient.

Drug allergy.

A patient may have a confirmed allergy to a medication that is required and for which there are no alternatives. Before administration, a test dose of the drug may be given. For IV medications, a very small dose can be given and then, at 10-minute increments, increasing amounts of the drug are infused until the full dose ordered by the health care provider is administered. Continuously stay with the patient and closely monitor for signs and symptoms of a reaction during this process. Resuscitation drugs and emergency equipment must be immediately available. This same process is repeated with each subsequent administration of the medication, and detailed documentation is required. If it is known in advance that the drug will be needed, the patient can be desensitized to the drug before its use.

Safety Alert

The Patient With Allergies

The medical record should be checked and the patient questioned about allergies before (1) giving medications or immunizations, (2) beginning radiographic studies using contrast media, and (3) minor or major surgery.

Food allergy.

Even though other diagnostic methods are available to test for food allergies, a less expensive approach known as the *elimination diet* should be tried first. Teach the patient to read product labels to identify offending substances used in the preparation or preserving of the food item. Tell the patient to eliminate one food at a time and to keep a detailed diary, recording everything ingested each day, including the additives and preservatives in each food product. The patient should start with a food that is believed to be the cause of adverse reactions (e.g., itching, bloating). If symptoms persist for a week to 10 days after eliminating one food product (e.g., milk and dairy products), the patient would resume intake of that particular food, and choose another one for elimination. This process continues until the offending food source is identified.

Latex allergy.

Assess each patient for latex allergies, because their presence may change the method of care delivery. Most items routinely manufactured with latex are now being produced with nonlatex alternatives, including gloves, Foley catheters, surgical drains, bandages, and condoms.

Safety Alert

Personal Protective Equipment

OSHA requires that employers furnish personal protective equipment for their employees at no cost to the employee, and nonlatex items should be made available for those with an allergy to latex. Severe latex allergies have caused some health care workers to change their work environment to one with little or no latex exposure.

Treatment

Drug therapy.

Drugs that help alleviate systemic reactions to allergens include epinephrine, antihistamines, bronchodilators, corticotropin (adrenocortotropic hormone), and cortisone (see [Chapters 13](#) and [14](#) for specific drug information).

Antihistamines (histamine-blocking agents) help control the symptoms of hay fever and hives by preventing the release of histamine during an allergic reaction ([Table 11-9](#)). The histamine-blocking action relieves itching, decreases swelling of mucous membranes and production of secretions, and reduces other symptoms of an allergic reaction. Diphenhydramine (Benadryl) is commonly used orally and topically to counteract many allergic symptoms.

 **Table 11-9**

Drugs Commonly Used to Treat Allergy

CLASSIFICATION	ACTION	SIDE EFFECTS	NURSING IMPLICATIONS
Antihistamines			
First-Generation Agents: tend to be short acting; impair concentration and can cause drowsiness			
Ethanolamines	Bind with H ₁ receptors on target cells, blocking histamine binding	First-generation agents cross blood–brain barrier, bind to H ₁ receptors in brain, cause sedation (diminished alertness, slow reaction time, somnolence), and stimulation (restless, nervous, insomnia).	Warn patient that operating machinery and driving may be dangerous because of sedative effect; drowsiness usually passes after 2 wk of treatment.
Clemastine (Tavist Allergy)	Relieve acute symptoms of allergic response (itching, sneezing, excessive secretions, mild congestion)	Sleepiness, fatigue, dizziness, headache, dry mouth, urinary retention.	Teach patient to take with full glass of water; report palpitations, change heart rate, a change in bowel/bladder habits.
Diphenhydramine (Benadryl)	Competitively blocks the effects of histamine at peripheral H ₁ receptor sites; has anticholinergic (atropine-like) and sedative	Patients vary in their sensitivity to these side effects.	Instruct patient not to use alcohol with antihistamines because of additive depressant effect.

	effects		
Tripeleannamine (PBZ)	Competes with histamine receptor sites	May cause palpitations, tachycardia, urinary retention or frequency.	Must take with food whole; do not crush.
Alkyamines		Cause less drowsiness.	
Brompheniramine maleate (Dimetane)	Antagonist of histamine H ₁ receptors	Severe constipation, urinary retention, dry mouth, blurred vision, tachycardia.	Do not use if patient is diagnosed with glaucoma.
Chlorpheniramine (Chlor-Trimeton)	Antagonist of histamine H ₁ receptors; serotonin-norepinephrine reuptake inhibitor	Dizziness, blurred vision, euphoria, anxiety, increased appetite.	
Azatadine (Optimine)	Histamine blocker	Dizziness, drowsiness	Teach patient to take with a full glass of water.
Promethazine (Phenergan)	Antihistamine and neuroleptic	Strong sedative effect, long-term use can lead to tardive dyskinesia.	Given preoperatively to some patients.
Second-Generation Agents: less likely to cause drowsiness			
Loratadine (Claritin)	H ₁ -receptor agonist with minimal sedative side effects; blocks H ₁ receptors and blocks effects of histamines (vasodilation, increased capillary permeability)	Second-generation agents have limited affinity for brain H ₁ receptors.	Teach patient to expect few, if any, side effects.
Cetirizine (Zyrtec)	Some also have anti-inflammatory properties	Causes minimal sedation; few effects on psychomotor activities or bladder function.	More expensive than classic antihistamines.
Fexofenadine (Allegra)	Interfere with mediator released from mast cells	Can cause menstrual cramping, diarrhea, nausea, and stomachache.	Rapid onset of action, no drug tolerance with prolonged use.
Desloratadine (Clarinex)			General interactions: Do not take with alcohol or any form of tranquilizer or sedative.
Decongestants			
Oral			
Pseudoephedrine (Sudafed)	Stimulate adrenergic receptors on blood vessels, promote vasoconstriction, and reduce nasal edema and rhinorrhea	CNS stimulation, causing insomnia, excitation, headache, irritability, increased blood and ocular pressure, dysuria, palpitations, tachycardia.	Advise patient of adverse reactions.
Phenylpropanolamine	Same as above	Same as above	Advise that some preparations are contraindicated for patients with cardiovascular disease, hypertension, diabetes, glaucoma, prostate hypertrophy, or hepatic and renal disease.
Topical (Nasal Spray)	Same as above	Same as above, plus rhinitis medicamentosa (rebound nasal congestion).	Teach patient that these drugs should not be used for >3 days or >4 times/day; longer use increases risk of rhinitis medicamentosa.
Oxymetazoline (Dristan)	Blocks action of histamine	Headache, bitter taste, somnolence, nasal irritation.	Teach patient can cause irregular heart rate, insomnia, high blood pressure. Stop medication and contact health care provider.
Phenylephrine (Neo-Synephrine)	Stimulate adrenergic receptors on blood vessels, promote vasoconstriction, and reduce nasal edema and rhinorrhea	CNS stimulation, causing insomnia, excitation, headache, irritability, increased blood and ocular pressure, dysuria, palpitations, tachycardia.	Advise patient of adverse reactions.
Azelastine (Astelin [nasal spray]; Optivar [eye drops])	Histamine antagonist, mast-cell stabilizer	Bitter taste, headache, nasal burning.	Advise patient not to drink alcohol or take other CNS depressants.

CNS, central nervous system; GI, gastrointestinal.

Antihistamines can cause drowsiness and impaired coordination, so there are restrictions on driving automobiles and operating machinery at the beginning of therapy. Other common side effects include dry mouth, urinary retention, weakness, and blurred vision. Antihistamines and decongestants can aggravate hypertension, narrow-angle glaucoma, or benign prostatic hyperplasia (enlarged prostate) and should be used with caution. Older adult men taking antihistamines may experience hesitancy while voiding, urinary retention, and difficulty with ejaculation; the offending drug should be discontinued if the problem cannot be resolved.

Anti-inflammatory drugs such as corticotropin and cortisone are administered to reduce the inflammatory response that occurs in an allergic reaction. If the respiratory tract is involved, bronchodilators can be given to help relieve dyspnea and wheezing. Tranquilizers and sedatives may be ordered to promote the rest needed for successful recovery from a severe reaction and aid in relieving the stress that may have occurred. Local reactions involving widespread and deep skin lesions are treated with salves such as calamine lotion, wet compresses, and soothing baths. The patient must also be protected from a secondary bacterial infection.

Desensitization.

When exposure to allergens cannot be avoided or if the symptoms cannot be managed successfully, desensitization (immunotherapy) may be suggested. The purpose is to decrease sensitivity to allergens. Regular injections of extremely small quantities of selected antigens are given daily, weekly, or monthly. The amount given is gradually increased until there is noticeable clinical improvement, and then a maintenance dosage is given. The program may last for years, but improvement should be noted in about 6 to 24 weeks after it is begun.

❖ Nursing Management

■ Assessment (Data Collection)

Identifying or isolating the allergens causing the patient's symptoms requires time and diligence.

☒ Focused Assessment

Indicators of Allergic Response

General

- History of food intolerances; colic; abdominal cramping; bloating; or pain, vomiting, and diarrhea in the absence of general illness
- History of unusual reaction to any drug, food, insect sting, odor, or fumes
- History of recurrent respiratory problems or seasonal flare-ups of any symptoms
- History of fatigue, wheezing, or shortness of breath on exertion
- Exposure to new personal hygiene products or cleaning products

Skin

- Itching, burning, dryness, scaling, irritations, inflammations, hives, rash (note symmetry and location), scratches, or urticaria

Eyes

- Burning, itching, tearing, history of sties
- Redness, discoloration below eyes (allergic shiners), conjunctivitis, rubbing, or excessive blinking

Nose

- History of nose twitching, stuffiness, recurring nosebleeds, sudden episodes of sneezing or snorting
- Allergic salute (pushing nose upward and backward with heel of hand), nasal polyps, nasal voice

Mouth and throat

- Open-mouth breathing, continual throat clearing, mouth wrinkling with facial grimaces, redness of throat, swollen lips or tongue, itchy palate

Ears

- History of hearing loss, drainage from ears

Neck

- Palpable, enlarged lymph nodes

Besides a food diary, the patient may need to keep track of any chemicals that are used (e.g., cosmetics, soaps, deodorants, household cleaners, garden products, etc.) for a few weeks. Recalling a family history of allergies and types of symptoms they displayed may also prove helpful. Repeated assessments may need to be planned over a period of weeks or months if the patient is reactive to a variety of allergens.

Health Promotion

Nursing Goals for Patients With Hypersensitivity Reactions

- Assist in the diagnosis of hypersensitivity.
- Help the patient identify the particular substance or substances that trigger an allergic response.
- Assist the patient in devising ways to avoid or at least limit exposure to these allergens.

- Relieve the symptoms of an allergy.
- Decrease the exaggerated response to the allergen(s).
- Provide health teaching.

Households have common allergens such as pet dander, dust, dust mites, cosmetics, cleaning agents, and dyes in fabrics and materials used in home furnishings. Overstuffed furniture, heavy draperies, and thick carpets contribute by holding particulate matter. Removal of carpeting, routine cleaning as well as daily dusting and vacuuming, and elimination of dust-harboring furnishings can help remove some allergens. Compliance with daily dusting and vacuuming is more likely if the individual's allergy is severe, prompting every effort to control it. Electrostatic filters and top-quality vacuum cleaners with high-efficiency particulate air (HEPA) filters are essential for those with severe inhalant allergies. It may be necessary to part with a cherished family pet or to overcome the habit of smoking and to ask others not to smoke. Purchase of HEPA air filters for the heating and air-conditioning unit may also be helpful. Molds grow in moist environments, so basements, building foundations, showers, and bathing areas are typically prone to mold growth. Routine cleaning and adequate ventilation can help reduce or eliminate mold growth in most homes. Houseplants should be removed if there is an allergy to mold. Dehumidifiers can reduce moisture in basements. Successful compliance with recommendations should reduce the frequency, severity, and symptoms of the allergic reaction.

Patients with allergy-induced skin conditions should be taught that a warm environment and sweating increase the sensation of itching. Advise the patient to keep cool without chilling and not to take excessively hot showers or baths. Over-the-counter topical lotions, as well as prescription medications and salves, can help relieve itching.

Avoiding exposure to allergens requires knowledge of the nature of the allergen, method of transmission, source or reservoir, and portal of entry. Alteration in habits and location may also help eliminate exposure. Successful management of hypersensitivity depends in large measure on the ability of the patient to understand the allergy and to follow the prescribed treatment regimen.

Clinical Cues

Nurses and others who handle certain drugs may develop allergies to these drugs. For example, penicillin and streptomycin can cause contact dermatitis in those who are regularly exposed to them. Hands should be washed thoroughly after handling antimicrobial agents.

Think Critically

What actions would you suggest for removing allergens from the home environment for someone allergic to mold, animals, dust mites, and smoke?

Anaphylactic Reaction and Anaphylactic Shock

Etiology and Pathophysiology

Anaphylaxis is a serious, life-threatening, whole-body allergic reaction. The cardiovascular system, respiratory system, gastrointestinal (GI) system, and skin all contain copious amounts of mast cells. Any agent that causes a severe hypersensitivity reaction can cause anaphylaxis. Substances commonly known to cause hypersensitivity and possible anaphylaxis are listed in **Box 11-8**. For anaphylaxis to occur, the allergen usually needs to be delivered systemically before the sensitized mast cells are triggered to react. An example of this is the parenteral delivery of an antimicrobial agent such as penicillin. When the reaction occurs, the affected cells swell and rupture, with the subsequent release of histamine. Histamine causes dilation of small blood vessels, a pooling of blood, and release of fluid into tissues. This may lead to circulatory collapse and profound shock ([Figure 11-8](#)). A less severe reaction usually occurs if the allergen is delivered by direct contact, inhalation, or ingestion.

Box 11-8

Substances Known to Cause Hypersensitivity and Possible Anaphylaxis

Drugs

- Aspirin
- Cephalosporins
- Chemotherapy agents
- Insulins
- Local anesthetics
- Nonsteroidal anti-inflammatory drugs (NSAIDs)
- Penicillins
- Sulfonamides
- Tetracyclines

Diagnostic and treatment agents

- Allergenic extracts for desensitization
- Blood products
- Iodine-containing contrast media used for radiographs

Antitoxin sera

- Botulinum antitoxin
- Diphtheria antitoxin
- Poisonous spider antitoxin
- Snake venom antitoxin
- Tetanus antitoxin

Foods

- Chocolate
- Milk
- Eggs
- Shellfish
- Fish
- Strawberries
- Wheat
- Nuts (especially peanuts)

Insect stings

- Ants (particularly fire ants)
- Bees, hornets, wasps, yellow jackets

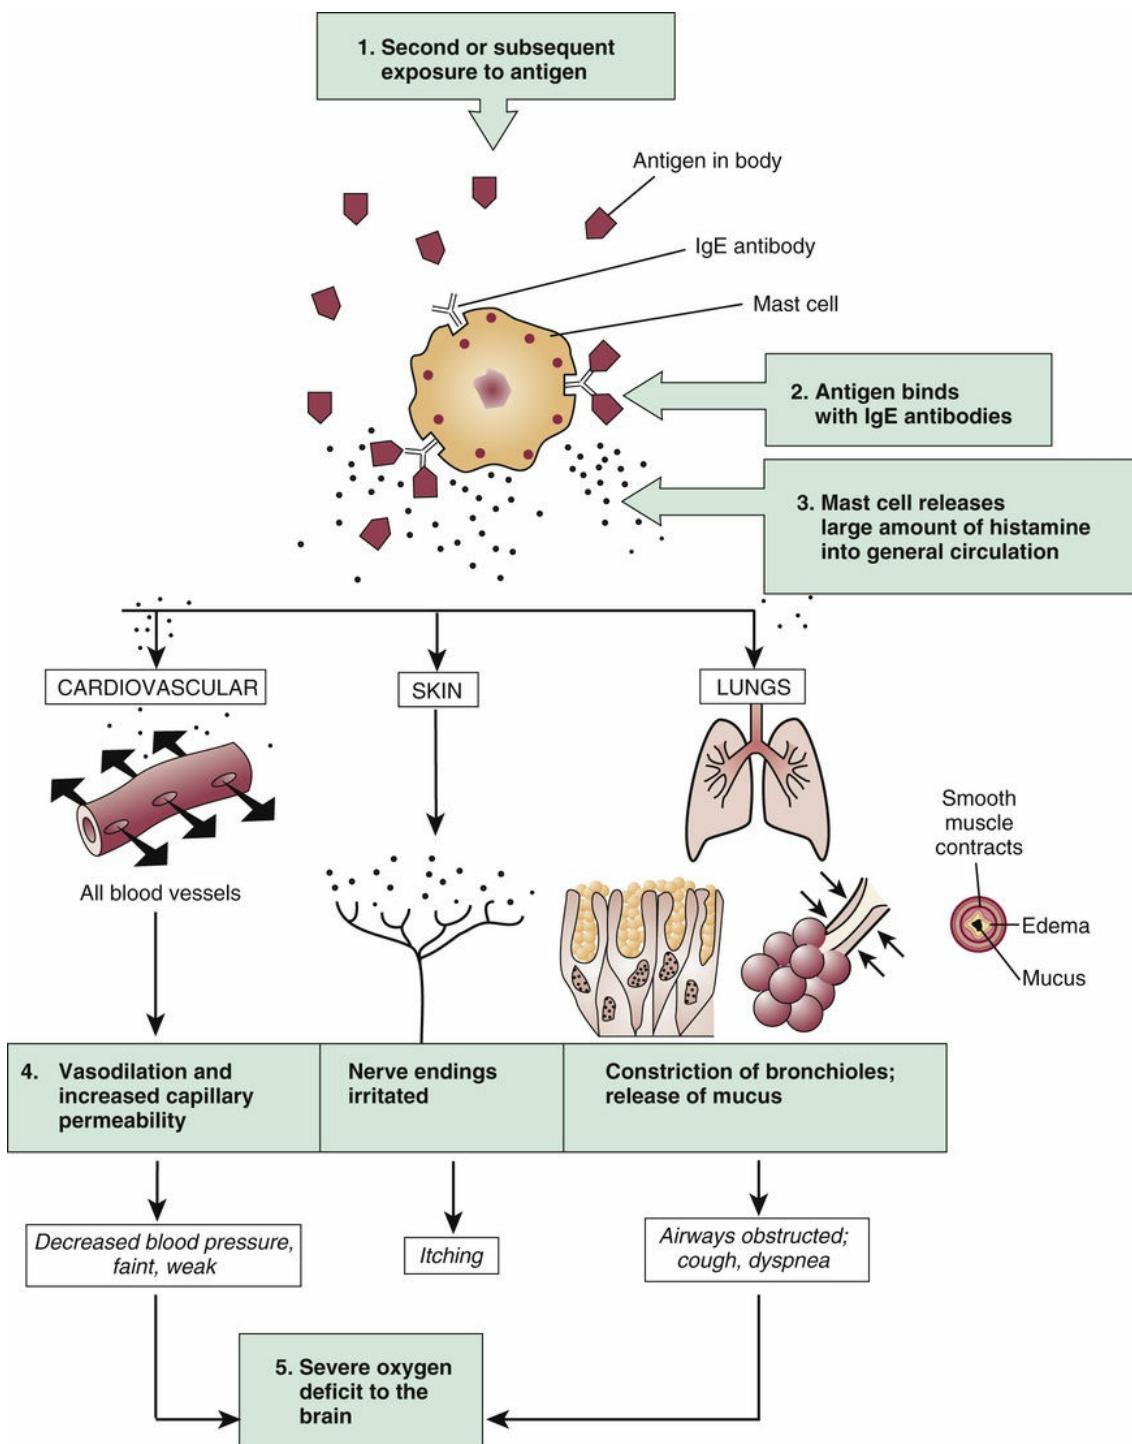

FIGURE 11-8 The effects of anaphylaxis. (From Van Meter KC, Hubert RJ: *Gould's pathophysiology for health professions*, ed. 5, Philadelphia, 2015, Elsevier Saunders.)

Non-IgE-dependent allergens.

IgE-mediated immune responses typically require repeated exposures for a reaction to occur. In the non-IgE-allergen response, a single encounter can lead to anaphylaxis or even death if not recognized immediately. Examples include iodine-based dyes for select radiologic studies and certain narcotics such as morphine and vancomycin, especially if they are administered too rapidly.

Nurses must be alert for previous allergic reactions and identify patients who are likely to experience a serious reaction. Before administering any medication or drug, verify the patient's known allergies. Patients and families should be actively involved in knowing and reporting allergies. The National Patient Safety Goals view this as a safety measure. **Check all the areas in the medical record where allergies are usually documented.** For example, the home page for the patient's electronic health record may have an allergy alert flag on it; the medical history obtained by the provider should contain information related to allergies; and the medication administration record (MAR), the multidisciplinary care plan, and the nurse's admission history may also contain allergy information.

Clinical Cues

Allergies to seafood indicate intolerance to iodine. This means there is potential for an allergic reaction to iodine-based contrast agents used in radiologic imaging studies. Be certain that the shellfish or iodine allergy is noted on the home page of the medical record, on the MAR, and in other locations where allergies are likely to be noted.

Signs and Symptoms

An anaphylactic reaction requires immediate action. The appearance of hives (**urticaria**) or swelling beneath the skin (**angioedema**) may signal the onset of an anaphylactic episode. Hives or sudden outbreaks of **wheals** (small areas of swelling) on the skin that itch and burn may appear without subsequent anaphylaxis.

Tachycardia, decreased pulses, and a rapid drop in blood pressure signal circulatory collapse, which can occur very rapidly. The patient will also exhibit increasing dyspnea because of the narrowing of the air passages (bronchoconstriction), accumulation of mucus, and wheezing. If an airway is not maintained, convulsions may occur because of oxygen deprivation. Treatment must be started immediately to avoid hypoxic brain injury or death within a matter of minutes.

Emergency supplies should be readily available whenever vaccines, serum for passive immunization, and highly allergenic drugs are administered. Anaphylaxis may be prevented if complete information is obtained before administration. Premedication with steroids and/or antihistamines can be administered if a substance needs to be given that the patient has shown sensitivity to in the past.

Clinical Cues

Many patients report allergies to medications that are actually manifestations of side effects, intolerance, or nonallergic adverse reactions. Nausea, constipation, diarrhea, coughing, or drowsiness may be side effects of medications, but reactions to drugs that do not involve the immune system are considered nonallergic adverse reactions. Careful questioning of the patient can help distinguish what kind of reaction the patient has experienced in the past.

Diagnosis

There is no test to confirm the diagnosis of anaphylaxis; rather it is the presenting symptoms, including sudden onset involving one or more body systems, producing one or more symptoms such as itching, hives, stridor, wheezing, or shock, that confirms the clinical diagnosis of anaphylaxis. Once the patient's condition has been stabilized, laboratory and other diagnostic tests may be performed to rule out other possible causes for the symptoms.

Treatment and Nursing Management

Treatment of anaphylaxis includes the following:

- Establishing a patent airway and administering oxygen to relieve the symptoms of dyspnea and hypoxia.

- Administering IV epinephrine to counteract the effect of histamine: relax the bronchioles, increase the cardiac output, and elevate the blood pressure.
- Administering antihistamine (e.g., diphenhydramine hydrochloride [Benadryl]) to stop the effects of the histamine released by the body cells.
- Instituting measures to prevent or control shock.
- Providing psychological support during the course of the **syndrome** (a group of symptoms that characterize a disorder or condition) and its treatment.

When there is difficulty with breathing because of swelling in the airway, provide high-flow oxygen. Although the patient is still able to move air in and out, giving inhaled medications to relax the airways helps maintain air exchange. If these measures are not effective, an emergency intubation, tracheotomy, or cricothyrotomy may be necessary.

Epinephrine is given to counter the allergic reaction. It can be given IV, intramuscularly, subcutaneously, or through an established endotracheal tube. **If the patient is taking beta blockers, they will hinder the effectiveness of the epinephrine.** Diphenhydramine is also used to alleviate the symptoms of the allergic reaction. Corticosteroids may also be given to control the inflammatory response and reduce symptoms.

During the crisis, vital signs and respiratory effort must be monitored continuously. Adequate pharmacologic support and IV fluids are important to maintain perfusion and an adequate blood pressure. See [Chapter 44](#) for additional information on treating shock.

Think Critically

What is the first thing you would do if a patient starts complaining of shortness of breath and wheezing just after you have administered an antibiotic by injection or IV infusion?

People who have extreme sensitivities to certain allergens should carry a medical alert card or wear an identification bracelet or necklace that contains the information. Several companies offer “medical jewelry” that can relay pertinent information. It also is advisable for individuals who are highly allergic to stings from bees, wasps, or other insects or who are severely allergic to nuts or some other food to carry an EpiPen or a small kit containing epinephrine, syringe, needle, tourniquet, and diphenhydramine hydrochloride with them at all times. These pens and kits are available at pharmacies but require a prescription. They are strongly recommended by allergists because of how quickly an insect sting or inadvertent ingestion of a food can produce a fatal reaction in someone who is highly sensitive. It is also advised that the patient inform coworkers or family members where it can be found should the kit be needed.

Get Ready for the NCLEX® Examination!

Key Points

- In immune deficiency disorders there is an insufficient production of antibodies, immune cells, or both, and the disorders may be congenital or acquired.
- Immunosuppression may be used therapeutically for a variety of conditions, such as tissue transplants, rheumatoid arthritis, and NHL.
- Body temperature should be closely monitored for significant changes, although immune-deficient patients may not have a temperature elevation even in the presence of infection.
- HIV disease in the United States is now a chronic controllable disease.
- HIV testing should be offered at the time of a complete physical examination for all sexually active patients.
- A barrier, such as a latex condom, should be used during insertive or receptive sexual intercourse to decrease the risk of acquiring HIV.
- Performing genotyping and phenotyping in a newly diagnosed HIV-positive person helps determine whether the person has any drug-resistant strains of HIV and guides therapy.
- The diagnosis of AIDS is made when the CD4 count is less than 200 cells/ μ L or by the presence of specific OIs.
- OIs secondary to AIDS cause increased morbidity and mortality.
- Wasting syndrome in an AIDS patient is defined as a weight loss of more than 10% of usual body weight.
- If a health care worker is exposed to blood or body fluids of an HIV-positive patient, the occupational health or the Infection Preventionist should be notified to assist with treatment and follow-up.
- The two most common sites of CMV infection are the retina and the GI tract.
- Autoimmune disorders are believed to be caused by the immune system reacting to the body's own cells and are typically treated by suppressing the immune system.
- In SLE, the body produces abnormal antibodies that attack the target tissues or cells. Inflammation of muscles, blood vessel abnormalities, and immune complex deposition in tissue occurs.
- Lymphoma starts in the lymph tissue when malignant lymphocytes multiply and crowd out normal cells; treatment depends on staging and the aggressiveness of the particular type of the disease.
- In HL, R-S cells are seen on microscopic examination of tissue.
- In NHL, the R-S cells are not present. NHL is further identified as B-cell or T-cell lymphoma.
- Nursing care for lymphomas focuses on preventing infection, managing the symptoms, and reducing the side effects of the therapies.
- In fibromyalgia, the most common feature is musculoskeletal pain that is diffuse and multifocal with flare-ups and remissions.
- Any agent that causes a severe hypersensitivity reaction can cause anaphylaxis.
- Nursing responsibilities in caring for patients with allergic conditions include assisting in the diagnosis of hypersensitivity, helping to identify substances that trigger an allergic response, assisting the patient to avoid or limit exposure to allergens, and relieving symptoms.
- Emergency equipment and medications must be available for an anaphylactic reaction, which is a life-threatening condition.

Review Questions for the NCLEX® Examination

1. The nurse reinforces the provider's order to draw blood for HIV genotyping. The patient asks, "How does that help in my treatment?" What is the best explanation for the test?

1. Confirms the presence of a viral autoimmune disease
2. Informs how much of the virus has been replicated
3. Determines the presence of any mutations in the virus
4. Reveals the viral load or count of the virus

NCLEX Client Need: Health Promotion and Maintenance

2. A patient known to be positive for HIV is admitted with oral thrush, recurrent vaginal yeast infections, and skin infections. What do these signs indicate?

1. Opportunistic infection
2. Antimicrobial resistance
3. Resistant strain of HIV
4. Sentinel infection

NCLEX Client Need: Physiological Adaptation: Alterations in Body Systems

3. Which statement(s) is/are true regarding HIV transmission? (*Select all that apply.*)

1. Breast milk can harbor the virus.
2. Proper use of PPE reduces the risk of disease transmission.
3. Needle exchange programs facilitate the spread of the virus.
4. Being assessed 2 hours after a blood-borne pathogen (BBP) exposure decreases the risk of conversion.

5. Monogamous relationships provide the best defense from the virus.

NCLEX Client Need: Physiological Adaptation: Pathophysiology

4. In determining the optimal therapy for a patient infected with HIV, what would the nurse consider in developing a nursing care plan? (*Place in order of priority.*)

1. Clinical data
2. Compliance with therapy
3. Medication tolerance
4. Support system
5. Patient expectations

NCLEX Client Need: Physiological Adaptation: Illness Management

5. A nurse is reviewing medication orders for a female patient with SLE who is positive for the presence of antiphospholipid antibodies. The nurse would seek clarification from the provider about which type of medication?

1. Oral contraceptives
2. Hydroxychloroquine (antimalarial)
3. Glucocorticoid medication
4. NSAID

NCLEX Client Need: Pharmacological and Parenteral Therapies: Medication Administration

6. A patient has the medical diagnosis of fibromyalgia. Which nursing problem is the highest priority for on this patient's care plan?

1. Airway congestion
2. Inability to comply with treatment regimen
3. Chronic pain
4. Potential for fluid imbalance

NCLEX Client Need: Physiological Adaptation: Illness Management

7. The nurse admits an older adult man with NHL. On initial assessment, the nurse notes that the patient is slightly confused, is irritable, is emaciated, has poor dentition, and is homeless. What is the priority nursing problem?

1. Potential for infection
2. Lack of coping ability
3. Alteration in body image
4. Inadequate knowledge of disease process

NCLEX Client Need: Physiological Adaptation: Alterations in Body Systems

8. A systemic autoimmune disease affects more than one type of body tissue or organ. Which would be considered systemic autoimmune disease(s)? (*Select all that apply.*)

1. Addison disease
2. Rheumatoid arthritis
3. Systemic lupus erythematosus
4. Goodpasture syndrome
5. Primary lymphedema

NCLEX Client Need: Physiological Adaptation: Pathophysiology

9. What are the advantages in performing a RAST? (*Select all that apply.*)

1. The patient does not have to refrain from taking antihistamine medications.
2. It is safer for patients with serious heart and lung problems.
3. There is no chance of experiencing an anaphylactic reaction because it is performed on the blood.
4. It can be used on patients whose skin condition is too severe to perform skin testing.
5. The results can be obtained within several hours.

6. It has greater specificity for allergens than other tests.

NCLEX Client Need: Reduction of Risk Potential: Diagnostic Tests

10. A patient with an immune disorder is very susceptible to infection. Which intervention(s) would be used in the care of this patient? (*Select all that apply.*)

1. All health care workers should perform scrupulous hand hygiene.
2. The patient should be instructed on how to wear PPE.
3. The patient is placed in Contact Isolation as soon as possible.
4. Caregivers with any type of infection should not be assigned to the patient.
5. A high-protein diet with nutritional supplements is encouraged.

NCLEX Client Need: Safety and Infection Control: Standard Precautions/Transmission-Based Precautions

Critical Thinking Questions

Scenario A

A nursing assistant was instructed to clean up equipment that was used in a bedside procedure. She accidentally sustains a needle stick while putting a used syringe into an overly filled sharps container in the room of an HIV-positive patient. The nursing assistant is crying hysterically and unable to act on her own behalf.

1. What should you do first?
2. Outline the steps of treatment and reporting for this type of incident.
3. What factors may have contributed to the accident?

Scenario B

Marilyn Jost, age 15, is highly allergic to penicillin and bee stings. The last time she experienced a reaction to a bee sting on her leg, the entire limb became swollen. Marilyn is active in the teen church group and frequently goes on camping trips. Her provider has suggested that she wear an identification bracelet stating her allergies and that she carry an emergency kit when she is on a camping trip. Her mother sees no need for these precautions because Marilyn is a perfectly healthy girl. Marilyn says she would not know what to do with the kit if she did get stung by a bee or wasp.

1. How would you explain to Marilyn and her mother the need for the identification bracelet and the kit?
2. How would you go about teaching Marilyn to use the emergency kit?

UNIT IV

Respiratory System

OUTLINE

Chapter 12 The Respiratory System

Chapter 13 Care of Patients With Disorders of the Upper Respiratory System

Chapter 14 Care of Patients With Disorders of the Lower Respiratory System

CHAPTER 12

The Respiratory System

Objectives

Theory

1. Describe the structure and function of the respiratory system.
2. Analyze three causative factors related to disorders of the respiratory system.
3. Summarize nursing responsibilities for patients undergoing diagnostic tests and procedures for disorders of the respiratory system.
4. Provide instructions to patients on measures to prevent long-term problems of the respiratory system.

Clinical Practice

5. Employ proper techniques for assessing the respiratory system.
6. Verify that problem statements/nursing diagnoses chosen for patients with problems of the respiratory system are appropriate.
7. Propose interventions for a patient who has a problem with oxygenation.
8. Teach a patient about smoking cessation.

wheezes (WĒZ-ĕz, p. 265)

Overview of Anatomy and Physiology of the Respiratory System

Functions of the Structures of the Upper Respiratory System

- Air passes through the nose, mouth, pharynx, larynx, and trachea and then into the lungs ([Figure 12-1](#)).

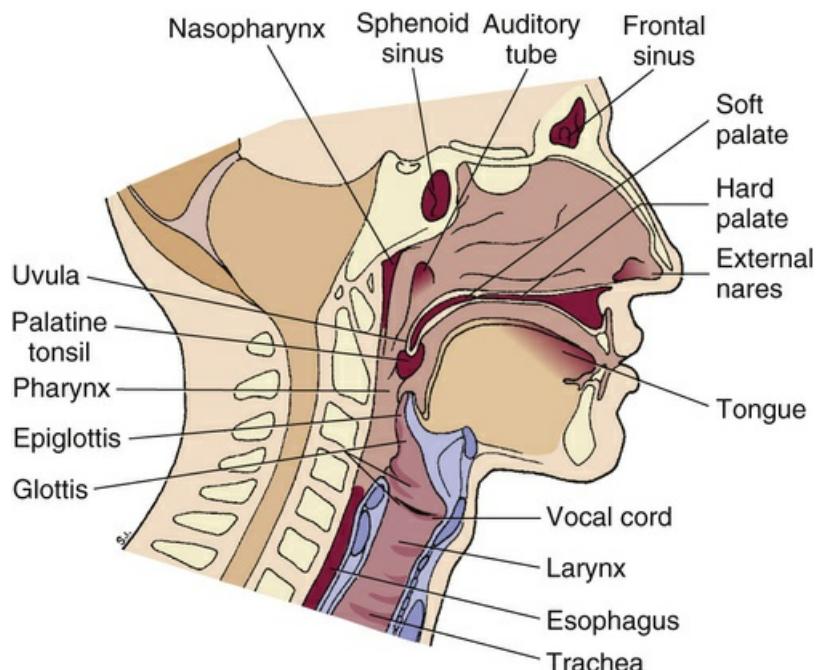

FIGURE 12-1 Structures of the upper respiratory tract.

- The nasal cavity is lined with mucous membrane that warms and moistens the air as it passes through.
- The mucous membrane secretes mucus, which traps dust particles and bacteria.
- The **cilia** (small, hairlike projections) propel the mucus toward the larynx, so the person can swallow or **expectorate** it (cough up and spit out).
- The paranasal sinuses (maxillary, frontal, sphenoid, and ethmoid) are air-filled cavities lined with mucous membrane and situated among the facial bones around the nasal cavity ([Figure 12-2](#)).

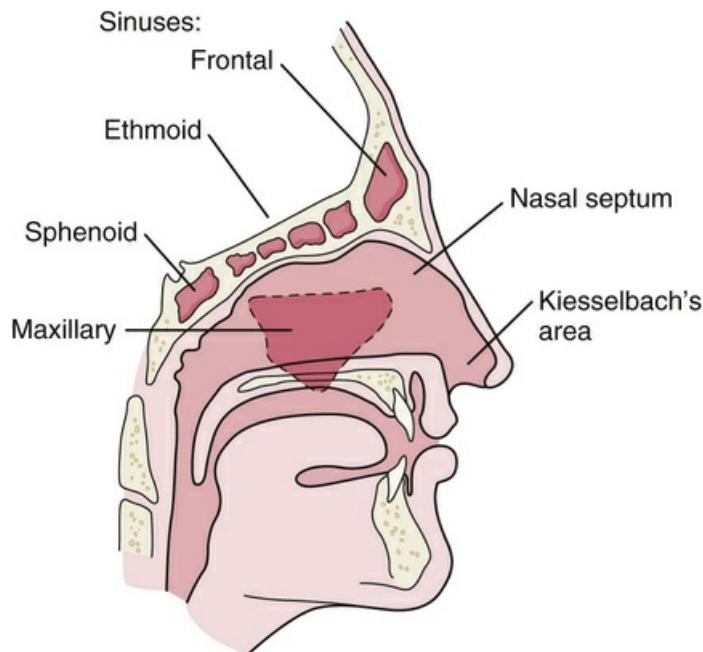

FIGURE 12-2 The paranasal sinuses.

- The sinuses reduce the weight of the skull, produce mucus, and influence voice quality.
- The pharynx, consisting of the nasopharynx, oropharynx, and laryngopharynx, is about 5 inches long and extends from the back of the mouth to the esophagus.
- The pharynx is a passageway for moving air to the lungs and food to the esophagus.
- The tonsils, which are part of the lymphatic system, are located in the oropharynx; the adenoids (also part of the lymphatic system) are located in the nasopharynx. If they become inflamed and enlarged, they may interfere with breathing. The epiglottis forms a hinged “door” at the entrance to the larynx.
- The larynx sits between the pharynx and the trachea. The vocal cords are located in the larynx.
- The trachea is made up of cartilage, smooth muscle, and connective tissue and is lined with mucous membrane and extends from the larynx to the bronchi; it is the “windpipe” and carries air to the lungs.

Epiglottis Protection of the Airway

- When swallowing begins, the epiglottis closes over the larynx, preventing aspiration of food and secretions into the lungs. Food is then directed into the esophagus.
- When the swallowing reflex is weak or absent, aspiration is a risk.

Production of Speech in the Larynx

- The glottis is the space between the folds of the vocal cords, which are made up of mucous membrane attached to the front and back of the larynx.
- When air from the lungs exits through the larynx, it causes rapid opening and closing of the glottis. Movements of the mouth, lips, jaws, and tongue convert the sounds made by the rush of air through the glottis into speech sounds.

Functions of the Structures of the Lower Respiratory System

- On inhalation, after passing through the nose, pharynx, larynx, and trachea of the upper respiratory system, air enters the left and right bronchi, which branch off of the trachea.
- The bronchi carry air into the lungs; the right lung has three lobes, and the left lung has two lobes.

Oxygen Delivery to the Alveolar Membrane for Diffusion Into the Blood

- The main bronchi divide into smaller and smaller bronchi, and then divide into bronchioles that

deliver the air to the alveoli (Figure 12-3). The right bronchus has less of an angle than the left bronchus; inhaled foreign objects tend to go into the right bronchus.

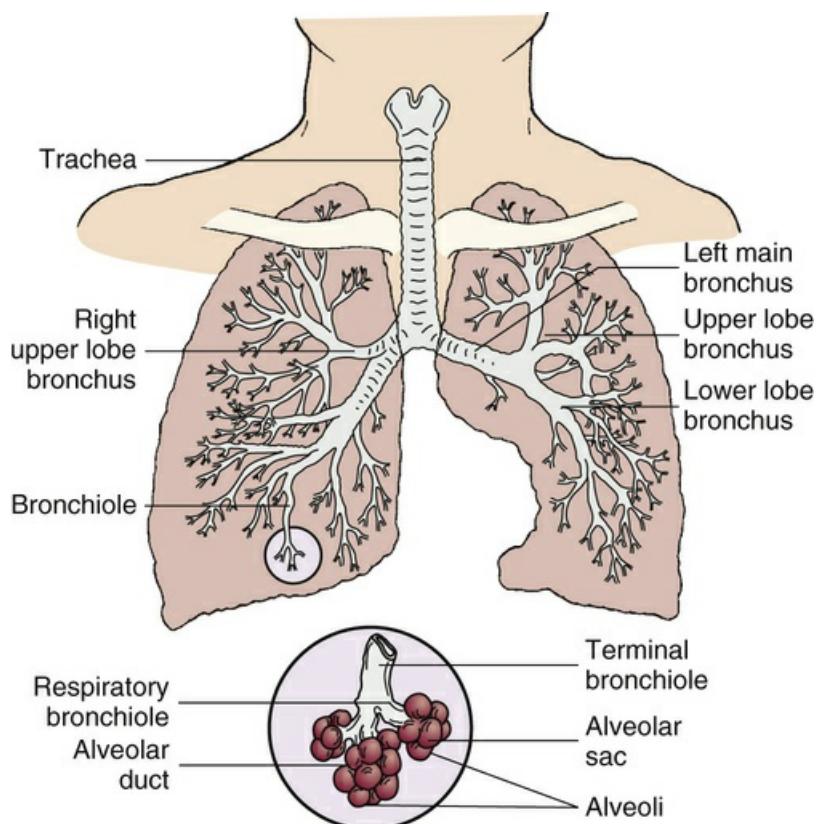

FIGURE 12-3 Structures of the lower respiratory tract and alveoli.

Protection of the Lungs

- The **pleura** is a serous membrane of two layers. One layer, the **visceral pleura**, covers each lung, and the **parietal pleura** lines the inner wall of the chest cavity. These two layers make up the **pleural sac**, which encloses each lung and the chest wall and is an airtight compartment. **If the pleural sac is punctured, air will rush into the pleural cavity and collapse the lung.**
- The pleural cavity is a potential space between the pleural layers where there is normally only a small amount of fluid.
- This small amount of fluid between the two layers of pleura lubricates the pleural cavity and prevents friction between the pleural layers with inhalation and exhalation.
- The mucous membrane lining the many small branches of the bronchial tree contains tiny hairlike projections (cilia) that trap and propel small inhaled foreign particles toward the entrance of the respiratory tract; the cough reflex works to expel the secretions and particles.
- If the particles advance to the lungs, the alveoli contain macrophages that quickly destroy inhaled bacteria and other foreign particles.

Control of Respiration

- The central nervous system controls both involuntary and voluntary respiration via the pons and the medulla. The vagus nerve supplies the pharynx, larynx, respiratory airways, and lungs.
- The brainstem chemoreceptors are sensitive to changes in carbon dioxide (CO_2) and hydrogen ions in the cerebrospinal fluid; the chemoreceptors in the aorta and the carotid arteries are sensitive to oxygen levels in the blood.
- The signals of changing levels of hydrogen ions (measured by pH), CO_2 , and oxygen (O_2) trigger

the respiratory center to send signals through the spinal cord and spinal nerves to the peripheral nervous system and to the phrenic and intercostal nerves that control the diaphragm and respiratory muscles.

- When CO₂ levels in the cerebrospinal fluid become higher than normal or the pH drops, the central receptors in the brainstem signal the nerves to initiate faster respiration to “blow off” the excess CO₂. Carbon dioxide levels give the primary signals for respiration.
- When arterial blood O₂ levels fall below normal, the respiratory centers in the aorta and carotid arteries signal the nerves to cause the lungs to inflate more fully, making the person breathe more deeply and at a faster rate.
- **When CO₂ levels are constantly high (as occurs with chronic lung disease such as emphysema), the body becomes accustomed to high CO₂ levels, and the respiratory drive is triggered by the receptors for low arterial O₂ instead of high levels of CO₂. If these patients are given too much oxygen, their respiratory drive is suppressed and they will stop breathing.** (Normal blood gas levels are listed in [Table 12-1](#).)

Effect of the Bones of the Thorax and the Respiratory Muscles on the Respiratory Process

- Inspiration (inhalation) and expiration (exhalation) occur by movement of the diaphragm and the intercostal muscles in the chest wall. During normal breathing, about 500 mL of air moves in and out of the lungs with each breath. The diaphragm is the primary respiratory muscle.
- When the diaphragm contracts, it moves downward; the other chest muscles contract, pulling the rib cage up and out, expanding the lungs and creating an area of negative pressure. Air from the atmosphere, which has a positive pressure, flows into the lungs.
- When the muscles relax, the rib cage moves back to its normal position, and the lungs return to a resting position, causing air to be passively pushed out in exhalation.
- **If damage to the spinal cord occurs above the level where the phrenic nerve branches off to control the diaphragm (C4), voluntary respiration ceases.**
- If the muscles of the diaphragm and chest (intercostals) are paralyzed, **apnea** (absence of breathing) occurs.
- The thoracic cage—composed of the thoracic vertebrae, the sternum, and the ribs—forms a stable unit that allows the respiratory muscles to function correctly. If any bones of the thorax or chest wall are injured or fractured, breathing can be affected. **Compliance** describes the elasticity of the lungs or how easily the lungs inflate; when compliance is decreased, the lungs are more difficult to inflate. Chronic obstructive pulmonary disease (COPD) and aging alter compliance because of damage in the alveoli.
- **Weakness of the respiratory muscles, such as occurs with neuromuscular diseases, also causes decreased respiratory ability.**
- **Kyphosis** (inward curvature and collapse) of the spine constricts the thoracic cavity and restricts the capacity of the lungs to expand fully.

Factors That Affect the Exchange of Oxygen and Carbon Dioxide

- Alveoli are tiny air sacs covered with a permeable membrane that come into contact with the pulmonary arterioles and venules; oxygen passes into the arterial blood, and carbon dioxide passes from the venous blood into the alveoli for exhalation.
- Surfactant is secreted by cells in the alveoli; it decreases surface tension on the alveolar wall so that diffusion of O₂ and CO₂ can take place. Surfactant facilitates expansion with inspiration and prevents alveolar collapse on expiration. When surfactant levels are low, alveoli cannot properly expand, and O₂ and CO₂ cannot cross the membrane adequately.
- When interstitial edema occurs in the lung tissue, the alveolar membrane is thickened and gases cannot diffuse across the membrane as easily. If fluid fills the alveoli, gases cannot diffuse across the membrane.

- Edema in the lungs occurs with infectious processes such as pneumonia and in disorders such as congestive heart failure.
- The major portion of the O₂ (about 97%) attaches to the heme portion of the hemoglobin molecule carried by the **erythrocytes** (red blood cells) and forms **oxyhemoglobin**. The plasma also transports a portion of each gas; about 3% of O₂ is dissolved in the plasma.
- CO₂, a cellular waste product, combines with water, forming carbonic acid; **dissociation** (uncombining) occurs, forming hydrogen ions and bicarbonate ions. About 77% of CO₂ is transported in the blood plasma in the form of bicarbonate ions. The remaining 23% of CO₂ combines with hemoglobin and is carried to the lungs. In the lung, the process reverses and the bicarbonate ions combine with hydrogen ions to form carbonic acid, which then dissociates into water and CO₂. The CO₂ diffuses across the alveolar membrane and is exhaled. The ability of the lungs to acquire oxygen is measured clinically by pulse oximetry (SpO₂). The ability of the lungs and chest to move air in and out of the body is termed **ventilation** and is clinically measured by end tidal CO₂ (ETCO₂ or capnography)

Effects of Aging on the Respiratory System

- The decrease in the immune system's efficiency makes older adults more susceptible to upper respiratory infections.
- Aging results in a decreased cough reflex and an increased potential for aspiration.
- Osteoporosis may cause kyphosis, which impinges on lung expansion.
- Adults age 70 years and older have some degree of change in connective tissue that causes decreased elasticity and affects lung function and ventilation.
- Total body water decreases to 50% after age 70 years; thus mucous and respiratory membranes are not as moist and mucous becomes much thicker.
- There is some impairment of the ciliary action, which makes it more difficult for older adults to remove mucus, and retained mucus provides a breeding ground for bacterial infection.
- There is a loss of normal elastic recoil of the lung during expiration, and older adults must use muscle action to complete expiration. This increases the work of breathing.
- Muscle atrophy may affect the respiratory muscles, diminishing their strength.
- Connective tissue changes and loss of elastic tissue in the alveoli causes the alveolar membranes to become baggy. Oxygen levels decrease for the older adult, with partial pressure of oxygen (PO₂) dropping to 75 to 80 mm Hg from the usual 80 to 100 mm Hg.
- There is a decreased response to **hypoxemia** (oxygen deficit in the blood) and hypercapnia (excessive amounts of carbon dioxide in the blood).

Causes of Respiratory Disorders

Trauma or disease can affect structures of the respiratory system, nerves controlling respiration, or diffusion of oxygen or carbon dioxide across the alveolar membranes. **Perfusion** (blood flow into cellular tissue) is essential to provide oxygen to the cells of the body. Blood must flow past the alveolar membrane for **diffusion** (Box 12-1) of oxygen and carbon dioxide to take place. Cardiac disease, emboli, and other disorders of the heart and pulmonary blood vessels may cause problems in the respiratory system.

Box 12-1

Terms Commonly Used in Respiratory Care

- *Diffusion:* The movement of oxygen and carbon dioxide across the alveolar-capillary membrane. It takes place between the gas in the alveolar spaces and the blood in the pulmonary capillaries.
- *Elastance:* The extent to which the lungs are able to return to their original position after being stretched or distended.
- *Hypoxemia:* Deficient oxygenation of the blood.
- *Hypoxia:* A broad term referring to diminished availability of oxygen to the body tissues.
- *Lung compliance:* The ability of the lungs to distend in response to changes in volume and pressure of inhaled air. Lung compliance first increases and then decreases with age as the lungs become stiffer and the chest wall more rigid.
- *Perfusion:* The delivery of fluid through the blood vessels to body tissues.
- *Pulmonary hygiene:* Methods used to clear secretions from the airways.
- *Resistance:* The force working against the passage of air. The major determinant is the radius of the airway.
- *Respiratory failure:* An abnormality of gas exchange with either an excess of carbon dioxide or a deficit of oxygen, or both.
- *Shunting:* Intrapulmonary shunting is the diverting of blood so that it does not take part in the gas exchange at the alveolar sites. When intrapulmonary shunting occurs, blood enters the left side of the heart without being oxygenated. It is, therefore, a possible cause of hypoxemia.
- *Surfactant:* A complex lipoprotein produced by cells lining the alveoli, which lowers surface tension within the alveoli. It prevents collapse of the lung by stabilizing the alveoli and decreasing capillary pressures.
- *Ventilation:* The movement of air from the external environment to the gas exchange units of the lung. It can be spontaneous or done by a mechanical ventilator.

The respiratory system is particularly susceptible to harmful substances in the environment. Inhalation of bacteria and other organisms can quickly produce an infection in either the upper or lower respiratory tract. Tobacco smoke, allergens, poisonous gases, and other toxic substances cause irritation and inflammation of the air passages and can lead to chronic inflammation, obstructive diseases, and tumors. There may be a familial tendency related to sensitivity to these toxins, which may result in asthma and other lung problems.

There are two major types of ventilatory diseases: **restrictive** and **obstructive**. **Restrictive diseases are characterized by decreased lung capacity or compliance.** The expansion of the lung and chest wall is limited either by abnormalities in the bony structures **or by inability of the lung**

tissue to expand. Arthritis increases stiffness of the chest wall and results in a decreased ability of the chest cavity to expand and contract. Scoliosis and kyphosis decrease the size of the chest cavity. **Pneumothorax** (collapsed lung) diminishes lung surface; neuromuscular disorders weaken the strength of the muscles of respiration (e.g., myasthenia gravis), and disorders of the lung (e.g., pneumonia, atelectasis, and fibrosis) increase stiffness and decrease lung volume.

Obstructive pulmonary diseases are characterized by problems moving air into and out of the lungs. Narrowing of the openings in the tracheobronchial tree increases resistance to the flow of air, making it difficult for oxygen to enter and contributing to air trapping; therefore exhalation is also difficult. Asthma, emphysema, and chronic bronchitis are examples of obstructive lung diseases. Tumors in the lung can also obstruct airflow to the alveoli.

Respiratory Disorders

Prevention

The best ways to prevent infection and inflammation of the respiratory system are to practice hand hygiene frequently; stay out of crowds, especially during cold and flu season; refrain from smoking; avoid known allergens as much as possible; maintain adequate nutrition; and obtain sufficient rest to help keep the immune system healthy. Nurses should identify persons who have a high risk for infection (Box 12-2) and refer them for appropriate vaccinations or teaching.

Box 12-2

Factors that Increase Risk for Respiratory Infection

- Age older than 65 years
- Cigarette smoking
- Residing in extended-care facilities
- Chronic respiratory disorders (includes asthma)
- Congenital or chronic cardiovascular disorders
- Chronic renal disease
- Diabetes mellitus or a chronic metabolic disorder
- Compromised immune response

Allergy to airborne substances causes the mucous membranes of the nose and sinuses to become irritated and inflamed. When these membranes are inflamed, bacteria and viruses can more easily invade the cells and cause infection. By controlling inhaled allergens, the incidence of upper respiratory infection (URI) can be decreased.

Older Adult Care Points

Older adults should not be exposed to children with colds and coughs. If an older adult is confined to the house or a long-term care facility, he or she will not have the immunity to common viruses and bacteria that younger, more socially active people do.

Elimination of widespread respiratory diseases such as the common cold and influenza is not possible; therefore nurses must practice good hand hygiene and use Standard Precautions and airborne or droplet precautions when working with patients with respiratory infections as per the Centers for Disease Control and Prevention (CDC) guidelines. For certain groups such as older adults and the chronically ill, immunization against influenza and pneumonia is an effective means of reducing the incidence of respiratory disease. Providers, nurses, and others involved in providing health care should also be immunized. Among the more serious reactions to influenza vaccine are allergic reactions, fever, malaise, or muscle soreness. Current research indicates that influenza vaccinations may increase the risk of Guillain-Barré syndrome (CDC, 2012). This immune-mediated disorder occurs in about 1 in 100,000 individuals. The incidence of Guillain-Barré has been noted to be higher in the patient population who had the flu than in the group just receiving the vaccine, so vaccination is recommended. The vaccine is prepared from chicken embryos; therefore screening patients for egg allergy is important; nonegg formulations are available. One of the most important preventive measures of lung tissue injury is avoiding prolonged and repeated inhalation of irritating substances. Such substances include tobacco smoke, industrial gases, coal dust, particulates from agricultural activities, soot and other carbons, and air polluted by

automobile exhaust. *Healthy People 2020 (2015)* goals include addressing outdoor air quality as well as reducing “illness, disability and death related to tobacco use and secondhand smoke exposure.” Smoking cessation efforts are supported by increasing insurance coverage for evidence-based interventions, increasing smoke-free environments, and strengthening tobacco laws. The Joint Commission has developed Core Measures for the assessment and treatment of tobacco use. Nurses participate by identifying patients at risk for tobacco-related disease and encouraging cessation programs.

Think Critically

Can you think of three changes in lifestyle that might prevent you or a family member from developing a chronic or serious respiratory disorder?

Health Promotion

Smoking and Tobacco Cessation

The Agency for Healthcare Research and Quality (AHRQ) provides a guide for clinicians that states the following: There are “five As” for helping your patients to quit smoking: **Ask** about tobacco use. **Advise** about the health benefits of quitting. **Assess** readiness to quit. **Assist** in creating a cessation plan. **Arrange** follow-up. For those patients who are resistant to the five As model, an alternative model is the “Five Rights.” Help the patient identify the personal **Relevance**, **Risks**, **Rewards**, and **Roadblocks**, and **Repeat** these at every visit (Agency for Healthcare Research and Quality, 2008). Other toolkits and strategies are available on the AHRQ website.

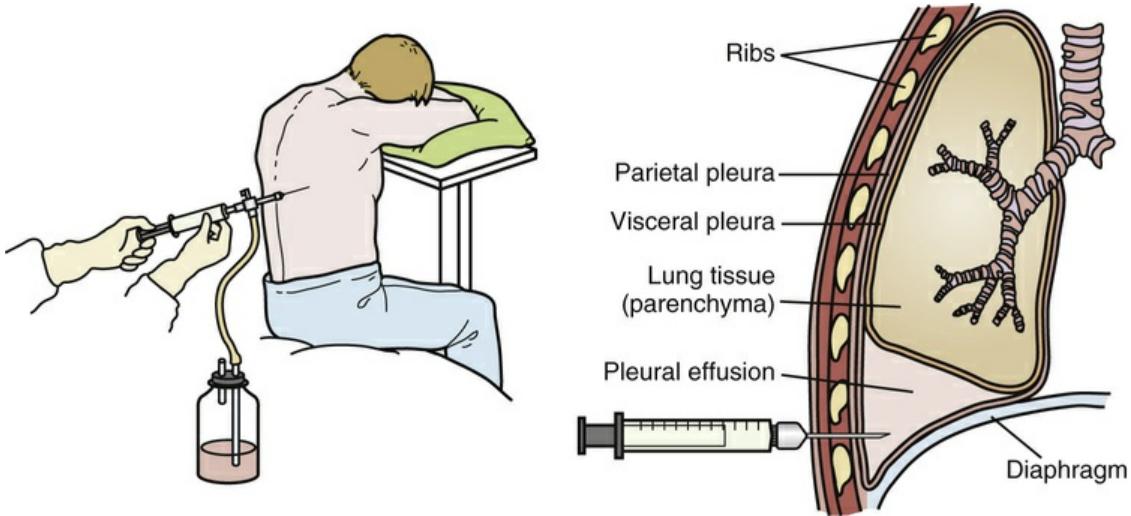

Diagnostic Tests and Procedures

Table 12-1 presents the most common diagnostic tests performed for problems of the respiratory system. A complete blood cell count with hemoglobin and hematocrit determinations is done to detect any deficiency in oxygen-carrying capacity of the blood. An elevated white blood cell count may indicate the presence of infection. Anterior-posterior and lateral chest radiographs are usually ordered when the patient has a lower respiratory tract problem that does not quickly resolve.

Table 12-1
Diagnostic Tests for Respiratory Problems*

TEST/PURPOSE	DESCRIPTION	NURSING IMPLICATIONS
Pulse Oximetry (SpO_2)	Device attaches to earlobe, pinna of ear, or fingertip.	Keep sensor intact on patient. Monitor and record SpO_2 readings.
To allow comparison of oxygenated hemoglobin to total hemoglobin	Sensor detects blood cells in capillaries using an infrared light source.	Report readings persistently below 95% to provider. Obstructions to blood flow, such as inflated BP cuff, peripheral artery disease, hypotension, or hypothermia, can cause false readings. Metallic nail polish and harsh ambient light interfere with readings. Performed by the nurse at the bedside, in home or clinic setting.
CO ₂ Monitoring (Called Capnography When Equipment Displays a Waveform)	Device can be part of an oxygen delivery system measuring end tidal CO ₂ (ETCO ₂) or a skin sensor measuring transcutaneous CO ₂ (PtCO ₂).	Make sure sensor is positioned properly to obtain readings. Explain the reason for the monitoring to the patient. Done at bedside by the nurse.
Sublingual CO ₂ Level	Probe of handheld device is placed under the tongue.	Reading takes 60-90 sec. Explain the procedure to the patient.
Arterial Blood Gas (ABG) Analysis	To determine whether there is adequate exchange of carbon dioxide and oxygen across alveolar membrane; to determine acid-base balance within the body; to determine hypoxemia	Explain procedure to patient; arterial puncture is briefly painful. Apply firm pressure for 5-10 min after specimen drawn. Compare laboratory results to normal values: pH: 7.35-7.45. Usually obtained by respiratory therapy or nursing personnel. In some states, phlebotomists need additional training to obtain arterial specimens. Arterial blood sample is drawn and tested for pH, PaO ₂ , PaCO ₂ , and HCO ₃ ⁻ . PaO ₂ : 80-100 mm Hg. PaCO ₂ : 35-45 mm Hg. HCO ₃ ⁻ : 22-26 mm Hg.
D-Dimer (Fibrin Split Products, Fibrin Degradation Products)	To assess thrombin and plasmin activity	Blood test that provides assay of fibrin degradation. No fasting is required.
Useful for assisting in the diagnosis of pulmonary embolism and disseminated intravascular coagulation (DIC)		Collect a venous blood sample in a light blue-top tube.
CBC	To identify adequacy of hemoglobin to carry oxygen and to determine whether an infection is present	Provides information on red cells and the body's immune response. Collect a venous blood sample in a lavender-top tube. Performed by the nurse or phlebotomist at the bedside in home or clinic setting.
Sputum Analysis		

To examine sputum from lower respiratory tract for bacteria, bacilli, or malignant cells; to determine color, consistency, and sensitivity of bacteria to specific antibiotics	Sputum specimen is examined and cultured for bacteria; acid-fast stain and Gram stain are done for tuberculosis bacillus; cytologic studies may be done to search for malignant cells. If bacteria are present, sensitivity studies to antibiotics are performed. Nucleic acid amplification can detect <i>Mycobacterium tuberculosis</i> earlier than culture and should be interpreted in correlation with acid-fast results.	Explain that specimen is desired from lower areas of lungs; may require respiratory therapy to obtain proper specimen. coaching in proper coughing technique. Best specimen is obtained in morning before eating or mouth care. Promote mouth care after obtaining specimen. Specimen is expectorated into sterile container.
Pulmonary Function Tests (PFTs)		
To determine integrity of mechanical function and gas exchange function of the lungs: volume of air lung can hold; rate of flow of air in and out of the lung; and elasticity, or compliance, of lung	Patient breathes in as much air as possible and then breathes out as much air as possible into a spirometer, indicating the forced vital capacity (FVC); forced expiratory volume in 1 sec (FEV ₁) is measured. Other measurements include total lung capacity (TLC), vital capacity (VC), tidal volume (TV), functional residual capacity (FRC), and residual volume (RV).	Should not be done within 1-2 hr of eating. No smoking for 4-6 hr before test. Patient is not to take any drugs or sedation. Patient may be instructed to stop bronchodilator and corticosteroid medications before the procedure. Explain procedure to patient. <i>Post-test:</i> Monitor vital signs and allow patient to rest, because test can be fatiguing. Some of the readings can be obtained at the bedside for an inpatient. Most full studies are done in a pulmonary laboratory as an outpatient procedure.
Chest Radiograph (X-Ray)		
To determine pathologic conditions in the lungs, such as pneumonia, lung abscess, tuberculosis, atelectasis, pneumothorax, and tumor; also gives indication of heart size and any abnormalities of bony structures	Front, back, and lateral views may be taken; fluoroscopy may be used to visualize lung and diaphragm movement.	Imaging procedures require specially trained personnel to perform. For outpatient procedures, tell patient to remove clothes down to the waist and put on gown provided so that i back. Will be asked to take a deep breath and hold it while the radiograph is taken. Portable x-rays can be taken when the patient is unable to stand or be transported to the stationary x-ray equipment.
Chest Computed Tomography (CT)		
To visualize soft tissue densities, tumors, and blood clots	Chest CT with 5- to 10-mm cross-sectional views of the entire thorax with 1-mm scans of suspicious areas. High-resolution CT may be used with computer enhancement of 1-2 mm sections.	Patient must be able to lay flat and still for several minutes. Must be done in the Imaging Department. Provide information about the test.
	Contrast agent may be used.	Check for sensitivity to iodine, shellfish, or the specific contrast medium
Lung Ventilation and Perfusion Scan (V-Q Scan)		
To assess lung ventilation and lung perfusion; to locate pulmonary embolism and diagnose tumor, emphysema, bronchiectasis, or fibrosis	<i>Perfusion scan:</i> An IV injection of radionuclide-tagged, macroaggregated albumin is given; decreased blood flow to any part of the lung is shown by decreased radioactivity in that area. <i>Ventilation scan:</i> Radioactive gas is inhaled and, when scanned, presents a pattern of ventilation in the lungs.	Assess for allergies. Ask patient to remove all metal jewelry from around the neck. Assure patient that amount radioactivity used is very small and is not harmful. An IV access will be inserted. Patient will be asked to hold i short period for the ventilation scan. Images are viewed by use of a scintillation scanner. This test is a nuclear medicine study and will be done by radiology technologists who are certified in conductir procedures.
Pulmonary Angiography		
To visualize pulmonary vasculature; to locate pulmonary embolus or other abnormality	Radiopaque contrast agent is injected via a venous catheter into the right side of the heart or the pulmonary artery. Radiographs are taken; fluoroscopy is used.	Check consent form. Assess for allergy to dye. Explain that patient may feel warm flush as dye is injected. The test will be done in a special procedure room in the Imaging Department by a physician. <i>Post-test:</i> Monitor vital signs and check dressing for signs of bleeding. The femoral vein is used for access, so bleed not as common as with arterial access. If procedural sedation was used, monitor patient per policy.
Bronchoscopy		
To inspect bronchi; to remove foreign objects or mucus plugs; to biopsy lesions	Preoperative sedation may be given. Throat is sprayed with local anesthetic and/or the patient is asked to gargle with topical anesthetic agents. With neck hyperextended, a flexible fiberoptic bronchoscope is guided into bronchi; biopsies are taken if needed; bronchial washings may be done, and debris is suctioned. Oxygen is administered; a patent IV line is necessary in case emergency drugs are needed and for administration of procedural sedation.	Keep patient NPO for 6 hr before test. IV access is initiated. Check consent form; administer preoperative sedat mouth care just before test. <i>Post-test:</i> For 2-4 hr, monitor vital signs, pulse oximetry readings, and level of consciousness. Observe for bleed dyspnea, wheezing, discomfort, and swelling of face and neck; sputum may be slightly blood-tinged at first. Pt on side until gag reflex has returned. Check for return of gag reflex by having patient take small sips of water. When gag reflex has returned, throat lozenges may be used for sore throat. The procedure must be performed in a negative airflow room with HEPA filtration. All personnel in the room personal protective gear appropriate to airborne precautions. Procedural sedation should only be administered credentialed to do so. The procedure is performed by a physician usually with assistance from respiratory therapy.
Laryngoscopy		
<i>Direct:</i> To detect or remove lesions, polyps, or foreign bodies in the larynx or to obtain biopsy specimens or tissue for culture	<i>Direct:</i> A fiberoptic laryngoscope is used; sedation and local or general anesthetic is administered. Performed by a physician in a surgical facility.	<i>Direct:</i> Patient should be NPO for several hours before procedure. Administer preprocedure medications; ensure respiratory status will be monitored closely. Advise that the room will be darkened. An ice collar may be applied postprocedure. A mild sore throat and hoarseness may occur.
<i>Indirect:</i> To assess function of the vocal cords or obtain tissue for biopsy	<i>Indirect:</i> A laryngeal mirror, head mirror, and light source are used. Inspection is performed at rest and during phonation. Performed by a physician. Can be done in an office or clinic setting.	<i>Indirect:</i> Patient will be upright for procedure. <i>Postprocedure:</i> Keep patient NPO until gag reflex has returned. Encourage fluid intake.
Mediastinoscopy		
To inspect the mediastinum and biopsy mediastinal lymph nodes To gain information from biopsies about lung metastasis, sarcoidosis, and granulomatous infections	Mediastinoscope is inserted via a small incision made at the suprasternal notch by a physician in an operating room.	Informed consent is required. Preoperative and postoperative care are the same as for other surgeries. The patient remains NPO after midnight the night before a morning procedure. Administer preoperative sedation before the procedure. <i>Postprocedure:</i> Observe for crepitus around insertion site indicating air from pneumothorax. Observe for disten and pulsus paradoxus, because a hematoma may be preventing cardiac filling.
Thoracentesis		
To remove pleural fluid, instill medication, or obtain fluid for diagnostic studies	With local anesthetic, and ultrasound guidance, a large-bore needle is inserted through the chest wall into the pleural space, and fluid is withdrawn with a syringe or into vacuum bottles by a physician at the patient's bedside. Aseptic technique must be used. Specimens are obtained for culture, microscopic examination, and stains. Medication may be instilled.	Requires signed consent. Explain procedure to patient. Take baseline vital signs. Position patient sitting, facing bed, and leaning over the overbed table with arms crossed on it; pillows or the back of a chair can also be used. respirations and skin color during procedure. Assist patient to remain still. Chest radiograph may be ordered a procedure. Monitor vital signs q15min for 1 hr or until stable, then routinely. Auscultate breath sounds frequently, cyanosis, hemoptysis, changes in breath sounds, and tachycardia should be reported immediately. C amount and appearance of fluid and condition of patient. Send specimens to the laboratory as ordered.

*Note: For tuberculosis test, refer to [Chapter 14](#).

BP, Blood pressure; HCO_3^- , bicarbonate ion; *HEPA*, high-efficiency particulate arresting; *IV*, intravenous(ly); *NPO*, nothing by mouth; P_{CO_2} , partial pressure of arterial carbon dioxide; P_{AO_2} , partial pressure of arterial oxygen.

Diagnostic visual examination of the nose, mouth, and throat.

The interior of the nose, mouth, and pharynx and the tonsils can be inspected by using a tongue blade and a good source of light. The nose is inspected for redness, swelling, discharge, and lumps. Using a nasal speculum, the head is tilted upward and the inside of the nares is inspected for pallor, redness, swelling, and polyps and for mucus color, consistency, odor, and amount. The hard and soft palates are inspected, and the mobility of the soft palate is evaluated by asking the patient to say "ah." The pharynx can be brought into view by asking the patient to say "ee." Presence of inflammation, lesions, plaques, or exudates is noted. The paranasal sinuses are assessed by observing for purulent discharge in the nares and by palpating over the sinus areas for tenderness. Sometimes sinus radiographs are ordered. Magnetic resonance imaging may be ordered to locate tumors and pathologic abnormalities of the esophagus and larynx.

Throat culture.

The most common reason for culturing pharyngeal secretions is to establish a definitive diagnosis of infection with *Streptococcus pyogenes* (strep throat). Rheumatic heart disease and glomerulonephritis can result if strep throat is not properly identified and treated. A "rapid strep test" is commonly performed in the provider's office or ambulatory clinic. A throat culture also is sometimes taken to establish a diagnosis of pneumonia, tonsillitis, meningitis, or whooping cough. These diseases can be particularly harmful to older adults, the debilitated, or very young patients.

Tuberculosis tests.

Sputum testing for acid-fast bacilli is ordered when tuberculosis (TB) is suspected. Sputum specimens should be collected just after the patient awakens in the morning. Ideally a total of three specimens on 3 consecutive days should be collected. Suctioning may be required to obtain the specimen. Airborne isolation precautions should be used until TB has been ruled out. Some strains of TB are resistant to conventional drug therapies. A test for TB drug susceptibility called *microscopic-observation drug susceptibility (MODS)* can produce results more rapidly and for less cost than standard cultures ([Wilson, 2013](#)). Current technology allows for molecular detection of drug resistance (MDDR), which examines TB DNA sequencing ([CDC, 2012](#)). A new simple blood test may replace the tuberculin skin test used for tuberculosis screening. The test identifies T-cell response to the TB antigens. Like the skin test, this test only identifies the activation of the body's immune response to the TB organism and does not distinguish between active and latent disease ([CDC, 2013](#); [Menzies, 2013](#)). 

Lung function tests.

Pulmonary function tests (PFTs) are useful in screening gross abnormalities in the respiratory system (Figure 12-4). The **forced vital capacity** (FVC) is affected by diseases that restrict lung motion. **Forced expiratory volume in 1 second** (FEV₁) gives an estimate of the amount of **obstruction** to the patient's airflow. The FEV₁ is lower in patients with obstructive pulmonary diseases such as emphysema and chronic bronchitis.

FIGURE 12-4 Patient undergoing pulmonary function testing administered by a respiratory therapist in the pulmonary laboratory.

The results of pulmonary function tests often are recorded in the following terms:

- *Total lung capacity (TLC)*: The volume (amount) of gas the lung can hold at the end of a maximal inspiration
- *Vital capacity (VC)*: The volume of gas that a person can exhale after inhaling as much air as possible (maximal inspiration)
- *Tidal volume (TV)*: The volume of gas either inspired or exhaled during each breath
- *Functional residual capacity (FRC)*: The volume of gas remaining in the lungs when the lungs and chest wall are at resting end-expiratory position (i.e., at rest at the end of a normal expiration)
- *Residual volume (RV)*: The volume of gas remaining in the lungs after a person has exhaled as much air as possible (maximal expiration)

Figure 12-5 shows the various subdivisions of total lung capacity.

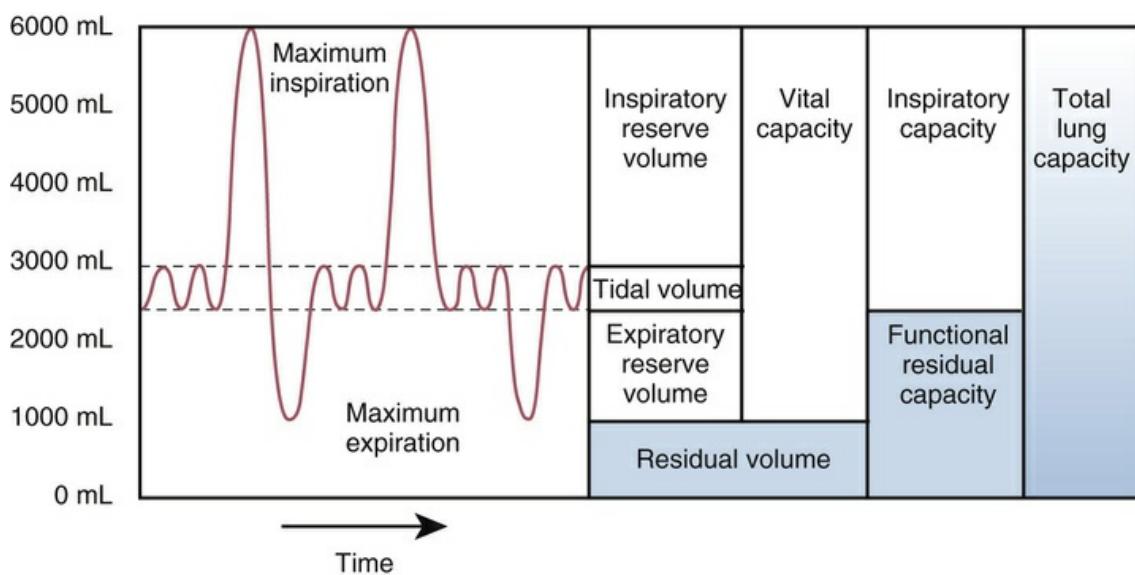

FIGURE 12-5 Comparison of respiratory volumes and capacities as measured by spirometry. (Volumes can vary by age, gender, height, or weight.)

Peak flowmeter.

Patients with asthma or COPD are often asked to check their peak expiratory flow with the use of a peak flowmeter (Figure 12-6). Normal peak flow values for adults are based on age, gender, height, and underlying lung disorder. Normal values range from 300 to 700 L/min but are assessed by comparison against a patient's baseline values. While standing or sitting upright, the patient exhales into the mouthpiece; a small arrow points to the maximum expiratory flow volume. The peak flowmeter is useful for knowing when additional medications are needed to prevent acute exacerbation of disease.

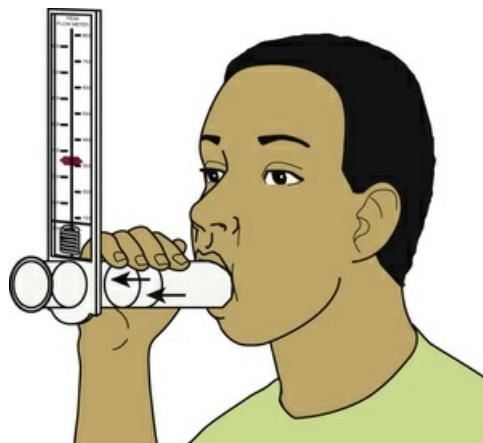

FIGURE 12-6 Use of a peak flowmeter to measure peak expiratory flow volume.

Lung biopsy.

When tumor is suspected, a lung biopsy may be obtained by bronchoscopy (Figure 12-7) or during open thoracotomy. Postprocedure care includes observing sputum for blood and monitoring vital signs closely. Nothing is given by mouth until the gag reflex returns. An open surgical biopsy will require usual postoperative care, including monitoring for bleeding, shortness of breath, and infection.

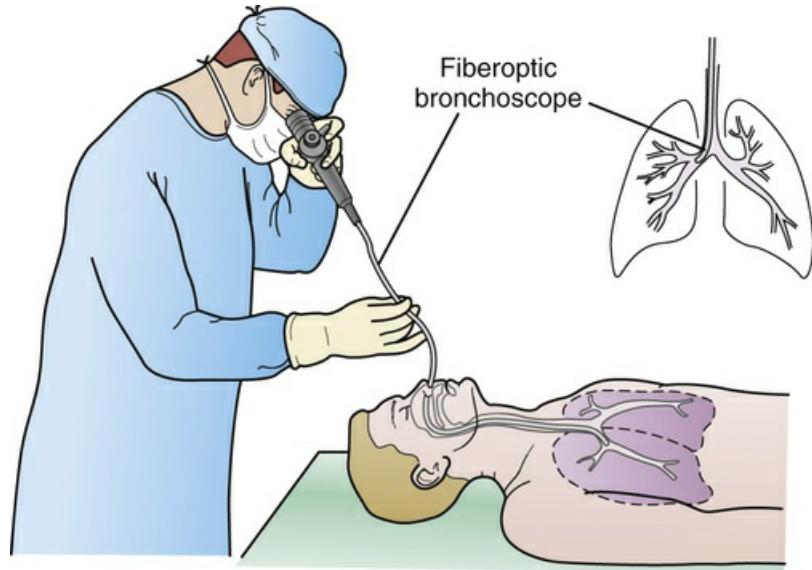

FIGURE 12-7 Fiberoptic bronchoscopy.

❖Nursing Management

■ Assessment (Data Collection)

History Taking

Observe respiratory function while you are talking with the patient and ask about frequency of URIs, known inhalant allergies, and sinus problems. If the patient is in obvious respiratory distress or complains of **dyspnea** (difficult breathing), ask only a few questions about the present illness and chief complaint. Later, during a formal admission interview and informal discussions with the patient and family, obtain more information to plan individualized nursing care.

Chest pain can occur with frequent coughing, pleurisy, or trauma to the lungs; however, whenever there is a complaint of chest pain, seek additional information and always consider cardiac problems. Patients with sinus problems may complain of headache, malaise, a bad taste in the mouth, nasal congestion or obstruction, purulent drainage from the nose, and painful upper teeth. Those with pharyngitis often report a sore or “scratchy” throat, malaise, headache, and sometimes a cough. Dysphagia also might be a problem for patients with pharyngitis, because swallowing involves pushing the food back against the inflamed oropharynx. **Hoarseness and loss of the voice (aphonia) are common symptoms of laryngitis.** Hoarseness or a sore throat that lasts longer than 2 weeks should be noted, because this may assist in the early detection of throat malignancy.

▣ Focused Assessment

Data Collection for the Respiratory System

History Taking

- Chief complaint and precipitating factors
- New onset of dyspnea or orthopnea
- Cough frequency with or without sputum production
- Measures used for symptom relief
- Medications, over-the-counter medicines, supplement use

- Personal smoking history, family smoking history
- History of respiratory disorders, such as asthma
- History of allergy or hay fever
- History of conditions such as sinusitis or bronchitis
- History of night sweats or tuberculosis
- History of other lung diseases, injuries, or surgeries
- History of alcohol consumption
- Occupational and environmental respiratory hazards
- Influenza and pneumonia immunization

Physical Assessment

- Skin color, peripheral and central
- Rate, depth, rhythm, and character of respiration; pulse oximetry readings; CO₂ readings
- Restlessness or agitation
- Posture: need to be upright or to lean forward
- Nose: deviation, flaring of nostrils, discharge, patency of nares
- Trachea position, palpation of neck lymph nodes
- Sinus pain on palpation
- Shape of chest and symmetry of chest expansion
- Use of accessory muscles for respirations: intercostal or supraclavicular retractions
- Shape of fingers, angle of nailbed
- Cough: frequency, characteristics
- Sputum: amount, character, color, presence of blood
- Systematic pattern of auscultation
- Listen for abnormal breath sounds or absence of breath sounds
- Any wheezes, fine or coarse crackles, or “rubs”?
- Do abnormal sounds clear up when patient coughs?

☒ Older Adult Care Points

When assessing an older adult patient, it is important to obtain a thorough smoking history and a history of alcohol intake throughout adulthood. **Approximately 90% of throat cancer occurs in people who both smoke and immoderately drink alcohol**, and it is four times more common among men ([American Cancer Society, 2015](#)).

⌚Physical Assessment

If the patient is not experiencing respiratory distress, start the assessment at the head and end with

lung auscultation. There may be facial puffiness over inflamed sinuses. Palpation of the neck may reveal enlarged lymph nodes. Observe skin color; **cyanosis** (bluish discoloration) of the skin is not a reliable indicator of hypoxemia. **Cyanosis occurs late in the process of oxygen depletion** and could indicate problems of circulation or hemoglobin deficiency. However, the presence of cyanosis is always of concern and prompts further assessment.

Note the posture of the patient, the amount of effort exerted to breathe, the way abdominal muscles and other accessory muscles of respiration are used, the number of words that can be said between breaths, and the rate and character of respirations. Is respiration rapid (**tachypnea**) or slow (**bradypnea**)? Is chest expansion equal when a breath is taken? Are there retractions? Is kyphosis or scoliosis present? Does the patient display or report coughing? A **productive** cough is moist and deep, often accompanied by bronchial crackles or wheezing, and ends in production of sputum. A **nonproductive** cough is dry and harsh, and no sputum is produced. **Sputum** refers to material brought up from the bronchial tree. It is not mucus from the sinuses, nasal secretions, or saliva. **Table 12-2** describes various characteristics and implications of sputum specimens.

Table 12-2
Characteristics of Sputum and Possible Causes*

CHARACTERISTIC	POSSIBLE CAUSE
Thick, tenacious, and “ropey”; difficult to cough up	Chronic bronchitis, emphysema
Scant, sticky, rust colored	Pneumococcal pneumonia
Frothy, pinkish or blood tinged	Pulmonary edema
Yellow, yellow-green, or grayish yellow, with foul odor or taste	Pulmonary infection
Blood tinged, bloody, or blood streaked	Tuberculosis, ulcerated pulmonary vessel, or bronchogenic carcinoma
Large amounts	Pneumonia or bronchitis
Scanty	Asthma
Very thick and viscous	Inadequate hydration
Large amounts, foamy, purulent, foul odor	Bronchiectasis

*Normal sputum is white and slightly viscous and has no odor or taste.

A patient with COPD may lean forward in a sitting position and use the abdominal muscles to force air out of the lungs. Other indications of difficulty breathing are elevating the shoulders and ribs, tensing the neck and shoulder muscles, and flaring of the nostrils. A retraction of the spaces below and around the sternum also might be observed in a patient in respiratory distress. Obstructive disorders can cause enlargement of the front-to-back (anterior-posterior) measurement of the chest wall, giving a barrel-like appearance to the chest (Figure 12-8) because of the presence of trapped air in the lungs and inadequate recoil. Over time there is a gradual elevation of the resting level of the diaphragm, which produces an increase in the size of the chest wall. Exhaling through pursed lips is a clue to obstructive disorders. By exerting back pressure into the lungs, the alveoli stay open longer, allowing for trapped air to escape. Clubbing of the fingers (Figure 12-9) may be seen in patients with lung tissue or heart disease, gastrointestinal disorders, or genetic causes. The cause of clubbing has not been identified (Schwartz, 2013). Note the number of pillows the patient uses to prop up in bed or if the head of the bed needs to be raised to facilitate breathing. This position indicates **orthopnea**.

Clinical Cues

Restlessness, agitation, or mental confusion or an increase in heart rate are early indicators of inadequate oxygenation of the blood. Make sure you have a baseline assessment of mental status and vital signs to be able to identify early changes.

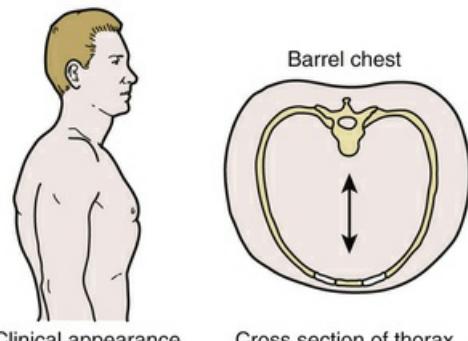

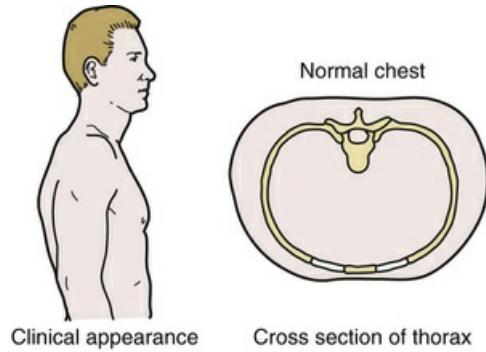

FIGURE 12-8 Barrel chest typical of a patient with chronic obstructive pulmonary disease.

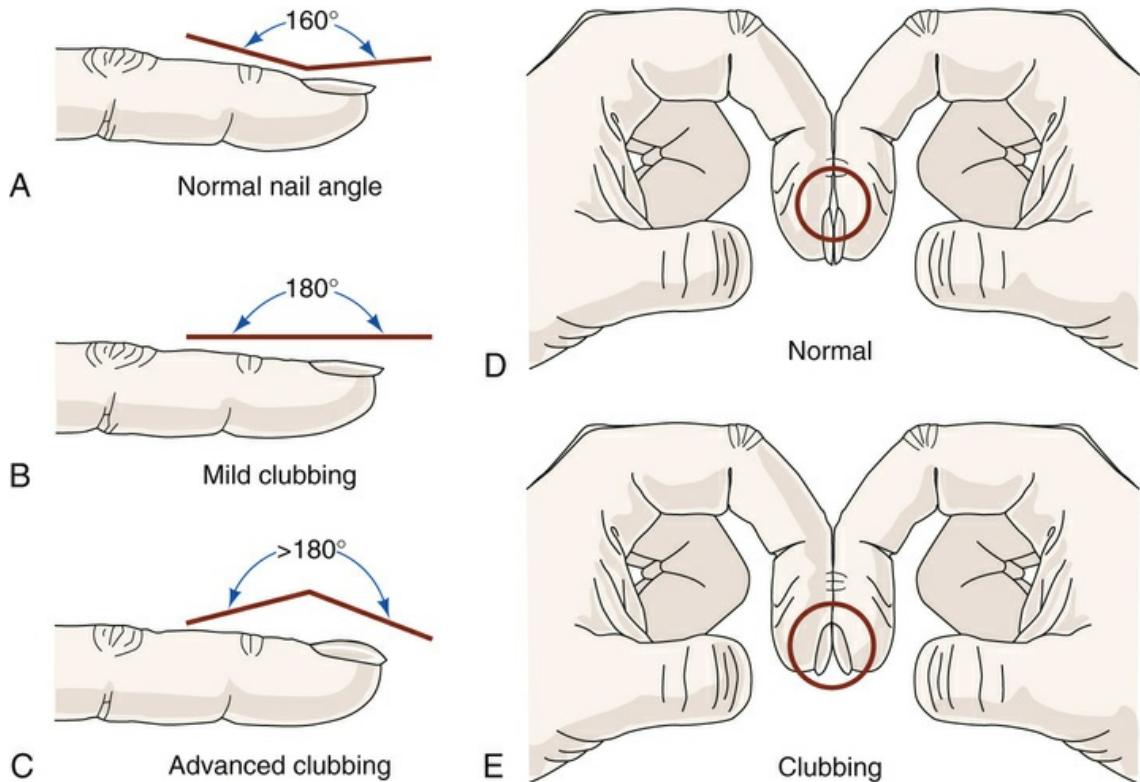

FIGURE 12-9 Clubbing of fingers. (From Copstead LC, Banasik JL: *Pathophysiology*, ed. 5, Philadelphia, 2012, Elsevier Saunders.)

To auscultate the lungs, first eliminate room noise and instruct the patient to sit up, if possible, so that the bed or back of the chair is not interfering with chest expansion. Ask the patient to remain

quiet and to breathe slowly and deeply through the mouth. Listen to one full breath in each location (Figure 12-10). Place the stethoscope diaphragm against the skin with moderate pressure. Move from one side of the midline of the chest to the other side; compare the sounds. Begin above the clavicles and progress downward in the intercostal spaces to above the sixth rib. On the back, start above the scapula and progress downward along the sides of the spine, and then toward the lateral areas above the tenth thoracic vertebra. Laterally, listen in the midaxillary line in three descending locations to just above the diaphragm. If the patient is short of breath, begin posteriorly at the bases of the lungs and work upward, because the patient may not be able to cooperate for the full sequence. Table 12-3 presents sounds normally heard in various locations.

Clinical Cues

Clean your stethoscope with alcohol or a disinfectant wipe between patients to decrease health care-associated infections.

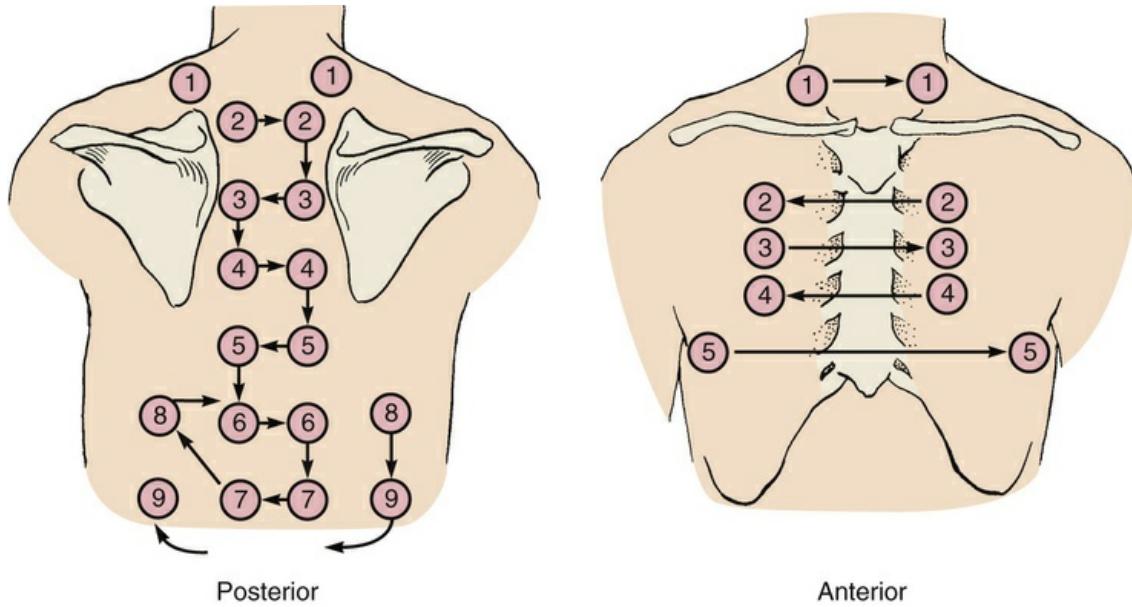

FIGURE 12-10 Sites for auscultation of the lungs.

Table 12-3

Normal Lung Sounds

TYPE OF SOUND	LOCATION WHERE NORMALLY HEARD*	DESCRIPTION OF SOUND
Vesicular breath sounds	Over lung tissue to level of sixth intercostal space	Low to medium pitch with a soft whooshing quality; inspiration is two to three times the length of expiration
Bronchovesicular breath sounds	Over the mainstem bronchi, below the level of the clavicles, beside the sternum; posteriorly: between the scapulae	Moderate to high pitch with a hollow, muffled quality; equal time of inspiration and expiration
Bronchial breath sounds	Over the trachea above the sternal notch (these sounds are abnormal elsewhere and often indicate atelectasis)	High pitch with a loud, harsh, tubular quality; inspiration half as long as expiration

*See Figure 13-6.

Listen for abnormal or **adventitious** sounds. **Wheezes** are a whistling, musical, high-pitched sound produced by air being forced through a narrowed airway. They are common in patients with asthma. Another type of coarse or sonorous wheezing sound (formerly known as *rhonchi*) is coarse, low-pitched, rattling sounds caused by secretions in the larger air passages. **Crackles** are produced by air passing through moisture in the smaller airways. **Fine crackles** are high in pitch and can be heard in patients who have atelectasis, fibrosis, pneumonia, or early congestive heart failure. **Coarse crackles** are louder and low in pitch and are heard in patients with bronchitis, pulmonary edema, and resolving pneumonia. **Fine crackles sound similar to the sound produced by rubbing hairs between the fingers close to the ear.**

Another abnormal sound is that of a **pleural friction rub**, which is a grating or scratchy sound similar to creaking shoe leather or an opening squeaky door; it occurs when irritated visceral and

parietal pleura rub against each other. This also produces pain. The sound (and pain) will stop if the patient is asked to hold the breath.

Stridor (“croaking” sounds) can be heard (without using a stethoscope) when there is partial obstruction of the upper air passages. These sounds are typically heard in children with croup but can also occur in adults with upper airway obstruction. The inflammation that is producing the obstruction often also affects the larynx, producing hoarseness. It is important to distinguish between airway swelling and foreign body obstruction as a cause of stridor. Presence of stridor requires prompt assessment and intervention.

Think Critically

How does shortness of breath affect a person's ability to speak?

Nursing Diagnosis

There are a variety of patient problems/nursing diagnoses that arise when breathing is altered or impaired. Lack of oxygen intake or distribution may cause fatigue and decreased ability to engage in activity. Alteration in roles, coping ability and body image may cause psychosocial issues. Pain from coughing or surgery on the respiratory system requires nursing interventions. Specific nursing diagnoses are chosen depending on the patient's actual problems. [Table 12-4](#) provides common problem statements for patients with respiratory problems. Other problems may be included in the care plan as they relate to secondary problems.

Table 12-4

Common Problem Statements, Expected Outcomes, and Interventions for Patients With Respiratory Disorders

PROBLEM STATEMENT	GOALS/EXPECTED OUTCOMES	NURSING INTERVENTIONS
Insufficient gas exchange due to decreased airflow and respiratory muscle fatigue	Patient will use modified breathing techniques to facilitate ventilation.	Instruct in techniques of pursed-lip breathing, diaphragmatic breathing, deep breathing, and effective coughing; teach relaxation techniques. Review medication dosages and schedule and proper technique for use of measured-dose inhaler with patient; assess effectiveness and compliance. Encourage use of incentive spirometer. Monitor pulse oximetry before, during, and after exertion. Begin stepped exercise program to improve plan for pacing activities of daily living.
Altered airway clearance due to viscous sputum	Patient will have thinner mucus that is easier to cough up. Fluid intake will increase to 3000 mL/day. Patient will demonstrate proper use of nebulizer.	Explain effect of inadequate fluid intake on liquidity of mucus; assess what fluids patient likes; advise to drink 8 oz of fluid every hour while awake; suggest use of room humidifier at home; review technique for using nebulizer and mucolytic agents. Obtain peak flow readings before and after nebulizer treatment.
Potential for respiratory infection due to compromised respiratory system and decreased resistance	Patient will reduce the number of respiratory infections per year.	Review ways to decrease contact with respiratory infectious organisms: avoiding people with colds, flu, and other infections; frequent hand hygiene. Teach to avoid respiratory irritants; stay in house when air pollution index is high; avoid smoke, dust, and cold air. Observe sputum for changes in color, consistency, odor, and amount; instruct to call clinic promptly if signs of infection occur; obtain culture for infective organism if indicated. Give influenza and Pneumovax vaccines. Encourage to maintain adequate nutrition.
Potential for decreased self-esteem due to inability to do ordinary activities	Patient will express improvement in self-concept within 3 mo. Patient will be able to resume desired activities within 3 mo.	Allow to verbalize concerns; assist to focus on activities possible; explore ways of continuing favorite activities using modifications. Give encouragement and praise for efforts in stepped exercise program.
Altered activity level due to dyspnea	Patient will be able to perform bathing and dressing without dyspnea within 3 mo. Patient will participate in and comply with stepped exercise program. Patient will display increased ability to tolerate activity by walking short distance without breathlessness.	Encourage use of pursed-lip and diaphragmatic breathing. Begin stepped exercise program as soon as acute respiratory infection has resolved. Alternate activity with rest periods, beginning with small increments of activity. Use oxygen as prescribed during acute episodes of dyspnea.
Anxiousness due to hypoxia and dyspnea	Patient will verbalize that anxiety has lessened within 1 wk.	Allow to verbalize concerns within ability to speak without becoming dyspneic. Encourage use of pursed-lip and diaphragmatic breathing to decrease dyspnea. Teach best positions to decrease dyspnea. Teach relaxation techniques; encourage practice. Interact with calm, reassuring manner.
Potential for health problems due to continued smoking	Within 1 wk patient will look at alternative ways to quit smoking. Patient will begin a smoking cessation program within 3 wk.	Explain the harmful effects of continued smoking. Motivate patient to quit smoking by emphasizing benefits of increased stamina and decreased dyspnea. Introduce to various methods and programs for quitting smoking. Get referral from physician for interventions requiring prescriptions. Introduce to people with equivalent lung disease who have quit smoking. Praise any effort at decreasing or quitting smoking.

Planning

A patient who has chronic **hypoxia** (oxygen deficiency) moves more slowly, takes more time to answer questions, and has less energy. For patients with a respiratory disorder resulting in hypoxia, consider comfort measures, time needed for eating or feeding, time for patient education, and consideration of psychosocial needs. Working with patients who have dyspnea requires planning

extra time to accomplish treatments and care.

The nursing goals for patients with a respiratory disorder are to:

- Promote oxygenation
- Prevent infection
- Prevent further lung damage
- Promote rehabilitation

Specific expected outcomes are individualized for each patient (see the Nursing Care Plans in [Chapters 13 and 14](#)).

■ Implementation

Examples of interventions and teaching for patients with respiratory disorders are presented in [Table 12-4](#). Interventions are discussed later in this chapter and in [Chapters 13 and 14](#).

■ Evaluation

Effectiveness of interventions for and treatment of patients with respiratory disorders is based on improved breathing pattern, pulse oximeter readings, arterial blood gas values, and lung sounds. Decreases in coughing, sputum production, wheezing, and signs of infection are other parameters that indicate improvements. Patient reports of lessened dyspnea, as well as more energy and ability to perform more self-care and other activities, indicate that interventions are effective. Reassessment is an ongoing nursing activity for patients with respiratory problems.

Common Respiratory Patient Care Problems

Airway Maintenance

A cough is usually a reflex triggered by a foreign substance or some other irritant in the respiratory tract. Coughing can be beneficial and should be encouraged if it is effective in clearing the air passages and removing accumulations of stagnant mucus. Explain that deep-breathing and coughing maneuvers help to remove sputum and decrease the likelihood of complications, such as pneumonia. (See [Chapter 4](#) for deep-breathing and coughing maneuvers.)

If coughing is excessive, the patient will tire and the respiratory tissues and thoracic structures can be traumatized, so **antitussive** agents may be used to inhibit the cough reflex in the cough center in the brain. Many sedative cough mixtures contain codeine or other drugs that decrease the desire to cough. The liquefying agents and diluents thin secretions and help the patient to expectorate (cough up secretions). Adequate hydration is the most effective method to liquefy secretions so they can be expectorated. Cough syrups are given to soothe the nerve endings in the upper respiratory mucosa. These medications are given in small doses to coat and protect the throat. **Water should not be taken immediately after a cough syrup, because it rinses off the topical application of the medication.**

In bacterial infections and chronic respiratory diseases, the sputum often is foul smelling, leaving a bad taste in the mouth and offensive breath odor. Mouth care is especially needed before meals, when the taste or odor of the sputum may adversely affect appetite. **Frequent mouth care also helps remove pathogenic microorganisms from the oral cavity and thereby diminishes the possibility that they will be aspirated deep into the air passages.**

Mechanical suctioning is indicated when the patient cannot clear the airway of excessive amounts of secretions. Removing secretions from the nose, mouth, and throat is a relatively safe and simple procedure. However, deep tracheal suctioning—whether through the nose, mouth, or endotracheal tube—should only be performed using strict aseptic technique and by someone experienced in the correct procedure.

The need for suctioning is based on patient assessment. Some patients may require suctioning only once or twice daily to remove deeply situated pools and plugs of mucus that cannot be coughed up. Others require suctioning every 10 to 15 minutes to clear their air passages. Remember, the purpose of suctioning is to facilitate breathing and to allow for an adequate exchange of carbon dioxide and oxygen in the lungs. Even though the procedure may be necessary, suctioning removes oxygen and is uncomfortable for the patient.

See Skill 13-1: Endotracheal and tracheostomy suctioning on Evolve. 

Altered Breathing Patterns

Dyspnea or Breathlessness

Administer O₂ as prescribed. Use a calm manner and assure the patient that everything possible is being done to bring relief of dyspnea. Coach the patient to perform pursed-lip and diaphragmatic breathing (see [Chapter 14](#)).

The high Fowler position is best for patients with dyspnea. Proper positioning and support allow the respiratory muscles to function at maximum efficiency. For severe dyspnea, the orthopneic position is most effective. *Orthopnea* means that the patient has trouble breathing when supine. The patient should sit upright, lean over the overbed table (which is padded with pillows), and elevate and round the shoulders to allow maximum expansion of the lungs ([Figure 12-11](#)).

Other pillows are placed on an overbed table to support the weight of the arms, shoulders, and head.

FIGURE 12-11 Orthopneic position.

Pressure from organs, fluid, or tissue below or near the lungs and diaphragm can impair breathing. A full stomach can contribute to dyspnea by limiting the amount of space available for expansion of the lungs. Abdominal distention resulting from edema or collection of flatus and fecal material can also make breathing more difficult. Obesity is a risk factor for dyspnea.

Dyspnea may or may not be a result of **hypoxemia** (low blood oxygen levels). Hypoxia (low levels of tissue oxygen) results from not enough oxygen being delivered in the bloodstream to the tissues. For oxygen to reach the tissues, the patient must be breathing adequately, have a patent airway, have lung tissue able to exchange gases, and have adequate hemoglobin to carry the oxygen. Alteration in any of these can affect delivery of oxygen to tissues.

The tissues most sensitive to changes in oxygen levels include the brain and heart; therefore clinical signs and symptoms of hypoxia show up first in these organs. Alterations in brain function include restlessness, anxiety, and confusion. Initially, subtle changes in cognitive ability may not be noticed until vital signs are affected. The heart rate will increase in an attempt to increase oxygen delivery. Blood oxygenation is monitored by pulse oximetry (SpO_2), which is a reflection of the arterial oxygen saturation (SaO_2). An SpO_2 greater than 95% is considered normal, and an SpO_2 of 92% or less (at sea level) suggests hypoxemia.

Hypercapnia

Hyperventilation, hypoventilation, and the effect of these abnormal breathing patterns on the acid-base balance of body fluids are discussed in [Chapter 3](#). Ventilation is the movement of air in and out of the lungs. The body's ventilation ability is measured by CO_2 levels. Levels of exhaled CO_2 can be monitored by devices inline to oxygen delivery systems (ETCO_2) ([Figure 12-12](#)). Blood CO_2 levels can be monitored by equipment similar to pulse oximetry. CO_2 levels obtained from these devices are similar to arterial blood gas PCO_2 levels. Capnography is the measurement and display of CO_2 levels. **Hypercapnia** (also called *hypercarbia*) is the retention of excessive amounts of CO_2 . It is the result of hypoventilation, during which the usual amount of CO_2 is not eliminated by exhalation.

FIGURE 12-12 Nasal cannula with ETCO₂ detection device

Hypocapnia

Hypocapnia, which is a deficit of CO₂, occurs as a result of hyperventilation and can result in respiratory alkalosis. Conditions associated with hypocapnia include (1) those in which there is an increased metabolic rate, such as thyrotoxicosis, persistent fever, and acute anxiety; (2) salicylate overdose; and (3) improper use of mechanical ventilation.

Clinical signs of respiratory alkalosis include hyperactive neuromuscular reflexes, tetany, carpopedal spasms, vertigo, blurred vision, and diaphoresis. Blood gas analysis will show a low partial pressure of arterial carbon dioxide (PaCO₂) and a high pH (alkalinity). CO₂ monitoring devices will show low levels of CO₂. The [Agency for Healthcare Research and Quality \(2012\)](#) recommends use of PtcO₂ and PtcCO₂ monitoring for patients requiring close observation of oxygenation and ventilation status.

Respiratory Failure

Carbon dioxide is a respiratory stimulant; hence **the body responds to excessive levels of CO₂ by increasing the rate and depth of respirations**. However, if the respiratory centers in the brain are exposed to higher than normal levels of CO₂ over a long time, they cease to react and do not adjust respirations in response to mildly elevated carbon dioxide levels. Over time the accumulation of CO₂ can cause a decreased level of consciousness up to and including coma.

Respiratory failure is defined by arterial blood gases: arterial oxygen (PaO₂) is below 50 mm Hg and the partial pressure of carbon dioxide (PCO₂) is equal to or greater than 50 mm Hg. Cardiac arrest can result from respiratory failure because of hypoxia and acid-base changes.

Other Ineffective Breathing Patterns

Additional respiratory patterns are shown in [Figure 12-13](#). Diseases, trauma, changes in neurologic function, and metabolic disorders can all alter breathing patterns. Careful assessment of the rate and characteristics of a patient's breathing and recognizing changes in patterns can give valuable information regarding overall clinical status.

Think Critically

Name four nursing interventions that will help a patient suffering from dyspnea.

Eupnea
Normal rate and rhythm

Tachypnea
Increased respirations

Bradypnea
Slow, regular respirations

Kussmaul's
Fast, deep respirations, with no expiratory pause. Seen in patients with diabetic acidosis and coma.

Biot's
Fast, deep irregular respirations, with periods of apnea. Seen in patients with increased intracranial pressure.

Cheyne-Stokes
Respirations become faster and deeper, then slower and shallower with a period of apnea. Seen in patients in coma resulting from disorders affecting the central nervous system.

Apneustic
Prolonged inhalation with a pause at peak inspiration, then a short exhalation followed by short periods of apnea. Seen when there is damage to the respiratory centers in the brain.

Apnea

Absence of breathing

FIGURE 12-13 Respiratory patterns. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 3, Philadelphia, 2009, Elsevier Saunders.)

Risk of Infection

Many acute URIs are transmitted by droplets; that is, the causative organisms are expelled along with the liquid secretions released during coughing and sneezing. These droplets are heavy and fall to surfaces fairly rapidly, usually within 3 feet of the patient. Diseases that are spread by airborne contamination have organisms that remain suspended in the air for long periods of time and float on air currents. These conditions require airborne precautions and special masks for health care providers.

Patients with chronic respiratory disorders—and all health care personnel—should carefully avoid contamination. Avoiding crowded places, performing frequent hand hygiene, and keeping the hands away from the face and mouth decrease the likelihood of infection. Standing to the side of a person who is coughing and sneezing reduces contamination. Hand hygiene should be implemented after each contact with a person with a respiratory disorder that produces airborne or droplet secretions, after removal of personal protective equipment, or after contact with articles contaminated by secretions. Instruct patients to use a folded tissue over the nose and mouth while sneezing and to turn the head away when in close contact with others. An alternative is to sneeze or cough into the crook of the elbow so that the hands are not contaminated. Tissues should be disposed of following Standard Precautions.

Older Adult Care Points

According to The [Joint Commission's Core Measures \(2015\)](#), health care providers should ask patients age 65 years and older if they have received pneumococcal vaccine to prevent pneumococcal bacteremia, and encourage vaccination if indicated.

Alterations in Nutrition and Hydration

Anorexia and inadequate nutrition are common in patients with respiratory disorders, particularly when the disorders are chronic in nature. The patient may have an impaired sense of taste or smell, or sputum can leave a bad taste in the mouth or cause nausea. The patient may fear that chewing and swallowing will bring on an attack of coughing or may be so tired that eating or preparing food is too exhausting.

Keep the patient's environment clean, uncluttered, and orderly. Dispose of used tissues promptly, and keep sputum cups covered and out of sight. Frequent oral hygiene and mouth care before meals can help diminish mouth odor and nausea and improve taste. Smaller, more frequent feedings of nutritious liquids and foods are preferable to three large, heavy meals.

Because there is increased energy expenditure when breathing is difficult, many patients have difficulty maintaining weight, even when they take in normal amounts of calories. Supplements such as Pulmocare have an increased fat content and provide more calories in smaller quantities and decrease the dietary production of CO₂. **When a patient is receiving mechanical ventilation, caloric needs rise.** Sometimes total parenteral nutrition or lipid infusions are necessary to prevent malnutrition for patients with COPD.

A fluid deficit is likely in patients with respiratory disorders because there is an increased loss of fluid in respiratory secretions. The patient usually breathes through the mouth and exhales large amounts of moisture from the body. Unless contraindicated, an intake of at least 3000 mL of liquid should occur each day. This intake may include low-sodium bouillon, fruit juices, and other liquids in addition to water.

Humidifying the air breathed by the patient is an effective way to minimize dehydration and moisturize the air passages. Humidification is especially important for patients whose secretions are thick and tenacious and difficult to cough up. Humidification of inhaled air is covered in [Chapter 14](#).

Fatigue

Hypoxia produces a loss of energy because it causes a disturbance in cellular metabolism. Patients with respiratory disorders often have hypoxia and use their energy just to struggle for breath and cough up secretions.

Patients with respiratory disorders, whether acute or chronic, have some degree of intolerance to physical activity and therefore need periods of rest throughout the day. Treatments and medications should be scheduled so that the patient can rest without interruption. To conserve energy, the patient should intermittently take short naps. Deep-breathing exercises and coughing techniques should be planned whenever the patient is able to do them with or without some assistance. These activities should be followed by good mouth care and a short period of uninterrupted rest. The goal of nursing care should be to achieve a satisfactory balance of rest and activity.

Get Ready for the NCLEX® Examination!

Key Points

- Inhalation of infectious organisms and chemical irritants causes respiratory problems.
- Cardiac disease can interfere with blood supply to the lungs and distribution of gases.
- There are two major types of ventilatory diseases: restrictive (decreased lung volume) and obstructive (narrowed air passages).
- Restrictive conditions, such as scoliosis and kyphosis, decrease lung capacity.
- Obstructive disorders cause problems moving air in and out of the lungs. Asthma, emphysema, and chronic bronchitis are obstructive disorders.
- Prevention of respiratory problems includes good health practices: rest, nutrition, personal hygiene, and avoiding known allergens. At-risk persons should be immunized against influenza and pneumonia.
- The incidence of respiratory ailments decreases for people who stop smoking.
- Effectiveness of interventions and treatment is identified by improvements in breathing pattern, PtcO₂ and SPO₂ readings, arterial blood gas values, and lung sounds. Decreased cough, sputum production, wheezing, and dyspnea are other parameters.
- Positioning in high Fowler position, or sitting with shoulders hunched and arms resting on knees with legs apart, eases breathing.
- Signs of respiratory acidosis are excessive PCO₂ and rapid respirations.
- Signs of respiratory alkalosis are tetany, carpopedal spasms, vertigo, blurred vision, diaphoresis, and low PCO₂ and high pH.
- Respiratory failure is defined as PaO₂ below 50 mm Hg and PCO₂ equal to or greater than 50 mm Hg.
- Abnormal respiratory patterns include Biot's respirations, Cheyne-Stokes respirations, Kussmaul's respirations, and apneustic respirations.
- Respiratory infections are transmitted by airborne or droplet secretions.
- Anorexia and inadequate nutrition are common with chronic respiratory disease.
- Patients should drink at least 3000 mL/day to help thin secretions. Humidification of air can help prevent fluid deficit.

Review Questions for the NCLEX® Examination

1. A 59-year-old male patient with hypertension and COPD states he is having trouble breathing. He appears to be in distress and has labored breathing. Put in order of priority the nursing actions to be taken.

1. Take vital signs, including pulse oximetry reading.
2. Report condition to provider.

3. Raise the head of the bed.

4. Auscultate lung sounds.

NCLEX Client Need: Reduction of Risk Potential

2. A nurse is caring for several patients who are scheduled for diagnostic testing for respiratory disorders. The patient who needs postprocedural care that includes frequent vital signs is the patient who had:

1. capnography.

2. a D-dimer test.

3. a ventilation and perfusion scan.

4. bronchoscopy.

NCLEX Client Need: Physiological Adaptation

3. A nurse is caring for a patient who is short of breath. The degree of shortness of breath can be assessed by which of the following?

1. Ability to speak

2. Breath sounds

3. Capnography

4. Nailbed color

NCLEX Client Need: Reduction of Risk Potential

4. A nurse is caring for a patient who has asthma. Which lung sound would the nurse expect to hear when auscultating this patient's lung fields?

1. Fine crackles

2. Stridor

3. Pleural friction rub

4. Wheezes

NCLEX Client Need: Physiological Adaptation

5. A nurse should observe for and report which abnormal breathing pattern that is most likely to occur in patients with increased intracranial pressure?

1. Cheyne-Stokes respirations

2. Kussmaul's respirations

3. Biot's respirations

4. Apneustic respirations

NCLEX Client Need: Reduction of Risk Potential

6. A nurse attends to the nutritional needs of a patient with chronic respiratory disease by providing oral care. What is the best rationale for this nursing action?

1. Low energy states diminish appetite.

2. Respiratory secretions leave a bad taste.

3. Chewing is believed to induce coughing spells.

4. Nasal congestion reduces the flavor of food.

NCLEX Client Need: Basic Care and Comfort

7. A nurse is caring for a patient who has had a thoracentesis with the removal of 800 cc of fluid. What finding would the nurse expect in the physical assessment of the patient postprocedure?

1. Slow heart rate

2. Clear lung sounds

3. Increased BP

4. Improved ventilation

NCLEX Client Need: Reduction of Risk Potential

8. While obtaining sputum for culture and sensitivity, the nurse notes that the specimen is thick, tenacious, and "ropey." This finding is most likely to be present in which disorder?

1. Pneumococcal pneumonia

2. Pulmonary edema

3. Chronic bronchitis

4. Tuberculosis

NCLEX Client Need: Physiological Adaptation

9. On initial assessment of a patient diagnosed with an acute exacerbation of COPD, the nurse is likely to find which sign(s) and symptom(s)? (*Select all that apply.*)

1. Tensing of the shoulder muscles
2. Inability to tolerate sitting up
3. Flaring of the nostrils
4. Ability to complete sentences with no effort
5. Sternal retraction

NCLEX Client Need: Physiological Adaptation

10. A 72-year-old patient has just returned to the nursing unit after a lung biopsy. The nurse watches closely for signs of which condition?

1. hypotension
2. hypercapnia
3. hyperventilation
4. hypovolemia

NCLEX Client Need: Reduction of Risk Potential

Critical Thinking Questions

Scenario A

Mr. Keelog is an older adult man who may have cancer of the larynx. He will undergo diagnostic procedures to confirm this diagnosis. You observe that he is not currently having respiratory distress and can answer your questions. He appears willing and able to listen to information.

1. What questions should you ask to identify if Mr. Keelog has risk factors for cancer of the larynx?
2. Identify at least four questions you would ask Mr. Keelog about his present status.
3. Describe the teaching plan that would be used for a patient undergoing a direct laryngoscopy.
4. What other diagnostic tests would have been done on this patient?

5. How can this type of cancer potentially be prevented?

Scenario B

Ms. Tiber has had frequent bouts of bronchitis. Her provider tells her that this disorder has caused some COPD.

1. What measures would you teach her to make breathing easier?
2. Why is it important to be cautious in giving oxygen to a patient with COPD? What might happen?

Scenario C

Mrs. Clampett is an older adult woman who comes to the clinic for an annual flu vaccination. She would like a “good physical check of my lungs” and information about how to prevent respiratory disorders.

1. What questions should you ask in obtaining a history about potential respiratory problems?
2. Describe how you would auscultate her lungs.
3. If you heard an abnormal lung sound such as “fine crackles,” what would you do?

CHAPTER 13

Care of Patients With Disorders of the Upper Respiratory System

Objectives

Theory

1. Recognize symptoms of disorders of the sinuses, pharynx, and larynx.
2. Describe the postoperative care for a patient undergoing a rhinoplasty.
3. Choose emergency measures for a patient with an airway obstruction.
4. Present a nursing care plan for a patient who had a laryngectomy.
5. Analyze safety factors to be considered when caring for a patient with a tracheostomy.

Clinical Practice

6. Institute measures to stop epistaxis.
7. Provide tracheostomy care.
8. Devise interventions for the psychosocial care of a patient who has undergone a laryngectomy.
9. Visit a patient who has a permanent tracheostomy and ask her to share some of her successful coping strategies.

Disorders of the Nose and Sinuses

The upper respiratory tract includes the nose and sinuses, mouth, pharynx, and larynx. Upper respiratory infections (URIs) include viral and bacterial infections resulting in cold, flu, pharyngitis, rhinosinusitis, epiglottitis, laryngotracheitis, and pertussis.

Upper Respiratory Infections and Rhinitis

The common cold—acute viral **rhinitis**—is an inflammation of the nose and upper respiratory tract. Other names for a cold include nasopharyngitis, rhinopharyngitis, acute coryza, or head cold. It is the most prevalent infectious disease among people of all ages. Many different strains of viruses can produce the symptoms of a common cold, which makes total immunity unlikely and developing a vaccination problematic. Avoiding exposure to those who have a cold and maintaining a state of good health are the only ways one can avoid “catching” a cold.

Etiology and Pathophysiology

Viruses are spread by airborne droplet sprays from infected people during breathing, speaking, coughing, or sneezing or by direct hand contact with a contaminated object and then contact between the hand and mucous membranes. Viruses can live on surfaces for prolonged periods. A chill, fatigue, physical or emotional stress, a compromised immune status, or inflammation caused by allergic rhinitis make one more susceptible to contracting an upper respiratory virus.

Allergic rhinitis may have many of the symptoms of a cold, except there is no fever. It is caused by reaction of the nasal mucosa to an allergen, such as pollen or dust.

Signs, Symptoms, and Diagnosis

The common cold usually starts with a mild sore throat or a hot, dry, prickly sensation in the nose and back of the throat. Within hours after the onset of a cold, the nose becomes congested with increased secretions; the eyes begin to water; and sneezing, malaise, and an irritating, nonproductive cough appear. The invading organism causes inflammation and swelling of the mucosa. Muscle aches and headache may occur. There usually is no elevation of temperature; if a fever does develop, it is low grade (<101° F [38.3° C]), as is typical with viral infections. In most instances, a cold will last 7 to 11 days, but it may take up to 14 days before all symptoms are gone.

Treatment and Nursing Management

There is no cure for the common cold. However, zinc lozenges have proven effective in limiting a cold's duration and severity for many people, if started at the first signs of symptoms (Hemila and Chalker, 2015). It is important to distinguish a cold from other URIs that may be bacterial and need antibiotic therapy or are conditions that in some patients can lead to more severe illness.

The treatment of allergic rhinitis is symptomatic. Antihistamines, steroids, and sprays that stabilize the mucous cell membranes are often prescribed (Table 13-1). The patient is taught to avoid the offending allergens as much as possible. This may include filters for room air. If the disorder is severe, an allergy evaluation is indicated so that a desensitization program can be started.

Complementary and Alternative Therapies

Alternative Treatment for an Upper Respiratory Infection

Echinacea; goldenseal; or a combination of herbs, minerals, vitamins, and amino acids such as those contained in over-the-counter products can be taken at the first sign of a cold or before going into crowded areas during cold season. These substances are believed to boost the body's immune response.

Table 13-1

Drugs Commonly Used to Treat Allergic Rhinitis and Sinusitis

Classification	Action	Nursing Implications	Patient Teaching
Antihistamines			
First-Generation Antihistamines			
Diphenhydramine (Benadryl) Clemastine (Tavist) Brompheniramine (Dimetane) Chlorpheniramine (Chlor-Trimeton)	Relieve sneezing, excessive secretions, itching, and nasal congestion Block histamine binding by binding with H ₁ receptor sites	Tend to cause sedation and slow reaction time May cause stimulation in some people May cause GI side effects: anorexia, constipation or diarrhea, or epigastric distress May cause urinary retention or frequency	Warn patient not to operate machinery and that driving may be dangerous because of sedation; this usually passes after the first 2 wk of treatment. Ask patient to report changes in heart rate, palpitations, or urinary retention or frequency. Warn that alcohol will have additive depressant effect.
Second-Generation Antihistamines			
Loratadine (Claritin) Fexofenadine (Allegra) Cetirizine (Zyrtec) Desloratadine (Clarinex) Levocaberizine (Xyzal)	Relieve sneezing, excessive secretions, itching, and nasal congestion. Are less likely to cross the blood-brain barrier producing less drowsiness than first-generation antihistamines	Have limited attachment to H ₁ receptors in the brain Do not cause sedation, and have less effect on reflexes Do not affect bladder function	Instruct not to take with alcohol or other CNS-active drugs. Warn not to take with any monoamine oxidase inhibitor. These drugs are more expensive than first-generation drugs.
Corticosteroid Sprays			
Betamethasone (Beconase) Budesonide (Rhinocort) Flunisolide (Nasalide) Fluticasone (Flonase) Triamcinolone (Nasacort) Ciclesonide (Omnaris) Mometasone (Nasonex)	Inhibit inflammatory response Have low systemic absorption with normal doses	Use can result in nosebleeds. Directing the nozzle away from the septum may help prevent nosebleeds. If saline irrigation is used as an adjunctive treatment it should be performed prior to the nasal spray.	Teach to use on a daily basis rather than PRN. Instruct to discontinue if infection occurs. May initially cause some burning in nostrils.
Mast Cell Stabilizer			
Cromolyn sodium spray (Nasalcrom)	Stabilizes mast cells, preventing inflammatory reaction	Minimal side effects	Instruct to begin 2 wk before pollen season starts and use throughout pollen season to prevent allergy symptoms. May be used prophylactically for isolated allergy (i.e., cat). Instruct to use 10-15 min before exposure.
Decongestants			
Oral Pseudoephedrine (Sudafed) <i>Spray</i> Oxymetazoline (Dristan) Phenylephrine (Neo-Synephrine) Saline nasal spray or rinse*	Promote vasoconstriction by stimulating adrenergic receptors on blood vessels Reduce nasal edema and rhinorrhea	May cause insomnia, headache, irritability, dysuria, palpitations, or tachycardia Can cause rebound nasal congestion	Some products are contraindicated for patients with hypertension, cardiac disease, glaucoma, diabetes, prostatic hypertrophy, or liver or renal disease. Teach to use only three or four times a day for no more than 3 days.
Other Categories			
Intranasal Antihistamines	Topical H ₁ receptor antagonists Inhibit the release of histamine May help relieve nasal congestion	May be absorbed systemically in some patients, producing sedation	Instruct not to use if patient has glaucoma or prostatic hypertrophy.
Intranasal Anticholinergic Agents	Inhibits vagally mediated reflexes Chemically related to atropine Reduces nasal secretions	Works best if used regularly at evenly spaced intervals	Teach that it may cause dry or bloody nose, throat irritation, or bad taste in mouth.

*Saline nasal sprays and rinses wash away pollen and dust, thin secretions, and soothe the nasal mucosa.

CNS, Central nervous system; GI, gastrointestinal; H₁, histamine-1; PRN, as needed.

A major goal in the care of a common cold is prevention of a secondary bacterial infection. Individuals with a cold should avoid contact with others to avoid contracting a bacterial infection or giving their viral infection to someone else. A person with a cold is contagious for about 3 days after symptoms first appear.

Colds are spread by droplet infection, and most people realize that coughing and sneezing will spread viruses. Coughing and sneezing into tissues does limit the viruses' travel by air, but the viruses are also very likely to be on the person's hands, where they can be transferred to anything touched. Hand hygiene is important in the prevention of spreading infection to others, and patients should also be taught not to share personal-use items, such as drinking glasses.

The patient should stay indoors, preferably in bed or resting, during the first few days of the illness. Fluid intake should be increased. Fruit juices are recommended, especially citrus juices, because of their vitamin C content. Mild nonprescription analgesics can help relieve the muscle aches and headache of a cold.

Older Adult Care Points

Older adults should be encouraged to stay away from people who have a cold or URI, because they have decreased immune function, and if a cold develops a secondary infection is more likely. Older patients should continue the extra fluids and rest until symptoms are resolved.

Safety Alert

Caution With Aspirin

The U.S. Surgeon General, the Food and Drug Administration, the Centers for Disease Control and Prevention, the American Academy of Pediatrics, the National Reye's Syndrome Foundation, and the World Health Organization recommend that aspirin and combination products containing aspirin not be given to children under 19 years of age during episodes of fever-causing or viral illnesses ([National Reye's Syndrome Foundation](#)). Adults taking anticoagulants or nonsteroidal anti-inflammatory drugs should only take aspirin under the direction of their physician, because aspirin will further prolong the clotting time.

Decongestant nose drops or sprays containing vasoconstrictors such as oxymetazoline (for the relief of nasal congestion) can have a rebound effect, leaving the nose "stuffier" if used for more than 3 days. Frequent use of saline nasal spray decreases congestion without side effects.

Antibiotics are not given, because a cold is a viral infection.

A bacterial infection, which requires medical treatment, is likely present when a "cold" persists for more than a week to 10 days without improvement, or if the patient begins to feel worse, has a temperature of 101° F (38.3° C), and develops chest pains or coughs up purulent sputum.

Think Critically

What are the various ways you can prevent contracting a cold?

Sinusitis

Sinusitis is an inflammation of the mucosal lining of the sinuses. *Rhinosinusitis* is the preferred term, because the nasal mucosa is almost always inflamed along with the sinuses. *Streptococcus pneumoniae*, *Moraxella catarrhalis*, or *Haemophilus influenzae* are the usual causative pathogens, and infection can spread from the nasal passages to the sinuses. Sinusitis often occurs after colds or other respiratory infections and during periods of uncontrolled allergic rhinitis. The nasal passages can be blocked by a **deviated septum**, which may occur congenitally, from injury to the nose, or by **nasal polyps**. Polyps occur from repeated inflammation of the nasal mucosa and are tissue growths that obstruct airflow. People with a deviated nasal septum or allergy problems tend to have recurrent sinusitis.

As exudate accumulates in the sinuses, pressure builds up, causing pain. Symptoms include tenderness over the sinuses, purulent drainage from the nose, nasal obstruction, and sometimes a nonproductive cough. The upper teeth may become painful.

Treatment of sinusitis includes relieving pain, promoting sinus drainage, controlling infection, and preventing recurrence. Hot, moist packs over the sinus area can be helpful. Inhalating moist steam keeps mucous membranes moist, and equipment for sinus irrigation to help to promote drainage is available at drugstores. Medications are prescribed to promote decongestion or vasoconstriction and to reduce swelling, to promote drainage, and to relieve pain. The infection may be treated with an antibiotic or anti-infective agent, often for at least 10 days. Rest, reduced stress, a balanced diet, and control of allergies can help prevent recurrence. Fluid intake should be increased. There is no scientific evidence for the common belief that dairy products increase the thickness of secretions or produce mucus. In studies, individuals who believe mucus production increases with dairy products reported increased mucus.

Think Critically

How would you know if you or a patient has a sinus infection rather than just an ordinary cold?

Acute or chronic sinus infection can cause a variety of complications, including septicemia, meningitis, and brain abscess. When sinus infection is chronic, surgery to clean out the sinuses may be necessary. A deviated septum can be surgically repaired, and polyps can be removed endoscopically if medical treatment is unsuccessful.

Complementary and Alternative Therapies

Treatment of Allergic Rhinitis and Sinusitis

Allergens in contact with mucus membranes prompt the inflammatory response. Eliminating the allergens can minimize the inflammation symptoms. Use of a Neti pot or other device to irrigate the sinuses will rinse out the allergens. A nasal filter device can be used to prevent the allergens from getting into the nasal passages.

Epistaxis

Epistaxis (nosebleed) is a common occurrence and usually results from crusting, cracking, or irritation of the mucous membrane covering the front (anterior) of the nasal septum. Anterior bleeds are the most common (90% to 95%). Blood loss is usually minimal, but about 6% of nosebleeds require medical attention. Decreased humidity, excessive nose blowing, allergy with inflammation, and nose picking may cause nosebleeds. Overuse of nasal spray, street drug use (particularly “snorting”), and tumors are other causes. Any condition that prolongs bleeding time or lowers the platelet count may predispose an individual to nosebleeds. Nosebleeds can also result from trauma, hypertension, and blood disorders such as leukemia. They are common in boys during pubescence.

Bleeding from the nose is the only sign of epistaxis. When epistaxis occurs, the patient should sit forward and apply direct pressure by pinching the nose just below the bone, close to the face, for 10 to 15 minutes. This position prevents blood from running down the back of the throat. Cold compresses or ice may be applied to the nose to constrict the blood vessels. If there is still bleeding at the end of a 10- to 15-minute period, repeat the process ([Figure 13-1](#)). If bleeding continues, the patient should go to the emergency department, where a provider will cauterize the bleeding vessels, solidly pack the nose, or insert a small balloon device to stop the bleeding ([Figure 13-2](#)). Once bleeding stops, the patient should rest quietly for a few hours and be instructed to avoid bending over and not to blow the nose, pick at it, or rub it for 24 hours after the nosebleed has stopped.

Clinical Cues

If a patient is having an active nosebleed, instruct her to spit the blood into a basin or tissue rather than swallowing it. Accumulation of blood in the stomach will eventually cause nausea and vomiting, and the patient's cooperation will help you to assess the amount of bleeding and may help prevent aspiration of the blood.

Patients on anticoagulants and antiplatelet medications are at increased risk of nasal bleeding when nasal cannula oxygen is administered for prolonged periods, causing drying of the mucosa.

FIGURE 13-1 Stopping a nosebleed by applying pressure to the nose.

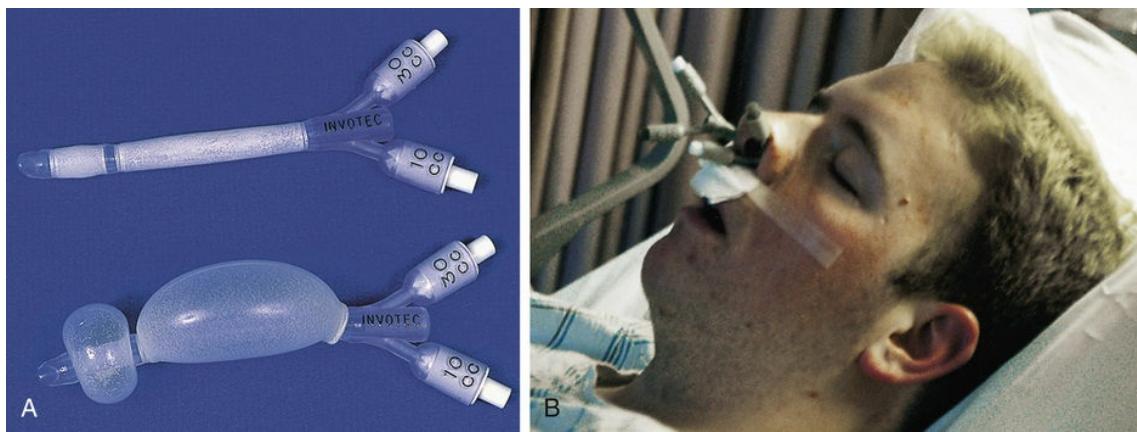

FIGURE 13-2 A nasal balloon device (A) is being used to control bleeding from epistaxis (B). (Courtesy of Invotec Corp.)

Pharyngitis

Etiology and Pathophysiology

Pharyngitis (inflammation of the pharynx), usually called a *sore throat*, may be caused by a virus, bacteria, or fungus. Most cases are viral. Acute **follicular pharyngitis** ("strep throat") is caused by beta-hemolytic streptococcal infection. Fungal pharyngitis occurs with long-term use of antibiotics or inhaled corticosteroids and in patients with immunosuppression, such as occurs with HIV or AIDS or during cancer treatment. **Laryngitis** (inflammation of the larynx with diminished voice or hoarseness) may occur if the infection progresses into the larynx. If the inflammation extends to the epiglottis, **epiglottitis** occurs; this is more common in children. Epiglottitis can cause an acute airway obstruction and should be monitored closely.

Signs, Symptoms, and Diagnosis

The symptoms include a dry, "scratchy" feeling in the back of the throat; mild fever; headache; and malaise. The throat, tonsils, palate, and uvula may be involved and will be reddened. If swelling of these structures is present, dysphagia may occur. Discomfort when swallowing one's own saliva is common but does not usually inhibit the ability to take adequate fluids and nourishment. With laryngitis, the voice may become hoarse or absent. The usual course for uncomplicated pharyngitis or laryngitis is 3 to 10 days. The diagnosis of pharyngitis is confirmed by clinical signs and symptoms. A throat culture is often performed to confirm or rule out streptococcal infection.

Treatment and Nursing Management

Uncomplicated viral pharyngitis usually responds to conservative measures, such as rest, warm saline gargles ($\frac{1}{2}$ to 1 tsp of table salt to a glass of warm water), throat **lozenges** (small medicinal tablets that dissolve in the mouth), antiseptic sprays, plenty of fluids, and a mild analgesic for aches and pains.

Bacterial pharyngitis requires antibiotic therapy, particularly if the infecting organism is *Streptococcus*. Chronic pharyngitis may require diagnostic procedures to determine the underlying cause and therapeutic measures such as humidification and filtering of environmental air. Fungal pharyngitis is treated with an antifungal agent but may be difficult to control in immunocompromised individuals.

Tonsillitis

Etiology and Pathophysiology

An infection with inflammation of the tonsils is usually caused by streptococci, staphylococci, or *H. influenzae* and is different from pharyngitis; however, symptoms may be somewhat similar. Acute tonsillitis may occur repeatedly, especially in those who have a low resistance to infection.

Signs, Symptoms, and Diagnosis

Acute tonsillitis occurs more commonly in young children. Symptoms include high fever, sore throat, general malaise, pain referred to the ears, and chills. Inspection of the throat reveals redness and swelling of the tonsils and surrounding tissues with patches of yellow exudate. The white blood cell count becomes elevated.

Chronic tonsillitis usually produces an enlargement of tonsillar tissue and adenoidal tissue. Chronic infection produces less dramatic symptoms than acute tonsillitis, but discomfort still occurs. A person with chronic tonsillitis and enlarged adenoids has frequent colds and appears to be in poor health.

Diagnosis is by physical examination and history. If a streptococcus infection is suspected, a throat culture or a “rapid strep test” may be performed.

Treatment

A throat culture is performed before treatment to check for the presence of *Streptococcus*, which can cause rheumatic fever or glomerulonephritis if not treated promptly. Acute tonsillitis is treated with warm saline throat gargles and the administration of specific antibiotics (usually penicillin) to destroy the pathogen. Nursing measures include bed rest, fever management, and a liquid diet to minimize trauma to the tissues and maintain hydration. After 24 hours taking antibiotics, the patient is no longer considered contagious (Shah, 2014).

Surgery is used to treat tonsillitis when it is recurrent or when enlargement of the tonsils and adenoids obstructs airways. Surgery is considered if the patient has more than seven episodes of streptococcal tonsillitis per year.

Think Critically

What would be appropriate foods to offer a patient with pharyngitis or tonsillitis?

Nursing Management

Preoperative care.

Tonsillectomy and adenoidectomy are generally done on an outpatient, same-day surgery basis. Preliminary laboratory testing and patient education begin before the patient is admitted. Physical preparation of the patient involves administration of preoperative medications as ordered, restricting the use of aspirin or other nonsteroidal anti-inflammatory medications, and restriction of the patient's diet for 6 to 8 hours before surgery. An elevation of temperature or any signs of URI should be reported, because surgery is usually postponed if these signs are present.

Postoperative care.

Although patients usually recover rapidly from tonsillectomy and adenoidectomy and rarely suffer any complications, be vigilant for signs of hemorrhage. Vital signs are checked frequently, and the patient is observed for frequent swallowing or clearing of the throat, which may indicate bleeding. Restlessness can be another clue to excessive bleeding. Sneezing, coughing, and vomiting can cause bleeding. An ice collar may be placed around the neck to reduce swelling and pain. A side-lying position when drowsy or semi-Fowler position when fully awake will help maintain a patent airway. The postoperative diet usually consists of cold or warm liquids, progressing to semisolid foods, for the first 24 hours. Avoiding red foods can help in distinguishing between ingested food and blood. Citrus fruits, hot fluids, and rough foods should be avoided until the throat has completely healed. Straws are not used because sucking may cause bleeding. Note that stools may be black due to the swallowing of blood. Written instructions for routine care, pain management, and emergency circumstances are reviewed with the caregiver and patient.

Think Critically

What sign would alert you to the probability that a tonsillectomy patient was experiencing bleeding and that the blood was running down the throat where you cannot see it?

Obstruction and Trauma

Airway Obstruction and Respiratory Arrest

Laryngeal edema caused by the inflammation of an infection or an allergic reaction, a crush injury of the larynx, or a foreign object or food that goes down the airway rather than the esophagus may obstruct the airway. If a person seems to be choking, encourage forceful coughing if possible. If the person cannot breathe or speak, he may make the universal signal for choking, signaling for help by grasping at the throat with the hands (Figure 13-3). If breathing is obstructed, abdominal thrusts should be performed² (American Heart Association, 2010). The arms are wrapped around the victim from behind. One hand makes a fist with the thumb inward, then the fist is positioned just above the umbilicus. The other hand wraps around the fist. Upward thrusts are delivered into the abdomen to try to dislodge anything stuck in the airway (Figure 13-4) (see Chapter 44). **In an unconscious adult or child older than 1 year, the most common cause of airway obstruction is the tongue.** An artificial airway may be orally or nasally inserted; it helps to keep the tongue in place (Figure 13-5).

Clinical Cues

Nasal or oropharyngeal airways can be inserted by the nurse. If indicated, an endotracheal tube would be inserted by a provider, respiratory therapist, or nurse anesthetist. The nurse's role in this emergency procedure would include obtaining the emergency airway equipment, including laryngoscope, 5- to 10-mL syringe, Ambu bag, suction equipment, lubricant, stylet, endotracheal tube, and a securing device. The nurse may also be required to oxygenate the patient using the Ambu bag, administer medications for rapid-sequence intubation, or assist in making the equipment available to the clinician performing the intubation.

FIGURE 13-3 The hands grasping the throat is the universal signal for choking.

FIGURE 13-4 Abdominal thrust.

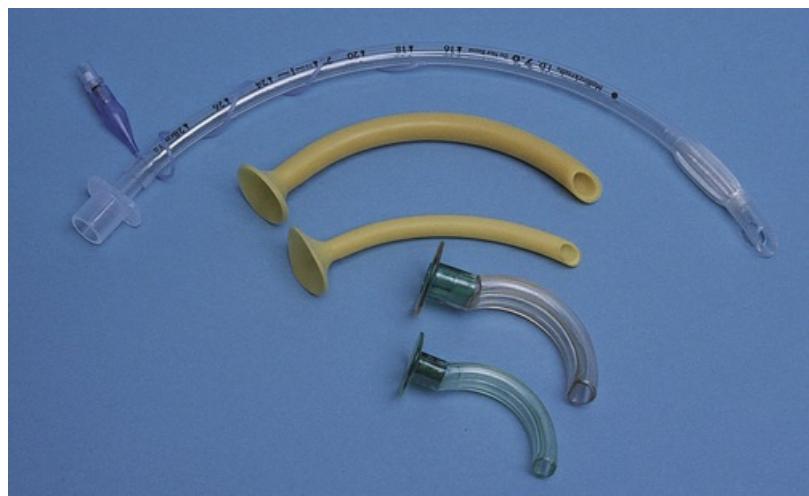

FIGURE 13-5 Types of airways inserted during a respiratory emergency (endotracheal [top], nasopharyngeal [middle], and oropharyngeal [bottom]). (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, St. Louis, 2013, Saunders.)

If the airway is obstructed for an extended period, the hypoxia may cause the heart to stop. If the obstruction is cleared but the patient has no pulse, cardiopulmonary resuscitation must be started (see Chapter 44).

Obstructive Sleep Apnea

Obstructive sleep apnea (OSA) is a condition in which, during sleep, the person is making breathing

effort but there is no or extremely limited airflow. Muscle relaxation at the back of the throat is the most common cause, allowing the tongue to fall back and block the airway. Snoring is common with this condition, and sleeping partners are usually the first to notice the problem. Daytime symptoms include fatigue, morning headaches, and difficulty concentrating. Physical examination of patients with OSA typically reveals obesity, enlarged neck circumference, and hypertension. A sleep study should be performed to determine the severity of the condition. Those with mild apnea may be treated with conservative measures such as weight loss, avoiding alcohol for 4 to 6 hours before bed, and sleep position modification. The first-line therapy for sleep apnea is nasal continuous positive airway pressure (CPAP) applied with nasal prongs. If that is unsuccessful, bilevel positive airway pressure (BiPAP) may be tried with a facemask or nasal mask (see [Chapter 14, Figure 14-10](#)). Oral appliances may be used to maintain an airway. If noninvasive therapies fail, the patient can be offered surgical interventions, including implantable devices that stimulate the nerves leading to muscles controlling the palate and tongue or surgical alteration of the upper airway. Untreated sleep apnea can contribute to myocardial infarction or stroke. Clinical guidelines require capnography (CO_2 monitoring) for postoperative OSA patients in addition to routine pulse oximetry monitoring after any surgical procedure (The [Joint Commission, 2012](#)).

Nasal Fracture

Nasal fracture often results from sports injuries, motor vehicle accidents, or physical assault and is the most common type of facial fracture. If the cartilage or bone is not displaced, complications are unlikely and no treatment is needed. Displacement of the cartilage or bone can interfere with airflow, cause deformity of the nose, and become a potential spot for infection.

Diagnosis is by visual inspection for deformity, a change in nasal breathing, and presence of **crepitation** (grating sound or a feeling of rough surfaces rubbing together) on palpation. It is important to determine whether other facial bones are also fractured. If the patient is seen within the first 24 hours after injury, a closed reduction is most often performed using local or general anesthetic. Treatment includes pain relief and the use of ice or cold compresses to reduce swelling.

If the fracture is severe, **rhinoplasty** (surgical reconstruction of the nose) may be performed to improve airflow and cosmetic appearance. Nasal packing, splints, or sutures may be used to stabilize the septum postoperatively. The patient will be given specific instructions depending on need. Drainage from the nose is expected, and a drip pad of folded gauze is secured as a "mustache" dressing beneath the nose.

The patient is observed for frequent swallowing postoperatively, which could indicate posterior nasal bleeding. Vital signs are monitored closely, and the amount of drainage on the dressing is observed. The patient should be encouraged to rest in a semi-Fowler position. Cool compresses are used to decrease nose and facial swelling. Forceful coughing and straining at stool (Valsalva maneuver) should be avoided. A humidifier may be used to decrease mucosal drying. Over-the-counter analgesics are usually adequate for pain control. After recovery from anesthesia, the patient is usually discharged to recuperate at home. It may take 6 to 12 months before the final result of the surgery is evident.

Cancer of the Larynx

Etiology and Pathophysiology

It was predicted that there would be 12,000 new cases of cancer of the larynx in 2013 ([American Cancer Society \[ACS\], 2014](#)). Approximately 75% to 90% of all patients who are diagnosed early and treated with radiation and/or surgery are cured. A clear association has been made in relation to cigarette or cigar smoking, excessive use of alcohol, and the development of laryngeal cancer. Lack of fruits and vegetables in the diet, gastroesophageal reflux disease, immunosuppression, and infection with human papillomavirus or *Helicobacter pylori* have all been linked to increased incidence of cancer of the larynx. Exposure over long periods to environmental pollutants, such as asbestos, paint fumes, or wood or coal dust, has been shown to be associated with increased risk ([ACS, 2014](#)). The most common malignant tumor of the larynx is squamous cell carcinoma. It grows from the mucous membrane lining the respiratory tract. Metastasis may occur to the lung.

Signs, Symptoms, and Diagnosis

The larynx (sometimes called the *voice box*) is directly involved with the production of vocal sounds. A tumor of the larynx will quickly produce persistent hoarseness that does not respond to usual methods of treatment.

Health Promotion

Signs of Possible Throat Cancer

Tell patients to seek medical attention if the following signs of cancer of the larynx or throat occur:

- Hoarseness lasting more than 3 weeks
- Sore throat that lasts more than 2 weeks
- Consistent pain in or around the ear when swallowing
- Difficulty swallowing
- Dry, persistent cough for no known reason
- Blood in phlegm or saliva lasting more than a few days
- Lumps or knots on the neck indicating enlarged cervical lymph nodes

After the cancer has spread beyond the vocal cords (and is much more difficult to treat), the symptoms may include difficulty in swallowing or breathing, halitosis, blood-tinged sputum, fatigue and weakness, a sensation of having a lump in the throat, cough, enlarged lymph nodes in the neck, pain in the region of the Adam's apple, or an airway obstruction.

Diagnosis is established by visualizing the larynx with a laryngoscope, by a computed tomography scan of the larynx and throat, by magnetic resonance imaging, and by microscopic examination of a sample of tissues taken from the site.

Treatment

Once the type of cancer is determined, it is staged for appropriate treatment. Outpatient treatment is common. Radiation alone is 85% effective in treating early cancer of the larynx. Radiation may be combined with endoscopic laser cordectomy for certain types of lesions. Brachytherapy (also called internal radiotherapy) along with external-beam irradiation (or external radiotherapy) is used for certain types of lesions. When possible for organ preservation, the surgeon may perform a partial **laryngectomy** in which the thyroid cartilage is split, and only the tumor and involved portion of the larynx and vocal cords are removed. A partial laryngectomy does not permanently eliminate voice sounds. A **tracheostomy** (surgical opening into the trachea) may be performed to facilitate breathing temporarily, but the **stoma** (opening) is eventually closed, and the patient may resume talking after the affected area is completely healed.

Microlaryngoscopy combined with laser treatment is now the method of choice for removing vocal cord polyps and carcinoma that has not spread. Cure rates for malignancy of the true vocal cords treated by laser are about 90%. Other advantages include the absence of mechanical trauma and swelling when laser is used, which means that the patient returns to normal activities within about 3 days. There is no need for extended voice rest; 2 days is usually sufficient.

A total laryngectomy is performed if the tumor has progressed to surrounding tissues, radiation therapy has failed, or better survival can be obtained by the more aggressive surgery. The surgeon excises the entire larynx, epiglottis, thyroid cartilage, hyoid bone, cricoid cartilage, and two or more rings of the trachea (**Figure 13-6**). Near-total laryngectomy preserves voice production and swallowing in advanced disease and is used when possible.

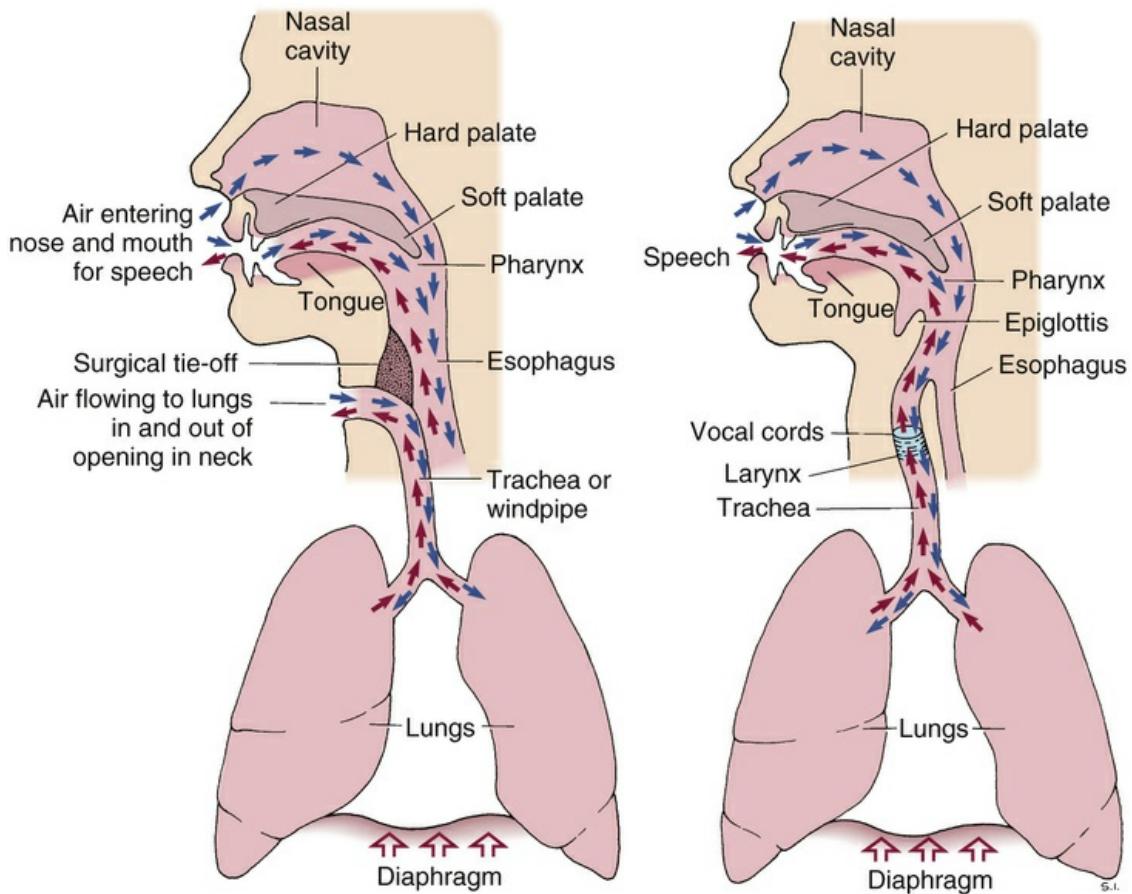

FIGURE 13-6 Airflow after laryngectomy (left) and in a normal respiratory tract (right).

If the tumor has extended to the lymph nodes, neck dissection is performed on the side of the lesion. In a radical neck surgery, all the muscle, lymph nodes, and soft tissue from the lower edge of the mandible to the clavicle and from the top of the trapezius muscle to the midline are removed. A modified radical neck dissection is more commonly performed and excises only the lymph tissue and surrounding structures directly affected by the cancer. A permanent tracheostomy is performed at the same time. A laryngectomy tube, which is shorter and wider than a tracheostomy tube, is put into place before discharge. After the stoma is completely healed and matured, about 6 weeks after surgery, the tube can be taken out as long as there is no compromise of the airway.

A thin feeding tube is placed during surgery for postoperative use for about 10 to 14 days. The patient has only intravenous fluids initially but then progresses to regular tube feedings. With healing, the danger of contaminating the operative site is no longer a concern and training in eating and swallowing are initiated. With the appropriate encouragement and practice, most patients can master the techniques to avoid the sensations of choking and gagging.

When the patient is discharged from the hospital, a visiting nurse, clinic nurse, or occupational therapist will work with the patient on eating skills. Some patients have to rely on a feeding tube if they cannot master the swallowing procedure without aspiration. The indwelling tube may then be replaced with a gastrostomy tube.

Think Critically

How can nurses help decrease the incidence of cancer of the larynx?

Endotracheal intubation and tracheostomy.

Endotracheal intubation means that an endotracheal tube is inserted into the trachea through the nose or the mouth with the use of a **laryngoscope**. An endotracheal tube is placed for airway protection against aspiration, when there is upper airway obstruction, and when mechanical

ventilation is necessary. Endotracheal tubes are used for short-term respiratory support, such as for immediate relief of airway obstruction, for patients with decreased level of consciousness because of trauma, during anesthesia, or for a few days postoperatively.

A **tracheostomy** is a surgical incision into the trachea for the purpose of inserting a tube for breathing. In a patient with a tracheostomy, there is no connection between the nose and mouth and the lower respiratory system (Figure 13-7, B). Tracheostomy is done:

- To assist or control ventilation by mechanical means over a prolonged period of time
- To facilitate suctioning of secretions in the air passages when the patient cannot cough
- To prevent aspiration of oral and gastric secretions (as in unconscious or paralyzed patients)
- To bypass a constricted or obstructed upper airway (e.g., from edema of the larynx, presence of a foreign body or tumor, surgical procedures involving the neck, severe burns, facial trauma, or chest trauma)

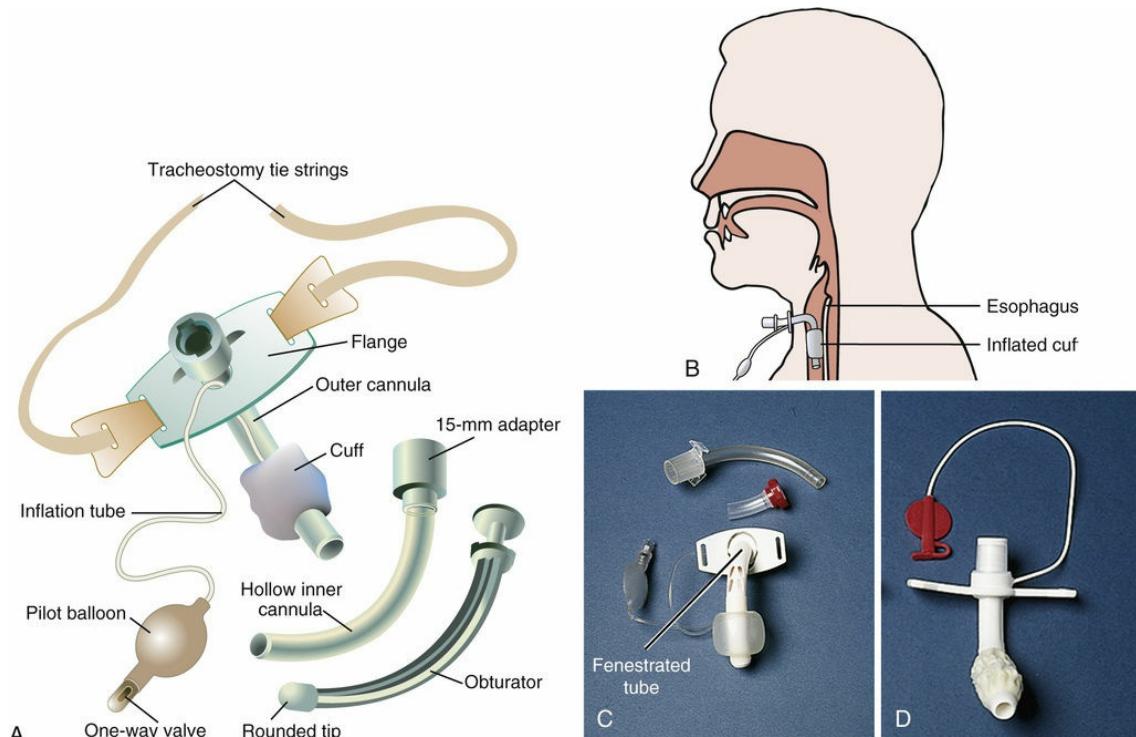

FIGURE 13-7 Types of tracheostomy tubes. **A**, Parts of a tracheostomy tube. **B**, Tracheostomy tube inserted in airway, shown with cuff inflated. **C**, Fenestrated tracheostomy tube with cuff, inner cannula, decannulation plug, and pilot balloon. **D**, Tracheostomy tube with foam cuff and obturator. Cuff is deflated on tracheostomy tube. (From Lewis S, Dirksen S, Heitkemper L, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 8, St. Louis, 2011, Mosby.)

Tracheostomy may be an emergency procedure or an elective operation. If passing an endotracheal tube through the nose or mouth is impossible or extremely difficult, a tracheostomy may be done to provide an airway. Some patients will need a tracheostomy tube for the rest of their lives because of anatomic changes in the throat. When a patient is expected to need an artificial airway for an extended period of time, tracheostomy is preferred over prolonged endotracheal intubation. Tracheostomy is usually considered after 1 to 3 weeks of intubation (Lindman et al, 2013). In the immediate postoperative period, patients with a tracheostomy may need mechanical ventilation and/or oxygen therapy (see Chapter 14).

Types of tracheostomy tubes.

Tracheostomy tubes are available in a variety of materials and styles. Most of the models are made of polyvinyl chloride (plastic) or silicone (see Figure 13-7). Tubes made of metal alloys are used chiefly for patients who need a permanent tracheostomy. The age of the patient and the purpose of the tube will determine what features are selected. They may be cuffed or uncuffed and may have a

reusable inner cannula or a disposable inner cannula. Single cannula tubes do not have an inner cannula. In a **double-cannula tracheostomy tube**, the outer cannula acts as a sleeve for the inner cannula, which can be removed for cleaning. The **obturator** (insertion guide) is used during insertion as a guide (the tip, shaped like an olive, extends beyond the end of the tube) to protect against scraping the sides of the trachea with the sharp edge of the tube (see [Figure 13-7, A](#)).

Fenestrated tubes have a small opening in the outer cannula that allows some air to escape through the larynx (see [Figure 13-7, C](#)). This helps prepare the patient for the time when the tracheostomy tube will be removed and breathing occurs normally again. If the fenestrated tube is cuffed and the cuff is not inflated, then the airflow allows for speech. A one-way tracheostomy valve box can be fitted into the tube opening. It allows air to be inhaled through the tracheostomy opening, but the valve closes when the patient exhales. This diverts the exhaled air through the larynx and enables the patient to speak.

A **cuffed tracheostomy tube** has a small balloon encircling its tracheal end. When the balloon is inflated, it fills the space between the outside of the tracheostomy tube and the trachea, thereby providing a seal and preventing the escape of air around the tube. When positive-pressure mechanical ventilation is administered, the air passes through the tracheostomy tube **only**, thus providing sufficient pressure to inflate the lungs. The cuffed tracheostomy tube may offer some protection against aspiration of mucus and fluids; however, the use of the cuffed tube does not replace careful nursing observation or interventions to prevent aspiration.

Foam-cuffed tracheostomy tubes have the cuff filled with a sponge-like material that is fully expanded at rest. To insert the tube, air must be withdrawn from the cuff so that the foam compresses, allowing for placement (see [Figure 13-7, D](#)). When in place, the cuff inflation line is left open to air, which allows for compression and expansion of the cuff with tracheal movement. Because of this there is minimal pressure exerted on the tracheal wall, decreasing the risk of tissue damage or necrosis.

Nursing Management

A patient with a new tracheostomy requires very specialized nursing care, especially if mechanical ventilation through the tube is required. **Immediate postoperative care focuses on maintaining a patent airway and observing for hemorrhage.** During the first 24 hours, the patient is monitored continuously for signs of respiratory distress. If the patient is unable to cough to remove mucus and drainage, tracheal suctioning is necessary. If the lumen is not kept open, the patient will suffocate. Suctioning is done with strict sterile technique to prevent infection. (Suctioning technique is presented in Skill 13-1 on Evolve.) See also [Nursing Care Plan 13-1](#). Adequate humidification of the inhaled air and hydration of the patient helps to thin secretions.

Clinical Cues

When you are suctioning a patient with a tracheostomy or endotracheal tube and using a sterile suction kit, ask an assistant to accompany you to deliver oxygen before and during the procedure (as needed). Oxygenation of the patient will prevent desaturation, and the assistance of a helper allows you to maintain sterile technique. Patients on mechanical ventilation can be preoxygenated with the ventilator and may have an inline suction device attached to the airway.

Nursing Care Plan 13-1

Care of a Patient With a Laryngectomy

Scenario

Mr. Collins had a supraglottic laryngectomy 5 days ago. He is having difficulty adjusting to his tracheostomy and frequently chokes when trying to eat or swallow secretions. He indicates, with pencil and paper, that he does not feel he can learn to speak again and is very anxious about choking; he is withdrawn.

Problem Statement/Nursing Diagnosis

Alteration in airway clearance/*Ineffective airway clearance related to secretions resulting from surgery and tracheostomy.*

Supporting Assessment Data

Objective: Unable to cough out secretions; becomes hypoxic when secretions build up, decreasing airflow.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Tracheostomy will be cleared by suctioning as needed.	Assess respiratory effort and rate; auscultate upper airways to determine needs for suctioning. Observe ostomy site for secretions. Suction as needed.	If rate or respiratory effort increases, the airway may be obstructed. Coarse sounds heard in the upper airways or secretions at ostomy site indicate need for suctioning. Suctioning secretions clears airway.	Respiratory rate varies; 18/min if patient is relaxed. Rate of 28-30/min when anxious or trying to cough out mucus. (Suctioning improves respiratory rate when mucus is cleared.) Suctioning is effective.
Patient will learn to suction own tracheostomy effectively by discharge.	Encourage patient to assist with procedure (e.g., have patient hold water for moistening catheter).	Having patient assist with small steps helps him to develop confidence for home care.	Patient is making attempts to learn suctioning technique.
	Teach to attach catheter to suction tubing; teach to suction self using mirror.	Knowledge and practice are essential for self-care.	Beginning to attempt to cough out secretions and suction.
	Praise for all attempts.	Praise reinforces patient's efforts and learning.	Positive reinforcement given for any attempt.
	Point out advantages of not being dependent on others for care of airway.	Provides incentive to learn self-care.	States wants to be independent.
Patient will learn to clear tracheostomy by coughing effectively.	Medicate for discomfort and encourage patient to cough to remove secretions without suctioning.	Lessened discomfort makes it possible to cough effectively.	Analgesia provided as ordered.
	Assist to an upright position of at least 45 degrees.	Sitting upright allows for full expansion of chest cavity.	Is able to place self in an upright position and reposition self as needed.
	Remind to hold tissues in front of tube rather than the mouth.	Secretions will be coughed out of the tube.	Holding tissues in front of tube when coughing.
	Instruct to breathe deeply for several seconds and to forcefully cough two or three times using the abdominal muscles.	Use of abdominal muscles increases the force and depth of the cough.	Able to perform deep coughing with support and coaching.

Problem Statement/Nursing Diagnosis

Altered skin integrity/Impaired skin integrity related to surgical incisions.

Supporting Assessment Data

Objective: Supraglottic laryngectomy and tracheostomy.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
No infection at incision sites as evidenced by absence of redness, swelling, or purulent discharge.	Clean around tracheostomy stoma with normal saline; q 4-8 h change gauze pad PRN.	Cleans away bacteria and helps prevent infection.	No evidence of infection. Slight redness around tracheostomy stoma.
Skin integrity will be intact within 6 wk.	Change tracheostomy ties or holder at least q24h and as needed.		Skin is intact; no redness or signs of irritation.
	Observe for signs of infection.	Early recognition ensures prompt treatment.	No signs of infection. Continue plan.

Problem Statement/Nursing Diagnosis

Altered communication ability/Impaired verbal communication related to loss of larynx.

Supporting Assessment Data

Subjective: No verbal communication.

Objective: Laryngectomy and tracheostomy.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will show interest in learning new style of speech within 6 wk.	Assist him to use dry erase board or paper and pencil for communication; show patience.	Provides for some means of communication.	Using communication tools.
	Obtain order for visit from rehabilitated patient who has mastered some form of speech.	Seeing an example reinforces the possibility of regaining a form of speech.	Visit scheduled.
	Encourage affiliation with community support group.	Support from people with a similar problem helps to decrease feelings of isolation and helplessness.	Advised about support group. Continue plan.

Problem Statement/Nursing Diagnosis

Potential for injury/Risk for aspiration related to choking when trying to swallow.

Supporting Assessment Data

Subjective: Writes that he does not feel he will be able to swallow or eat by mouth again.

Objective: Chokes when tries to swallow saliva; tends to aspirate.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will not experience injury from aspiration of food or fluids.	Place in an upright position before eating or medication administration and maintain for at least 1 hr.	Gravity facilitates the downward movement of the food bolus.	Able to place self in an upright position; acknowledges need to remain upright for 1 hr after eating.

	Teach to hold his breath and perform the Valsalva maneuver while swallowing.	Valsalva maneuver closes the glottis over the tracheal opening in the throat, preventing food from entering the trachea.	Is practicing, but is having trouble coordinating the breathing and Valsalva maneuver and swallowing.
Patient will learn to swallow without aspirating within 6 wk.	Teach to keep neck relaxed forward, take small bite of food, keep chin toward chest, swallow, then forcibly exhale.	Exhaling forcibly after swallowing will expel particles that accidentally end up in the trachea.	Is still choking when he tries to swallow. Revise plan: Obtain consultation with speech therapist for swallowing exercises.

Critical Thinking Questions

- What psychosocial problems might Mr. Collins experience?
- How can you motivate Mr. Collins to participate in suctioning his tracheostomy?

The lungs should be auscultated (1) before suctioning to assess the need and (2) afterward to verify that the procedure successfully cleared the airways. Head-to-toe assessment is performed as for any surgical patient (see [Chapter 5](#)).

When the patient has a tracheostomy tube with a cuff, the cuff must be inflated just enough to seal the trachea without causing extreme pressure against the tracheal wall; otherwise depression of the surface blood vessels in the tracheal wall will cause necrosis. Cuff pressure is checked with a manometer each shift and each time the degree of cuff inflation is changed.

Assignment Considerations

Reporting on a Patient With a Tracheostomy

Instruct the UAP to immediately report coughing episodes or coarse gurgling sounds produced by a patient with a tracheostomy. Explain that you must be notified so that you can perform an immediate assessment and possible suctioning to alleviate an airway obstruction.

Preventing infection is another nursing responsibility. The incision is an open wound with minimal dressings and is an ideal entryway for infectious organisms. Tracheostomy care is a sterile procedure until the stoma is well healed (see Skill 13-2 [on Evolve](#)). **When changing the ties or Velcro tube holder of the tracheostomy tube, the tube should be manually held in place; otherwise the tube may be dislodged by coughing.** (Coughing frequently occurs when the tube is moved or manipulated.)

If the patient is to go home with a tracheostomy, techniques for suctioning and providing the necessary tracheostomy care are taught to both the patient and a family member or caregiver.

Patient Teaching

Home Care of a Tracheostomy

The patient and family should be taught the following points:

- Clean the stoma with normal saline and cotton-tipped sterile applicators, removing all secretions, on a daily basis and as needed.
- Replace the commercially slit gauze pad around the tube as frequently as needed when it becomes soiled. (Do not cut regular gauze pads, because the loose threads can be aspirated.)
- It is best to have two people help change the ties or tube holder, because movement of the tube can easily cause the patient to cough and expel the tube from the stoma.
- Prepare the new ties before loosening the old ones. If a device with self-sticking ties is used, attach the new holder before removing the soiled holder.
- Hold the tube securely in place with thumb and forefinger while the ties are loose.
- Stand to the side of the stoma when providing care, because if the patient coughs, mucus may be expelled.

Psychological support of the tracheostomy patient and family is essential. The patient has to learn to breathe in a totally different way and cannot speak or call out for help. She may be able to use a Passy-Muir speaking tracheostomy valve ([Figure 13-8](#)). Verbal reassurance will show awareness of apprehension and readiness to help. Explanations about what is being done and why it is being done are given each time tracheostomy care is provided. Teaching begins as soon as the patient is alert after the tracheostomy tube is placed. The patient may experience grief over losing her natural voice and the ability to eat normally if a total laryngectomy has been done. She will need help in facing a future in which she will not be able to speak normally. A radical neck dissection may create body image disturbance, because the procedure is somewhat disfiguring. Initially, depression is common. Contact with others who have had the surgery may help the patient focus on the benefits of lifesaving surgery.

Nutrition Considerations

Assisting the Patient With Swallowing After a Partial Laryngectomy

- Explain that swallowing food without choking is possible.
- Arrange a visit from a partial laryngectomy patient who has mastered the technique.
- Begin practice with soft or semisolid foods.
- Supervise initial practice and explain that someone needs to be with the patient when she eats until swallowing without choking is mastered.
- Teach to swallow by asking the patient to:
 - Take a deep breath and bear down to close the vocal cords.
 - Place a small bite of food in the mouth.
 - Tip the chin toward the chest and swallow.
 - Emit a cough to rid the throat of any food particles.
 - Swallow again.
 - Cough again.
 - Begin breathing normally again.
- Offer encouragement for each effort.

FIGURE 13-8 **A**, Passy-Muir speaking tracheostomy valve. **B**, Patient using a Passy-Muir valve. (Courtesy Passey-Muir, Inc., Irvine, Calif.)

The laryngectomy patient will need to be provided with a means of communication such as a pad and pencil, a dry erase board, a picture board device, or electronic devices with appropriate software.

Once the tracheal stoma is healed, protection of the tracheal opening from dust and lint can be accomplished through the use of a simple gauze covering or high-necked clothing. The patient also should be told to avoid swimming and to use care when taking a shower or tub bath so that water is not aspirated through the opening. To protect the patient from inhalation of extremely cold air (she no longer breathes through her nose and mouth, which normally warm the inspired air), the patient may wear a small scarf over the opening during the winter.

Rehabilitation.

Proper rehabilitation is important in the acceptance of surgery and the consequences. The speech therapist helps the patient to master a new form of speech. Many people are able to learn esophageal speech; first they master the art of swallowing air and then moving it forcibly back up through the esophagus; then they learn to coordinate lip and tongue movements with the sound produced by the air passing over vibrating folds of the esophagus. The sounds may be somewhat hoarse but are more natural than the sounds produced by an artificial larynx. For patients who cannot master esophageal speech, a tracheoesophageal prosthesis can be implanted. A fistula is made between the esophagus and trachea; a silicone prosthesis is inserted after the fistula heals. The patient covers the opening of the prosthesis with a finger or closes a special valve that diverts air from the lungs up through the trachea into the esophagus and out of the mouth. Lip and tongue movements form speech as the air is expelled.

An electronic artificial larynx is a battery-powered device that is externally applied to the skin of the esophagus to simulate speech. The sounds are not voicelike but are understandable and make it

possible for the patient to communicate (Figure 13-9).

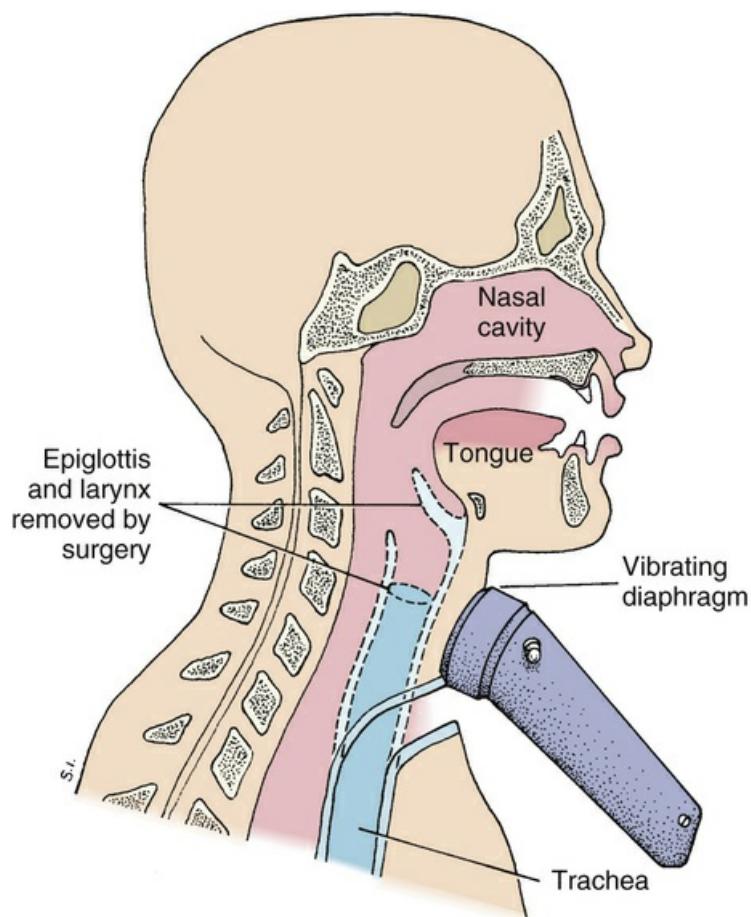

FIGURE 13-9 External electronic larynx. The vibrating cap of the electronic larynx is held against the throat with sufficient pressure to maintain firm contact. Sound vibrations are transmitted into the lower portion of the pharynx and transformed into speech by the normal movements of the tongue, lips, and teeth.

Another option is an electronic speech aid that has a small tube device that can be inserted into the mouth. The patient can push a button device implanted in the throat that allows diaphragmatic speech.

Throughout the United States, groups have been organized for laryngectomy patients who wish to get together for social and rehabilitation purposes (see Online Resources).

Think Critically

Can you identify all of the health care professionals who would be involved in the collaborative care of a patient undergoing a total laryngectomy and radical neck dissection?

Community Care

One of the primary aspects of community care for nurses is to promote immunization for influenza and pneumonia. Remind the public that frequent hand hygiene and covering the mouth when coughing or sneezing are simple measures that prevent the spread of URIs.

Home Care

Home care nurses follow up with patients who have had surgery or need further teaching or assessment. Reminding patients to take all prescribed antibiotics as directed is very important in preventing the development of disease-resistant strains of bacteria ([Centers for Disease Control and Prevention, 2013](#)). The home care nurse will also help patients with throat cancer or surgeries address nutritional concerns, provide wound care, supervise self-care techniques for care of a tracheostomy, and provide psychosocial support.

Tracheostomy care in the home setting differs from hospital procedures. In the home, suction catheters may be used longer and can be disinfected for reuse. Once the stoma is healed, the patient learns to adapt supplies to her needs. The nurse can help identify community resources that can help meet the needs of the patient.

Extended Care

Extended-care facility nurses must be vigilant for signs of URI among residents to prevent the spread of infection. If you have a contagious URI, do not expose your older adult patients. Stay at home or diligently wear a mask and perform hand hygiene. Adequate protein stores and hydration will promote immunity for your patients. Timely immunization against influenza and pneumonia is a top priority. Assist residents with hand hygiene and remind everyone to cover sneezes and coughs to decrease the spread of URIs within the facility.

Get Ready for the NCLEX® Examination!

Key Points

- If a cold persists or high fever develops, the patient should obtain medical attention.
- Rhinitis may be allergic in origin. If it interferes with lifestyle or productivity, desensitization is an option.
- Sinusitis symptoms include headache, fever, tenderness over the sinuses, purulent drainage from the nose, painful upper teeth, and malaise. A nonproductive cough may be present.
- Epistaxis is caused by many factors, such as irritation from nose blowing, hypertension, trauma, blood dyscrasias, decreased humidity, and nose picking. Apply direct pressure to the nose for 10 to 15 minutes to stop bleeding; cold compresses or ice are helpful.
- Pharyngitis is inflammation of the pharynx, or sore throat, that is viral, bacterial, or fungal in origin. Treatment for viral pharyngitis is rest, warm saline gargles, throat lozenges, and a mild analgesic. A throat culture and antibiotics are common for bacterial pharyngitis.
- Treatment and nursing interventions for tonsillitis consist of warm saline gargles, throat lozenges, rest, and antibiotics.
- When a tonsillectomy is performed, check vital signs frequently; keep the patient on her side or abdomen as long as there is drainage from the throat; and limit diet to soft, nonirritating foods until the throat is no longer sensitive. Observe for frequent swallowing, which may indicate blood running down the throat.
- Rhinoplasty is performed for severe nasal fracture; the postoperative priority is to monitor for and control bleeding.
- Risk factors for cancer of the larynx include smoking, immoderate alcohol use, chronic laryngitis, and abuse of vocal cords. Persistent hoarseness is a first sign of cancer of the larynx; later signs are pain in the throat, coughing, dysphagia, a lump in the throat, or pain in the region of the Adam's apple. Surgical treatment for laryngeal tumor is laser treatment, partial or total laryngectomy, and possible radical neck dissection.
- Endotracheal intubation or tracheostomy provides an artificial airway. Major concerns of an artificial airway are maintaining an open airway and preventing infection.
- Promote immunization for influenza and pneumonia. Teach prevention of infection by hygiene measures—proper hand hygiene and covering the mouth when coughing or sneezing.

Review Questions for the NCLEX® Examination

1. On initial assessment, a patient who just had tonsillectomy and adenoidectomy is restless and swallows frequently. What is the most likely explanation?

1. Excessive thirst
2. Swelling in the neck
3. Bleeding
4. Sore throat

NCLEX Client Need: Reduction of Risk Potential

2. A 45-year-old man who is eating steak suddenly rises from his seat. His hands are grasping his throat. What actions should be performed? Identify the correct sequence.

1. Position your open hand just above the umbilicus.
2. Wrap your arms around the man from behind.
3. Deliver upward squeeze thrusts.
4. Ask the man if he is choking.

NCLEX Client Need: Physiological Adaptation

3. When caring for a patient who had a rhinoplasty, the nurse should perform which intervention(s) in the immediate postoperative period? (*Select all that apply.*)

1. Observe for frequent swallowing.
2. Monitor amount of drainage on dressing.
3. Position patient flat on the back.
4. Apply warm compresses.
5. Provide humidified oxygen.

NCLEX Client Need: Reduction of Risk Potential

4. The spouse of a patient with a tracheostomy asks, "What is the purpose of the cuff on the tracheostomy tube?" What is the best response?

1. "It holds the tube in place."
2. "It allows the ventilator to deliver a full breath of air."
3. "It prevents the development of pneumonia."
4. "It reduces the risk for tracheal wall necrosis."

NCLEX Client Need: Physiological Adaptation

5. A patient has sinusitis. Which nonpharmacologic intervention(s) would be appropriate? (*Select all that apply.*)

1. Apply ice packs over the sinus area.
2. Suggest inhalation of moist steam.
3. Increase fluid intake.
4. Position with the head lower than the shoulders.
5. Rest and reduced stress.
6. Use of a sinus irrigation kit.

NCLEX Client Need: Basic Care and Comfort

6. While deciding whether to sign the surgical consent for tracheostomy, the patient's spouse asks, "What is the purpose of this procedure?" Which response(s) demonstrate(s) nursing knowledge regarding the procedure? (*Select all that apply.*)

1. "The procedure facilitates suctioning of respiratory secretions."
2. "The procedure prevents recurrence of respiratory arrest."
3. "The procedure prevents hospital-acquired pneumonia."
4. "The procedure bypasses an obstructed upper airway."
5. "The procedure is a temporary airway for face and neck injuries."

NCLEX Client Need: Physiological Adaptation

7. A 55-year-old man with a new tracheostomy is unable to cough. Breath sounds are diminished. Pulse oximetry is 88% on 100% humidified air. What is the priority nursing action?

1. Provide positive ventilation.
2. Suction respiratory secretions.
3. Administer pain medications.
4. Humidify inhaled air.

NCLEX Client Need: Physiological Adaptation

8. A patient is newly diagnosed with a squamous cell carcinoma of the larynx. What is an early sign and symptom for this diagnosis?

1. Crepitation
2. Hoarseness
3. Frothy sputum
4. Drooling

NCLEX Client Need: Health Promotion and Maintenance

9. A student is caring for a patient diagnosed with OSA. The patient is not convinced that the CPAP machine is worth the effort. What is the most important reason for the patient to receive treatment?

1. Use of the CPAP machine will decrease the risk of pneumonia.
2. Use of the CPAP machine will improve energy levels.
3. Untreated OSA can lead to heart attack and stroke.
4. Untreated OSA can lead to upper airway cancers.

NCLEX Client Need: Health Promotion and Maintenance

10. A nurse is caring for a patient who is postoperative for tonsillectomy. Within the first 24 hours, which food item would be the most appropriate to offer the patient?

1. Orange juice
2. Warm tea
3. Snack crackers
4. Popsicles

NCLEX Client Need: Basic Care and Comfort

Critical Thinking Questions

Scenario A

Mr. Kim has undergone diagnostic procedures to confirm suspected cancer of the larynx. He has been admitted to the hospital for a laryngectomy.

1. What is the primary postoperative issue related to Mr. Kim's nutritional status?
2. Identify interventions and teaching points that will allow Mr. Kim to eat and swallow safely.
3. Devise a postoperative nursing care plan for Mr. Kim, including interventions for psychosocial

problems.

4. What resources in the community could be suggested to help Mr. Kim adjust to his laryngectomy?

Scenario B

Mr. George has undergone a total laryngectomy and radical neck dissection.

1. What structures would have been removed during this surgery and how would his life be affected?
2. How often should his tracheostomy be suctioned?
3. How might you facilitate communication with Mr. George during the postoperative period?

Scenario C

You are not scheduled to work today or tomorrow and you are glad, because you don't feel very well and suspect that you might have a cold.

1. What are the signs and symptoms of the common cold?
2. What measures will you take to prevent the spread of the virus to your family?
3. Describe the interventions that you will use to manage your own symptoms at home.

CHAPTER 14

Care of Patients With Disorders of the Lower Respiratory System

Objectives

Theory

1. Compare and contrast nursing care for patients with bronchitis, influenza, pneumonia, empyema, and pleurisy.
2. Choose nursing interventions appropriate for the care of patients with problem statements of Alteration in airway clearance, Altered breathing pattern, Altered gas exchange, and Fatigue due to hypoxia.
3. Analyze ways a nurse can contribute to prevention and prompt treatment of tuberculosis.
4. Summarize the pathophysiologic changes that occur during an asthma attack.
5. Evaluate problems that occur with aging that may cause a restrictive pulmonary disorder.
6. Describe the specifics of nursing care for a patient who has had thoracic surgery and has chest tubes in place.

Clinical Practice

7. Complete a nursing care plan, including home care, for a patient with chronic obstructive pulmonary disease.
8. Review nursing interventions for a tracheostomy patient receiving oxygen therapy.
9. Teach a patient how to use a peak flowmeter.
10. Observe a respiratory therapist (RT) who is responsible for a patient on a mechanical ventilator and identify how RTs and nurses work together to deliver safe care.

KEY TERMS

- aerosols (ÄR-ö-söls, p. 314)
- asthma (ÄZ-mă, p. 301)
- atelectasis (ä-tĕ-LĒK-tă-sĭs, p. 294)
- bronchiectasis (brōng-kē-ĚK-tă-sĭs, p. 299)

sarcoidosis (sär-koy-DŌ-sīs, p. 298)
subcutaneous emphysema (süb-kū-TĀ-nē-ěs ēm-fī-SĒ-mă, p. 312)
thoracentesis (thō-ră-sěn-TĒ-sīs, p. 298)
thoracotomy (thō-ră-KÖT-ō-mē, p. 312)
thrombolytic (thrōm-bō-LĪT-īk, p. 309)
tuberculosis (TB) (tū-BĚR-kū-LŌ-sīs, p. 294)
ventilator-associated pneumonia (VAP) (p. 293)

Respiratory Infectious Diseases

Acute Bronchitis

Acute bronchitis is often an extension of an upper respiratory infection involving the trachea (**tracheobronchitis**) and is usually viral in origin. Other causes of acute bronchitis include inhalation of physical or chemical agents such as dust, automobile exhaust, industrial fumes, and tobacco smoke.

Early symptoms of acute bronchitis are similar to those of the common cold. Cough producing some sputum is the most common symptom. Sore throat, runny or stuffy nose, headache, muscle aches, and fatigue are also typical. The provider relies on history and signs and symptoms for diagnosis.

Symptomatic treatment includes humidification using either warm or cool moist air. Cough suppressants or bronchodilators are used to reduce coughing and soothe the irritated tracheal and bronchial mucosa. Nutrition and fluid balance should be maintained. Rest is recommended to prevent progression from an acute condition to a chronic one. Antibiotics are used if a sputum culture identifies specific bacterial organisms.

Influenza

Etiology

Influenza is an acute, highly infectious disease of the upper and lower respiratory tracts that occurs in isolated cases or in epidemics. Every year there are between 25 and 50 million cases resulting in more than 200,000 hospitalizations and between 30,000 and 40,000 deaths. Influenza is caused by three major types (A, B, and C) and numerous subtypes of influenza viruses. Type A is the most virulent and usually affects young adults first and then spreads to the very young and very old in the community. Influenza is spread by direct and indirect contact with infected people by coughing and sneezing and by virus transferred from contaminated hands to objects.

Pathophysiology

The influenza viruses affect the respiratory mucosa, causing inflammation and destruction of tissue, which sheds the virus into the secretions. The inflammation may involve the lungs, pharynx, sinuses, and eustachian tubes. The damaged tissue provides an environment for the growth of bacteria that cause secondary infection.

Signs and Symptoms

The first symptoms of influenza appear suddenly 2 to 3 days after exposure and include headache, fever (often 101° to 103° F [38° to 40° C]), chills, and muscle aches. Sore throat, hacking cough, runny nose, nasal congestion, light sensitivity, nausea, vomiting, and diarrhea can also occur. Virus is usually shed for 1 to 2 days before the onset of symptoms.

Diagnosis

Chest radiographs and auscultation are usually normal. The white cell count is normal or slightly below normal. Diagnosis is usually based on clinical findings. To confirm the diagnosis, viral culture, serology, rapid antigen testing, or polymerase chain reaction and/or immunofluorescence assays must be performed. The Centers for Disease Control and Prevention (CDC) recommends testing only when the results will alter treatment decisions ([CDC, 2013](#)).

Treatment and Nursing Management

Antibiotics are given only if there is evidence of bacterial infection secondary to the viral infection. Antibiotics are not effective against viral illness and are contraindicated. Antiviral medications may be used in specific patient populations. If a person is known to be at high risk for influenza and has been exposed to type A influenza, the provider may choose to provide prophylaxis with an antiviral agent such as amantadine (Symmetrel), rimantadine (Flumadine), zanamivir (Relenza), or oseltamivir (Tamiflu). These drugs must be started within 48 hours of the start of symptoms.

Uncomplicated influenza usually is managed more effectively by nursing interventions than by drugs or other forms of medical treatment. Nursing interventions for patients with flu symptoms might include:

- Increase oral fluid intake to at least 3000 mL per 24 hours, unless contraindicated.
- Encourage patient to take analgesics when discomfort first appears.
- Offer saline gargles for a sore throat.
- Administer suppressant cough medicine at bedtime and during the night as prescribed.
- Perform mouth care at least every 4 hours, before each meal, and more frequently if the patient reports a bad taste in the mouth or has halitosis from sputum.
- Cater to the patient's food and drink preferences within the limits of dietary restrictions.
- Give antipyretics and use cooling measures to reduce high fever.
- Humidify inhaled air.
- Splint chest and abdomen with a pillow during coughing attacks.
- Apply emollient to the lips and nares as needed.
- Clear the nostrils as much as possible to prevent mouth breathing.
- Provide for periods of uninterrupted rest.
- Protect from and monitor for secondary infections such as pneumonia, otitis media, and sinusitis, because the weakened immune system causes greater susceptibility.

Health Promotion

Protection From Influenza

 The 2009 Advisory Committee on Immunization Practices recommends annual influenza vaccination for the following groups ([CDC, 2014](#)):

- People at high risk for influenza-related complications and severe disease, including:
 - Children ages 6 to 59 months
 - Pregnant women
 - People older than 50 years
 - People of any age with certain chronic medical conditions
- People who live with or care for persons at high risk, including:
 - Household contacts who have frequent contact with people at high risk and who can transmit influenza to those individuals
 - Health care workers

Complementary and Alternative Therapies

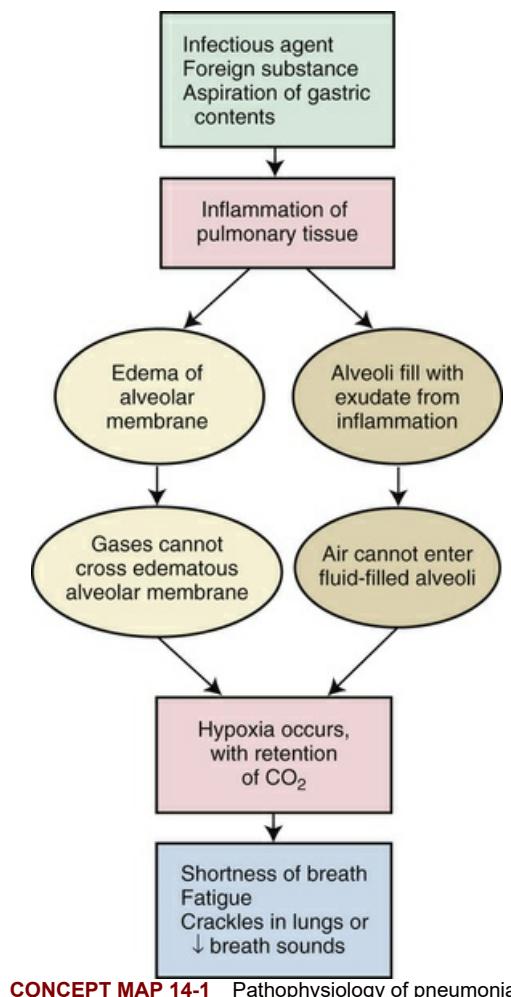

Alternative Therapy for the “Flu”

Elderberry extract has been used for centuries as a treatment to ease symptoms of the flu, colds, and sinus infections. The extract has been proven to inhibit transmission of the flu virus and also has antimicrobial effects on bacteria ([Krawitz et al, 2011](#)).

Pneumonia

Etiology and Pathophysiology

Pneumonia is an extensive inflammation of the lung with either consolidation of the lung tissue as it fills with exudate or interstitial inflammation and edema. It can affect one (most common) or both lungs or only one lobe of a lung (lobar pneumonia). In 2010, 49,597 people died of pneumonia; it is the ninth leading cause (combined with influenza) of death in the United States ([National Vital Statistics Reports, 2013](#)). Bacteria or viruses may cause pneumonia; bacterial pneumonia is more common and is associated with greater symptoms and risks. Pneumonia is classified as community acquired or hospital acquired. Viral pneumonia does not produce exudate; it causes interstitial inflammation and tends to be less severe than bacterial pneumonia. Any respiratory infection in an already debilitated patient can have severe consequences. In otherwise healthy individuals, viral pneumonia is usually a mild, self-limiting illness. *Streptococcus pneumoniae* (pneumococcus) is the most common cause of bacterial pneumonia. Pathogenic microorganisms are always present in the upper respiratory tract; pneumonia can occur when resistance is lowered by some other factor, such as chronic disease, alcoholism, debilitation, physical inactivity, or extremes in age (very young or very old). In many instances pneumonia occurs after an influenza infection. [Concept Map 14-1](#) presents the pathophysiology of pneumonia.

CONCEPT MAP 14-1 Pathophysiology of pneumonia.

Pneumonia also can result from inhalation of irritating gases (*chemical pneumonia*) or accidental aspiration of foods or liquids that cause a pneumonitis progressing to pneumonia (*aspiration pneumonia*). *Hypostatic pneumonia* results from lying in bed for extended periods because of the lack of physical exercise and inadequate aeration of the lungs. Fungi also may cause opportunistic pneumonia in immunocompromised patients. Fungi found in the environment in defined

geographic regions or fungi normally found in the body can both cause pneumonia in patients with congenital or acquired immunocompromise.

Prevention

People who are older than 65 years and those with chronic respiratory disease should receive the pneumococcal pneumonia vaccine. A second dose may be needed 5 years after the first dose for immunocompromised patients or those older than 65 years.

A variety of nursing interventions can help prevent pneumonia, including:

- Strengthening the patient's natural defenses and avoiding infection.
- Ensuring frequent turning, coughing, and deep breathing for postoperative patients or those who are otherwise unable to ventilate their lungs adequately.
- Watching for vomiting and initiating a side-lying position for patients with decreased consciousness, such as patients recovering from anesthesia.
- Maintaining elevation of the head of the bed at 30 to 45 degrees for patients at risk for aspiration with meals or who are receiving tube feedings (unless contraindicated). Check residual before each feeding, or once every 4 hours (Bell, 2011).
- Avoiding thin liquids for patients who are at risk for aspiration.
- Faithfully following principles of cleanliness and asepsis when caring for debilitated patients and those most susceptible to infection.
- Encouraging the pneumonia vaccine for those most at risk for developing the disease.
- Encouraging immunization against influenza.

Cultural Considerations

Ethnic Considerations for the Pneumococcal Vaccine

The Advisory Committee on Immunization Practices (Nuorti, 2010) has recently clarified that routine use of pneumococcal polysaccharide vaccine is not recommended for persons of Alaskan Native or American Indian heritage unless they have underlying medical conditions such as chronic lung, liver, or renal disease. However, local public health authorities may consider recommending the vaccine for occurrences of increased risk.

Patients are at risk for **health care-associated pneumonia (HCAP)** (formerly known as *nosocomial pneumonia*). These at-risk circumstances include **hospital-acquired pneumonia (HAP)**, in which symptoms occur more than 48 hours after admission, or **ventilator-associated pneumonia (VAP)**, in which pneumonia occurs 48 to 72 hours after endotracheal intubation. HCAP is also associated with nursing home or long-term care; intravenous (IV) therapy, chemotherapy, immunosuppressive treatment, wound care; severe chronic obstructive pulmonary disease (COPD); child care facilities, hospitals, and dialysis centers (CDC, 2014). HAP is a major problem that lengthens hospital stays and increases the cost of health care. VAP is the most common health care-associated infection (HAI); however, vigilant and aggressive nursing and respiratory care can greatly decrease the incidence.

People who are on gastrointestinal acid-suppressive therapy should be educated that this may make them more susceptible to community-acquired pneumonia. The research shows mixed results on a direct link, but experts agree that caution should be taken, particularly in the older adult population (O'Neill et al, 2013). Normal gastric acid helps prevent pathogens from colonizing the upper gastrointestinal tract, where they can then be introduced into the respiratory tract.

Signs, Symptoms, and Diagnosis

In typical infectious pneumonia, there is usually a high fever accompanied by chills, a cough that produces rusty or blood-flecked sputum, sweating, chest pain that is made worse by respiratory movements, and a general feeling of malaise and aching muscles. Diagnosis is confirmed by chest radiograph, which reveals densities in the affected lung.

In atypical pneumonia, body temperature can be normal or subnormal, breath sounds can be normal with perhaps only occasional crackles and wheezes, and there may be no pleural

involvement and therefore no pain, dry cough, or feeling of extreme fatigue. Chest radiography reveals diffuse, patchy areas of density.

Treatment

Typical pneumonia is treated with IV or oral antibiotic agents, such as erythromycin, macrolides (clarithromycin [Biaxin]), cephalosporins, aminoglycosides, or fluoroquinolones such as ciprofloxacin (Cipro).

Atypical pneumonia caused by *Mycoplasma* species usually is treated with erythromycin, clarithromycin, or azithromycin. Viral, atypical pneumonia requires no anti-infective therapy, but antiviral medication may be administered. *Pneumocystis jiroveci* (formerly *Pneumocystis carinii* and still referred to as PCP) infection associated with AIDS is treated with aerosolized pentamidine or trimethoprim-sulfamethoxazole (Bactrim) given IV or orally depending on the severity of the infection. According to practice guidelines, the first antibiotic dose should be administered within 4 hours of presentation whenever the admission diagnosis⁸ is community-acquired pneumonia. The timeliness of this therapy is related to decreased mortality rates. Supplemental oxygen is provided as needed. Some patients require mechanical ventilation.

Complementary and Alternative Therapies

Treatment for Pneumonia

Barberry root bark is used against bacteria, fungi, and viruses as well as other organisms and is an alternative treatment for pneumonia. It has antimicrobial action against both gram-positive and gram-negative bacteria. It should not be used during pregnancy, because it can cause spontaneous abortion.

Think Critically

Identify five signs or symptoms found on assessment that might correlate with a diagnosis of pneumonia.

Nursing Management

The nursing care plan for a patient with pneumonia should include interventions to:

- Promote oxygenation
- Control elevated temperature
- Maintain nutritional and fluid intake
- Provide adequate rest
- Monitor vital signs and respiratory status
- Relieve pain and discomfort
- Provide good oral hygiene
- Prevent irritation of the lungs by smoke and other irritants
- Avoid secondary bacterial infections

Clinical Cues

The first signs of decreasing oxygenation may be restlessness or confusion. The patient may want to sit upright to allow for better chest excursion. Respiratory rate will increase, and later there will be flaring of the nares, then retraction of intercostal muscles if the condition worsens. Cyanosis is a very late sign.

The patient should breathe deeply and cough 5 to 10 times each hour while awake to prevent atelectasis, which can lead to pneumonia. It is important to assess for signs of increasing impairment of gas exchange. Unless contraindicated, fluid intake should be increased to 2500 to 3000 mL/day. Because abdominal distention, nausea, and vomiting also may accompany

pneumonia, nursing interventions to deal with these problems may be indicated. Other problems include altered states of consciousness (delirium and confusion) or the development of such complications as empyema and congestive heart failure. For young adults, convalescence with rest should extend for at least a week after acute symptoms subside. Older adults require several weeks before usual activities can be resumed without experiencing fatigue.

Atelectasis

Atelectasis is an incomplete expansion, or collapse, of alveoli. It may occur from compression of the lungs from a lesion in the thorax, a decrease in surfactant, or bronchial obstruction that prevents air from reaching the alveoli. Postoperatively it results from retained secretions that accumulated during anesthesia, positioning on the operating room table for an extended period without movement, and hypoventilation related to surgical pain. It usually is a reversible condition. Breath sounds are diminished when the airways are collapsed, and oxygen saturation (SaO_2) will decrease. Treatment consists of expelling secretions by coughing. Deep breathing and use of the incentive spirometer help to keep the alveoli open and functional.

Clinical Cues

If your postoperative patient has crackles in the bases of his lungs, have him take several deep breaths and cough. Listen again; if the crackles are gone, atelectasis has just been cleared.

Older Adult Care Points

Older adults are more at risk for influenza and pneumonia because of a less efficient immune system, decreased action of cilia, and decreased elasticity and tone of respiratory muscles.

- Confusion often is the most obvious sign of atypical pneumonia in older adults.
- It may take 6 to 12 weeks after a bout of pneumonia for an older adult patient to be able to resume normal activities without experiencing acute fatigue.
- Older adult patients may never quite regain the former level of wellness after a serious episode of pneumonia.
- Teach older adults to seek medical attention quickly if symptoms of pneumonia occur.

Fungal Infections

The most common fungal lung infections are coccidioidomycosis and histoplasmosis.

Coccidioidomycosis occurs primarily in the western United States, and exposure occurs by inhaling dust during desert recreational activities or when working in occupations that require digging in the earth. Typically, there are no symptoms or mild respiratory symptoms, but 40% will have cough, fever, pleuritic chest pain, myalgias, and arthralgias. Sometimes a flat red rash with dark red papules occurs. Histoplasmosis occurs in central and eastern portions of North America. The fungus lives in moist soil such as that in which mushrooms grow, on the floors of chicken houses and bat caves, and in bird droppings. Clinical signs are fever, fatigue, cough, dyspnea, and weight loss over 1 to 2 months.

Other fungal respiratory infections, such as blastomycosis, cryptococcosis, aspergillosis, and candidiasis, are seen mostly in immunocompromised people or those with cystic fibrosis. PCP is found only in immunocompromised patients and is highly lethal (see [Chapter 11](#)). Although classified as a fungal infection, PCP does not respond to antifungal treatment, and trimethoprim-sulfamethoxazole (Bactrim) is the preferred therapy. Fungal infections are diagnosed by history, signs and symptoms, and positive skin test reaction to the fungus.

Tuberculosis

Etiology

Pulmonary **tuberculosis (TB)** is an infectious disease characterized by lesions within the lung tissue. The lesions may degenerate and become necrotic, or they may heal by fibrosis and calcification. The causative organism is the true tubercle bacillus *Mycobacterium tuberculosis*. **Latent TB infection (LTBI)** refers to an infection with *Mycobacterium tuberculosis* but no current active disease. LTBI may develop into active TB if the immune system is weakened by a serious illness such as HIV, or when the system is less efficient, as with advanced age.

Tuberculosis is spread through airborne particles that carry the TB bacilli and are inhaled by a susceptible individual. The droplets can remain suspended in the air for several hours. Infection most often occurs after prolonged exposure, but not everyone contracts the disease, even after close and extensive contact with infected persons.

Cultural Considerations

Ethnic Occurrence of Tuberculosis

American Indians, Alaska Natives, Asian/Pacific Islanders, black non-Hispanics, and Hispanics have a high incidence of TB. The disease is most prevalent in people older than 65 years in these groups. For the first few years of residence in the United States, new immigrants from areas where TB is prevalent have incidence rates similar to those of their former country.

Tuberculosis is a major health problem throughout the world and is second only to HIV-AIDS as the most frequent cause of death for a single infectious agent worldwide ([WHO, 2014](#)). The incidence of TB in the United States has steadily been declining since 1992. In 2012 63% of the reported TB cases in the United States occurred among foreign-born persons ([CDC, 2013](#)). In countries where there are high rates of TB, the World Health Organization strongly recommends the widespread use of bacille Calmette-Guérin (BCG) vaccine, which seems to reduce the morbidity of TB. The vaccine's ability to increase resistance is in question, so it is not used in the United States.

Pathophysiology

Mycobacterium is an acid-fast, aerobic, slow-growing bacillus. When the organism enters the lungs, a local inflammatory reaction occurs, usually in the upper lobe. It takes 2 to 12 weeks for organisms to replicate in sufficient numbers to prompt enough of an immune response to be detected by a TB skin test. Bacilli migrate to the lymph nodes and activate a cell-mediated hypersensitivity response. This triggers granuloma formation with influx of macrophages and lymphocytes at the site of inflammation. The bacillus is walled off, forming a **tubercle**. Caseation necrosis (a core of cheeselike material) develops in the center of the tubercle. In a healthy person, the initial lesions may heal and become latent before any signs or symptoms of the disease occur. Over time the tubercles eventually calcify. Bacilli may remain viable in a dormant state inside the tubercle for many years. In the unhealthy individual, the bacilli spread to other parts of the lung and to other organs.

Signs and Symptoms

The onset of TB is gradual; a patient may have an active, progressive lesion before symptoms appear. Typical symptoms are cough, low-grade fever in the afternoon, anorexia, loss of weight, fatigue, night sweats, and sometimes **hemoptysis** (blood in sputum). Tight or dull chest pain and mucopurulent sputum may occur as the disease progresses. Persons with LTBI are asymptomatic and have a negative chest radiograph.

Older Adult Care Points

The older adult population may not experience the expected signs and symptoms of TB, because the immune response is not as strong. In many instances active TB infections present as chronic pneumonitis.

Diagnosis

Early detection of TB is of great importance because:

- The anti-TB drugs are more effective in the early stages of the disease.

- The period of disability is much shorter.
- The complications are fewer.
- The spread to others can be prevented.

Tuberculin skin testing.

Food handlers, those working with children, and health care workers must be periodically tested. Others who are symptomatic or have been exposed to someone with TB should be tested. Skin testing for TB is done by the Mantoux test. In this test, 0.1 mL of purified protein derivative (PPD) tuberculin is injected intradermally. The test is called the *tuberculin skin test (TST)* (formerly known as *PPD test*). The test is positive when the swelling at the site of injection is more than 5 mm in diameter 48 to 72 hours after injection in people who have a history of contact with infectious TB or in immunocompromised patients. Induration of more than 10 mm in diameter is positive in recent immigrants from countries where TB is prevalent, in medically underserved groups, and the homeless (Figure 14-1). For those persons at low risk, induration of more than 15 mm is considered positive. Skin testing is only contraindicated for those who have had a severe reaction. Vaccination with BCG is not a contraindication but must be considered when interpreting the results (CDC, 2012).

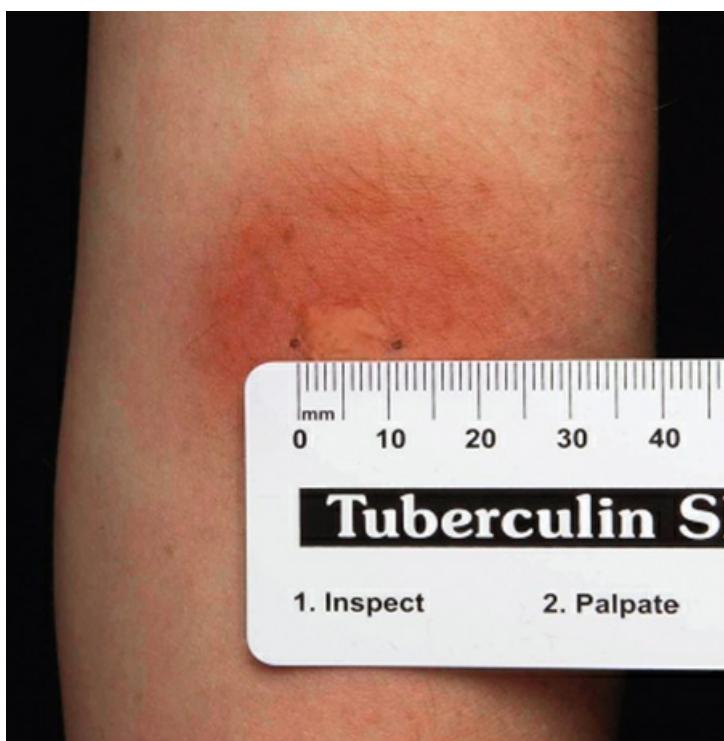

FIGURE 14-1 Positive TB skin test. Raised area (induration) is measured, not the entire reddened area. (Courtesy CDC: Tuberculosis tuberculin skin testing, 2012. Retrieved from: <http://www.cdc.gov/tb/publications/factsheets/testing/skintesting.htm>).

A positive tuberculin test indicates that the person has been infected with the tubercle bacillus; however, it does not indicate whether the disease is active or inactive, only that the body tissues are sensitive to tuberculin. A positive reaction indicates a need for further evaluation. Once positive, subsequent TSTs will always be positive.

Blood testing.

Two blood tests are approved by the U.S. Food and Drug Administration (FDA): the QuantiFERON-TB Gold (QFT-GIT) and T-SPOT.TB test (T-Spot). The tests are interferon-gamma release assays (IGRAs) that measure the patient's immune system reaction to TB. They do not distinguish between active and latent TB. They are less likely to produce false-positive readings and require only one visit to the clinic or office for a blood draw, rather than the two required for the

TST (the second visit is for reading the result). The tests are accurate even for people who have had BCG.

Radiographic examinations and sputum cultures.

A radiographic examination of the chest may or may not reveal tubercular lesions in the lung, but calcified and healed lesions can usually be seen on radiographs. A **diagnosis of active TB is established when the tubercle bacillus has been found in the sputum or gastric washings**. A sample of stomach contents may be examined (*gastric analysis*) if an adequate sputum specimen cannot be obtained. Gastric washings are done rarely in adults but more commonly in children. Sputum cultures are slow growing, and culture results take 1 to 3 weeks to allow identification of the bacillus. The culture report also indicates to which medications the organism is sensitive.

Treatment

Uncomplicated pulmonary TB is managed in the outpatient setting. Only those who are extremely debilitated or suffering from another chronic illness are hospitalized. Treatment of active TB consists of at least four drugs for an extended period of time (Table 14-1). The drugs are given in varying combinations and varying numbers of days per week. The treatment protocols outline the initial 2-month phase followed by a choice of several options for the continuation phase of either 4 or 7 months. Noncompliance is an issue because of side effects, the requirement to avoid alcohol, and the long duration of therapy. Drug combinations are available that make compliance easier for patients: Rifamate, which contains rifampin (RIF) and isoniazid (INH), and Rifater, which contains RIF, INH, and pyrazinamide (PZA). Effective cure can be obtained within 6 to 9 months for most patients with pulmonary TB. A two-drug regimen of INH and RPT on a once weekly dosing schedule for 12 weeks is used for LTBI.

Complementary and Alternative Therapies

Vitamin D Speeds Up Clinical Recovery From Tuberculosis

Vitamin D has been found to be effective in the treatment of TB (Salahuddin et al, 2013). Supplementation with vitamin D activates the immune system. White blood cells convert vitamin D into an active form that helps make a protein that kills TB bacteria. This may be why moving to a sunny climate and a solarium environment helped people with TB in the past.

Table 14-1

Drugs Commonly Used in the Treatment of Tuberculosis

Daily Dosage	Other Dosing Schedules	Most Common Side Effects	Test for Side Effects	Remarks
Primary Drugs				
Isoniazid (INH) 5 mg/kg up to 300 mg/24 hr PO or IM	15 mg/kg PO, or IM 2 or 3 times a week Usual dose 900 mg total	Peripheral neuritis, hypersensitivity, jaundice	AST/ALT monthly Drug levels: 3-5 mg/L at 2 hr	Bactericidal agent. Pyridoxine as prophylaxis for neuritis; 25-50 mg/24 hr as treatment.
Ethambutol (EMB) (Myambutol) 15-25 mg/kg PO up to 1600 mg/24 hr	35-50 mg/kg PO twice per week up to 4000 mg Or 20-35 mg/kg	Optic neuritis (reversible with discontinuation of drug; very rare at 15 mg/kg), skin rash	Baseline and monthly red-green color discrimination and visual acuity Drug levels: 2-6 mg/L at 2 hr	Use with caution with renal disease or when eye testing is not feasible.
Rifampin (RIF) (Rifadin) 10 mg/kg up to 600 mg/day PO or IV	10 mg/kg PO or IV 2 or 3 times per week up to 600 mg/day	Rash, hepatitis, febrile reaction, purpura (rare)	AST/ALT monthly in patients with preexisting liver disease Drug levels: 8-24 mg/L at 2 hr	Bactericidal agent. Orange secretion color. Affects action of other drugs.
Pyrazinamide (PZA) 15-30 mg/kg up to 2 g/day PO	50 mg/kg PO twice weekly up to 2 g/dose	Hyperuricemia, hepatotoxicity	Uric acid, AST/ALT	Under study as first-line drug in short-course regimens.
Rifabutin (RBT) 5 mg/kg (300 mg) PO	5 mg/kg (300 mg) PO 2 or 3 times weekly	Causes discoloration of urine. Neutropenia, leukopenia	CBC	May be used as a substitute for RIF.
Rifapentine (RPT) 600 mg PO once weekly for 4 months during continuation phase.	600 mg twice per week during intensive phase	Hypertension, headache, dizziness	Hepatic enzymes, bilirubin, CBC	May be used once a week in combination with INH in select patients in the continuation phase of treatment.
Secondary Drugs				
Streptomycin (SM) Capreomycin (Capastat) Cycloserine (Seromycin) p-aminosalicylic acid Ethionamide* (Trecator) Kanamycin* (Kantrex) Levofloxacin* Moxifloxacin* Gatifloxacin*				These drugs are reserved for special situations such as drug intolerance or resistance.

*Not approved by the U.S. Food and Drug Administration for use in the treatment of tuberculosis.

ALT, Alanine aminotransferase; AST, aspartate aminotransferase; IM, intramuscularly; IV, intravenously; PO, orally.

Adapted from Lewis SL, Heitkemper MM, Dirksen SR: *Medical-surgical nursing: Assessment and management of clinical*

problems, ed. 8, St. Louis, 2011, Mosby.

A new drug, pretomanid, that seems to be extremely effective in quickly killing TB has completed clinical trials and is in data analysis ([Working Group on New TB Drugs, 2013](#)). A shorter treatment time could improve compliance with medication therapy. There is an increase in the incidence of multidrug-resistant TB, and patients with these infections do not fare well. For this reason, directly observed therapy (DOT) is recommended for patients who are known to be at risk of noncompliance with therapy ([CDC, 2012](#)). DOT involves visual observation of the ingestion of each required dose of medication for the entire course of treatment. Often a public health nurse administers the medication at a clinic site. Follow-up visits are necessary for 12 months after completion of therapy to monitor for the presence of resistant strains.

Legal and Ethical Considerations

Noncompliance With Medication

When someone is found to have TB and the person is noncompliant with the treatment, is it legal or ethical to compel the person to come for treatment? What will happen if the person is allowed to remain in the community without treatment?

Nursing Management

A complete history and assessment of TB risk factors is needed. A focused assessment of the respiratory system is performed (see Focused Assessment).

Nursing objectives are to control the spread of the infectious agent, promote immunity, and strengthen potential recovery in a patient with an infectious disease. Problem statements/nursing diagnoses for the patient with TB may include:

- Altered breathing pattern due to decreased lung capacity.
- Absence of compliance due to lack of knowledge of disease process and long-term requirements for treatment.
- Altered activity tolerance due to fatigue, febrile status, and poor nutritional status.
- Altered Nutrition due to anorexia, fatigue, and productive cough.

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

Control of infection.

Airborne Infection Isolation in addition to Standard Precautions (see [Appendix B](#)) are recommended for hospitalized patients who have active TB and are just beginning drug therapy. The patient is placed in a negative-pressure isolation room with an anteroom. A high-efficiency particulate air (HEPA) respirator mask that tightly fits the face or use of a powered air purifying respirator (PAPR) is required for all personnel when caring for the patient. The home care patient does not need Airborne Infection Isolation because family members have already been exposed by the time of diagnosis. Patients and families should be educated about the importance of medication compliance and the basic principles of infection control: covering the mouth when coughing or sneezing, disposing of tissues in plastic bags, practicing good hand hygiene, and wearing a mask when in contact with crowds until medication effectively suppresses the infection. Sputum examinations are required monthly during the course of treatment. When sputum cultures are negative and the clinician evaluates the effectiveness of the treatment, the patient is considered no longer infectious and may resume work and other usual social activities.

Close contacts are monitored with skin or blood testing. If the TST or IGRA result is positive, the contact is treated with INH, RPT, or RIF depending on whether the type of TB is known to be drug resistant. HIV infected, pregnant, or breastfeeding individuals as well as infants and children have specific recommended drug combinations and doses. The CDC website has the most current treatment recommendations.

Promotion of immunity.

Improving living conditions and carrying out sound health practices are essential to maintaining a natural resistance to TB. The populations most at risk for contracting TB are those with an

insufficient immune system. That is why the very young and the very old as well as those with immunosuppression from disease or disease treatment are at increased risk.

Several vaccinations are in clinical trials in the hopes of boosting immunity to the TB organism. Good ventilation and healthful living can prevent the spread of TB.

Support.

When a person first learns that he has [tuberculosis](#), he will need support in sorting out his feelings and overcoming any fears and misinformation he might have.

It is also important that the patient name all close contacts, so that they can be notified and appropriately tested and treated. Giving the names of contacts may be very difficult for the patient because of the social stigma that is still attached to TB in certain cultural groups.

Extrapulmonary Tuberculosis

It is possible for the tubercle bacillus to attack and damage parts of the body other than the lungs. This is called *extrapulmonary* or *miliary tuberculosis*. The areas most commonly affected are the lymph nodes, bones, meninges, digestive system, urinary system, and reproductive system. Presenting signs and symptoms are dependent on the body system affected. Tuberculosis of the spine, called *Pott disease*, can cause **kypnosis**, or “hunchback,” but the condition is rare in the United States.

Occupational Lung Disorders

Coal dust; dust from hemp, flax, and cotton processing; and exposure to silica in the air can cause work-related lung disorders. Asbestos exposure may cause mesothelioma, a rare cancer of the chest lining ([Mesothelioma Research Foundation of America, 2015](#)). Asbestos exposure also causes scarring of lung tissue. The other exposures cause obstruction of small airways or scarring and loss of elasticity and compliance. Occupational history is part of the respiratory assessment.

Restrictive Pulmonary Disorders

Restrictive pulmonary disorders are caused by decreased elasticity or compliance of the lungs or decreased ability of the chest wall to expand. Disorders of the central nervous system or of the neuromuscular system can cause a restrictive lung disorder. Myasthenia gravis and arthritis are examples of extrapulmonary causes. **Kyphosis** of the spine or severe **scoliosis** may hamper lung expansion, but the lung tissue remains normal. Obesity is becoming a major cause of restrictive lung disease.

Interstitial Pulmonary Disease

Sarcoidosis

Sarcoidosis is a lung disease characterized by granulomas. This disease causes fibrotic changes in the lung tissue and other tissues over time. A cellular immune response seems to be responsible, but the exact cause is unknown. Sarcoidosis is 10 times more common in African Americans than in whites, and most cases occur between ages 20 and 40 years. The fibrotic changes cause a reduction in functional lung tissue. Although there is no specific treatment for sarcoidosis, most patients recover without treatment.

Pulmonary Fibrosis

Pulmonary fibrosis occurs from environmental pollutants, some medications, and interstitial lung diseases that scar the lungs. Occupational inhalation of lung irritants, smoking, and radiation treatments to the chest are risk factors. Signs and symptoms are exertional dyspnea, nonproductive cough, and inspiratory crackles and sometimes clubbed fingers. Diagnosis is by chest radiograph and pulmonary function testing. There is a 30% to 50% survival rate at 5 years after diagnosis. Treatment is with corticosteroids, immunosuppressants, and the antifibrotic agent colchicine. Lung transplantation is an option for some patients.

Pleurisy

Pleurisy—an inflammation of the pleura—can be caused by tuberculosis, pneumonia, neoplasm, or pulmonary infarction. Pleurisy pain is sharp and abrupt in onset and is most evident on inspiration. This causes shallow breathing. A pleural friction rub may be heard. Treatment is aimed at the underlying cause and providing pain relief. Lying on the affected side or splinting the affected side during coughing may provide some relief. An intercostal nerve block may be performed for severe pleurisy pain.

Pleural Effusion

Pleural effusion is a collection of fluid in the pleural space. Transudate is a thin fluid containing no protein that passes from cells into interstitial spaces or through a membrane. A transudate occurs in noninflammatory conditions and is often a result of congestive heart failure, chronic liver failure, or renal disease. Exudate is thicker; contains cells, proteins, and other substances; and is slowly discharged from cells into a body space or to the outside of the body. Exudative pleural effusion is caused by increased capillary permeability characteristic of the inflammatory reaction. This type of effusion occurs with lung cancer, pulmonary embolism, pancreatic disease, and pulmonary infections.

When pleurisy is accompanied by effusion of serous fluid, the provider may perform a **thoracentesis** (removal of fluid from the pleural cavity) for diagnostic tests or symptom relief. It is not uncommon for as much as 500 mL to be removed during a thoracentesis (see [Table 12-1](#)).

Empyema

Empyema occurs when the fluid within the pleural cavity becomes infected and the exudate becomes thick and purulent. The most common organisms causing this type of infection are staphylococci and streptococci. One or more chest tubes are inserted, and a closed drainage system

is established to remove fluid from the pleural cavity. A specimen of the fluid is sent for a culture and sensitivity, which determines the choice of antibiotic therapy.

Obstructive Pulmonary Disorders

Obstructive pulmonary disorders are characterized by problems with moving air out of the lungs, contributing to air trapping, thus making exhalation difficult. Asthma, emphysema, bronchiectasis, cystic fibrosis, and chronic bronchitis are examples of diseases that cause chronic airflow limitation (CAL). The increase in the morbidity and mortality rates resulting from obstructive disorders is attributed to cigarette smoking and rising levels of air pollution. A third factor is genetic. **Alpha₁-antitrypsin (AAT)** is a serum protein that inhibits the activity of the enzyme **elastase**, which tends to break down lung tissue. In the absence of AAT, lung tissue is more easily destroyed by the enzyme. Patients with a deficiency of AAT may develop severe lung disease at an early age. Cystic fibrosis is also genetically acquired.

Bronchiectasis

Bronchiectasis is a chronic respiratory disorder in which the bronchi are permanently dilated. It occurs as a result of frequent respiratory infections or inflammation. Frequent aspiration of food particles can also cause the condition. In the United States, about one third of all bronchiectasis is caused by cystic fibrosis.

Cystic Fibrosis

Cystic fibrosis (CF) is a genetic disease (more common among whites) in which there is excessive mucus production because of exocrine gland dysfunction. The lungs, intestines, sinuses, reproductive tract, sweat glands, and pancreas are all affected. It is diagnosed by history, physical examination, and a positive sweat test.

Lung damage occurs in CF because of excessive secretion of abnormally thick mucus, impairment of ciliary action in the lungs, airway obstruction, and repeated infections, which cause scarring. It was once a pediatric disease, because children with CF died before reaching adulthood. Individuals with CF now live into their 40s and beyond with aggressive respiratory treatment and antibiotics. Current research has identified that the gene that causes CF can be damaged in more than one way. Ivacaftor is a new treatment that is effective in 4% of patients with CF by supplying the chemicals missing as a result of gene malfunction. A drug in clinical trials will address another 10% of patients, but 70% to 75% of patients with CF have a different problem with the gene for which an effective treatment has not been developed. These medications actually treat the problem rather than the symptoms, and the progress made so far is encouraging and has improved life for many patients. Treatment of symptoms includes bronchodilators, expectorants, oral pancreatic enzymes, double doses of fat-soluble vitamins, and mucolytics. A high-protein, high-calorie, moderate-fat diet is prescribed. Dornase alfa (Pulmozyme) reduces the frequency of respiratory infections and improves pulmonary function for patients with CF by decreasing the viscosity of sputum. DNase, a recombinant deoxyribonucleic acid (DNA) medication, is also used to reduce the thickness of the sputum. Breathing exercises and chest physiotherapy are used daily. A handheld device called a flutter valve, that looks like a fat pipe, is used to loosen secretions. By exhaling actively into the pipe, the device causes vibrations of the airway walls, loosening secretions so that they can be coughed up. Lung transplantation is a possible lifesaving measure. The Cystic Fibrosis Foundation is hopeful that the new drug therapies will eliminate the need for lung transplants for patients with CF.

Chronic Obstructive Pulmonary Disease

The World Health Organization uses the term **COPD** to describe a condition that includes two diseases, **emphysema** (Figure 14-2) and **chronic bronchitis**. Approximately 12.7 million people in the United States have COPD, and 24 million have impaired lung function with probable underlying COPD ([American Lung Association, 2010](#)).

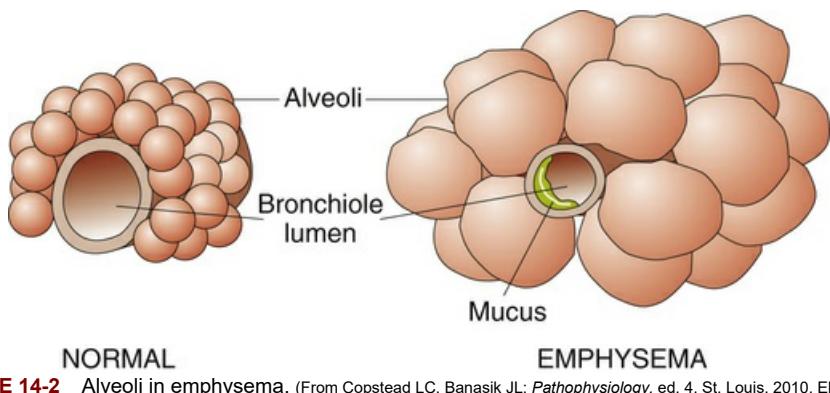

FIGURE 14-2 Alveoli in emphysema. (From Copstead LC, Banasik JL: *Pathophysiology*, ed. 4, St. Louis, 2010, Elsevier.)

Etiology and Diagnosis of Chronic Obstructive Pulmonary Disease

Smoking and AAT deficiency are causes of emphysema and chronic bronchitis. Air pollution and occupational exposure are other risk factors. Tobacco smoke exposure accounts for as much as 90% of COPD risk, including smoking and secondhand smoke. AAT deficiency is the cause for less than 1% of cases. Firefighters, welders, farmers, and others who have repetitive exposure to dust and particulate matter are in the high-risk group. Diagnosis is by history, physical assessment, and spirometry readings before and after bronchodilator treatment. A chest radiograph is not useful in diagnosing COPD, but it can help rule out other causes of the symptoms.

Treatment of Chronic Obstructive Pulmonary Disease

COPD is treated with bronchodilators and anti-inflammatory agents. When bacterial infection is present, antibiotics, and sometimes steroid anti-inflammatory agents, are used. In later stages of disease, when hypoxemia is present, oxygen therapy is initiated. **Oxygen is always used cautiously in patients with COPD, because they have adjusted to high levels of CO₂; they become dependent on low oxygen levels to stimulate breathing.** Smoking cessation is very important. Respiratory rehabilitation programs can help increase exercise tolerance and improve quality of life.

Nutrition is very important for patients with COPD, because the extra work of breathing uses more calories, and anorexia may be present. Extra protein is required to repair damaged tissues. It is beneficial to maintain as normal a weight as possible for height and age.

For severe emphysema, surgical interventions have been shown to be helpful in selected patients. Lung volume reduction surgery (LVRS) removes portions of damaged lung tissue. This allows for greater expansion of the residual tissue. This intervention has had more success for patients with upper-lobe emphysema. Lung transplantation may be considered for patients meeting selection criteria.

■ Nutritional Considerations

Nutritional Suggestions for Patients With Chronic Obstructive Pulmonary Disease

The following tips may help patients with COPD:

- Drink 6 to 8 glasses of noncaffeinated fluids per day to keep mucus thin and easier to cough up. Check with your provider if you are on fluid restrictions.
- Rest before eating.
- Avoid overeating, and avoid foods that cause gas or bloating, because a distended stomach may make breathing more difficult.
- Eat four to six small meals a day rather than three regular meals, to decrease stomach fullness and reduce fatigue.
- Eat a well-balanced diet with adequate protein.

- Avoid lying down for an hour after eating.
- If you become short of breath while eating or right after meals:
- Clear the airway 1 hour before eating.
- Take small bites and chew food slowly.
- Choose foods that are easy to chew.
- Drink beverages at the end of the meal rather than during it.
- Use your oxygen cannula while you eat.
- Take in sufficient calcium via dairy products, vegetables, and supplements—steroid medications put you at risk for osteoporosis.
- Cook when feeling most energetic; make extra portions and freeze them for easy, quick, reheatable dinners.

Complementary and Alternative Therapies

Ginger, Cinnamon, Chili, and Garlic for Emphysema

Ginger and cinnamon are aromatic digestives that provide benefit for emphysema patients. Very small doses of *Capsicum annuum* (chili) or garlic can be useful as mucolytic agents ([Bone and Mills, 2013](#)).

Complications of Chronic Obstructive Pulmonary Disease

Cor pulmonale.

Cor pulmonale is enlargement of the right side of the heart as a result of pulmonary hypertension caused by constriction of the pulmonary vessels in response to hypoxia. To overcome the increased pressure in the lungs, the right side of the heart has to pump more forcefully, causing enlargement. Constant hypoxia stimulates erythropoiesis, with resulting polycythemia and increased viscosity of blood. Eventually right-sided heart failure causes systemic venous congestion, which manifests as distended neck veins, right upper quadrant tenderness from an engorged liver, peripheral edema, weight gain, gastrointestinal distress, and ascites. Treatment is continuous low-flow oxygen and medications to treat both the heart failure and the fluid volume overload.

Gastroesophageal reflux disease.

Gastroesophageal reflux disease (GERD) is twice as likely to occur in patients with COPD. It can worsen the symptoms of COPD; the reflux of acid in the esophagus stimulates bronchoconstriction, and microaspiration may contribute to lung tissue damage ([Kim et al, 2013](#)).

Think Critically

List five nursing interventions that might help your patient with COPD prevent episodes of dyspnea.

Emphysema

Pathophysiology

In **emphysema**, there is destruction of alveolar and alveolar-capillary walls, as well as narrowed and tortuous small airways. This leads to large, permanently inflated alveolar air spaces. Air that is inhaled becomes trapped, and it becomes harder to exhale air than to inhale it (see [Figure 14-2](#)). As emphysema progresses, lung elasticity decreases.

Signs and Symptoms

Dyspnea is an early symptom of emphysema. There is minimal coughing with small amounts of mucoid sputum. As the disease progresses, dyspnea worsens and eventually interferes with activities of daily living. The diaphragm becomes permanently flattened by overdistention of the lungs, the muscles of the rib cage become rigid, and the ribs flare outward. The patient develops a “barrel chest” (see [Chapter 12](#), [Figure 12-8](#)).

To compensate for the loss of normal muscular action, the patient begins to use the neck and shoulder muscles. The shoulders are held high in an attempt to enlarge the space for lung expansion. The patient may look anxious or tense. The skin is a pink tone in whites even though hypoxia may be present. Early in the disease process carbon dioxide is usually not retained, and therefore an acid-base imbalance is unlikely. As the disease progresses, both hypercapnia and hypoxemia as well as chronic respiratory acidosis are usually present.

Chronic Bronchitis

Pathophysiology

In chronic bronchitis there is excess secretion of thick, tenacious mucus that decreases ciliary function, interferes with airflow, and causes inflammatory damage to the bronchial mucosa. Airways become edematous and narrowed, and air trapping occurs. Initially the larger airways are affected, and then the smaller airways also become obstructed. Inflammation of the bronchi is considered chronic when a recurrent cough is present for at least 3 months of each year for at least 2 years. Respiratory infections occur frequently because the thick mucus provides a growth medium for bacteria.

Signs and Symptoms

Symptoms can range from a mildly irritating “cigarette” cough in the morning with production of small amounts of sputum to a severe, disabling condition. The latter extreme is characterized by increased resistance to airflow, hypoxia, and development of hypercapnia (excess CO₂).

Pulmonary function testing reveals an increased residual volume caused by the premature closure of the narrowed airways during exhalation. The patient has a marked increase in partial pressure of arterial carbon dioxide (PaCO₂) levels and a marked decrease in partial pressure of arterial oxygen (PaO₂) levels. **The retention of carbon dioxide and deficiency of oxygen give the skin and/or mucous membranes a reddish-blue color.** The reddish color is also related to an increase in the red blood cell count (**polycythemia**) that is an attempt by the body to compensate for chronic hypoxia. Hemoglobin and hematocrit levels are elevated for patients with chronic bronchitis. [Table 14-2](#) presents a comparison of emphysema and chronic bronchitis.

Table 14-2
Comparison of Pulmonary Emphysema and Chronic Bronchitis

Clinical Features/Characteristics	Emphysema	Chronic Bronchitis
Age of onset (years)	40-50	30-40
Pathophysiology	Destruction of alveolar walls Loss of elasticity, impaired expiration, hyperinflation	Increased mucous secretion, inflammation and infection, obstruction of airways
Health history	Generally healthy	Frequent URI, acute episodes
Smoking	Usually	Usually
Clinical features		
Barrel chest	Yes	May be present
Weight loss	May be severe in late disease	Uncommon
Shortness of breath	Absent early; pronounced late in disease	Early symptom; especially with activity
Decreased breath sounds	Yes	Variable
Wheezing	Usually absent	Variable
Sputum	Absent or develops late in disease	Early sign; frequent infections with purulent sputum
Cyanosis	Usually absent; appears late in disease with low PaO ₂	Yes; worsens as disease progresses
Cor pulmonale	Occasional	Common
Polycythemia	May appear in advanced disease	Commonly present
Blood gases	Normal until late in disease	May display hypercapnia Hypoxemia common

PaO₂, Partial pressure of arterial oxygen; URI, upper respiratory infection.

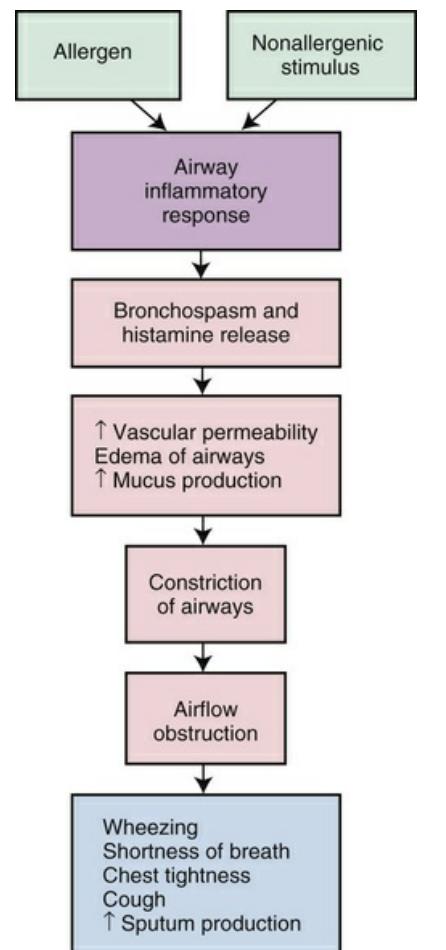

Asthma

Etiology

Factors implicated in the occurrence of asthma include allergens, viruses and other infectious agents, occupational and environmental toxins, exercise, perfumes, genetics, obesity, and emotional stress. *Healthy People 2020* objectives include reducing deaths, hospitalizations, emergency department visits, and activity limitations related to asthma.

Pathophysiology

Asthma is a chronic lung disease characterized by reversible airway obstruction, airway edema or swelling from inflammation, and increased airway hypersensitivity to a variety of stimuli. With asthma, a precipitating factor creates inflammation of the airways, which causes bronchospasm and edema. Cough usually indicates obstruction of the larger airways. Dyspnea, another common symptom, is indicative of inflammation of the airways, mucosal edema, and excessive secretion of mucus, which cause a plugging of the small airways. With bronchoconstriction, there is further obstruction and narrowing of the airways, limiting airflow (Figure 14-3 and Concept Map 14-2).

CONCEPT MAP 14-2 Pathophysiology of asthma.

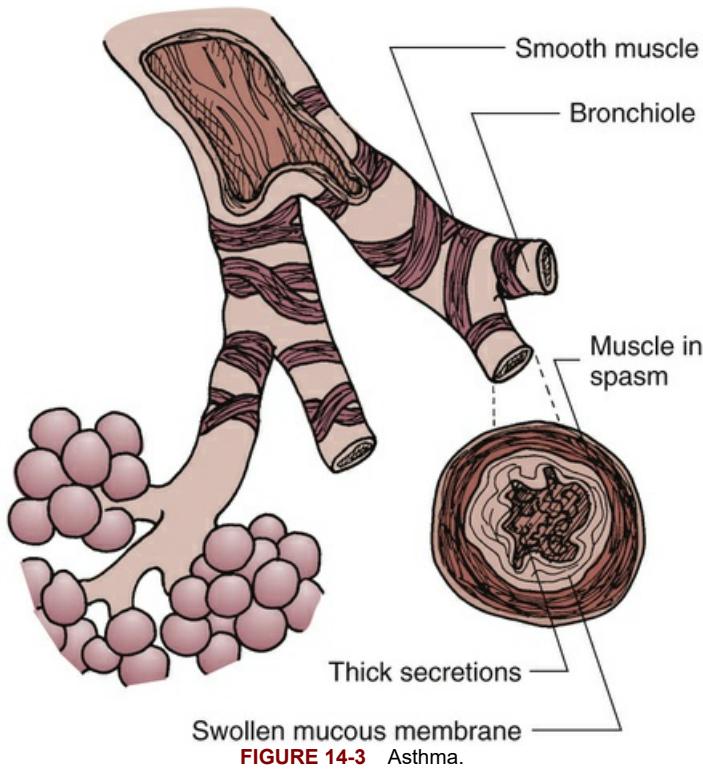

FIGURE 14-3 Asthma.

Signs, Symptoms, and Diagnosis

Diagnosis is by history, physical examination, pulmonary function testing, arterial blood gas analysis, and chest radiograph. The symptoms may be continuous or episodic. Findings include wheezing, cough that is worse at night, difficulty breathing, and chest tightness.

Unrelieved asthma attacks become **status asthmaticus** and are very serious. **Respiratory distress without wheeze is an ominous sign for the asthma patient; this suggests further constriction with very little air movement.** Patients and nurses must know that a severe, acute asthma attack can cause death from hypoxia.

Clinical Cues

If your patient takes an angiotensin-converting enzyme (ACE) inhibitor, teach him to report a cough (which can be caused by this medication). Excessive coughing can trigger or worsen an asthma attack.

Treatment

Asthma is classified by a step system, based on the degree and frequency of symptoms and broken into age groups. See **Table 14-3** for an example of treatment for adults. The goals of medical treatment are to manage the underlying symptoms and include:

- Minimizing irritation of the air passages and relieving obstruction by secretions, edema, or bronchospasm
- Preventing or controlling infection and allergy
- Increasing the patient's tolerance for activity
- Determining the best drug combinations in the smallest dosages that will control symptoms

Table 14-3

The Step System of Asthma Treatment

Clinical Manifestations	Treatment Recommendations
I. Mild Intermittent Symptoms or episodes occur less than once a week.	No daily medication needed.

Episodes/exacerbations are short, lasting only a few hours. Symptoms are present at night no more frequently than twice per month. PFTs are normal between episodes. During episodes/exacerbations, FEV ₁ or PEF is at least 80% of normal. PEF variability is less than 20%.	Use of short-acting inhaled beta agonist during episodes (rescue inhaler). Increased use of rescue inhaler indicates the need to start long-term therapy.
II. Mild Persistent Symptoms or episodes occur more than once per week but not daily. Symptoms are present at night more than twice per month. During episodes/exacerbations, FEV ₁ is at least 80% of normal. PEF variability is 20%-30%. Episodes affect sleep and activity.	Use of a daily anti-inflammatory. Inhaled corticosteroid (ICS). Inhaled cromolyn. Leukotriene antagonist. Use of a rescue inhaler for relief during episodes.
III. Moderate Persistent Symptoms occur daily. Symptoms or episodes occur more than once per week. Symptoms are present at night at least once per week. During episodes/exacerbations, FEV ₁ is only 60%-80% of normal. PEF variability is greater than 30%.	Daily use of ICS (low to moderate dose). Use of long-acting inhaled beta agonist (bronchodilator). Use of a rescue inhaler for relief during episodes (more than 2 days per week, the patient should be evaluated for progression to step IV).
IVa. Severe Persistent Episodes/exacerbations are frequent. During episodes/exacerbations, FEV ₁ or PEF is less than 60% of normal. Physical activity is limited. Symptoms are frequently present at night. PEF variability is greater than 30%.	Daily use of ICS (medium dose) and long-acting inhaled bronchodilator or ICS (medium dose) and either a leukotriene receptor antagonist or theophylline.
IVb. Severe Persistent, Not Responsive to the Previous Step	High-dose ICS and long-acting beta agonist. Omalizumab for patients with exposure to nonseasonal allergens. Lowest possible daily dose of oral corticosteroids.

FEV₁, Forced expiratory volume in 1 second; *ICS*, inhaled corticosteroid; *PEF*, peak expiratory flow; *PFTs*, pulmonary function tests.

Adapted from Ignatavicius DD, Workman L: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 6, Philadelphia, 2010, Elsevier Saunders.

Bronchodilators in the form of beta-adrenergic agonists, theophyllines, or anticholinergic agents such as ipratropium bromide (Atrovent) are mainstays of therapy. Corticosteroids, mucolytics, and antibiotics may also be prescribed (Table 14-4). Oxygen is prescribed for moderate and severe hypoxemia. For acute episodes of hypoxemia, O₂ is given to raise the SpO₂ to 92 mm Hg or greater.

Clinical Cues

A metered-dose inhaler (MDI) is incorrectly used much of the time. The inhaler should be held 1 to 2 inches in front of the mouth. A slow deep breath is started through the mouth, then the activator is depressed. If patients put their mouth around the inhaler mouthpiece, they do not get all of the dose. This is only for liquid inhalers, not dry powder inhalers.

Table 14-4

Commonly Prescribed Drugs for Chronic Obstructive Pulmonary Disease and Asthma*

Classification	Action	Nursing Implications	Patient Teaching
Bronchodilators			
Short-Acting Beta-Adrenergic Agonists			
Albuterol (Proventil, Ventolin) Pirbuterol (Maxair) Levalbuterol (Xopenex)	Stimulates beta-adrenergic receptors, producing bronchodilation Increases ciliary action and mucus clearance Selectively stimulates beta-adrenergic receptors, producing bronchodilation	All may be administered by MDI. Some can be administered orally or by nebulizer. Monitor tachycardia, BP changes, nervousness, palpitations, muscle tremors, and dry mouth. May cause nausea, headache, insomnia, and hypokalemia. Acts in 5-10 min and lasts for 3-4 hr.	Should not be used in patients with cardiac disorders or angina. Increase fluid intake; watch for signs of potassium deficit. Wait 5 min before using a glucocorticoid inhaler (anti-inflammatory). Teach to use MDI correctly.
Anticholinergics			
Ipratropium (Atrovent)	Causes bronchodilation by blocking action of acetylcholine	Do not mix with cromolyn sodium. Use cautiously in those with narrow-angle glaucoma, prostatic hypertrophy, or bladder neck obstruction.	Do not take more than two puffs at a time. Avoid excessive use of caffeine.
Ipratropium and albuterol (Combivent)	Causes bronchodilation by stimulating beta-adrenergic receptors, and blocking action of acetylcholine		
Tiotropium bromide (Spiriva)	Causes bronchodilation by inhibiting receptors on the smooth muscle		
Long-Acting Beta-Adrenergic Agonists			
Salmeterol (Serevent) Formoterol (Foradil) Olodaterol (Striverdi Respimat)	Relaxes bronchial smooth muscle, producing bronchodilation	Monitor for tachycardia, muscle tremors, hypokalemia. Salmeterol should be combined with fluticasone (Advair). Fomoterol should be combined with budesonide.	Not to be used for acute symptoms or exacerbations.
Methylxanthine Derivative			
Aminophylline (Theo-Dur, Slo-Bid, Uniphyl, Aerolate, Uni-Dur)	Relaxes bronchial smooth muscle, improves diaphragm contractility, increases ciliary action and mucus clearance, stimulates respiration and pulmonary vasodilation, improves exercise tolerance	Administered orally or IV. CNS effects cause nervousness, irritability, headache, and insomnia. Causes tachycardia, BP changes, dysrhythmias, muscle twitching, flushing, anorexia, nausea and vomiting, epigastric pain, and diarrhea. Several drugs may increase theophylline levels. Monitor theophylline levels.	Length of drug action is decreased by smoking. Take with food to decrease GI effects. Lie down if dizziness occurs. Take medication regularly and only as prescribed. Teach to take pulse. Instruct not to use OTC medications without checking with health care provider. Wear an ID bracelet stating asthmatic status. Check interactions with herbal products.

Anti-Inflammatory Agents†			
Bclomethasone (Vanceril, Beclot) Triamcinolone (Azmacort) Flunisolide (AeroBid) Fluticasone (Flovent) Budesonide (Pulmicort) Ciclesonide (Alvesco) Mometasone (Asmanex)	Provides anti-inflammatory and immunosuppressive effect, decreasing edema in airways Decreases mucus secretion	All can be administered by MDI. Work synergistically with beta-adrenergic agonists. May affect potassium and glucose levels. Monitor weight. May mask infection. Monitor for edema. May have transient unpleasant taste.	Rinse mouth after each use of inhaler to prevent oral fungal infection. Do not discontinue use abruptly. Wash inhaler with warm water and dry after each use.
Cromolyn (Intal) Nedocromil (Tilade)	Stabilizes cell membranes possibly by inhibiting release of histamine and SRS-A by acting on mast cells	Cromolyn nebulizer may be preferred for some patients if MDI is inadequate.	Therapeutic response may occur within 2 wk, but doctor may suggest a 4- to 6-wk trial. Some patients may experience a bad taste with nedocromil.
Combination Agents			
Leukotriene Modifiers			
Zafirlukast (Accolate) Montelukast (Singular)	Blocks action of leukotrienes in the lung once they are formed Provides both bronchodilation and anti-inflammatory effects	Administered orally. May cause headache, dizziness, nausea, vomiting, diarrhea, fatigue, or abdominal pain. Not to be used for acute asthma episodes.	Should take drug 1 hr before or 2 hr after meals daily. Increase fluid intake. Do not stop taking other asthma medications.
Leukotriene Inhibitor			
Zileuton (Zyflo)	Inhibits the synthesis of leukotrienes, providing bronchodilation and anti-inflammatory effect	Administered orally. Monitor liver enzymes. May cause dizziness, insomnia, dyspepsia, and abdominal pain. May interfere with warfarin (Coumadin) therapy and theophylline. Is not used to treat acute asthma attacks.	Check all medications and OTC drugs for ephedrine, which will increase stimulation. Teach to avoid alcohol. Notify health care provider of nausea, vomiting, anxiety, or insomnia. Continue to take even if symptom free.
Immunomodulators			
Omalizumab (Xolair) Subcutaneous injection	Decreases mast cell mediator release from allergen exposure	Currently FDA is reviewing the possible association between omalizumab and an increased risk of heart attack, abnormal heart rhythm, heart failure, and stroke.	Subcutaneous dose is administered every 2-4 wk.
Phosphodiesterase 4 Inhibitors			
Roflumilast	Reduces the release of inflammatory mediators, countering tissue damage	Not a bronchodilator; is not used for acute bronchospasm. Increased risk of adverse psychiatric effects.	Can be taken with or without food. Risk of weight loss. Consult with provider before using OTC medications.
Cilomilast	Reduces the release of inflammatory mediators Reduces mucus hypersecretion and airway remodeling	Not a bronchodilator; is not used for acute bronchospasm.	Nausea is the principal side effect.
Mucolytic			
Acetylcysteine (Mucomyst)	Breaks down mucoproteins by enzyme action Decreases viscosity and aids in mobilization of secretions	Administered by nebulizer. Nausea and vomiting may occur. May cause bronchospasm or hemoptysis. Usually combined with bronchodilator. Monitor respirations.	Warn that secretions may become profuse. Teach that unpleasant odor will decrease with use. Discoloration of solution after bottle is opened does not impair its effectiveness.

*Many other drugs are also prescribed for asthma.

†Systemic corticosteroids (hydrocortisone, methylprednisolone, or prednisone) may be administered orally or intravenously when severe or refractory asthma attacks occur.

BP, Blood pressure; CNS, central nervous system; FDA, Food and Drug Administration; GI, gastrointestinal; IV, intravenously; MDI, metered-dose inhaler; OTC, over the counter; SRS-A, slow-reacting substance of anaphylaxis.

Asthma patients are taught to use a peak flowmeter to determine the drug dosage needed to control the asthma, to predict the effectiveness of therapy, and to detect airflow obstruction buildup before it becomes serious and requires hospitalization (see [Chapter 12, Figure 12-6](#)). Peak flow monitoring is based on the greatest airflow velocity that can be produced during a forced expiration that starts from fully inflated lungs.

Patient Teaching

Using a Peak Flowmeter

Peak flow should be monitored daily. Readings are recorded and compared with the baseline of the patient's personal best peak flow. If a reading is 60% below the patient's best, treatment should be adjusted. When the reading is in the "green zone," airflow is normal; in the "yellow zone," the usual airflow has decreased and routine medications should be increased; and in the "red zone," rescue medications are needed and the health care provider should be notified. To properly use a peak flowmeter, instruct the patient to:

- Set the pointer to zero.
- While standing, take a deep breath.
- Put the mouthpiece in the mouth and clamp the lips firmly around it for a tight seal.
- Blow into the meter as hard and fast as possible.

- Record the value and reset the pointer.
- Rest for a couple of breaths.
- Repeat the procedure for a total of three readings.
- Record the highest reading on the peak flow sheet.

Clinical Cues

When a patient has respiratory distress in an emergency situation, apply high-flow oxygen and monitor the saturation level with a pulse oximeter. **Observe and monitor continuously.** Immediately alert the RN and the provider. If there is a history of COPD, the O₂ rate should be changed, as ordered, to a lower flow of 1 to 3 liters by nasal cannula after the respiratory crisis has resolved.

Nursing Management and Rehabilitation

Rehabilitation and education of the patient and family are the chief long-term goals of nursing intervention. With proper home care, patients with chronic lung disease can live longer and have a higher quality of life, reduce the number of hospitalizations and provider visits, and have fewer psychosocial problems related to inactivity and a feeling of hopelessness. This means working with the patient, identifying specific difficulties he is experiencing, assessing current ability to cope with them, and devising plans to accomplish specific goals for improvement. To prevent frequent hospitalizations for acute flare-ups of the disease, the patient should be taught how to avoid bronchial irritation and infection and prevent such complications as right-sided heart failure (cor pulmonale).

It is very important for the family to be educated of the need for appropriate exercise and activity, and of the patient's natural desire for independence. Families may be overprotective, because the episodes of dyspnea are very distressing.

Patient Teaching

Instructions for Patients With Chronic Respiratory Disease

- To make mucus more liquid and easier to cough up, drink at least 2 and preferably 3 quarts of liquid every day.
- Normal sputum is white and slightly viscous and has no odor or taste. Changes in sputum should be reported to your health care provider.
- When you exert yourself, as in lifting something or getting up from your chair, exhale slowly through pursed lips. You should do the same when you are walking for exercise. It is natural to hold your breath during exertion, so you may need practice exhaling on exertion.
- Eat three or four small, balanced meals rather than one or two large ones each day.
- Practice your breathing exercises every day without fail.
- Try to avoid crowds during the flu and cold seasons.
- Do not take over-the-counter drugs unless directed by your provider. They can interact with your prescribed drugs. Antihistamines can dry out the mucus even more and make it more difficult for you to clear your air passages.
- Do not smoke or inhale the tobacco smoke of others.

Smoking cessation.

All patients should be encouraged to quit smoking; however, smoking cessation is critically important for those with asthma or COPD, because quitting in the early stages of COPD can slow the progression of the disease. After quitting smoking, pulmonary function gradually improves, and after 10 to 20 years the chance of lung cancer is again equal to that of a nonsmoker. Smoking cessation information must be offered to all inpatients as part of The Joint Commission's Core Measures. Hospitals are required to track efforts and report them as part of the accreditation process. In addition to community resources such as support groups and information sessions, nicotine patches, nicotine gum, nicotine nasal spray, and nicotine inhalers can help wean patients off the addictive nicotine. Prescription medications such as bupropion (Wellbutrin), an antidepressant that helps alleviate some of the nicotine withdrawal symptoms, and varenicline (Chantix), which prevents withdrawal symptoms, are currently being used and might be most effective in combination use.

Work with the patient to develop a plan that seems possible to achieve. Decreasing stress levels and improving coping techniques aid success for patients who are trying to quit smoking. Help patients to review what has helped or hindered past attempts to quit. Identify social settings that contribute to smoking, and explore substitute activities. Encourage patients to share their decision to quit with friends and family, and ask friends and family not to undermine the attempt to quit. Set a definite stop smoking date, and include specific ways to reach the goal. Exercise is a good distracter for the urge to use tobacco. A support group can be very helpful. Encouragement and praise for progress in quitting smoking are essential components of the treatment program. The American Lung Association has both literature and community programs available to assist patients.

Psychosocial care.

The patient often needs help with adjustment to alterations in roles and lifestyle. He may have problems with self-esteem, body image, and sexuality that stem from his chronic disease. A trusting relationship between nurse and patient facilitates discussion of personal concerns and provides a means to explore possible solutions or adaptations for problems in these areas. Referral to community support groups also can be beneficial, because the patient then has an opportunity to see and hear how others in his situation have learned to cope and adapt.

Patient and family teaching.

The teaching plan for a patient with a restrictive airway disease is extensive and includes:

- Management of medications and side effects
- Use of respiratory therapy measures and care of equipment
- Management of dyspnea
- Control of the immediate environment and avoidance of allergens
- Maintenance of nutrition
- Balancing exercise and adequate rest
- Awareness of signs of complications
- Need for close medical supervision

Education of the patient and family can be overwhelming; allow enough time for them to gain confidence in one aspect of care before introducing more information. An action plan for patient education and self-management can be helpful. See www.nhlbi.nih.gov, www.lung.org, www.cic.gov, or other online sources for an asthma action plan.

Most patients with chronic respiratory disease have difficulty getting sufficient rest and sleep because of dyspnea, anxiety, and decreased mobility. Sedatives and tranquilizers are contraindicated because they tend to depress respiration. Tension and anxiety often can be relieved if the patient is taught some relaxation techniques, but it takes a bit of practice to use them whenever relaxation is needed (see Chapter 7). Simply telling him to relax or to stop worrying is not helpful; he is using almost every muscle in his body to struggle for breath or is extremely tense in anticipation of breathlessness. Some patients become very agitated and talkative. You should display a calm attitude, stay with the patient, and encourage him to breathe, not talk.

Lung Cancer

Etiology

Lung cancer is the leading cause of cancer deaths worldwide. In the United States in 2013 there were about 228,190 new cases of lung cancer and 159,480 deaths ([American Cancer Society, 2014](#)). Lung cancer typically occurs in people 40 years of age or older. **Cigarette smoking is the primary cause (90%).** A person living with a smoker has twice the risk of lung cancer as someone not regularly exposed to smoke. Other risk factors are increasing air pollution, asbestos exposure, lung diseases such as TB and COPD, and radon exposure. About 15% of patients diagnosed with lung cancer survive more than 5 years. The percentage is low because often lung cancer is not detected until it is at an advanced stage.

Pathophysiology

Non-small cell lung cancer (NSCLC) includes adenocarcinoma, squamous cell, and large cell carcinoma and accounts for about 85% of all lung cancers. Small cell lung cancer (SCLC) makes up the other 15%. Small cell or “oat” cell tumors grow rapidly and are often located near a major bronchus in the central part of the lung. Non-small cell tumors are usually found in the lung periphery and have undifferentiated cells that have slow growth and tend to metastasize.

Chronic irritation of the epithelial tissue in the lung causes changes in cell structure. This makes the tissue more vulnerable to the carcinogens and irritants inhaled when smoking or breathing air with particulate matter. Dysplasia develops, and the tumor grows. Common sites of metastases for cancer of the lung are the brain, bone, and liver.

Signs and Symptoms

At first there are few symptoms, usually only a cough and some wheezing. As the tumor grows larger, the patient may have some pain or discomfort in the chest, exertional dyspnea, and expectoration of blood-streaked sputum. More specific symptoms depend on the location and size of the malignant tumor and the areas to which it has metastasized. If, for example, the malignancy has involved the esophagus, there will be ulceration, bleeding, and dysphagia. Tumors pressing against the trachea can produce hoarseness and paralysis of the vocal cords. Fatigue, anorexia, and weight loss are common, because lung cancer is usually advanced when discovered.

Diagnosis

Multiple tests are used to diagnose and stage lung cancer. These include chest radiograph; sputum cytology; low-dose computed tomography (CT); magnetic resonance imaging (MRI); cytology of specimens obtained by mediastinoscopy, bronchoscopy, or thoracentesis; fine-needle biopsy of the tumor; and video-assisted thoracoscopic surgery (VATS).

Treatment

Treatment is based on the type of cancer—small cell or non-small cell—and its stage. It may be possible to remove the affected area of the lung by surgery if the malignancy is in its earliest stages and is localized. Surgical procedures include wedge resection, in which a small area of the lung is removed; segmental resection, which includes removal of lung tissue and surrounding blood vessels and bronchioles; lobectomy, with removal of an entire lobe of the lung; and **pneumonectomy**, in which an entire lung is removed. Lobectomy is the most common procedure used for small cell lung cancer. Radiation may be used before and after surgery; however, some types of lung cancers are radiation resistant. Small cell tumors respond dramatically to chemotherapy, but if the disease is extensive, the malignancy tends to recur because of metastasis that occurred before diagnosis. Five drugs are used in various combinations to treat small cell tumors: irinotecan, carboplatin, cisplatin, doxorubicin, and etoposide. A drug once used to treat rheumatoid arthritis shows promise for some types of lung cancer. The drug aurothiomalate (ATM) is a targeted therapy that prevents normal cells from turning into cancerous tumor cells. Phase II trials are under way ([American Lung Association, 2014](#)).

NSCLC is very aggressive and difficult to treat; unless caught in the very early stages, the prognosis for this cancer is not good. The treatment for stage I and II lesions is surgical resection. For higher stages, combinations of one or two chemotherapy drugs, biotherapy agents, radiotherapy, and photodynamic therapy (PDT) are used, depending on the stage of the cancer and the symptoms of the patient. For PDT, the patient is given a drug that is taken up by the tumor cells,

making them very sensitive to light and/or heat. The tumor is then exposed to a laser beam that destroys the malignant cells. The laser is introduced into the bronchi via a bronchoscope. Tumors in the main bronchi are particular targets for this type of therapy. Several drugs have been released over the past 10 years for treatment of NSCLC. None have shown improvements in mortality. Current research is focusing on the genetic characteristics of individual tumors and tailoring chemotherapy to target the specific tumor. One clinical trial found that patients with metastatic NSCLC who were placed in the palliative care limb of the protocol had a better quality and length of life than did those in the standard oncology care group ([Tan, 2014](#)).

Nursing Management

Care of a patient undergoing thoracotomy for cancer of the lung is discussed later in the chapter. See [Chapter 8](#) for nursing care of patients with cancer. You must educate the patient about tests and treatments; this may help to reduce the patient's and family's anxiety.

Pulmonary Vascular Disorders

Pulmonary Embolism

Etiology and Pathophysiology

Pulmonary embolism (PE) occurs when a pulmonary vessel is plugged with a mass or clot. Emboli can occur in solid, liquid, or gas forms and can occur from fracture of a long bone (fat embolus), from amniotic fluid during childbirth, from air introduced through a central line, or from clots formed elsewhere in the body (such as from a deep venous thrombosis or thrombi that form in the heart when the patient has dysrhythmias). Regardless of the origin of the embolus, there is interference with blood flow in the lung distal to the point where the embolus lodges. The obstruction causes shunting, and blood flows past the alveoli without receiving oxygen or without giving up carbon dioxide. The consequences of pulmonary embolism can be minor or life-threatening.

Older adults are especially prone to developing deep venous thrombosis (DVT) when they are immobilized from surgery or for a major illness. Long airplane flights and sitting for long periods with the legs crossed are other potential causes of DVT. All hospitalized patients are screened for their DVT risk and appropriately anticoagulated as part of The Joint Commission's Core Measures. Most pulmonary emboli are a result of thrombus formation that then becomes mobile and travels to the lungs.

Signs and Symptoms

Symptoms depend on the size and location of the clot in the lung and whether it is one clot or multiple small clots. The general symptoms are respiratory distress with dyspnea, chest pain, cough, hemoptysis, and anxiety. Hypotension, tachycardia, or confusion may occur. A sudden onset of dyspnea and a drop in SpO₂ in a patient at risk of thrombus formation is very suggestive of PE.

Diagnosis

Diagnosis is made by ruling out other problems, such as heart failure, and by tests to support a diagnosis of PE. The [Institute for Clinical Symptoms Improvement \(ICSI\) \(2013\)](#) offers guidelines. First, a clinical pretest probability score should be determined, based on presence of symptoms and risk factors. Plasma D-dimer testing is recommended when a PE is initially suspected (see [Chapter 12, Table 12-1](#)). Computed tomographic pulmonary angiography (CTA) is ordered (unless contraindicated—in which case a ventilation/perfusion scan is performed). The CTA will help with the diagnosis of PE or identify another cause for the symptoms. Other tests include a chest radiograph, an echocardiogram, arterial blood gases (ABGs), and an electrocardiogram (ECG). These tests look for other causes of symptoms and do not diagnose a PE.

Treatment

Oxygen therapy is initiated to decrease hypoxia. Treatment depends on the size and location of the embolus. Intravenous heparin is usually begun and continued for 5 to 10 days or until the warfarin levels are therapeutic (international normalized ratio [INR] **of at least** 2.0). Warfarin (Coumadin) is initiated several days before discharge and is continued at home for up to 1 year. Rivaroxaban (Xarelto) may be initiated for patients not admitted and are being treated as outpatients.

Thrombolytic (dissolves thrombi) therapy using alteplase or reteplase is reserved for large emboli that cause hemodynamic instability. Pulmonary embolectomy may be beneficial to patients with severe right ventricular dysfunction and cardiogenic shock ([McFadden, 2010](#)). An inferior vena cava (IVC) filter may be placed to prevent future clots from traveling to the lungs from the lower extremities. Recent reports of complications related to the filters have made placement of the device controversial.

Nursing Management

Initial care for a patient who might be experiencing a PE is to remain calm, stay with the patient, raise the head of the bed to a high Fowler position, begin low-flow O₂ therapy, assess vital signs,

notify the provider of the patient's symptoms, start a peripheral IV, and administer heparin when it is ordered. Prepare the patient for the diagnostic tests and for probable treatment. Prevention is the best intervention, and DVT prophylaxis is implemented for all inpatients. Early identification and notification of the provider for any change in condition indicating possible PE is an important nursing responsibility. The patient is kept on bed rest in the semi-Fowler position initially, but turning, deep breathing, and coughing are important to prevent atelectasis.

Primary Pulmonary Hypertension

Pulmonary arterial hypertension (PAH) is elevated pressure in the pulmonary artery. It is caused by a variety of mechanisms. Older terminology delineated primary and secondary PAH, but current labeling is done by groupings based on pathophysiology, clinical symptoms, and treatment options. The classic symptoms are dyspnea and fatigue. Other symptoms are chest pain with exertion, dizziness, and syncope. The disorder eventually causes right-sided heart enlargement (cor pulmonale), followed by heart failure.

There is no cure for PAH, but treatment can improve or relieve symptoms and increase the quality and length of life. Treatment of an underlying cause can help improve symptoms. Drug therapies are concentrated on lowering pulmonary pressures by vasodilating the vessels. Calcium channel blockers and the prostacyclin epoprostenol (Flolan) promote pulmonary vasodilation. Calcium channel blockers are administered orally, but epoprostenol must be continuously administered through a central IV line. Other medications include oral phosphodiesterase type 5 inhibitors, endothelin-receptor antagonists, and soluble guanylate stimulators. Anticoagulants, diuretics, digoxin, and supplemental oxygen may be used according to guidelines. Lung transplantation is reserved for patients with pulmonary hypertension who do not respond to epoprostenol and who progress to severe right-sided heart failure.

Lung Transplantation

Lung transplantation is a viable option for a variety of end-stage lung diseases. Options include single lung, bilateral lung, and heart-lung transplantation. Patients must undergo extensive evaluation and psychological counseling and meet stringent criteria. There must be no history of malignancy within 2 years, no presence of HIV, no substance addiction (e.g., alcohol, tobacco) for 6 months, and no renal or liver impairment. The average wait for a suitable organ is longer than 1 year. The most common cause of death after lung transplantation is infection, which often occurs within 4 to 6 weeks. Immunosuppressive therapy is lifelong to prevent organ rejection. After transplantation and stabilization, patients enter a rehabilitation program to improve physical endurance.

Chest Injuries

The major complications of chest trauma involve either the lungs and air passages or the heart and major blood vessels, and the patient can rapidly deteriorate. Major concerns in the care of patients with chest injuries are:

- Maintenance of an airway
 - Ensuring adequate ventilation
 - Treatment of circulatory problems to ensure circulation of oxygenated blood
- (See [Chapter 44](#) for additional information about chest trauma.)

Pneumothorax and Hemothorax

Pneumothorax and **hemothorax** often occur as a result of a blunt (nonpenetrating) or penetrating injury to the chest wall. These conditions can cause partial or total collapse of one or both lungs. The space within the pleural membranes is an airtight compartment with **negative pressure**. This negative pressure allows for the tidal movement of air in and out of the lungs. If, however, there is a break in the airtight compartment—either along the surface of the lung or from outside the pleural sac—air rushes in and collapses the lung. **Pneumothorax is a threat in chest injury, and usually present in the period after thoracic surgery.** The condition also can occur spontaneously when there is a rupture of the alveoli. This is called *spontaneous pneumothorax*. Tall, thin people and smokers are more prone to spontaneous pneumothorax. Cases have occurred after scuba diving, flying, or mountain climbing.

A pneumothorax may require nothing more than rest and the administration of oxygen to relieve discomfort. If the amount of air in the pleural space is minimal, a large-bore needle may be used to aspirate it. For greater amounts of air or fluid, a thoracostomy tube (chest tube) may be inserted and connected to water-seal drainage to remove the air and allow re-expansion of the lung ([Figure 14-4](#)).

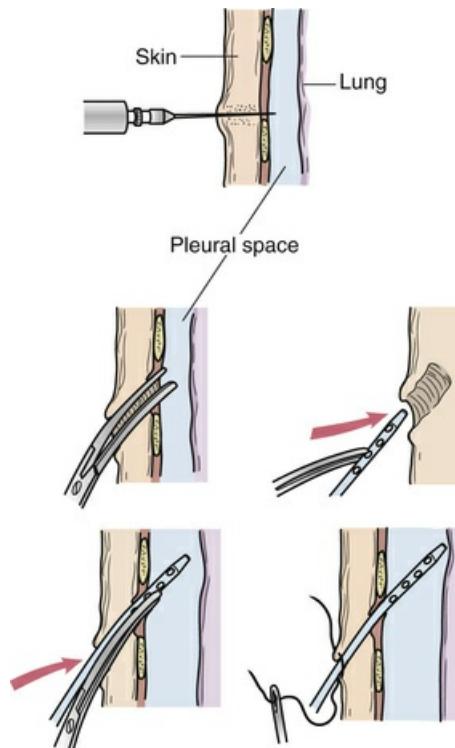

FIGURE 14-4 Insertion of a thoracostomy tube (chest tube).

Hemothorax is the presence of blood within the pleural cavity caused by laceration of the lung, heart, or blood vessels within the thorax. The accumulation of blood in the pleural cavity can cause

partial or total collapse of the lung. There also is the possibility of mediastinal shift in hemothorax and the likelihood of impaired venous return to the heart. The blood is removed with a thoracostomy tube and chest drainage.

For a patient with pneumothorax, hemothorax, or a combination of the two—hemopneumothorax (Figure 14-5)—assess for a history of acute or chronic respiratory disease, accidental injury to the chest, or chest surgery. The patient may complain of sudden chest pain or a feeling of tightness in the chest. There is an increase in both pulse rate and rate of respirations, a drop in blood pressure, and the absence of normal chest movements and absent or diminished breath sounds on the affected side.

Think Critically

You come upon an automobile accident and stop to assist. You have your stethoscope in your car. Name three assessment criteria that would lead you to believe that the driver of the vehicle has suffered a pneumothorax.

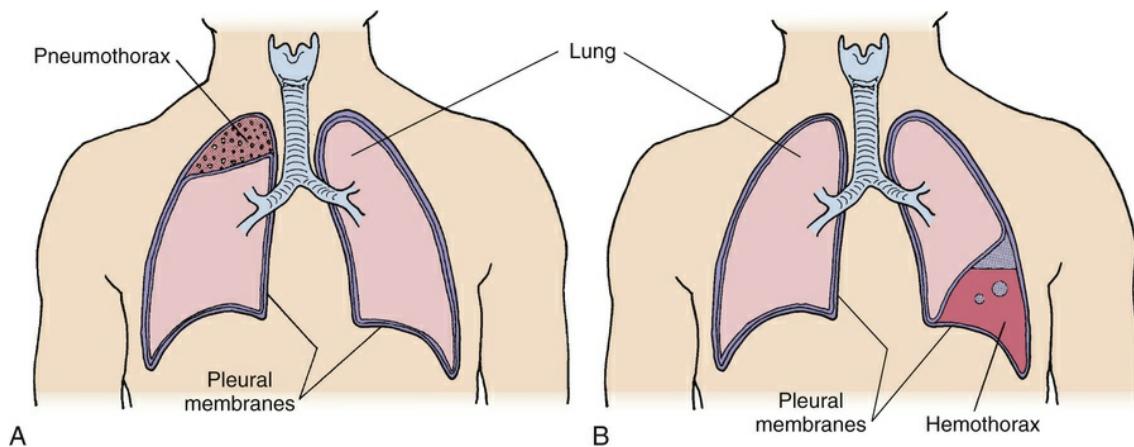

FIGURE 14-5 A, Pneumothorax. B, Hemothorax.

Lung Disorders

Pulmonary Edema

Pulmonary edema is an abnormal collection of fluid in the interstitial spaces of the lung and inside the alveoli. Acute pulmonary edema is a medical emergency. Pulmonary edema is classified as cardiogenic or noncardiogenic depending on the cause. Left ventricular heart failure is a common cause. See [Chapter 19](#) for assessment and treatment of heart failure. Noncardiogenic causes include neurogenic pulmonary edema, drowning, acute glomerulonephritis, inhalation injury, allergic reaction, and acute respiratory distress syndrome (ARDS).

Nursing care involves placing the patient in high Fowler position. Oxygen is started immediately, and continuous positive airway pressure (CPAP) or intubation may be necessary. Furosemide is given for fluid diuresis, and morphine reduces anxiety and the workload on the heart. Drugs for the underlying heart disorder or other condition also are administered. The nurse must closely monitor intake and output and perform continuous respiratory and cardiac assessment to evaluate the effectiveness of treatment.

Acute Respiratory Distress Syndrome

Etiology and Pathophysiology

Acute respiratory distress syndrome (ARDS) is a form of acute lung injury (ALI) that results from pulmonary changes that occur with sepsis, major trauma, major surgery, or any critical illness. When the alveolar capillary membrane is injured, it becomes more permeable to intravascular fluid. Alveoli fill with fluid, and oxygen and carbon dioxide cannot cross the membrane into and out of the capillaries. Pulmonary edema and lung stiffness occur, resulting in severe hypoxemia. ARDS is particularly dangerous when a patient has multisystem disorders; the mortality rate in these patients is 25% to 40%. Improvements in treating the underlying cause as well as interventions for ARDS have improved survival rates.

Signs, Symptoms, and Diagnosis

Dyspnea, tachypnea, tachycardia, and hypoxemia occur. Auscultation may reveal fine, scattered crackles. There is increasing hypoxemia and respiratory alkalosis from the tachypnea. As ARDS progresses, symptoms worsen because of increased fluid accumulation and decreased lung compliance. The onset may be as soon as 12 to 48 hours after the initiating event.

Diagnosis is by physical presentation, history of a disorder or event known to cause ARDS, ABG determination, and chest radiograph. The chest radiograph will show bilateral infiltrates, sometimes called *whiteout*, in the absence of heart failure. The sudden onset and hypoxemia despite supplemental oxygen completes the diagnosis. The PaO_2 is divided by the fraction of inspired oxygen (FiO_2); if the result is 200 or less, the diagnosis is ARDS. Results of less than 300 constitute a diagnosis of ALI.

Treatment and Nursing Management

Treatment for ARDS is ventilatory support with low tidal volumes to prevent additional pressure-related lung injury, positive end-expiratory pressure (PEEP) or CPAP, treatment of the underlying disorder, careful fluid and electrolyte management, and total care for basic needs. Drug therapies have not been shown to be an effective intervention for ARDS. Because infection and sepsis are often the cause of ARDS, early administration of appropriate antibiotics is essential to halt the infectious process.

Nutritional support is essential in prevention of complications and modulation of the stress response. Enteral nutrition is the preferred route of administration. Prone positioning has been shown to improve oxygenation but not overall survival. Patients with ARDS will be on mechanical ventilation in an intensive care setting.

Respiratory Failure

Respiratory failure is the result of insufficient oxygen or excessive carbon dioxide.

Hypoxemic respiratory failure (type I) occurs when PaO_2 is lower than 60 mm Hg and a normal or low PCO_2 is present. This is a result of insufficient oxygen passing from the alveoli to the capillaries. For example, in pneumonia or with a massive pulmonary embolism, fluid fills the alveoli and interferes with gas exchange at the alveoli-capillary interface.

Hypercapnia (also called *hyperventilation*) is the result of hypoventilation, during which the usual amount of carbon dioxide is not eliminated by exhalation. In hypercapnic respiratory failure (type II) the PCO_2 is greater than 50 mm Hg. It is common for hypoxemia to be present in type II respiratory failure. Carbon dioxide is a respiratory stimulant, and the normal response to excessive levels of carbon dioxide is an increase in respiratory rate. If, however, the respiratory centers in the brain are continuously exposed to higher-than-normal levels of carbon dioxide, as in COPD, they become less reactive, and a drop in the respiratory rate occurs. Chronic lung disease may result in a chronic state of respiratory failure. Many patients live in a constant hypoxic state and are always short of breath. Abruptness of onset and severity of symptoms identify the acuteness of the condition. Signs and symptoms of respiratory failure include restlessness, agitation, or confusion. An increase in respiratory rate, pulse, and blood pressure signals a physiologic attempt to compensate for inadequate oxygenation. The patient may sit upright and bend forward and be unable to speak without pausing for breath. Diaphoresis and retraction of accessory respiratory muscles occur as the work of breathing increases. Cyanosis is a late sign of hypoxemia. The final outcome can be cardiac arrest from respiratory acidosis.

Safety Alert

Recognition and Response to Changes in Patient Condition

An essential National Patient Safety Goal is to improve the recognition and response to changes in patient condition. Particularly for patients who are at risk for retaining carbon dioxide, do not assume that lethargy and drowsiness are secondary to the patient's having a "restless, sleepless night." Assess breathing patterns and respiratory rate and carefully compare the current mental status to baseline. Check pulse oximetry and PtCO_2 readings. Notify the provider if you suspect respiratory failure, and obtain an order for ABGs.

Respiratory failure is treated with oxygen and respiratory therapy, including mechanical ventilation, measures to reduce and remove secretions, drugs to reduce bronchospasm and airway inflammation, and correction of acidosis. Treatment of the underlying cause is also necessary. Acute respiratory failure will be managed in an intensive care unit setting because mechanical ventilation is usually required. Extracorporeal membrane oxygenation (ECMO) may be used in some patients.

By vigilant observation and assessment of patients with respiratory problems and close attention to turning, deep breathing, and coughing, you can often prevent respiratory failure. Nursing measures are incorporated to relieve anxiety and agitation. Monitoring fluid balance is particularly important when there is concurrent heart or multiorgan failure.

Common Therapeutic Measures

Intrathoracic Surgery

Intrathoracic surgery, such as resection of lung tissue and other pulmonary structures, requires opening the chest wall and entering the pleural cavity. An intrathoracic approach is also necessary to repair the heart and great vessels or defects of the esophagus.

VATS is replacing the standard **thoracotomy** (incision with entry into the thorax) for many procedures. About 70% of thoracic procedures can be performed in this manner, including pulmonary resections, biopsy or resection of mediastinal tumors or masses, and drainage of pleural effusions. As with laparoscopic procedures performed in the abdominal cavity, several incisions are made to introduce the scope, camera, and necessary instruments. At any time a VATS procedure can be converted to an open thoracotomy if needed.

Preoperative Care

Assessment of the patient's respiratory status before thoracic surgery depends on whether the surgery is elective or emergent. If there is time, a health history as well as subjective and objective assessment data should be obtained before the surgery (see [Chapter 12](#)).

Preoperatively, efforts are made to improve the respiratory status of the patient as much as possible. Special exercises may be prescribed to strengthen the chest, shoulder, and accessory muscles of respiration and to remove accumulated secretions from the air passages.

When standard thoracotomy is to be performed, arm and leg exercises are taught preoperatively to prevent thrombophlebitis and problems with movement. Movement of the arm may be very painful because of positioning during surgery or the surgical involvement of muscles that control the arm. "Frozen" (immobile) shoulder can occur if the arm is not exercised. With VATS, this complication is less likely to occur.

Preoperative patient education focuses on teaching information to improve lung ventilation and to prepare for postoperative equipment such as chest tubes, suctioning, mechanical ventilation, and use of an incentive spirometer.

Postoperative Care

During the immediate postoperative period, nursing assessment and intervention focus on routine positioning, turning, coughing, and deep breathing; procedure-specific observations; and attention to chest tubes and the closed drainage system. A patient who has had thoracic surgery should be ambulatory as soon as possible. An advantage of VATS is that the patient is out of bed and into a chair within 4 to 6 hours of surgery; pain is less. The standard thoracotomy patient has a 4- to 6-week recovery, whereas the VATS patient resumes activities of daily living in 3 to 4 days and can even return to work within 1 week. To promote early mobility, pain management is essential. Surgical pain causes the patient to take shallow breaths and limit movement that causes pain. Adequate pain management will facilitate deep breathing and mobility, both of which are essential in preventing complications.

Special observations include watching for signs of pneumothorax, hemothorax, or both; observing for symptoms of respiratory distress; and auscultation and palpation of the upper chest and neck for swelling caused by **subcutaneous emphysema** (an accumulation of air or gas under the skin, which feels like bubble wrap on palpation). Subcutaneous emphysema is also called **crepitus** and can occur when air leaks into the tissues around chest tubes. It could be a sign of malfunctioning of the drainage system and should be reported. Inspecting the drainage system for air leakage is essential. Assessing for signs of infection, both respiratory and incisional, is also a nursing responsibility.

Gastric distention and paralytic ileus are possible complications of standard thoracic surgery. **Distention of the stomach and intestines is particularly hazardous for the post-thoracotomy patient, because distention can cause these organs to push up on the diaphragm and impair ventilation, which is already compromised by the surgery.**

Positioning for comfort, optimal ventilation, and adequate drainage of the operative site is important during post-thoracotomy care. In most cases the patient is allowed to lie on his back and operative side. Many surgeons do not permit lying on the unaffected side, because this position

diminishes the expansion of the good lung. When the patient has a tube inserted for drainage from the operative site, lying on the operative side facilitates the flow of drainage. Care must be taken when positioning the patient to prevent kinking the chest tubes.

An understanding of the surgical procedure performed and a careful adherence to mobility orders are essential for safe movement of thoracotomy patients. A pneumonectomy patient has had an entire lung removed. Over time the body will accommodate for the space previously occupied by the lung; however, in the immediate postoperative period certain positions may put tension on the bronchial stump. Surgeon preference will dictate acceptable patient positioning for any thoracic surgery.

Care of patients with chest tubes and closed drainage.

Regular and frequent monitoring of patients with chest tubes with an understanding of why the tube has been placed will help with early identification of problems requiring intervention. It will also allow for assessment of effectiveness of the therapy (Figure 14-6). There are three major areas of assessment:

1. The respiratory status of the patient
2. The site at which the tube is inserted into the chest and the length of the tube (for kinks or clots)
3. The amount and character of the drainage in the collection chamber

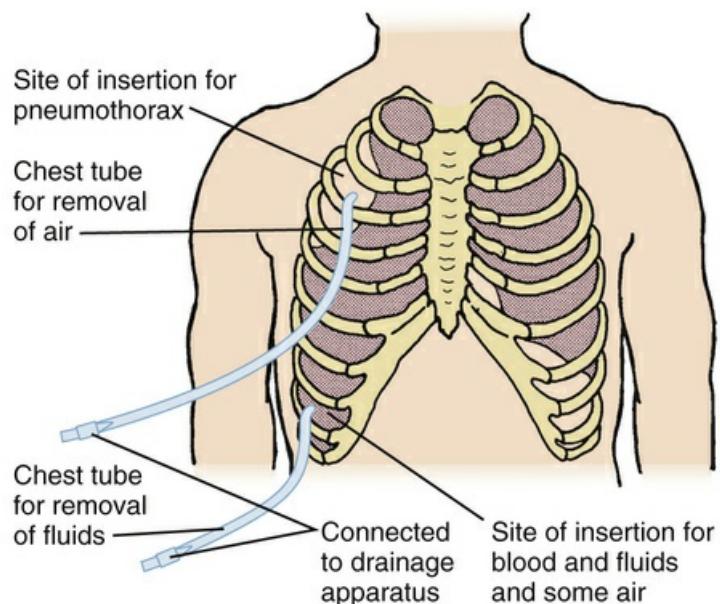

FIGURE 14-6 Location of sites for insertion of chest tubes for drainage of air and fluids.

The patient is assessed for ease of breathing, pain or discomfort, level of consciousness and orientation, and anxiety and restlessness. The rate and character of respirations are noted, as are breath sounds. The entry site is assessed for unusual drainage, infection, integrity of sutures, and the presence of subcutaneous emphysema. The chest tube will be attached to a drainage system. Commercial disposable plastic water-seal drainage systems are the most common. The drainage system should (1) provide for drainage of air and blood from within the pleural cavity and (2) allow for gradual re-expansion of the lung by isolating the intrathoracic pressure from atmospheric pressure. Figure 14-7 shows a disposable system. Note that the water in the left-hand chamber serves as a suction control chamber. When the unit is attached to wall suction there will be bubbling in the compartment. The level of fluid determines the amount of suction applied to the chest. Increasing the wall suction will increase the bubbling but does not change the degree of suction. Slow gentle suction is adequate. The middle chamber is the water-seal chamber that prevents air from entering the chest cavity. Tidaling (movement with breathing) should occur in this chamber. If

air is being removed from the chest, then bubbles might be observed in this chamber. The collection chamber—located on the far right of the device—is calibrated for accurate measurement of drainage from the chest. When caring for a patient with a closed drainage system, the following precautions should be kept in mind:

- Remember that the pleural cavity is an airtight compartment. The apparatus and all connections must remain airtight at all times; all connections should be taped.
- Do not allow the tubing to become kinked or obstructed by the weight of the patient.
- Never pin the tubing to the bedclothes.
- Do not empty chest tube drainage containers. The system must remain closed. Replace the unit when the drainage chamber is full.
- The system operates by gravity and must remain below the patient's chest level at all times.
- The amount of drainage expected will vary according to why the tube was inserted. Find out from the surgeon how much drainage is expected and when to call.
- If the chest tube becomes unattached, do not clamp the tube; place the end of the tubing in a container of sterile water. This creates a “water seal” and can prevent tension pneumothorax. Temporary clamping may be performed by the surgeon to assess lung function or occasionally by the RN to check for the source of air leaks.
- Persistent bubbling in the water seal chamber indicates an air leak. Fluid in the chamber **should** fluctuate with inhalation and exhalation. Occasional bubbles may appear with breathing, sneezing, or coughing. If a pneumothorax is present, bubbling will occur with inspiration, as air is forced out of the area of the pneumothorax.
- A “puffed-up” appearance of the patient's chest or neck could be subcutaneous emphysema.
- Dressings may be reinforced but are not changed except by order of the surgeon. Dressings must be occlusive and not allow air in around the chest tube.

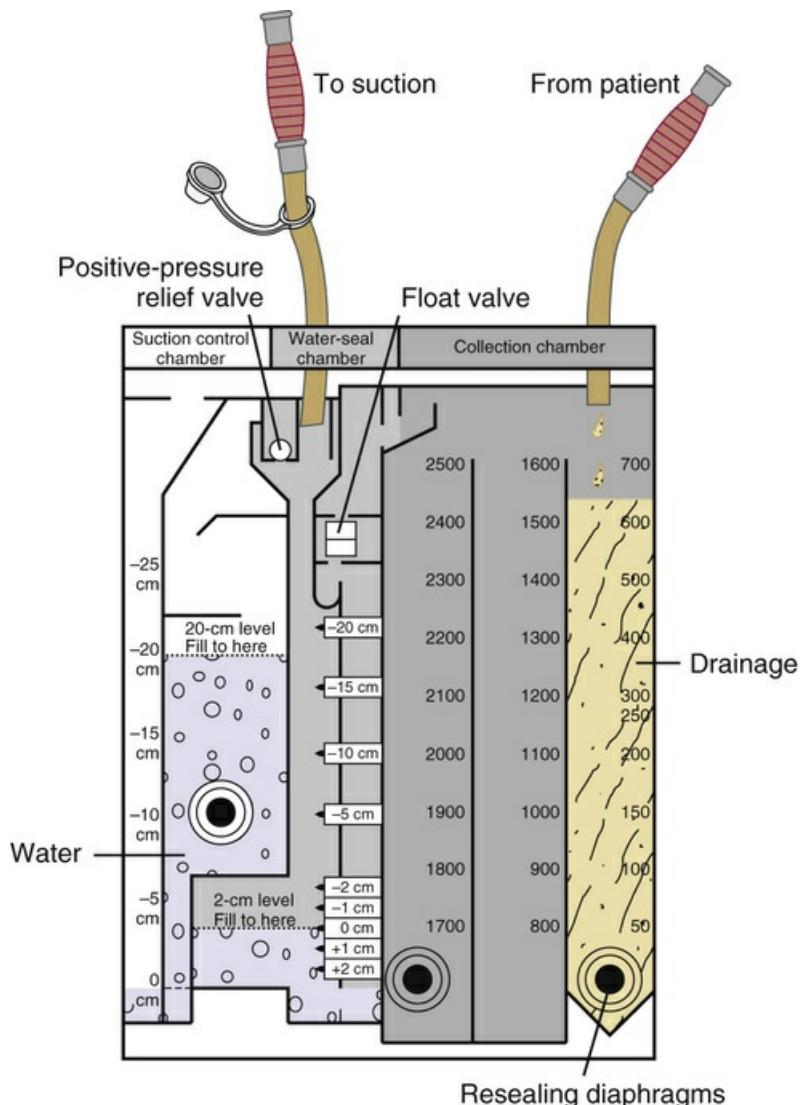

FIGURE 14-7 Disposable water-seal drainage system; note the three chambers. (From Harkreader H, Hogan MA: *Fundamentals of nursing: Caring and clinical judgment*, ed. 2, Philadelphia, 2004, Saunders.)

Other devices such as a flutter valve, or Heimlich valve, may be substituted for chest drainage systems. This valve permits the flow of air and fluid from the pleural space into a collection area but prevents the return flow of air or fluid; the Heimlich valve is inserted between the chest tube and the drainage collection apparatus or may be used without a collection device if only air is being evacuated.

Ambulatory patients may be using a small portable chest drainage system that has only one chamber with a dry seal and does not contain water. The system is used for certain patients who have less than 500 mL of drainage daily. The collection chamber must be emptied when full. Two other devices, the Pneumostat and the Pleurx pleural catheter, are available for chest drainage for home care patients. Each comes with specific care directions.

A dry-suction system is sometimes used in place of water-seal suction. It provides more consistent flow because the suction adjusts automatically to changes in the patient's pleural pressure or to fluctuations in wall suction pressure. The regulator within the unit is preset to $-20\text{ cm H}_2\text{O}$ but can be changed to range from -10 to $-40\text{ cm H}_2\text{O}$.

Specialized chest drainage systems are used to collect the patient's blood from the chest after surgery so that it can be reinfused in an autologous transfusion.

Think Critically

Your patient is 1 day postoperative. What would you do if the fluid in the drainage chamber of the

closed-chest drainage system had not increased over the past 4 hours?

The patient should be medicated 30 to 60 minutes before the removal of a chest tube. When the surgeon removes the chest tubes, the incision is covered with a dressing containing sterile petroleum jelly to close off the opening so that air does not enter the pleural space. This type of dressing is also applied if a chest tube is accidentally pulled out. Auscultate the lungs after chest tube removal to verify that a pneumothorax has not occurred. Eventually the incision will seal itself. A sample plan with interventions for a patient having thoracic surgery is shown in [Nursing Care Plan 14-1](#).

Think Critically

What would you do if you went to assess your first-day postoperative standard thoracotomy patient and the water in the closed drainage system waterseal chamber was not fluctuating with the patient's breathing?

Nursing Care Plan 14-1

Care of a Patient With Lung Cancer

Scenario

A 62-year-old female smoker with a diagnosis of early lung cancer is scheduled for a right thoracotomy and lobectomy. She has no other medical problems except mild arthritis, for which she occasionally takes aspirin.

Preoperative Problem Statement/Nursing Diagnosis

Insufficient knowledge/*Deficient knowledge related to postoperative care for thoracotomy.*

Supporting Assessment Data

Subjective: "I've never had surgery before."

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will verbalize understanding of postoperative routine of frequent monitoring of vital signs, chest tube care, and respiratory treatments.	Explain purpose and show tubes, drainage apparatus, and oxygen equipment. Explain need for early ambulation. Describe methods of pain control.	Being familiar with equipment and what to expect after surgery decreases fear of the unknown.	Verbalizes understanding of what equipment is for. Says will try to ambulate this afternoon. States understanding of PCA pump for pain control. Outcomes met.
Patient will demonstrate use of spirometer and coughing and deep-breathing exercises.	Teach deep breathing, coughing, use of incentive spirometer. Obtain return demonstration.	Learning the techniques before surgery facilitates postoperative performance.	Uses spirometer correctly and is able to demonstrate coughing and deep breathing.
Patient will be mobile and active after the surgery to prevent postoperative complications before discharge.	Teach leg exercises; flex and extend ankles and knees, circular rotation of ankles, and gluteal tightening. Ambulate to determine preoperative abilities.	Teaching before surgery empowers patient and provides time to practice techniques and ask questions. Ambulating before surgery gives baseline information.	Is practicing leg exercises enthusiastically. "Hope I can keep this up after surgery." Ambulates independently with steady gait. Easily walks full length of pre-op teaching unit without distress.

Postoperative Problem Statement/Nursing Diagnosis

Altered gas exchange/*Risk for impaired gas exchange related to surgical removal of portion of lung and possible complications.*

Supporting Assessment Data

Objective: Thoracotomy and lobectomy.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will display normal respiratory rate and normal oxygenation before discharge.	Position on back or operative side; turn, cough, deep breathe, and use incentive spirometer q2h; splint incision with small pillow to minimize pain.	Position allows good lung to fully expand. Incentive spirometer use opens alveoli, promoting better gas exchange and prevent atelectasis.	Assisted to turn q2h; using spirometer and coughing q2h. Splints incision when coughing.
	Administer oxygen as ordered.	Oxygen saturation should be maintained at ordered parameter.	Receiving oxygen at 3 L via nasal cannula.
	Monitor vital signs and respiratory effort, and auscultate lung fields q4h; pulse oximetry readings q1h, monitor blood gas levels.	Respiratory rate, lung sounds, blood gas levels, and pulse oximetry readings provide data regarding respiratory status and can indicate decline or improvement.	BP 134/82, P 85, RR 28/min. Left lung with normal breath sounds; right lung with diminished sounds in bases and absent over middle lobe area. SaO ₂ 95% average.
	Encourage use of PCA to promote better cooperation with respiratory therapy, coughing, and deep breathing, but avoid oversedation and respiratory depression.	If pain is minimized, patient is able to more fully expand the lungs and to perform coughing and deep-breathing exercises.	Using PCA appropriately; pain at 4 on a scale of 1-10.
	Maintain intact, functioning closed-chest water-seal	Intact system prevents air from entering pleural	Chest drainage system intact with 150 mL drainage.

	drainage system. Observe for signs of subcutaneous emphysema.	space and collapsing lung.	No subcutaneous emphysema; no signs of respiratory distress (i.e., labored, uneven respirations; no subjective SOB).
	Monitor abdomen for signs of distention or ileus.	Distention can cause pressure on diaphragm and decrease lung expansion.	Abdomen soft and nondistended.

Postoperative Problem Statement/Nursing Diagnosis

Potential for infection/*Risk for infection related to surgical incision and chest tubes.*

Supporting Assessment Data

Objective: Thoracotomy and lobectomy; chest tube in place.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
No signs of infection as evidenced by clean incision, temperature in normal range, normal WBC count, and clear breath sounds during hospitalization.	Use aseptic technique for dressing changes and care of chest tube.	Prevents introduction of pathogenic organisms.	Very small amount of pink-tinted drainage on old dressing. Dressing changed, as ordered, with aseptic technique. Incision intact.
	Assess temperature trends q24h; monitor WBC count.	Provides data that might indicate beginning infection.	Temp 99.4° F (37.4° C) CBC results pending.
	Observe wound for signs of infection.	Early detection and reporting results in early intervention.	No redness, swelling, or pain to surrounding tissues. Dressing dry and intact.
	Protect from people with infections.	Helps prevent exposure to respiratory infection.	Note placed on door advising visitors, who may have infection, to check with nurses before entering.
	Maintain adequate nutrition and fluid intake.	Adequate fluid and nutrition are required for healing.	Taking clear liquids. IV line patent at 125 mL/hr.
	Auscultate lungs each shift and as needed for changes in respiratory status.	Auscultating at the beginning of the shift establishes baseline for comparison.	Breath sounds clear but diminished in bases and absent over right middle lobe.
	Administer antibiotics as ordered.	Antibiotics may be ordered prophylactically because of weakened immune system.	Antibiotics are en route from the pharmacy, will be administered as soon as available. Continue plan.

Problem Statement/Nursing Diagnosis

Anxiety/*Anxiety related to diagnosis of cancer of the lung, treatment, and prognosis.*

Supporting Assessment Data

Subjective: "I'm scared. I don't want to die of cancer. Will I have to have chemotherapy? Will there be a lot of pain?"

Objective: Anxious look on face.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will be less anxious about treatment and disease process by discharge.	Establish trusting relationship; use active listening. Encourage verbalization of fears and concerns; answer questions honestly.	A trusting relationship promotes sharing of feelings and fears.	Using active listening, but patient is not verbalizing details.
	Engender hope; discuss what patient can do to optimize chances of survival: quit smoking, exercise program, diet, relaxation techniques, stress reduction.	Hope allows patient to focus on the future. Active participation in her own survival is empowering and increases feelings of control over the disease.	Reminded that many people have lived for many years after having lung cancer. Discussed aids for quitting smoking. Not willing to try relaxation exercise yet.
	Advise that oncologist will discuss modes of treatment when pathology report is completed. Type of tumor, growth, and aggressiveness dictate treatment.	Giving correct information and explaining why more information is not immediately available helps to decrease anxiety.	Advised that oncologist would be in tomorrow morning to talk about options. States that she would like to have her family present for that discussion.
	Assure that pain control is possible.	Fear of pain and uncertainty about ability to withstand pain is a major source of anxiety.	Visibly relieved when reassured about pain management. Continue plan.

BP, Blood pressure; *CBC*, complete blood count; *IV*, intravenous; *P*, pulse; *PCA*, patient-controlled analgesia; *RR*, respiratory rate; *Sao₂*, oxygen saturation; *SOB*, shortness of breath; *WBC*, white blood cell.

Critical Thinking Questions

- Why should this patient not be positioned on the nonoperative side after surgery?
- What would you do if you noticed that the suction control chamber on the disposable water-seal chest drainage system was not bubbling?

Medication Administration

Bronchodilators are drugs that directly act on and relax the smooth muscle of the bronchi and thereby relieve bronchospasms. Box 14-1 lists general nursing implications for these drugs. Liquefying agents help to thin the bronchial secretions, making them less tenacious. Anti-infective agents used for respiratory infections include the tetracyclines, penicillins, cephalosporins, macrolides (clarithromycin [Biaxin]), fluoroquinolones (ciprofloxacin [Cipro]), and the sulfa drugs.

Box 14-1

General Nursing Implications for the Administration of Bronchodilators

When giving a bronchodilator drug, you should:

- Follow the standard procedures for checking identification of the patient, using the “Six Rights,” verifying allergies, and monitoring for side effects and drug interactions.
- Auscultate the lungs to ascertain the types of lung sounds present.
- Take the pulse and count respirations to establish ranges before drug administration.
- Use these drugs cautiously in patients with cardiac disease, because they affect heart action.
- Consult the provider before administering a bronchodilator to a patient who has a current cardiac dysrhythmia.
- Give each dose of the drug as close to the ordered time as possible to maintain a steady blood level of the drug.
- When the patient is taking theophylline, check drug serum levels; the therapeutic range is 10 to 20 mcg/mL. If the level is above 20 mcg/mL, withhold the drug and notify the provider.
- Warn older adult patients that bronchodilators may cause dizziness and to take precautions when changing positions.
- Monitor the patient for effectiveness of the drug by performing a respiratory assessment.

Regarding possible side effects or adverse effects of the drug, you should:

- Warn the patient about the possibility of paradoxical bronchospasm and advise him to consult the provider if this happens before administering another dose.
- Tell the patient to chew sugarless gum or suck on hard candy to relieve dry mouth.
- Monitor the patient for specific side effects of each drug; general side effects of bronchodilators are dry mouth, insomnia, nervousness, dizziness, palpitations, gastrointestinal upset, and changes in blood pressure.

You should teach the patient taking a bronchodilator drug to:

- Take the drug with a full glass of water; if it causes gastrointestinal upset, take the drug with a meal.
- Take the drug 15 to 60 minutes before exercising (check specific time for individual drug because time depends on form of the drug [i.e., inhalant or oral tablet]).
- Follow correct procedure for inhaling the drug: shake the inhaler gently before using, clear the nose and throat, take a deep breath, relax, and completely exhale before inhaling drug.

Adapted from Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 8, St. Louis, 2011, Mosby.

Corticosteroids are a major part of inhalation therapy for patients with COPD. Inhaled steroids at doses used routinely for COPD and asthma are not significantly absorbed systemically and do not produce the same side effects as oral steroids. Acute respiratory problems are sometimes treated with oral corticosteroids. When corticosteroids are prescribed, the patient must be aware that steroids may blunt the inflammatory response normally seen in early infection. Long-term steroids should not be abruptly discontinued; these drugs must be slowly tapered over several days. Oral

steroids contribute to potassium loss, and replacement may be necessary. Blood glucose is closely monitored for elevation. Gastrointestinal prophylaxis is recommended to counter gastric irritation.

Antihistamines are used to treat respiratory symptoms of an allergic disorder. They reduce the secretions and swelling of the nasal and bronchial mucosa. Decongestants are prescribed for symptoms of the common cold and sinusitis. **Leukotriene** inhibitors are the newest addition to the treatment for asthma. They help control symptoms by blocking the activity of substances that mediate inflammation.

Aerosols are fine suspensions of very small particles of a liquid or solid that constitute a gas. Several delivery systems provide aerosolized medications. MDIs are used to deliver a variety of drugs to respiratory patients. The patient should be taught² to use an MDI properly. MDIs deliver liquid medication, and dry powder inhalers (DPIs) deliver the dose in powder form. Bronchodilators, liquefying agents, and some anti-infective agents may be administered directly onto the mucous membranes of the respiratory tract by a **nebulizer** (device producing a fine spray) and mechanical ventilator.

A nebulizer can provide aerosolized medications via mouthpiece, face mask, face tent, or tracheostomy collar. Nebulizers are available for use at home. In the hospital, the nebulizer is attached to oxygen so that hypoxemia can be treated as medication is being administered. Nebulizer treatments are usually 20 to 30 minutes long and are given two, three, or four times a day.

The patient is taught to breathe through the mouth during the treatment. He should sit in a comfortable chair. Halfway through the treatment and after the treatment, deep breathing and coughing are performed to raise loose mucus.

Humidification

Without adequate water and humidity, mucous secretions become extremely thick and tenacious, and the mucous membranes become dry, crusted, irritated, and more susceptible to invasion by pathogenic microorganisms. For oxygen delivery of 4 L per minute or less, humidification is not necessary. Room air is not artificially humidified. At low flow rates, the largest volume of inhaled gas is room air, and the normal physiologic mechanisms function to humidify the inhaled oxygen and room air. With tracheostomies and high-flow oxygen delivery, humidification is needed. Highest humidification is achieved with warmed fluids, although room temperature fluid can be used.

Pulmonary Hygiene

Patients with chronic pulmonary disease can benefit from a program of pulmonary hygiene that is designed to remove secretions and to enable more efficient exchange of oxygen and carbon dioxide. Pulmonary hygiene programs include administering prescribed drugs; humidifying inhaled air; medication therapy via nebulizer, DPI, or MDI; chest physiotherapy; and breathing exercises. Several devices are available to help clear mucus and open airways and can be used at home.

Chest physiotherapy includes postural drainage (when possible) and percussion and vibration. **Postural drainage** involves positioning the patient so that the forces of gravity can help remove secretions deep in the bronchi and lungs ([Figure 14-8](#)). Tapping, clapping, and vibrating techniques are used primarily for cystic fibrosis for the purpose of dislodging mucous plugs so that they can be coughed up more easily. The provider or physical therapist will give specific directions, and therapy must be provided by someone who has been instructed in the proper technique. Family members can be taught the procedures, if needed, for home care.

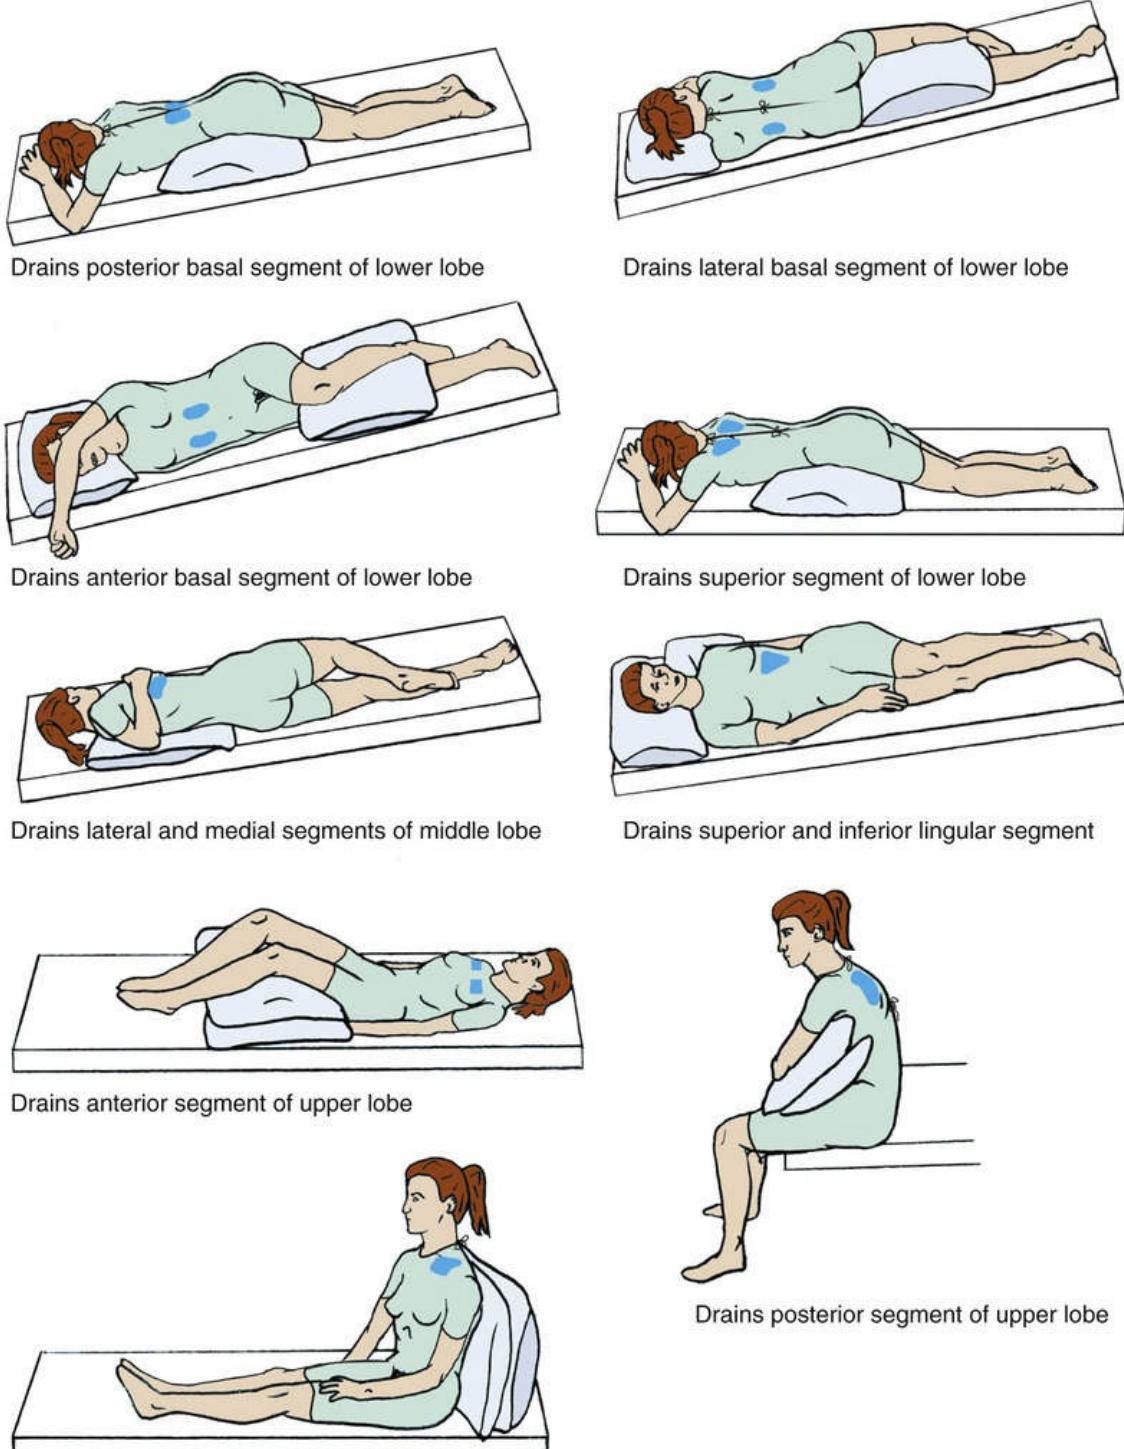

FIGURE 14-8 Positions for postural drainage. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, St. Louis, 2013, Saunders.)

Because there is likely to be some gagging during coughing episodes that take place during postural drainage, it is best to carry out the procedure before meals, when the stomach is relatively empty and vomiting is less likely. If the patient is to have postural drainage only once a day, drainage should be done in the morning to remove secretions that have accumulated during the night. After postural drainage is completed, good mouth care—including brushing the teeth and using a refreshing mouthwash—should be performed.

Older Adult Care Points

Older adult patients with osteoporosis are at risk for fractures of the vertebrae and ribs. Clapping should not be used on these patients; vibrating techniques are more appropriate.

Patient Teaching

Pursed-Lip Breathing

- Sit up tall and move the back away from the chair; place the feet about shoulder-width apart. Lean forward slightly with hands or elbows on the knees.
- Close the mouth, and breathe in through the nose.
- Purse the lips as though to gently whistle or blow out a candle; keep the lips and cheeks relaxed.
- Blow through relaxed pursed lips, exhale slowly, and do **not** force the air out of the lungs (this can bring about the collapse of the airway structures).
- Breathe out slowly without puffing out the cheeks; control the flow of exhaled air as if you wanted to cause a candle to flicker but not extinguish.
- Take twice as much time to let the breath out as it did to take it in.
- Tense the abdominal muscles to force as much air from the lungs as possible.
- Use pursed-lip breathing during any physical activity.
- Refrain from holding your breath when lifting objects or performing other physical activities.

The purpose of performing breathing exercises is to strengthen the abdominal muscles so that they can push upward against the diaphragm and assist in the expiration of air from the lungs. These exercises also help overcome rigidity of the thorax so that the lungs can inflate and deflate more easily. Patients who follow the exercises prescribed for them often find that they can lead more active and useful lives than formerly possible because their exertional dyspnea is less severe ([Cecily and Alotaibi, 2013](#)). The muscles of their body are stronger; thus there is less risk for complications that accompany immobility. The exercises also help patients to cough up secretions that would otherwise remain in the lower bronchi and serve as a growth medium for bacteria or a cause of atelectasis.

Patient Teaching

Abdominal (Belly) or Diaphragmatic Breathing

- Initially practice lying down.
- Lie on the back with the knees bent. Take a deep breath through the nose with the abdomen relaxed and, with the palm of one hand, feel the abdomen rise. Exhale slowly to a count of four.
- Exhale slowly through pursed lips, tightening the abdominal muscles that push the diaphragm up, forcing more air out of the lungs.
- Once comfortable with the abdominal breathing technique, use it when standing or sitting. This type of controlled breathing will provide more endurance during physical activity.

Oxygen Therapy

Oxygen is a drug, and it must be prescribed and administered in specific doses to avoid O₂ toxicity.

The dosage of O₂ is stated in terms of *concentration* and *rate of flow*. High concentrations (above 50%) may be prescribed to treat acute conditions in which the patient can benefit from prompt treatment of hypoxia, as in myocardial infarction and pulmonary edema. The rate of flow may be as high as 12 L/min. Methods of administration are divided into high-flow and low-flow systems (Figure 14-9 and Table 14-5).

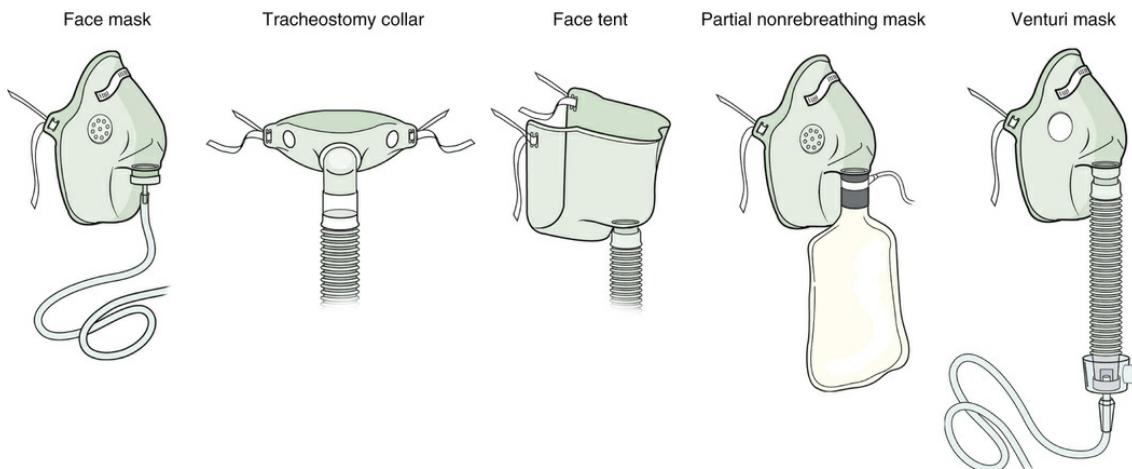

FIGURE 14-9 Various oxygen delivery devices. (From deWit SC, O'Neill P: *Fundamental concepts and skills for nursing*, ed. 4, St. Louis, 2013, Saunders.)

Table 14-5
Advantages and Disadvantages of Common Oxygen Delivery Devices

Method	O ₂ Delivery	Advantages	Disadvantages	Nursing Implications
Nasal cannula (nasal prongs)	Low concentrations; dependent on rate and depth of breathing <i>Flows:</i> 1 L = 24% O ₂ 2 L = 28% O ₂ 3 L = 32% O ₂ 4 L = 36% O ₂ 5 L = 40% O ₂ 6 L = 44% O ₂	Patient can move about, eat, and talk while receiving oxygen. Most COPD patients can tolerate 2 L/min flow.	Restless patients can easily dislodge the prongs. Risk of skin irritation at nares, ears, and cheeks. Flow rate 3 L and above requires humidification to prevent drying and irritation of nasal mucosa.	Prongs should be facing down toward mouth when inserted in nose; check frequently because patients tend to replace the prongs incorrectly. Make sure prongs are patent.
Simple face mask	Low to medium concentrations; 35%-50% can be achieved with flow rate of 6-12 L/min.	Mask provides adequate humidification; delivers oxygen quickly for short-term therapy.	Discomfort and risk of pressure necrosis caused by tight seal between face and mask. Device must be removed for patient to eat, drink, or take medications. Muffles voice when talking. Requires at least 5-L flow to prevent accumulation of CO ₂ in mask.	Wash and dry under mask and wipe out mask q1-2h. Mask must fit snugly. May need to pad straps at ears to prevent skin irritation and possibly necrosis.
Partial non-rebreather mask	Higher concentrations; 40%-60% at flow rates of 6-10 L/min.	Mask is lightweight; reservoir contains 100% oxygen for breathing. One tab on the mask prevents limitation on the amount of exhaled CO ₂ that is "rebreathed" by the patient.	Risk of pressure necrosis with long-term use. Cannot be used with high humidity.	Flow of O ₂ should be high enough that the bag does not deflate during inspiration. Check skin under straps frequently.
Nonrebreather mask	Highest concentrations; 60%-90% can be achieved.	Delivers high concentration of oxygen. One-way tabs on the mask prevent the patient from rebreathing exhaled CO ₂ .	Cannot be used with high humidity. Flow rate must be sufficient to prevent bag from deflating during inspiration.	Mask should fit snugly; check skin contact areas for pressure necrosis.
Venturi mask	Delivers consistent FiO ₂ regardless of breathing pattern. Concentration and liter flow marked on mask apparatus; available for 24%, 28%, 31%, 35%, 40%, and 50% O ₂ .	Mask can provide good humidification; good for delivering low, constant O ₂ concentrations to patient with COPD.	Discomfort and risk of skin irritation. Must be removed for eating, drinking, and taking oral medications. Talking is muffled.	Air ports must not be occluded. Check skin contact areas frequently.
Transtracheal catheter	Delivers oxygen efficiently.	Flow requirement is reduced 60%-80%, increasing time oxygen is available from portable source. Catheter is less visible. Less nasal irritation occurs.	Catheter replacement is an invasive procedure. Not appropriate for someone with excessive mucus production.	Patient and family teaching about catheter replacement.
Tracheostomy collar	Delivers O ₂ and humidification via tracheostomy; must be connected to a nebulizer with FiO ₂ set at 24%-100%.	Adds humidity to help liquefy secretions. Lose some of O ₂ flow because collar is not tight fitting and sits loosely over the tracheostomy.	Must drain condensation in tubing often. Risk of respiratory infection.	Drain condensation from tubing into receptacle; being careful not to allow fluid to go into tracheostomy. Remove and clean collar device and check skin under straps at least q4h.
T-bar (Briggs adapter)	Delivers O ₂ and humidification to tracheostomy or endotracheal tube; must be connected to a humidifier FiO ₂ set at 24%-100%.	Attaches directly to the tracheostomy. Adds humidity to liquefy secretions.	Must drain condensation in tubing often. Risk of respiratory infection.	Drain condensation from tubing into receptacle; be careful not to get fluid into tracheostomy. Remove and clean T-bar device q4h.

COPD, Chronic obstructive pulmonary disease; FiO₂, fraction of inspired oxygen.

Moderate concentrations of oxygen are prescribed when increased metabolic rate raises the consumption of oxygen or when there is poor distribution of oxygen because of heart failure. The

concentrations of O₂ given in a moderate dosage are about 28% to 30% at a rate of flow of 4 to 7 L/min.

Low concentrations of O₂ of about 24% to 28% delivered at a rate of 1 to 3 L/min are indicated when the patient needs oxygen over an extended period. These percentages and rates of flow are approximate amounts. The exact dosage delivered depends on the method of administration and the patient's individual breathing pattern. Although oxygen is essential to life, excessive amounts are toxic. High concentrations of inhaled oxygen can cause lung injury much like that in ARDS. Short-term O₂ therapy, which is the administration of O₂ to treat hypoxemia, is indicated when:

- There is an inadequate intake of oxygen because of obstruction or restriction of airflow through the air passages.
- Oxygen is not distributed throughout the body because of circulatory failure.
- There is an inadequate supply of hemoglobin to transport the oxygen.
- Carbon dioxide or other gases displace the oxygen in the blood.

Objective criteria for oxygen needs include maintaining the SaO₂ greater than 92% and the PaO₂ greater than 60 mm Hg (for disorders such as COPD).

Outward signs of hypoxia vary among patients, but dyspnea, restlessness, and confusion are the most common signs. Blood gas analysis is the most reliable indicator. For bedside assessment pulse oximetry is quick and noninvasive and gives a snapshot of oxygen saturation.

Long-term O₂ therapy for patients with asthma or COPD is used to:

- Relieve hypoxemia
- Reverse tissue hypoxia and its signs and symptoms
- Allow the patient to function better mentally and physically, thereby increasing self-reliance

Oxygen orders for long-term management are prescribed in liters per minute or a specific FiO₂. For acute situations orders are given to maintain an oxygen saturation at or above a certain level. You or respiratory therapist titrates the oxygen delivery to achieve the intended outcome.

Nursing Management

Check the O₂ delivery system at the beginning of the shift and then periodically to verify that the flow is set according to the provider's order or that the target Spo₂ is being maintained. Check the tubing to see that it is not kinked and that it is connected to the oxygen source. Make sure that the patient is wearing the delivery device. Oxygen is not explosive; however, oxygen does support combustion, which means that a spark or flame can cause a major fire. Smoking is not allowed when oxygen is used. The tubing should be kept off the floor, and the connections should be handled aseptically to prevent contamination of the system. Most health care facilities are smoke-free institutions, but patients and families need to be taught safety principles if oxygen is to be used at home. Open flames for cooking are also a risk.

When oxygen therapy is discontinued after long-term use, it is usually done gradually. The patient is "weaned" from dependence on oxygen by gradually reducing the dosage, until room air is tolerated.

Think Critically

Can you describe the assessment points you would cover at the beginning of the shift for a patient who is receiving oxygen therapy? Consider both the patient and the oxygen setup system.

Mechanical Ventilation

Mechanical ventilation is needed when the patient cannot maintain adequate ventilation because of respiratory, neurologic, or neuromuscular problems or trauma. In the acute care setting the most commonly used method is positive-pressure ventilation.

The pressure delivered is greater than that within the airway and alveoli; therefore gas flows into the lungs, either assisting or controlling inhalation. When the pressure is released, exhalation is passive without effort by the machine or the patient. Ventilators are classified by how the inspiratory cycle is terminated. An endotracheal tube or tracheostomy tube must be in place for use

of most mechanical ventilators (see [Chapter 13](#)).

Pressure-cycled ventilators deliver air into the lungs up to a preset pressure. The Babybird and the Siemens Servo are examples of this type. These are mainly used for infants and children.

Volume-cycled ventilators deliver a preset volume of gas with preset pressure limits. Adequate tidal volumes will be delivered even when airway resistance is great (e.g., in patients suffering from severe obstructive lung disease). If the ventilator meets too much pressure, an alarm sounds to indicate that the correct tidal volume is not being delivered. This is commonly caused by excessive secretions in the lungs, and suctioning is needed.

High-frequency jet ventilation provides good ventilation with the use of relatively small tidal volumes at very high respiratory rates. The oxygenation and ventilation are accomplished by gas diffusion and convection rather than a high flow of gas. Because the intrathoracic pressures needed for this type of ventilation are much lower, there are fewer complications (e.g., barotrauma, hypotension, and pneumothorax) than with other types of ventilation.

Modes of Ventilation

In **controlled-mode** ventilation, the machine is set to deliver a fixed number of breaths per minute, at a set volume. The machine does not allow for spontaneous respirations. Controlled-mode ventilation is used during periods of central nervous system depression, such as during anesthesia, sedation, and drug overdose.

Assist-mode ventilation decreases the work of breathing for the patient. When the patient takes a breath, the machine delivers a set tidal volume. Assist-mode ventilation is combined with the control function to provide an assist-control mode. If the patient's respiratory rate falls, the machine will deliver a set number of breaths per minute; if the patient initiates a breath, the machine finishes it at the set tidal volume. The patient can breathe above the rate set on the ventilator. **Intermittent mandatory ventilation (IMV)** and **synchronized intermittent mandatory ventilation (SIMV)** are the most common modes of ventilation found in critical care settings. These allow the patient to breathe spontaneously and yet provide a preset number of ventilator breaths at a preset tidal volume, to ensure adequate ventilation without respiratory muscle fatigue. SIMV is triggered by the patient's inspiratory effort to initiate the machine breath. During mechanical ventilation, it is possible for a patient's respiratory muscles to weaken from lack of use. One of the advantages of SIMV mode is that the patient's respiratory muscles are at work during spontaneous breathing, keeping the muscles toned, and this makes it easier to wean the patient from the ventilator.

In PEEP, the pressure in the airways never falls below a certain level (usually between 5 and 15 cm H₂O). This holds the smaller air passages open, thus limiting atelectasis. It also expands alveoli so that there is more time for gas to diffuse across the membrane and correct hypoxemia. PEEP is used for ARDS and respiratory failure. PEEP increases intrathoracic pressures, which can diminish venous return to the heart, thereby decreasing cardiac output and blood pressure.

Pressure support ventilation.

In pressure support ventilation (PSV), the patient breathes spontaneously, but PSV decreases the work of drawing gases through the ventilator tubing, thus decreasing patient fatigue. PSV is used as an adjunct to standard ventilator modes. PSV has proven very beneficial during weaning from IMV.

Continuous positive airway pressure.

CPAP and bilevel positive airway pressure (BiPAP) can be used for patients who are breathing spontaneously but are showing signs of hypoxemia. It is used for infants with mild respiratory distress syndrome (RDS) and for adults in the early stages of respiratory failure. The therapy can be delivered via the ventilator in an intubated patient, usually for weaning purposes. CPAP and BiPAP not delivered through an artificial airway is considered *noninvasive positive pressure ventilation (NPPV)*.

Noninvasive positive pressure ventilation.

NPPV is used in the hospital and in the home to provide ventilation assistance for patients who need help with oxygenation or air movement. NPPV may be used to improve oxygenation and ventilation so that endotracheal intubation is not needed. It is only used in spontaneously breathing patients who can maintain their own airway. Carefully monitor carbon dioxide levels, oxygen

saturation, hemodynamic stability, level of consciousness, ability to clear secretions, and ability to tolerate the mask or prongs. If treatment outcomes are not met, intubation with mechanical ventilation may be necessary. In the home setting, NPPV is used in the form of CPAP or BiPAP primarily for sleep apnea. The delivery devices use room air and not oxygen for gas delivery. The primary function is to keep positive pressure in the airway to prevent it from closing during sleep. Delivery of supplemental oxygen is not a goal of the therapy ([Figure 14-10](#)).

FIGURE 14-10 Management of sleep apnea often involves sleeping with a nasal mask in place. The pressure supplied by air coming from the compressor opens the oropharynx and nasopharynx. (From Lewis S, Dirksen S, Heitkemper L, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 8, St. Louis, 2011, Mosby.)

Nursing Management

Care for a patient who is receiving mechanical ventilation requires extensive training and supervised practice. The patient will require protection from infection, continuous monitoring of vital signs, observation for hypoventilation and hyperventilation, measurement of intake and output, and prevention of disabilities from inactivity. When caring for a patient on mechanical ventilation, you should:

- Check the provider's order each shift and then check the ventilator for the proper settings: mode, FiO_2 (the oxygen concentration that is delivered), respiratory rate, tidal volume, peak inspiratory pressure, and PEEP.
- Check alarms to see that they are turned on. Alarms should not be turned off when disconnecting the patient to suction, because the alarms may not be reactivated.
- Keep tubing clear of pooled water; empty the water into an appropriate receptacle as needed.
- Check for tension or stretching of the ventilator tubing every time a patient is repositioned.

The patient is observed for signs of complications, such as gastric distention, pneumothorax, and impaired cardiac output from decreased venous return, and the need for increasingly higher pressures to deliver the set tidal volume—which can indicate stiffening of the lungs (decreased compliance). Prevention of ventilator-associated pneumonia includes multiple nursing interventions. Auscultate the lung fields to be certain that both lungs are being ventilated. Monitor ABG levels to determine the effectiveness of ventilation treatment.

Safety Alert

Preventing Ventilator-Acquired Pneumonia

Use of a “ventilator bundle” helps prevent ventilator-acquired pneumonia. The Agency for

Healthcare Research and Quality recommends: (1) elevation of the head of the bed to 30 to 45 degrees, (2) continuous removal of subglottic secretions, (3) change of ventilator circuit no more often than every 48 hours, and (4) hand hygiene before and after contact with every patient. In addition, facility bundle policy may include checking the residual volume in the nasogastric tube, providing oral care with chlorhexidine, deep vein thrombosis prophylaxis, and peptic ulcer prophylaxis (AHRQ, 2011).

For ventilation to be effective, the lungs must be kept clear of secretions. Many patients can cough up secretions and do not need to be suctioned; others may need suctioning as frequently as every 15 minutes. Endotracheal and tracheal suctioning must be done with strict aseptic technique because of the high risk of respiratory infection. In intubated patients an inline suction catheter is used for secretion removal.

An intubated patient on a ventilator cannot talk, so alternative means of communication such as a dry erase board, VitalVoice communication device, electronic device, or paper and pencil are offered. In the acute phase of mechanical ventilation, patients may be sedated. Nurses and other staff need to communicate with the patient assuming they can hear what is being said and explain all procedures and activities.

Additional calorie intake is needed just to maintain weight when a ventilator is used. Continuous enteral feeding is the method most often used to prevent malnutrition in these patients. You should monitor nutritional parameters.

If a ventilator alarm sounds and the problem cannot be located quickly, the patient should be disconnected from the machine and ventilated with a manual resuscitator bag and oxygen until the problem is solved. **Table 14-6** summarizes the dangers of mechanical ventilation.

Think Critically

You have just assisted another nurse in turning a patient who is being mechanically ventilated. The patient has been positioned on the left side and the ventilator is on the right side of the bed. What would you check before you leave the bedside?

Table 14-6
Dangers of Mechanical Ventilation

Danger	Manifestations
Barotrauma	Sudden increase in peak inspiratory pressure; absent breath sounds over one area of lung; pneumomediastinum; pneumothorax; subcutaneous emphysema; high-pressure alarm goes off frequently.
Oxygen toxicity	Parenchymal damage and absorption atelectasis; alveolar membrane damage; nonproductive cough; decreasing vital capacity; decreased compliance; increased peak inspiratory pressure.
Impaired cardiac output	Decreased blood pressure; poor peripheral perfusion; decreased level of consciousness.
Infection	Change in sputum color, quantity, and consistency; crackles and rhonchi; increased white blood cell count; fever; infiltrate on chest radiograph.
Fluid retention	Increasing body weight; fluid intake more than output; peripheral edema; crackles in lungs or diminished breath sounds.
Gastric distention	Increasing abdominal girth; complaint of distention; tender to palpation.
Gastrointestinal bleeding	Positive stool guaiac; "coffee-grounds" aspirate from gastric suction; dropping hemoglobin; black or bloody stool.

Community Care

Home care nurses may be the first to notice that a patient needs home oxygen therapy; also chronic respiratory patients must be monitored for early signs of complications, such as heart failure. Most patients diagnosed with sleep apnea are using BiPAP or CPAP machines in the home, and home health nurses monitor and teach about use of the machine. Outpatient clinic nurses may be the first to notice that respiratory patients are having an increased number of sick days with an increased severity with each episode. Careful history and screening should be conducted to determine whether there is an occupational exposure to an irritant or if the patient is developing hypersensitivity. The nurse can advocate for spirometry, because it is a good test for detecting nonmalignant occupational lung diseases. Community nurses participate in infection control by identifying and referring potential and active cases of tuberculosis within the community.

Working with patients to promote compliance with their exercise and medication regimen is a primary function of the nurse in the community. Teaching use of the peak airflow meter and the MDI can save health care dollars by decreasing serious episodes of acute respiratory dysfunction.

Rehabilitation (see [Chapter 9](#)) of chronic respiratory patients is directed at:

- Improving breathing
- Improving activity tolerance
- Decreasing infection
- Preventing acute episodes

Get Ready for the NCLEX® Examination!

Key Points

- Symptoms of influenza are headache, fever, chills, and muscle aches, followed by hacking cough, runny nose and nasal congestion, and sensitivity to light.
- Hospital-acquired pneumonia can often be prevented by use of aseptic technique and good respiratory care. Older adults are at special risk for pneumonia.
- Symptoms of bacterial pneumonia are high fever, chills, cough with rusty sputum, chest pain, diaphoresis, malaise, and aching muscles. There will be diminished or abnormal breath sounds.
- Fluids (unless contraindicated) should be increased for patients with respiratory infections.
- Treatment of tuberculosis requires multiple medications for a period of 6 to 9 months (see [Table 14-1](#)).
- Restrictive lung disorders include pleurisy, pleural effusion, pulmonary fibrosis, kyphosis, severe scoliosis, and arthritis of the chest wall.
- Chronic obstructive lung disorders include emphysema and chronic bronchitis. Smoking cessation is one of the most important measures in the treatment of obstructive lung disease.
- Emphysema causes destruction of the terminal respiratory units and narrowed, stiff airways with loss of lung elasticity; it causes air trapping and CO₂ retention.
- Chronic bronchitis causes inflammation, excess secretion of mucus, chronic cough, increasing resistance to airflow, and hypoxia. In asthma, bronchospasm and excessive secretion of mucus with bronchoconstriction cause decreased airflow and hypoxia. A severe asthma attack can kill, if not relieved.
- COPD patients are taught diaphragmatic breathing and pursed-lip breathing techniques to assist aeration of the lungs.
- The primary cause of lung cancer is cigarette smoking. Symptoms of lung cancer include cough, wheezing, chest discomfort, exertional dyspnea, and expectoration of blood-streaked sputum. Treatment includes surgery, radiation, chemotherapy, and biotherapy agents.
- Signs and symptoms of pulmonary embolus are dyspnea, chest pain, cough, hemoptysis, and anxiety. Anticoagulant therapy is used for prevention or treatment of pulmonary embolus.
- Pneumothorax and hemothorax decrease lung capacity; treatment includes chest tubes and a closed drainage system.
- Pulmonary edema is a medical emergency. Symptoms include severe dyspnea; orthopnea; noisy respirations; pink frothy sputum; pale, cold, clammy skin; anxiety; restlessness; and possibly confusion.
- ARDS is life threatening and is treated with ventilatory support with PEEP.
- Respiratory failure occurs as type I hypoxic failure and type II hypercapnic failure.
- Frequent respiratory assessment is essential for a patient with chest tubes. Nursing care includes positioning on the back or on the operative side or according to provider orders; checking tubing for kinks; and reporting abnormal chest drainage.
- O₂ is a medication used to treat hypoxemia and can be toxic. High concentrations of O₂ are not used for COPD patients because it can diminish their drive to breathe; use only low-flow oxygen of 1 to 3 L/min.
- Mechanical ventilation is necessary after chest surgery and for respiratory failure, ARDS, flail chest (see [Chapter 44](#)), and neuromuscular disorders that interfere with the respiratory muscles. Nursing care includes carefully checking ventilator settings each shift, ensuring that alarms are on, auscultating the lungs to be sure both lungs are being ventilated, suctioning as needed, administering nutritional therapy, and observing for complications.

Review Questions for the NCLEX® Examination

1. A nurse is caring for a patient with signs and symptoms of influenza. What home care for this respiratory condition would be appropriate?

1. Schedule adequate periods of exercise and activity.
2. Provide warming measures.
3. Restrict fluid intake.
4. Consider analgesics and antipyretics.

NCLEX Client Need: Pharmacological Therapies

2. A 58-year-old man is admitted with bacterial pneumonia. He has high fever accompanied by chills, a cough productive of rust-colored sputum, and a general feeling of malaise. The medical diagnosis is confirmed by:

1. blood cultures.
2. chest radiographs.
3. white blood cell count.
4. bronchoscopy.

NCLEX Client Need: Reduction of Risk Potential

3. Which patient is at greatest risk for developing a pulmonary embolism? The patient who:

1. has a central line that was started 2 days ago
2. is 3 months pregnant with her first child
3. has been immobile for 1 week and is mildly dehydrated
4. is ambulating 2 days after abdominal surgery

NCLEX Client Need: Reduction of Risk Potential

4. A frail 40-year-old woman is admitted with complaints of fever, fatigue, coughing, difficulty breathing, and weight loss. Place the following nursing interventions in priority order.

1. Auscultate lung sounds.
2. Assess work of breathing and oxygen saturation.
3. Review the physician orders and implement.
4. Weigh the patient.

NCLEX Client Need: Reduction of Risk Potential

5. Which person should be advised not to have the tuberculosis (TB) skin test? The person who:

1. is symptomatic after a short exposure to someone with TB.
2. had a bacille Calmette-Guérin (BCG) vaccine 2 years ago.
3. works with children at a large day care center.
4. works as a waitress in a small local restaurant.

NCLEX Client Need: Health Promotion and Maintenance

6. A nursing student is reviewing signs and symptoms with a group of people who are at risk for lung cancer. The nurse would intervene if the student says:

1. "Weight loss and fatigue are the first symptoms to manifest."
2. "An occasional cough or wheezing would be the first signs."
3. "Hoarseness could occur if a tumor presses against the vocal cords."
4. "Deep bone pain could occur because the cancer may spread to the bones."

NCLEX Client Need: Health Promotion and Maintenance

7. Which action is appropriate in the care of a patient who is on mechanical ventilation?

1. Instruct the respiratory therapist to check the ventilator settings and alarms.

2. Auscultate the lungs bilaterally to ensure that both lungs are being ventilated.
3. Disconnect the alarms before suctioning or before turning the patient.
4. Perform endotracheal suctioning every 15 minutes, using sterile technique.

NCLEX Client Need: Reduction of Risk Potential

8. A 55-year-old man was admitted for complaints of a recurring irritating "smoker's" cough with small amounts of sputum and was diagnosed with chronic bronchitis. What is the most likely clinical finding?

1. Nonproductive cough
2. Decreased white blood cells
3. Dry mucous membranes
4. Elevated hemoglobin and hematocrit

NCLEX Client Need: Reduction of Risk Potential

9. A patient is immobilized and has been lying in bed for an extended period. What nursing intervention(s) should be done to prevent hypostatic pneumonia? (*Select all that apply.*)

1. Avoid immunizations because of weakened state.
2. Assist the patient to turn at least every 2 hours.
3. Instruct the patient to cough and deep breathe.
4. Allow nothing by mouth to prevent aspiration.
5. Practice scrupulous hand hygiene.

NCLEX Client Need: Reduction of Risk Potential

10. The nurse admits a patient who was diagnosed with active pulmonary tuberculosis. What nursing intervention(s) would help control the spread of the disease? (*Select all that apply.*)

1. Implementing airborne isolation.

2. Assigning the patient to a positive-pressure isolation room.
3. Wearing a HEPA respirator mask when providing direct patient care.
4. Explaining the importance of covering the mouth when smiling.
5. Practicing good hand hygiene.

NCLEX Client Need: Safety and Infection Control

Critical Thinking Questions

Scenario A

You are assigned to take care of Janet Blair, a 26-year-old married mother of two small children who has pneumococcal pneumonia. She is receiving oxygen by nasal cannula at 3 L/min and has "activity as tolerated." ordered. IV antibiotics are being administered and she is receiving nebulization treatments from respiratory therapy. She is very weak, has a temperature of 104.6° F (40.3° C) and sometimes experiences delirium.

1. What would be an appropriate plan of care for Janet?
2. How would you evaluate the effectiveness of the nursing interventions listed on the plan of care?
3. What psychosocial problems might Janet have? How would you help her with these?

Scenario B

Mrs. Wester is 62 years old. She has had emphysema for several years but has not sought help in coping with the problems associated with the chronic lung disease. While in the hospital with an acute respiratory infection, she becomes very depressed and says she will never be able to take care of herself again because of her breathlessness. She has not been taught any techniques for pulmonary hygiene. She is not willing to give up smoking.

1. What do you think might be the attitude of some health care professionals in regard to Mrs. Wester's problems? What is your personal response to Mrs. Wester's situation?
2. Devise a teaching plan to help her with her problem of fatigue and breathlessness.
3. List interventions that would be appropriate in helping with her nutritional and hydration needs.

Scenario C

Mr. Cohen is admitted to the hospital for a lobectomy. His diagnosis is early lung cancer. He is 56 years old and has worked in a cotton mill since he was 16. He is slightly underweight but is physically strong and has an optimistic outlook about his surgery and chances for recovery.

1. What special preoperative instruction would you expect Mr. Cohen to need?
2. What nursing interventions would you expect to be on his postoperative nursing care plan?
3. How would you help Mr. Cohen deal with the diagnosis of cancer, treatment, and prognosis?

Scenario D

Mr. Azale has recently been diagnosed with asthma. He is coming to the clinic for ongoing management of the condition. He wants to understand the disease and be an active participant in

his own health care.

1. Prepare a teaching plan to help him understand his condition and self-care.
2. Describe what you would tell Mr. Azale about the possibility of having a severe, acute asthma attack.

UNIT V

Hematologic System

OUTLINE

Chapter 15 The Hematologic System

Chapter 16 Care of Patients With Hematologic Disorders

CHAPTER 15

The Hematologic System

Objectives

Theory

1. Review the structures and functions of the hematologic system.
2. Differentiate between the various types of blood cells and their functions.
3. Examine factors that may alter the function of the hematologic system.
4. Explain ways in which the nurse might help prevent blood disorders.
5. Relate at least five different kinds of information that can be obtained from a complete blood count (CBC).
6. Illustrate ways to accomplish hemostasis.
7. Apply the nursing process to patients with hematologic system disorders.

Clinical Practice

8. Explain the procedure and care for a patient receiving bone marrow aspiration.
9. Perform a focused assessment on a patient with a problem of the hematologic system.
10. Plan appropriate nursing interventions for patients with hematologic system disorders.

KEY TERMS

- agranulocytosis** (ăh-grăñ-ū-lō-sī-TŌ-sīs, p. 331)
aplastic anemia (ă-plăs-tĭk ă-NĒ-mē-ă, p. 331)
dyscrasias (dīs-KRĀ-zhē-ăz, p. 330)
erythropoiesis (ĕ-rīth-rō-pō-Ē-sīs, p. 328)
hemarthrosis (hē-măr-THRŌ-sīs, p. 336)
hematocrit (hē-MĀT-ō-krit, p. 332)
hemolysis (hē-MŌL-ī-sīs, p. 330)
iatrogenic (ī-ă-trō-JĒN-ik, p. 330)
jaundice (JĀWN-dīs, p. 336)
leukopenia (lū-kō-PĒ-nē-ă, p. 331)
melena (MĒL-ĕh-nă, p. 336)
petechiae (pě-TĒ-kē-ă, p. 336)
phagocytosis (făg-ō-sī-TŌ-sīs, p. 329)
polycythemia (pōl-ē-sī-THĒ-mē-ă, p. 336)
thrombocytopenia (thrōm-bō-sīt-ō-PĒ-nē-ă, p. 331)

Overview of Anatomy and Physiology of the Hematologic System

Functions of Blood

- Transportation of water, oxygen, nutrients, hormones, enzymes, and medications to the cells
- Transportation of carbon dioxide and other waste products away from the cells
- Regulation of fluid volume and electrolyte distribution
- Regulation of pH and acid-base balance with its buffering ability
- Regulation of body temperature
- Providing clotting factors for hemostasis

Components of Blood

- Blood is composed of formed elements and plasma (Figure 15-1).

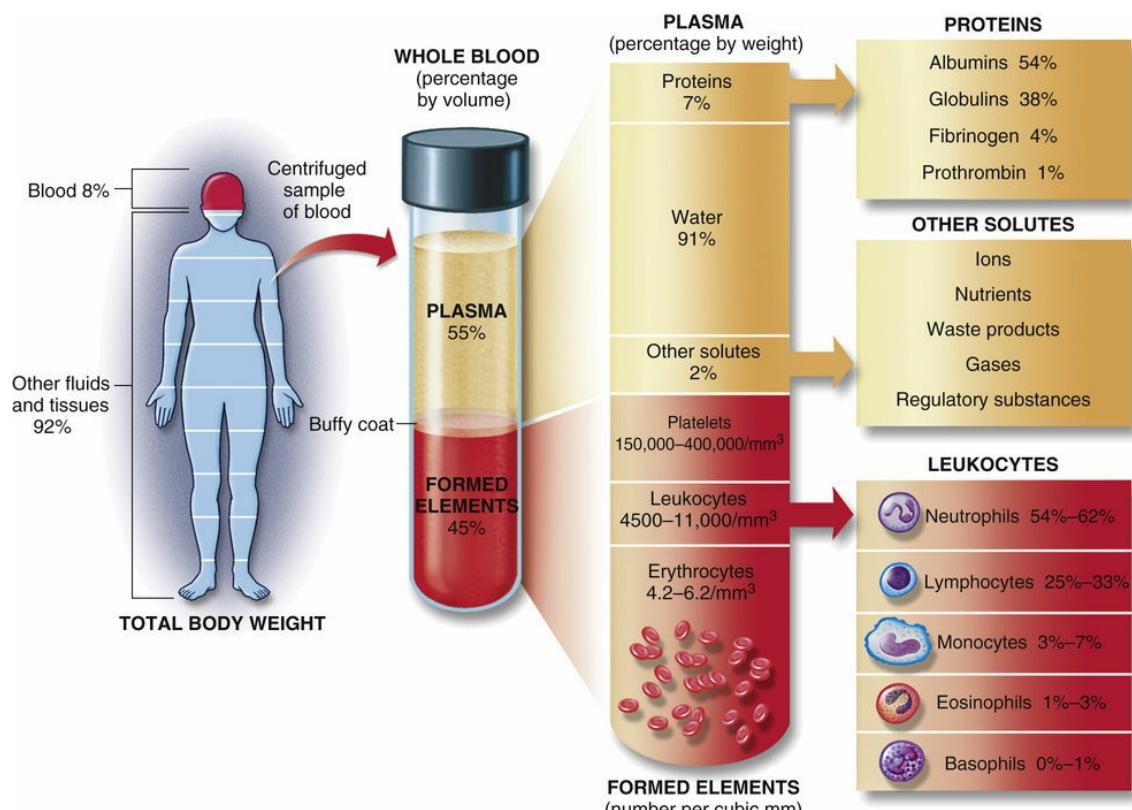

FIGURE 15-1 Components of blood. (From Patton KT, Thibodeau GA: *The human body in health and disease*, ed. 6, St. Louis, 2014, Mosby.)

- The formed elements are erythrocytes, neutrophils, lymphocytes, monocytes, eosinophils, basophils, and platelets.
- Plasma contains proteins, water, salts, dissolved gases (such as CO_2), bicarbonate (HCO_3^-), hormones, glucose, and wastes.
- The plasma proteins are albumin, globulins, and fibrinogen.

Functions of the Plasma Proteins

- Albumin raises osmotic pressure at the capillary membrane, preventing fluid from leaking out

into the tissue spaces. (Osmotic pressure is covered in [Chapter 3](#).)

- The alpha and beta globulins work as carriers for drugs and lipids by combining with them and transporting them throughout the body; gamma globulins act as antibodies.
- Fibrinogen is essential to the formation of blood clots.

Production of Blood Cells

- Blood cells develop from stem cells located in the bone marrow through [erythropoiesis](#) ([Figure 15-2](#)).

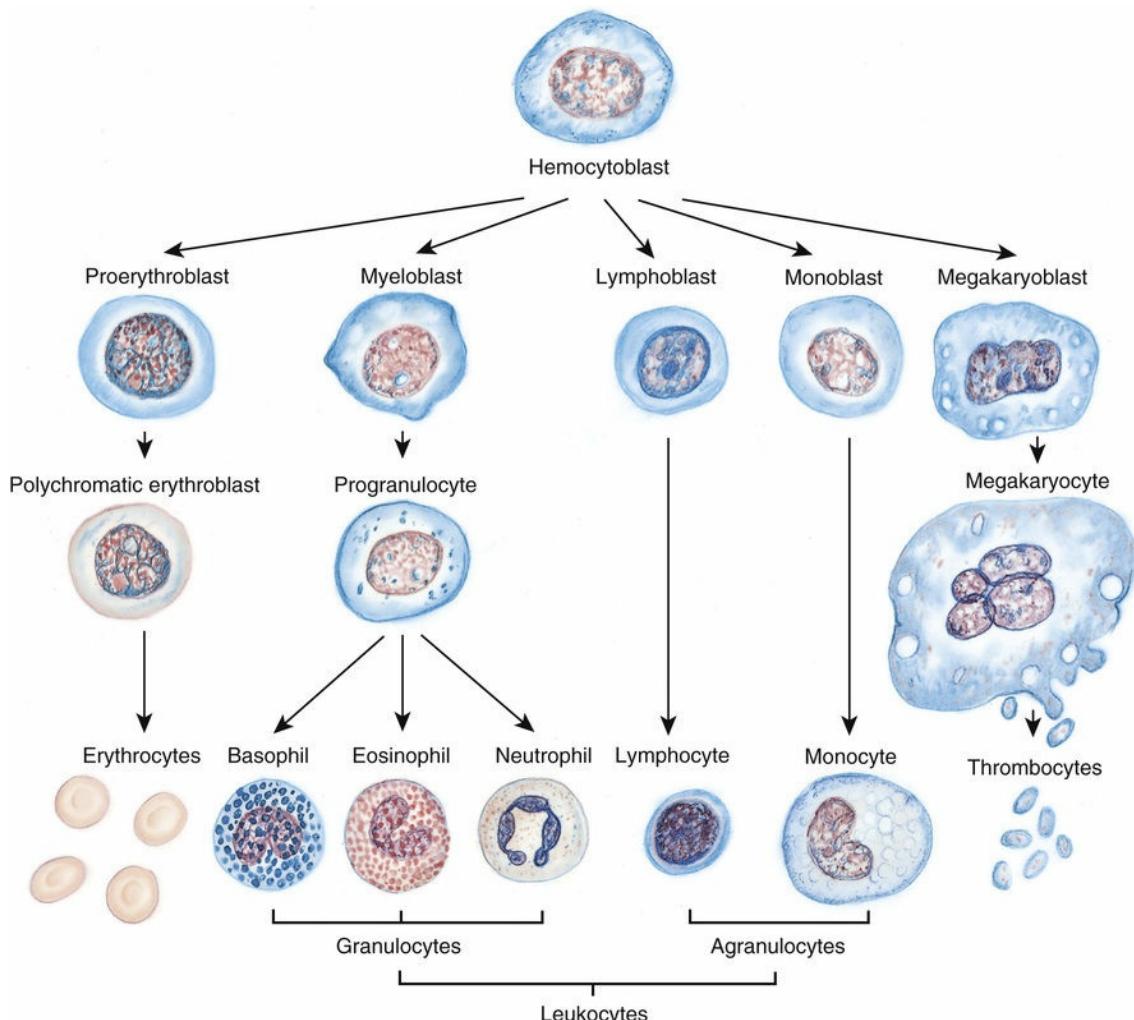

FIGURE 15-2 Erythrocytes (RBCs), leukocytes (WBCs), and thrombocytes (platelets) are the end products of erythropoiesis. (From Applegate E: *The anatomy and physiology learning system*, ed. 4, Philadelphia, 2010, Saunders.)

- The kidney makes most of the body's erythropoietin stimulating factor, which then prompts the liver to release erythropoietin for erythrocyte production.
- Erythropoiesis requires iron, vitamins B₁₂, C, and E, folic acid, and amino acids—all of which are obtained from proteins.

Functions of the Red Blood Cells

- Red blood cells (RBCs, or erythrocytes, the most numerous of the blood cells) contain hemoglobin, which carries oxygen to the cells and a portion of carbon dioxide away from the cells.
- Each person has a hereditary blood type based on the antigens on the RBCs. This can be A, B, AB,

or O.

- The normal laboratory range of RBCs for adults is 4.2 to 6.2 million/mm³ and varies by gender.
- The normal laboratory range for hemoglobin in adults is 12 to 18 g/dL and varies by gender.
- Decreased numbers of RBCs or decreased hemoglobin results in a reduction in the amount of oxygen that can be carried to the cells of the body.
- RBCs live for approximately 120 days.
- The spleen and the liver remove old, damaged red cells.

Functions of the White Blood Cells

- White blood cells (WBCs, or leukocytes) provide the first line of defense against microbial agents.
- The normal adult laboratory range for total leukocytes (WBCs) is 4500 to 11,000/mm³; they have a life span of about 13 to 20 days.
- Leukocytes migrate from the bone marrow cells out into the tissues and are carried by the bloodstream to locations where they are needed.
- Leukocytes are divided into granulocytes (meaning “with granules”) and agranulocytes (meaning “without granules”) in the cell nucleus (see [Figure 15-2](#)).
- Granulocytes are divided into neutrophils, eosinophils, and basophils and are produced in the red bone marrow.
- Neutrophils make up 54% to 62% of the WBC count and work by engulfing and destroying bacteria by the process of **phagocytosis**, which means “to consume or swallow up other cells or particles.”
- An infection in the body stimulates increased production of neutrophils, resulting in a higher-than-normal WBC count, or leukocytosis.
- Eosinophils, which make up 1% to 3% of the total WBCs, help detoxify foreign proteins; eosinophils increase in number during allergic reactions and in response to parasitic infections.
- Basophils, which compose up to 1% of the total WBC count, release histamine in response to allergens and help prevent clotting in the small blood vessels.
- Agranulocytes consist of lymphocytes and monocytes. They are produced in the red bone marrow and in lymphatic tissue.
- Lymphocytes, which account for 25% to 33% of WBCs, are produced in the red bone marrow and the lymphatic tissue. Lymphocytes occur as B cells and T cells. B lymphocytes change into plasma cells that produce immunoglobulins responsible for the humoral immune response.
- Some T cells are killer cells that fight antigens and provide cell-mediated immune response (see [Chapter 10](#)).
- Monocytes compose 3% to 7% of the WBCs and become macrophages (large mononuclear monocytes) that migrate out into the tissues, where they become phagocytes, fighting infection and ridding the body of foreign substances. They engulf bacteria and foreign substances and eliminate them from the body.
- A differential blood cell count gives information about the numbers of different types of leukocytes present in the blood and about the type of inflammatory process that is occurring.

Platelets and Their Function

- Platelets, also called *thrombocytes*, are fragments of megakaryocytes that are produced by the bone marrow.
- Platelets provide the first line of protection, after vasospasm (contraction of a vessel), to prevent bleeding by promoting clotting when the wall of a blood vessel has been damaged.
- Platelets are involved in maintaining hemostasis by a complex process that balances the production of the clotting and dissolving factors.
- Fibrin strands derived from the plasma protein fibrinogen attach to aggregated platelets to help form a clot.
- Platelets are small, formed elements of the blood active in the clotting process. Platelets tend to

adhere to damaged or uneven surfaces and to clump together.

- The normal laboratory platelet count range for adults is 150,000 to 400,000/mm³; the life span of a platelet is about 10 days.
- Although the body can withstand a substantial drop in the number of platelets, when the platelet count is low, there is risk of spontaneous bleeding into the skin, kidney, brain, and other internal organs.

Interaction of the Lymphatic System With the Vascular System

The lymphatic system consists of lymph nodes, lymph channels, the spleen, and the thymus gland (see [Chapter 10](#)). The spleen, located in the upper left abdominal cavity below the diaphragm and behind the stomach, filters the blood, removing pathogens, old blood cells, and debris, and produces lymphocytes (see [Figure 10-2](#)). It is a reservoir for extra blood; in response to hemorrhage, it contracts, and by contraction, the spleen releases some of its stored blood into the cardiovascular system. If the spleen is removed, its functions are taken over by other lymph tissue and by the liver.

Lymph vessels collect excess fluid and protein from the interstitial spaces and return it to the bloodstream. Lymph nodes (bundles of lymphatic tissue) filter out leukocytes and cell debris from inflammations and infections before the lymph is returned to the bloodstream.

Changes of the Hematologic System That Occur With Aging

Plasma volume decreases after age 60 years; older individuals have less blood volume. This means less blood reserve in case of blood loss. In addition, bone marrow activity decreases by about 50% as years advance; the marrow becomes infiltrated with fat and fibrotic tissue. Reduced bone marrow inhibits full production of blood cells, so the immune response is decreased, making the older person more susceptible to infection. There is less antibody response to foreign proteins, a decreased secretion of intrinsic factor from the stomach, and decreased absorption of vitamin B₁₂, leading to pernicious anemia from B₁₂ deficiency.

In older adults, new cells are produced at a slower rate, and correction of anemia becomes a longer process. Antibody response to vaccines is also decreased. There is now a super-strength flu vaccination for patients age 65 years and older that is intended to compensate for this decreased response.

When blood loss occurs, an older adult patient is at greater risk for hypovolemia and shock. Blood is more prone to coagulate, because platelets tend to aggregate more with advancing age, and there are alterations in clotting activity. The increased incidence of thrombosis in coronary and cerebral arteries may be related to changes in clotting activity. Daily low-dose aspirin sometimes is prescribed to counteract this phenomenon.

Pigment loss and yellowish cast to the skin are common changes associated with aging; these routine skin changes make pallor and jaundice more difficult to discern in older adults.

Causes of Hematologic Disorders

Hematology is the study of blood, blood components, and blood-forming tissues. The lymphatic system, which drains the fluid from the spaces around each cell and channels it into the circulatory system, is discussed in [Chapter 10](#). Anemias, blood loss and hemorrhage, and hemolysis are all types of hematologic disorders you may encounter during patient care. Several disorders that interfere with normal function of the blood are inherited. Hemophilia, sickle cell disease, and thalassemia types of anemias are examples. Accidental tearing or cutting of the vessels of the cardiovascular system and surgery causes bleeding and loss of blood. Blunt trauma to the spleen, such as might occur in an automobile accident, may cause tearing and massive internal hemorrhage. Chemicals and transfusions of the wrong blood type can cause **hemolysis** (destruction of red blood cells).

Cultural Considerations

Genetic Hematologic Tendencies

- African Americans have the highest incidence of sickle cell disease.
- Pernicious anemia is more prevalent among those of Scandinavian descent and among African Americans.
- People of Middle-Eastern origin may have a genetic predisposition to thalassemia.

Some blood disorders are **iatrogenic**; that is, they are brought on by medical treatment. For example, blood **dyscrasias** (imbalance in numbers of types of cells) or other pathologic conditions of the blood can be induced through at least four kinds of actions:

- Bone marrow suppression, which interferes with the production of blood cells
- Interference with normal cell function
- Destruction of the blood cells by cytotoxic drugs[®]
- Destruction of cells by a transfusion reaction of mismatched blood

Some antineoplastic drugs, for instance, act to depress the bone marrow, which inevitably causes a reduced supply of blood cells. Other drugs, such as phenytoin (Dilantin), primidone (Mysoline), and oral contraceptives, can produce anemia by interfering with the absorption and utilization of folic acid, a substance needed to produce RBCs. Diuretics such as furosemide (Lasix) and hydrochlorothiazide (HydroDIURIL) sometimes cause **leukopenia** (decreased numbers of white cells), **aplastic anemia** (deficient cell production resulting from a bone marrow disorder), and abnormally low counts of platelets and granulocytes. Procainamide hydrochloride (Pronestyl) and quinidine, which are used to correct dysrhythmias of the heart, also can cause **thrombocytopenia** (too few platelets), **agranulocytosis** (decrease in granulocyte production), and aplastic anemia. Most drugs are powerful chemicals that are capable of producing undesirable side effects, even though the drugs can be of great value.

Clinical Cues

If a patient is showing signs of a blood disorder, review the medications that are being taken, and note their side effects.

Nutritional deficiencies, such as low protein or lack of vitamin C, can interfere with erythropoiesis and normally functioning blood cells. Abnormal red cells are more prone to rapid destruction, which can result in anemia. Bone marrow damage from toxic substances may also interfere with the production of blood cells. Malignant conditions such as leukemia cause growth

of abnormal blood cells and interfere with the production of normal cells. **Box 15-1** presents factors that alter hematologic system function.

Box 15-1

Factors That May Alter Function of the Hematologic System

Genetic Disorders

- Hemophilia
- Sickle cell disease
- Agranulocytosis
- Fanconi syndrome

Hemorrhage (Anemia)

- Surgical blood loss
- Blood loss from childbirth or spontaneous abortion
- Traumatic blood loss

Anemia

- Iron deficiency
- Folic acid deficiency
- Pernicious anemia
- Chronic slow blood loss
- Aplastic anemia

Hemolysis

- Blood transfusion reaction
- Genetic types of anemia

Bone Marrow Suppression

- Antineoplastic agents used in treatment of cancer
- Radiation treatment used for cancer
- Excessive exposure to ionizing radiation
- Exposure to toxic chemicals that damage bone marrow
- Drugs that suppress the bone marrow

Bone Marrow Proliferation or Abnormality

- Leukemia

■ Nutrition Considerations

Nutrients Needed for Building Red Blood Cells (Erythropoiesis)

NUTRIENT	ROLE IN ERYTHROPOEISIS	FOOD SOURCES
Cobalamin (vitamin B ₁₂)	RBC maturation	Red meats, especially liver
Folic acid	RBC maturation	Green leafy vegetables, liver, meat, fish, legumes, whole grains
Iron	Hemoglobin synthesis	Liver and muscle meats, eggs, dried fruits, legumes, dark green leafy vegetables, whole-grain and enriched bread and cereals, potatoes
Vitamin B ₆	Hemoglobin synthesis	Meats (especially pork and liver), wheat germ, legumes, potatoes, cornmeal, bananas
Amino acids	Synthesis of nucleoprotein	Eggs, meat, milk and milk products (cheese, ice cream), poultry, fish, legumes, nuts
Vitamin C	Conversion of folic acid to its active forms; aids in iron absorption	Citrus fruits, leafy green vegetables, strawberries, cantaloupe

RBC, Red blood cell.

Prevention of Hematologic Disorders

When considerable blood is lost through hemorrhage, the patient becomes anemic. Sometimes excessive blood loss can occur during menstruation. Prevent hemorrhage after surgery or childbirth by vigilantly assessing the amount of blood loss and by instituting measures to stop the loss if it is excessive.

Clinical Cues

The average amount of blood loss from menstruation is less than 80 mL per cycle. A better way to estimate that blood loss is to count the number of saturated pads or tampons. Each saturated pad is equal to about 50 mL of blood loss.

Nurses can help prevent anemia by promoting proper nutrition and by educating the public about the possibility of nutritional anemia. Nutritional anemia is a particular concern for individuals who subsist mostly on “fast food.”

Older Adult Care Points

An older adult, especially one who lives alone, is at high risk of poor nutrition. Problems with arthritis, vision, and chronic diseases make it more difficult for older adults to shop for food and to prepare food. As a result, an older adult may substitute cookies, toast, or cereal for a well-balanced meal. It is important to obtain a food intake history.

Secretion of intrinsic factor from the stomach and absorption of vitamin B₁₂ is decreased in older adults. The lack of these substances can lead to pernicious anemia from B₁₂ deficiency (see [Chapter 16](#)).

Monitoring patients for drug side effects and alerting the provider should blood-related side effects occur can prevent a serious blood disorder from developing. Carefully monitoring blood transfusions and promptly reporting any untoward reaction may decrease the incidence of hemolysis from a reaction.

Health Promotion

Preventing Blood Disorders

- Caution the public about the dangers of exposure to ionizing radiation and harmful chemicals to help decrease the incidence of blood disorders related to harmful substances.
- Suggest genetic counseling (for the possibility of transmitting a genetic blood disorder to offspring) to those adults who have such a genetic disorder.
- Inform patients about medications they are taking that can cause blood disorders; remind patients to be alert for signs of excessive bruising or easy bleeding. Suggest that CBCs be checked periodically, for monitoring purposes.

Diagnostic Tests and Procedures

A surprising amount of information can be obtained from a stained blood film using only a 5-mL sample of uncoagulated blood. Each of the formed elements can be studied for shape, maturity, and number. Other kinds of studies include those done to measure the rate at which RBCs settle out from plasma (called the *sedimentation rate*) and to separate and classify various kinds of proteins, including antibodies, in the plasma. Explain the venipuncture procedure and the purpose of the test to the patient. Many patients have a great fear of needles. Others are concerned about having what seems like a lot of blood withdrawn. A few words of assurance and explanation can do much to relieve anxiety about a needle stick and to promote cooperation. Use Standard Precautions and aseptic technique for the venipuncture and the correct tubes for each sample. Wear latex or impermeable gloves any time a venipuncture is performed, and dispose of phlebotomy equipment according to Standard Precautions (see Appendix B).

Think Critically

The CBC of your patient shows the following values:

- RBCs: 4.8 million/mm³
- WBCs: 6.7 million/mm³
- Hemoglobin: 10.2 g/dL
- Platelets: 250,000/mm³

What abnormalities, if any, do these results indicate?

Leukocyte counts provide information about infection and possible immune disorders (see Chapter 10). Data about the number of platelets are valuable in diagnosing a variety of diseases affecting—or affected by—the clotting of blood. There are at least 12 different types of hemoglobin in human blood. The types are designated by letters—for example, hemoglobin A is normal adult hemoglobin, hemoglobin F is normal fetal hemoglobin, and hemoglobin S is found in sickle cell disease. A **hematocrit** is a test that measures the volume of blood cells in relation to the volume of plasma. When there has been a loss of body fluids but no loss of cells (as in dehydration), the cell volume is high in proportion to the amount of liquid (plasma) in the bloodstream (i.e., the hematocrit rises). When either hemorrhage or anemia has depleted the supply of cells, the blood is “thinned” and the cell volume is low. Table 15-1 presents the most common diagnostic tests and related nursing care for the hematologic and lymphatic systems.

Clinical Cues

- Increased numbers of eosinophils often indicate allergy.
- A viral infection prompts the production of additional lymphocytes.
- Bacterial infection stimulates the production of neutrophils, and segmented neutrophils (segs) increase.
- Ongoing bacterial infections cause immature neutrophils to appear in the blood as **bands** (immature forms of segmented granulocytes). This is referred to as a “shift to the left.”
- A “shift to the right” occurs when there are more mature neutrophils than usual; this occurs with anemia from vitamin B₁₂ or folic acid deficiency.

Table 15-1

Diagnostic Tests for Disorders of the Hematologic System

TEST AND NORMAL RANGE	PURPOSE	DESCRIPTION	NURSING IMPLICATIONS
Complete blood count (CBC)	Determine whether abnormalities are present in the numbers of blood cells or types of blood cells; assess the amount of hemoglobin present. Useful to diagnose anemia.	Fill a lavender-top tube containing EDTA with a venous sample of blood. Use a site where there is little chance of dilution from intravenous solution. Mix the blood and the EDTA by gently rotating the tube.	Warn the patient that a "stick" is about to occur, but that the pain will be short-lived. Apply pressure directly to the puncture site after withdrawing the needle; at the antecubital space, do <i>not</i> have the patient flex the arm, because this tends to cause a hematoma.
Erythrocytes			
Hemoglobin: females: 12.0-16.7 g/dL; males: 13.0-18.0 g/dL			
Red blood cell (RBC) count: females: 4.2-5.4 million/mm ³ ; males: 4.6-6.2 million/mm ³			
Hematocrit: females: 37%-47%; males: 40%-54%			
Leukocytes			
White blood cell (WBC) count: 4500-11,000/mm ³			
Differential Count			
Granulocytes			
Neutrophils: 54%-62% of WBCs			
Eosinophils: 1%-3% of WBCs			
Basophils: 0%-1% of WBCs			
Agranulocytes			
Lymphocytes: 25%-33% of WBCs			
Monocytes: 3%-7% of WBCs			
Thrombocytes (platelets): 150,000-400,000/mm ³ of blood			
Mean corpuscular hemoglobin (Hb) (MCH): 26-34 pg/cell			
Mean corpuscular Hb concentration (MCHC): 32-36 g/dL			
Mean corpuscular volume (MCV): 80-96 µm ³			
Erythrocyte Sedimentation Rate (ESR)			
Winrobe: Males: 0.5 mm/hr Females: 0- 15 mm/hr	To detect inflammation and infection.	Fill a blue-top tube with venous blood. The laboratory determines the rate at which the RBCs settle.	Explain that this test helps diagnose an inflammatory process but is nonspecific
Westergren: Males: 0- 15 mm/hr Females: 0- 20 mm/hr			
Hemoglobin Electrophoresis			
Hemoglobin A _{1c} : 3%-5% Hemoglobin A ₂ : 1.5%-3% Hemoglobin F: <1% of total	Useful in diagnosing various types of anemia. Useful for diagnosis and monitoring of diabetes mellitus.	Performed on venous sample using lavender-top tube with EDTA.	Same as for CBC.
Blood Typing			
ABO Rh testing	Used to determine blood type. Useful for detecting unexpected antibodies.	Performed on venous sample using red-top tube. Some specific types of ABO/Rh tests use lavender-top tube with EDTA	Same as for CBC.
Tests for Anemia			
Ferritin, serum: 20-200 ng/mL Total iron-binding capacity: 250-410 mcg/dL Saturation: 20%-55%	Detect reason for anemia.	Obtain a venous blood sample of 5-7 mL in a red-top tube.	Same as for CBC.
Reticulocyte count: 0.5%-2%, or 30,000-130,000 per microliter.	Helps distinguish between different types of anemia. Monitors bone marrow function.	Same as for CBC.	Same as for CBC.
Coagulation Tests			
Prothrombin time (PT): 12-14 sec Activated partial thromboplastin time (APTT): 20-25 sec Bleeding time, iv: 2.75-8.0 min	Determine abnormalities of clotting time.	Performed on a venous blood sample; use a blue-top tube	Same as for a CBC; pressure may need to be applied longer than usual if the patient has an abnormal clotting time or is on heparin or warfarin therapy.
International normalized ratio (INR) Normal: 1-2 Prevention and treatment of VTE, PE, VHD: 2-3 Other: 3-4.5	Standardized blood clotting test for tests run at different laboratories.		
D-Dimer			
Negative: <0.5 µg/mL	Provides assay of fibrin degradation to assess thrombin and plasmin activity. Useful for diagnosing pulmonary embolism and disseminated intravascular coagulation (DIC).	Collect blood sample in a blue-top tube.	No fasting is required.
Sickledex			
0	Tests for the presence of hemoglobin S.	Performed on a venous blood sample; use a lavender-top tube.	Client may be anxious about the result; be sensitive to patient emotions. Positive result indicates need for genetic counseling.
Bence-Jones Protein Test			
Presence of Bence-Jones proteins in the urine is abnormal.	Assists in the diagnosis of multiple myeloma.	Obtain a 10-mL fresh morning specimen of urine in a clean container. Must be refrigerated or tested immediately.	Explain the procedure to the patient.
Schilling Test			
≥7% excreted within 24 hr	Determines ability to absorb vitamin B ₁₂ used to diagnose pernicious anemia.	Radioactive B ₁₂ is given orally, followed in 2 hr by an intramuscular injection of B ₁₂ . A 24-hr urine specimen is collected.	Assess kidney function. Requires an 8- to 12-hr fast. No B vitamins for 3 days prior; no laxatives for 24 hr. Subnormal levels of B ₁₂ in the urine indicate the lack of intrinsic factor, which facilitates absorption of vitamin B ₁₂ .
Bone Marrow Aspiration and Biopsy			
Normal cell counts	Helps diagnose blood disorders. Assists in identifying certain anemias, leukemia, and thrombocytopenia.	Cells are withdrawn by needle from the sternum or iliac crest. Leukocytes, platelets, and erythrocytes are examined in the various stages of	Explain that the aspiration is done at the bedside. Seek an order for prebiopsy medication to decrease the discomfort. Explain that there is a feeling of pressure when the needle is

		development to determine abnormalities.	inserted and sharp, brief pain when the marrow is aspirated. The area of aspiration is surgically prepped. The patient must hold perfectly still. Pressure is applied to the site afterward to prevent hematoma formation. Post-test, observe for swelling and tenderness, indicating continued bleeding or infection.
--	--	---	--

EDTA, Ethylenediaminetetraacetic acid, an agent used to reduce blood clotting; *PE*, pulmonary embolism; *VHD*, valvular heart disease; *VTE*, venous thromboembolism.

Note: Normal values differ among laboratories.

Nursing Management

Assessment (Data Collection)

History

Assess patients for signs and symptoms that indicate abnormalities in the blood. Abnormal symptoms result from too little circulating blood or too little hemoglobin, too few platelets, deficiency of normal neutrophils or lymphocytes, and too many abnormal blood cells. **When there is insufficient hemoglobin to carry oxygen to the cells, signs of oxygen deficit occur.** Perform a focused assessment to obtain an appropriate history. Inquire about renal disease, which may be a cause of anemia.

Focused Assessment

Data Collection for the Hematologic System

History Taking

Ask the patient the following questions:

- Do you or does anyone in your family have a genetic blood disorder (hemophilia, thalassemia, sickle cell trait or disease, aplastic anemia, agranulocytosis, or thrombocytopenic purpura)?
- What is your occupation?
- Have you ever been told you had anemia?
- Do you become easily fatigued?
- Do you have frequent sore throats or other infections?
- Do you frequently feel as though you have a fever?
- Do you ever have night sweats?
- Are your joints painful? Do they swell?
- Do you bruise easily or develop pinpoint blood spots?
- Do you suffer from itching?
- Do you have any swollen lymph nodes in the groin or armpits?
- Do you ever have tingling or numbness in the extremities?
- Do you have frequent headaches? Palpitations?
- Have you become more irritable than usual?
- Do you get dizzy frequently? Do you suffer fainting spells?
- Do you get short of breath when you walk a short distance or when you climb stairs?

- Do your gums bleed when you brush your teeth? Does your tongue get sore? Do you have frequent mouth sores?
- Do you have any difficulty eating?
- How much alcohol do you drink in a day?
- Do colds or infections seem to last a long time for you?
- Do you often feel fatigued even when not doing much?
- Have you been exposed to chemicals, such as pesticides, cleaning agents, or industrial chemicals of any kind?
- Have you ever noticed that you have black, tarry-looking stool? Smoky or brown urine?
- Do you have stomach pain or indigestion or ever had an ulcer?
- Are your menstrual periods unusually heavy?
- What do you usually eat for each meal?
- Are you often cold when others are not?
- Are there cultural factors you would like considered?
- What are your expectations of treatment?

Physical Assessment

Head and Neck

- Color of conjunctiva and sclera of eye
- Condition of gums, oral mucous membranes, and tongue
- Presence of enlarged cervical lymph nodes

Skin

- Color (pale) (check conjunctivae, palms of hands, and roof of the mouth in people with dark skin)
- Condition of fingernails (brittle, spoon-shaped)
- Presence of ecchymoses or petechiae
- Jaundice
- Nasal or gingival bleeding
- Hair (dry, brittle, thinning)

Chest and Abdomen

- Presence of swollen lymph nodes in armpits or groin
- Rapid respirations; shortness of breath on exertion
- Rapid pulse rate at rest
- Widened pulse pressure (greater distance between systolic and diastolic pressure)

- Epigastric tenderness
- Abdominal distention

Extremities

- Presence of swollen or painful joints
- Different lengths of fingers and toes

Urine and Stool

- Signs of blood

Physical Assessment

Skin. Although pallor may be a sign of anemia, it is not the most reliable sign. Many other factors can affect a person's complexion and skin color, including thickness of the skin, amount of skin pigment, and number and distribution of blood vessels near the surface of the skin. Pale mucous membranes or pale conjunctiva of the eye are better indicators of anemia. A very ruddy complexion with a red, florid appearance is typical of an excessive number of red blood cells (**polycythemia**).

Jaundice, or a yellowing discoloration of the skin and sclera of the eyes, can occur as a result of excessive destruction of red blood cells (hemolysis). When red blood cells are ruptured, bilirubin is released. The pigment eventually finds its way into the bloodstream, where it causes jaundice. If hemolysis is occurring, the urine will often contain bilirubin, giving urine a brown tea color.

Bruises; purplish patches; and small, red, pinpoint lesions (**petechiae**) are typical of thrombocytopenic purpura, a hemorrhagic disease sometimes associated with a decrease in the number of circulating platelets. For dark-skinned people, check the palms of the hands and soles of the feet for petechiae. Bleeding under the skin and formation of bruises in response to the slightest trauma are common in anemias, leukemias, and diseases affecting the bone marrow and spleen. These appear as darker areas on brown-skinned people.

Older Adult Care Points

- Older adults bruise more easily because of thinner skin and greater fragility of blood vessel walls.
- Aspirin, omega-3 fatty acids, vitamin E, ginkgo biloba, and some prescription drugs also may make older adults more prone to bruising.
- Bruising is not necessarily an unusual sign in this age group.

Cyanosis, or a bluish tint to the skin, can indicate hypoxia resulting from inadequate numbers of circulating erythrocytes. The gums or the roof of the mouth are the best places to check for a bluish color in dark-skinned people.

Mucous membranes. Nutritional deficiencies contributing to anemia and resultant hypoxia may cause sore and painful gums and tongue. The patient may have difficulty chewing and eating. The tongue may be smooth and beefy red. Bleeding of the gums may occur with toothbrushing when the platelet count is low.

Abdomen. Stomach pain or nausea can be caused by bleeding ulcers (a common cause of chronic blood loss). Black, tarry stools or coffee-ground emesis indicates gastrointestinal (GI) bleeding. Hiatal hernia also can cause a chronic blood loss.

Assignment Considerations

Observing for Blood

If a nursing assistant will be assisting the patient with toileting, remind that person to check the stool for signs of **melena** (dark stool containing blood pigments) and the urine for a smoky color

(indicating blood).

Clinical Cues

For hospitalized patients with thrombocytopenia, abdominal girth should be measured daily to detect internal bleeding. Mark the lateral aspects of the abdomen where the measuring tape is placed and measure at the umbilicus. Put the measuring tape in the same place each day.

Swollen and painful joints. Bleeding into the joints (**hemarthrosis**) is not uncommon in certain kinds of anemia or in hemophilia. This might be evidenced by swelling and slight redness in the area of the joints, or the patient may move more slowly and with obvious discomfort.

Lymph tissue involvement. Enlarged lymph nodes occur in a number of different blood disorders, as well as in infections and immune disorders. The nodes most often inspected and palpated are those under the arm, in the neck, and in the inguinal (groin) region. Lymph node enlargement is often found while bathing a patient or helping her with activities of daily living (ADLs).

Assignment Considerations

Changes to Report

When assigning tasks to a CNA or UAP, ask the person to report any swellings he notices when assisting the patient with bathing. State that the patient may bruise easily and ask for a report of any new bruised areas or patient complaints of bleeding of gums or elsewhere.

Enlargement of the spleen, which also accompanies polycythemia and several other blood disorders, might be described by the patient as a feeling of fullness on the left side of the upper abdomen. Palpate the abdomen gently in a patient with a suspected blood disorder. Do not palpate deeply if there is tenderness in the area of the spleen, because this could cause rupture of the spleen.

Mental state. Irritability and mental depression are often found in patients with blood disorders. Irritability, dizziness, difficulty in concentrating, and headache may be caused by a decreased supply of oxygen to the brain. Depression often accompanies the chronic lack of energy, difficulty in eating and enjoying food, and the many other problems from which patients with blood disorders often suffer.

Older Adult Care Points

An older adult who has developed pernicious anemia may present with confusion and a loss of mental faculties. This state may be initially believed to be Alzheimer disease. A blood count is important to establish the correct diagnosis.

Activity intolerance. Physical activity increases the demand for oxygen, but if there are not enough circulating RBCs to carry the necessary oxygen, the patient becomes physically weak and unable to engage in physical activity without severe fatigue. Note whether the patient is able to do things for herself or needs help to complete specific ADLs.

Think Critically

- Can you name four signs or symptoms that you might encounter when taking a patient's history that could indicate your patient may be anemic?
- How can the conjunctiva and the sclera of the eye provide information about anemia or jaundice?
- What signs and symptoms might indicate that the patient is suffering a chronic blood loss?

Nursing Diagnosis

Problem statements/nursing diagnoses for hematologic and lymphatic disorders are based on the problems the disorders cause for the patient. Problem statements/nursing diagnoses commonly associated with hematologic disorders are listed in **Table 15-2**. They must be individualized for each patient. Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

Table 15-2

Common Problem Statements/Nursing Diagnoses, Expected Outcomes, and Interventions for Patients With Blood Disorders

Problem Statement/Nursing Diagnosis	GOALS/EXPECTED OUTCOMES	NURSING INTERVENTIONS
Altered nutrition/Imbalanced nutrition related to iron deficiency blood loss, or vitamin B ₁₂ deficiency	Protein levels will be within normal limits within 6 wk. Hemoglobin levels will be within normal range within 3 mo. CBC will show increasing RBCs and Hb within 3 wk. The patient will administer her own B ₁₂ injections on a regular schedule.	Teach the patient about foods that meet required needs. Obtain dietary consultation as needed. Administer iron preparation; if liquid, give through straw. Give iron with juice or food containing vitamin C. Warn that stool may be greenish black. Monitor CBC count for evidence of increase in RBCs and Hg. Administer vitamin B ₁₂ as ordered; advise that lifetime therapy is needed.
Altered tissue integrity/Impaired tissue integrity related to inflammation of mucous membranes	The patient will perform mouth care diligently on schedule. Patient will display normal-appearing mucous membranes.	Give gentle mouth care before meals and q2h. Provide bland, easily chewed foods.
Altered activity tolerance/Activity intolerance related to decreased RBCs or Hb	Patient will use oxygen as ordered. Patient will alternate activities with rest. Patient will seek assistance with ambulation when dizzy.	Administer oxygen by nasal cannula at 3-6 L/min as ordered for patient with sickle cell crisis. Space activities, allowing rest periods for patient with fatigue. Assist with ADLs to prevent fatigue. If dizzy, caution to change position slowly; call for assistance with ambulation.
Pain/Pain related to ischemia and swollen joints	Patient will verbalize that pain is controlled by analgesics. Patient will verbalize that pain has decreased within 48 hr.	Elevate swollen joints and apply hot or cold packs. Teach to avoid strenuous exercise. Use bed cradle to support bed covers. Administer analgesics as ordered PRN.
Potential for injury due to low platelet count	Platelet count will be within safe limits after platelet administration. Patient will have no new hematoma formation or other evidence of bleeding.	Assess for signs of internal bleeding (bruises, blood in urine or stool); measure abdominal girth daily. Minimize trauma; handle gently. Apply ice packs and gentle pressure if hematoma seems to be forming. Monitor administration of platelets PRN. Use small-gauge needle for injections; rotate sites. Avoid injections, if possible. Apply pressure to puncture site or any invasive procedure for 10 min. No rectal meds. Use toothettes/no toothbrush.
Potential for infection due decreased leukocytes	Patient will have no evidence of infection.	Observe for early signs of infection and report. Take temperature q4h. Use strict aseptic technique for wound care and invasive procedures. Use protective isolation as needed. Teach patient good personal hygiene. Avoid sick people, crowds. Maintain integrity of skin and mucosa. Administer anti-infective drugs precisely as ordered.
Insufficient knowledge due to substances that damage bone marrow	Patient will verbalize knowledge of drugs and chemicals that are harmful to the bone marrow within 1 wk.	Assess for exposure to substances that could have damaged the bone marrow. Teach about drugs and chemicals that are harmful to bone marrow and how to prevent damage. Seek feedback to validate understanding of content taught.
Anxiety due to unknown outcome of diagnostic tests and knowledge of disease, treatment, and prognosis	Patient will verbalize purpose and expected experience for each diagnostic test ordered. Patient will verbalize fears regarding disease, treatment, and prognosis.	Provide teaching regarding each diagnostic test. Encourage verbalization of fears. Offer emotional support to patient and family.
Decreased self-esteem due to inability to perform usual activities	Patient will define ways to cope with physical limitations. Patient will verbalize strengths. Patient will discuss possibility of seeking counseling.	Assist to cope with limitations of the illness. Help plan ways to maintain appropriate activity. Help to focus on the things she can still do. Obtain counseling referral if psychological disturbance indicates need.
Altered family coping due to expenses of treatment and possible death of patient	Patient and family will seek assistance from community resources as needed. Patient and family will verbalize understanding of disease, treatment modalities, and their implications.	Refer leukemia patient and family to community resources, such as the American Cancer Society, for assistance. Assist family and patient to understand the disease, treatment modalities, and their implications. Encourage attendance for all family members in a support group. Obtain referral to social worker for further assistance. Encourage open communication within family.

ADLs, Activities of daily living; CBC, complete blood count; Hb, hemoglobin; PRN, as needed; RBCs, red blood cells.

■ Planning

Plan nursing care to provide rest periods for the patient. For patients with anemia, plan dietary teaching or consultation with the dietitian. **Patients with a blood abnormality are at higher risk for infection, so it is extremely important to use aseptic technique.** Patients with a blood abnormality should not be exposed to people who are ill with contagious diseases, such as colds or influenza. Nursing goals include:

- Prevent infection.
- Conserve the patient's energy and prevent undue fatigue.
- Correct nutritional deficiencies.
- Provide treatment to halt or slow the disease process.
- Control pain or discomfort.

Specific expected outcomes are written for individualized problem statements/nursing diagnoses.

■ Implementation

Handle patients with blood dyscrasias gently to prevent bruising and hematomas. Take care to apply pressure for 5 to 10 minutes after injections or venipuncture. Good skin care is essential, because the skin acts as a protective barrier against infection. Teach about nutrition and medication administration, prevention of infection, and measures to prevent bleeding. Pain control is important for patients with sickle cell anemia in crisis, patients with hemophilia with hemarthrosis, and patients with advanced leukemia.

■ Assignment Considerations

Report Oozing of Blood

Although you are responsible for checking patients for signs of bleeding, when a patient with a blood disorder has had blood drawn or an invasive procedure, ask the CNA or UAP to report any oozing noticed at the site or on bandages when he is providing basic care such as feeding or toileting.

■ Think Critically

When caring for a patient who has been in an automobile accident and has sustained trauma to the trunk of the body, what laboratory values should you check daily?

See [Table 15-2](#) for specific interventions for patients experiencing blood disorders. Other interventions are included in the discussion of the various disorders in [Chapter 16](#).

■ Evaluation

The evaluation process provides data to determine whether the specific outcome criteria are being met for each patient. Monitor laboratory values for blood counts and determine whether counts are improving to determine whether treatment and nursing actions are meeting the patient's needs. Assess for side effects and evaluate how the patient is tolerating the medication or other treatment for the underlying disorder.

■ Home Care Considerations

Evaluating Treatment

It is important that each home care nurse evaluate how closely the patient is following the prescribed treatment plan. Determine whether the treatment is effective, and if it is not effective, consult the provider about changing the plan.

■ Clinical Cues

When a patient with leukemia is undergoing chemotherapy, evaluate the blood count results to confirm that safe levels of leukocytes and platelets are present before administering another dose of a drug that inhibits their production.

Common Problems Related to Disorders of the Hematologic System

Excessive Bleeding

When injury has occurred, or spontaneous bleeding happens, you should immediately apply pressure to stop the bleeding (Figure 15-3). Severe bleeding can lead to irreversible hypovolemic shock and circulatory collapse from loss of intravascular fluid. Blood loss from an artery is bright red and will gush forth in spurts at regular intervals as the heart contracts. Blood from a severed or punctured vein leaks slowly and steadily and is dark red. Box 15-2 presents methods of controlling bleeding. If bleeding occurs in a patient who does not have sufficient clotting factors, a transfusion of that factor or of platelets will be ordered. See Chapter 16 for information on transfusions.

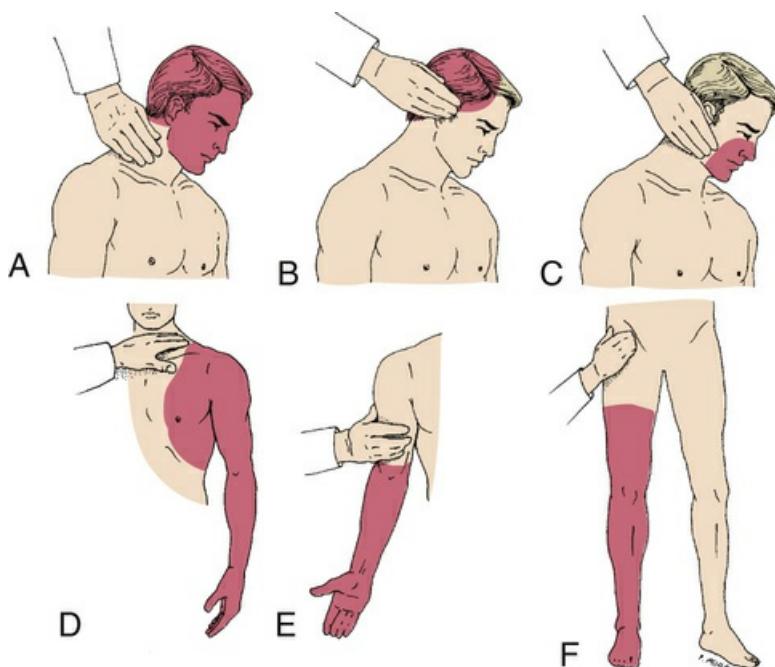

FIGURE 15-3 Locations of commonly used digital pressure points to stop hemorrhage. The screened areas are those within which hemorrhage may be controlled by pressure on a specific artery. **A**, Carotid artery. **B**, Temporal artery. **C**, External maxillary artery. **D**, Subclavian artery. **E**, Brachial artery. **F**, Femoral artery.

Box 15-2

Techniques to Control Bleeding*

- Position the body part that is bleeding over a firm surface and immobilize the part.
- Place a sterile dressing or clean cloth over the wound.
- With the flat palm of the hand or several fingers, apply direct pressure on the wound continuously for 5 minutes.
- Check whether bleeding has stopped after 5 minutes; if bleeding is still occurring, apply pressure continuously for another 10 minutes.
- When bleeding has stopped, gently remove hand pressure and apply a pressure dressing over the cloth or dressing by folding another dressing or piece of cloth several times and tying it firmly

over the wound.

- Check circulation distal to the wound to be certain that the pressure dressing is not so tight that circulation below the wound is cut off.
- Reinforce the dressing as needed by applying yet another layer of dressing as blood soaks through; do not remove previously applied dressings.
- If direct pressure will not stop the bleeding, and bleeding is considerable, apply pressure over the artery leading to the wound. (**Cut off arterial flow only as a last resort.**)
- Check for adequate pressure over the artery by determining a lack of pulse distal to the wound and patient report of a sensation of tingling and numbness in the wound area.

*Severe bleeding can lead to irreversible hypovolemic shock from loss of intravascular fluid and to circulatory collapse.

Excessive Clotting

Patients with certain disorders, such as polycythemia vera, and patients with high platelet counts are at risk for increased bleeding. Watch for symptoms of phlebitis (see [Box 15-1](#)).

Clinical Cues

Blood loss in the GI tract from an ulcer, tumor, or hiatal hernia can be in small amounts or in a large enough amount to make stool appear black (melena). Loss of 50 to 75 mL of blood from the upper GI tract is required before melena will appear.

Fatigue

Help decrease fatigue by spacing activities throughout the day, with frequent rest periods. Assure the patient that her stamina will improve as her red cell count and hemoglobin rise. Work with the patient and family to decrease chores and expectations while fatigue is being experienced. Fatigue is common with anemia, and it affects all aspects of the patient's life.

Anorexia

Serve small, frequent meals high in protein, vitamin C, and iron, unless contraindicated. Provide mouth care before each meal. Offer foods that are appealing to the patient. Keep the eating environment pleasant and free of odors. Ask family to sit with the patient, to offer socialization and encouragement during meals.

Pain

If the patient is experiencing pain, all comfort measures should be employed. Assess pain level at least every 4 hours and medicate as ordered. Teach relaxation and imagery and assist the patient to perform these techniques (see [Chapter 7](#)). Pain may escalate quickly for a patient with sickle cell anemia who is in crisis, so assess pain level at least every 2 hours.

Infection

When a patient is moderately to severely anemic, the oxygen-carrying capacity of the blood is considerably decreased. Less than optimal tissue perfusion and tissue hypoxia make it easier for pathogens to invade and cause infection. When WBCs are decreased or abnormal, there are fewer cells to fight infection. Patients with abnormalities of the blood need to be taught how to protect themselves from infection. Good hand hygiene is essential. Staying away from crowds and individuals with infections is necessary. Getting enough sleep and eating a well-balanced diet help keep the immune system as healthy as possible under the circumstances. Prophylactic antibiotics

may be given in certain situations. Precautions for patients who are prone to infection because of neutropenia are discussed in [Chapters 8 and 10](#).

If the patient develops an infection, close monitoring of therapy and symptoms is needed. Rest, plenty of fluids, and sufficient protein and vitamin C are required to help the patient heal.

Bone Marrow Failure

Bone marrow failure occurs from abnormal cells overcrowding the normal cells or from inadequate production of normal cells. Leukemia causes overproliferation of abnormal cells in the bone marrow. Chemotherapy and radiation, thrombocytopenic purpura, and chemical toxicity can be factors in bone marrow failure. Predisposition to anemia, thrombocytopenia, and decreased WBCs occur. Sometimes bone marrow recovery occurs if the toxic agent is avoided, but usually a bone marrow transplant or stem cell transplant is necessary.

Get Ready for the NCLEX® Examination!

Key Points

- When the number of RBCs or hemoglobin is decreased, the amount of oxygen that reaches the cells is reduced.
- Leukocytes are the first line of defense against microbial agents.
- Neutrophils perform phagocytosis.
- Lymphocytes such as B cells and T cells destroy foreign proteins.
- Platelets are the first line of cell protection to prevent bleeding when trauma has occurred.
- When the platelet count is low, spontaneous bleeding may occur.
- Bone marrow activity decreases by 50% in older adults.
- Blood in older adults coagulates more easily because of platelet **aggregation** (sticking together).
- Hemophilia, sickle cell disease, and certain types of anemias that cause blood disorders are inherited.
- Blood dyscrasias may be caused by drugs, radiation, or toxic substances (see [Box 15-1](#)).
- Nutritional deficiencies can cause anemia.
- A CBC with a differential count (count of the different types of white cells) can help diagnose many blood disorders (see [Table 15-1](#)).
- Bone marrow aspiration is used to diagnose a variety of blood disorders.
- A history is gathered and a focused physical assessment is performed for patients with a suspected blood disorder.
- There are common problem statements appropriate for patients with a blood disorder (see [Table 15-2](#)).
- Preventing infection, conserving energy, controlling pain, and correcting the underlying cause are the goals of care for patients with a blood disorder.
- Patients with blood disorders must be handled gently.
- Checking serial CBCs is part of the evaluation process.
- Methods to stop bleeding should be taught to patients and families.
- Self-care measures are taught to each patient to prevent infection.

Review Questions for the NCLEX® Examination

1. For a patient with the clinical finding of leukocytosis, the nurse should:

1. initiate transmission-based isolation precautions.
2. inspect for signs of active bleeding.
3. anticipate a possible provider order for antibiotic coverage.
4. schedule periods of rest and activity.

NCLEX Client Need: Physiological Integrity

2. For an older adult patient admitted for recent falls, which clinical finding(s) relative to the hematologic system would be associated with the aging process? (*Select all that apply.*)

1. Decreased hematocrit and red blood cells
2. Decreased antibody buildup from flu immunization
3. Prolonged prothrombin time and sedimentation rate
4. Increased neutrophils to fight infection
5. Increased coagulability, which predisposes to clots

NCLEX Client Need: Safe and Effective Care Environment

3. A patient works in a chemical plant. When answering an assessment question, he tells the nurse he wears protective clothing, mask, and equipment when handling any chemicals and he avoids coming into contact with radiation. This is an example of:

1. Unreasonable environmental fear.
2. Decreased risk for blood disorders.
3. Decreased risk for idiopathic thrombocytopenic purpura.
4. Protection against pernicious anemia.

NCLEX Client Need: Health Promotion and Maintenance

4. A patient is told that her hematocrit is very low. What symptoms would you expect the patient to experience?

1. Increased energy because of the increased percentage of red blood cells
2. Fatigue related to reduced oxygen transport
3. Reduced mobility caused by decreased lubrication of the joints
4. Increased thirst from salt retention

NCLEX Client Need: Physiological Integrity

5. A patient displays characteristic purple spots and patches. This assessment finding is called _____ and is often caused by _____.

1. ecchymosis; vitamin B₁₂ deficiency
2. thrombocytopenic purpura; platelet deficiency
3. angioedema; iron deficiency anemia
4. petechiae; bruising of the skin

NCLEX Client Need: Physiological Integrity

6. A nurse formulates the following expected outcome for a patient admitted with hemarthrosis: "The patient will have no new hematomas or other evidence of bleeding." The most appropriate nursing intervention would be to:

1. suggest the patient use a soft toothbrush.
2. handle the patient very gently, protecting joints.
3. keep the skin well lubricated.
4. place the patient on a mechanical soft diet.

NCLEX Client Need: Health Promotion and Maintenance

7. A nurse taking care of an older adult woman with pernicious anemia demonstrates understanding of the functional implications by:

1. promoting adequate rest.
2. actively listening to the patient's concerns.
3. monitoring for bleeding.
4. administering antibiotics.

NCLEX Client Need: Physiological Integrity

8. After removing a peripheral vascular access device, the nurse notes bleeding at the site. Put the following nursing actions in order of priority:

1. Tape a sterile dressing over the site.
2. Check for other areas of bleeding.

3. Apply direct pressure.
4. Elevate the extremity.

NCLEX Client Need: Safe and Effective Care Environment

9. A nurse initiates neutropenic precautions for a patient who has undergone chemotherapy. Which nursing action(s) would be considered appropriate? (*Select all that apply.*)

1. Use clean technique for wound care and invasive procedures.
2. Use transmission-based isolation precautions as needed.
3. Allow all visitors as desired.
4. Maintain integrity of skin and mucosa.
5. Provide analgesics, as needed.

NCLEX Client Need: Safe and Effective Care Environment

10. To confirm the diagnosis of pernicious anemia, the patient undergoes a Schilling test. This test involves a(n):

1. oral dose of vitamin B₁₂ followed by collection of a 24-hour urine specimen.
2. oral dose of a multivitamin containing B₁₂, followed by an injection of B₁₂.
3. B₁₂ injection followed by collection of a 24-hour urine specimen.
4. dose of radioactive vitamin B₁₂ followed by an injection of B₁₂ and collection of a 24-hour urine specimen.

NCLEX Client Need: Physiological Integrity

Critical Thinking Questions

Scenario A

You come upon an automobile accident and stop to help.

1. The first victim has a gash in his thigh and blood is spurting at regular intervals from the wound. What method would you use to stop the bleeding?
2. The second victim has a bleeding wound on the forehead. What method would you use to stop

the bleeding?

Scenario B

Mr. Jones has a disorder that has caused leukopenia. He lives alone. To prepare him for discharge home, you need to provide teaching for him.

1. What would you teach him about preventing infection?
2. What would you suggest regarding visitors who wish to see him?
3. What would you tell him about performing necessary errands?

Scenario C

Your 38-year-old male patient has a history of seizures and takes phenytoin. He has developed mild hypertension and takes hydrochlorothiazide to control his blood pressure.

1. What would you teach him about measures to prevent blood disorders?
2. What would you recommend to him for monitoring possible problems?

CHAPTER 16

Care of Patients With Hematologic Disorders

Objectives

Theory

1. Examine the causes of the various types of anemias.
2. Develop a plan of care for a patient with an anemia.
3. Explain the pathophysiology and care of sickle cell disease.
4. Compare cell abnormalities of polycythemia vera with those of leukemia.
5. Formulate a teaching plan for a patient with leukemia.
6. Illustrate why multiple myeloma is a disease affecting older people.
7. Discover the problems and treatments a patient with hemophilia faces.

Clinical Practice

8. Considering the goals of care, write expected outcomes for each of the appropriate problem statements for a patient with a blood disorder.
9. Prepare to provide preprocedure and postprocedure care for the patient undergoing a bone marrow aspiration.
10. Perform an assessment on a patient with a suspected hematologic disorder.
11. Assist with the development of a plan of care for an adult with leukemia.
12. Assess for signs and symptoms of disseminated intravascular coagulation.

KEY TERMS

thrombocytopenia (thrōm-bō-sīt-ō-PĒ-nē-ă, p. 357)

Disorders of the Hematologic System

Anemia

In the human body, healthy red blood cells (RBCs) carry oxygen to tissues. A balance is maintained between the production of new RBCs and the disposal of old “worn-out” RBCs. Anemia occurs when something interferes with this balance or interferes with the maturation of cells. **Anemia** is a state in which there are insufficient numbers of functioning RBCs, or a lack of hemoglobin, to meet the demands of the tissues for oxygen.

Etiology

There are three major classifications of anemia, according to cause:

- Anemia resulting from blood loss
- Anemia resulting from a failure in blood cell production
- Anemia associated with an excessive destruction of red cells

Rapid, severe bleeding leads to anemia from blood loss, **hypovolemia** (decreased volume of circulating blood), and, potentially, shock. A blood loss that leads to anemia may result from severe trauma to the blood vessels and massive hemorrhage, or the blood loss may be more gradual, as from a small, bleeding peptic ulcer that causes a chronic blood loss.

The amount of blood loss that leads to hypovolemic shock varies, depending on the ability of the patient's body to compensate for the lost fluid volume. A blood loss of even 500 mL in an adult who had normal circulating volume may cause hypovolemic shock. See [Chapter 44](#) for the treatment of shock. [Table 16-1](#) correlates amount of blood loss and consequent clinical manifestations.

Clinical Cues

The classic signs and symptoms of hypovolemic shock are falling blood pressure; rapid, weak pulse; cool, damp skin; thirst; decreased urine output; and restlessness progressing to decreased consciousness.

Table 16-1
Clinical Manifestations of Acute Blood Loss

VOLUME LOST	CLINICAL MANIFESTATIONS
10%	None
20%	At rest, no signs or symptoms; slight postural hypotension when standing; tachycardia with exercise
30%	Blood pressure and pulse normal when supine; postural hypotension and tachycardia with exercise
40%	Below-normal blood pressure, central venous pressure, and cardiac output at rest; rapid, thready pulse and cold, clammy skin
50%	Shock and potential death

Adapted from Lewis SL, Dirksen SR, Heitkemper MM, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2014, Mosby.

Anemia caused by a failure in cell production is the result of either a deficiency of certain substances necessary for the formation of RBCs or abnormal functioning of bone marrow. Examples of this type of anemia are:

- Nutritional anemia, in which there is an inadequate intake of foods containing proteins, folic acid, and iron
- Anemia resulting from bone marrow suppression caused by toxic substances
- Pernicious anemia, in which there is faulty absorption of specific nutrients, such as vitamin B₁₂

Iron or folic acid may not be well absorbed in people who have an intestinal malabsorption syndrome.

Hemolytic anemias, in which red cells are destroyed prematurely in the body, have many causes. Hemolytic anemia can be a result of genetic defects that affect cell structure, causing the cells to disintegrate quickly. Some of the hemolytic anemias, such as **thalassemia**, are inherited, whereas others are acquired when erythrocytes are exposed to poisonous agents, such as chemicals or certain bacterial toxins.

Immune reactions can cause blood cell **hemolysis** (destruction of red cells). The presence of

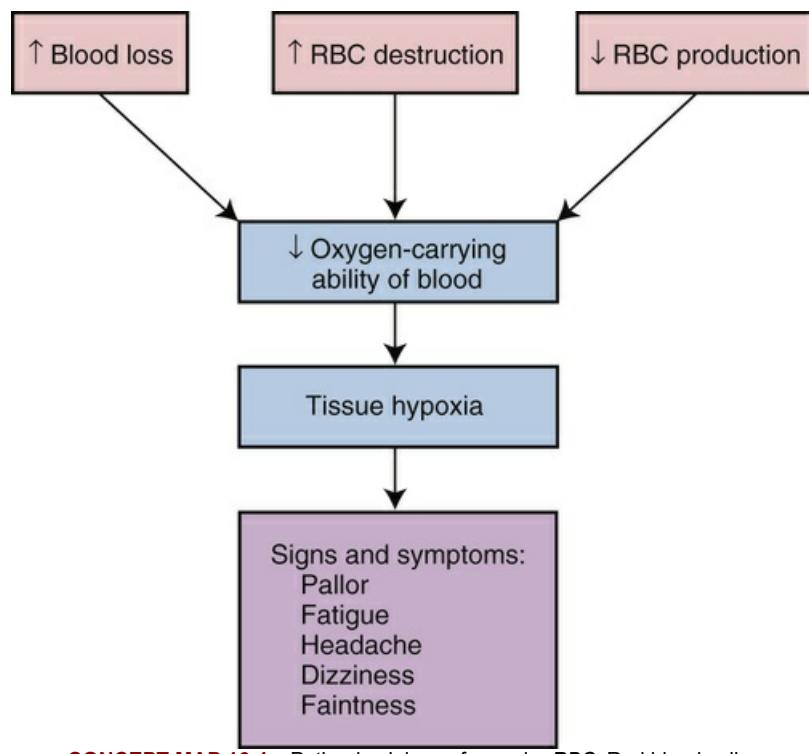

Toxins in the blood, infections such as malaria, transfusion reactions, and changes in blood chemistry may cause red cell hemolysis. Blood incompatibility in the newborn (**erythroblastosis fetalis**) is another cause.

Older Adult Care Points

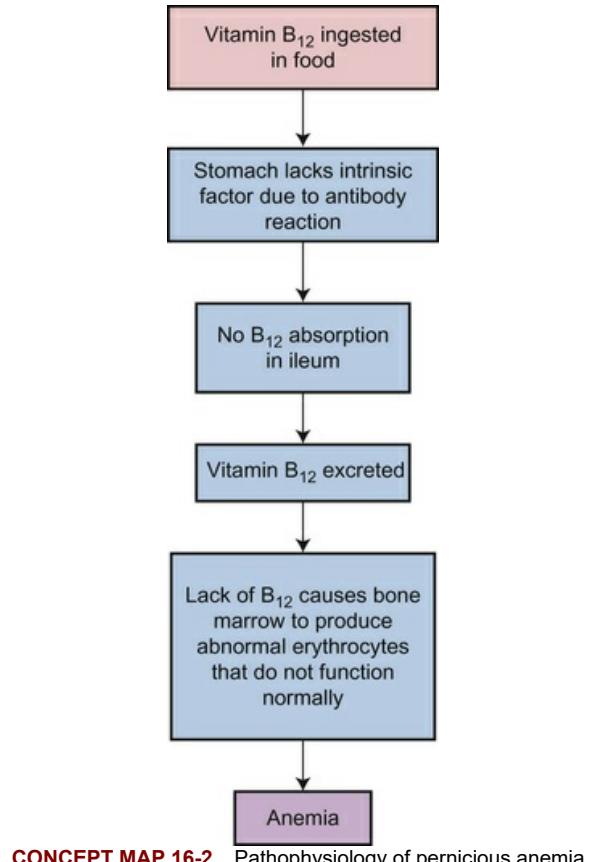

There is about a 20% incidence of anemia among older adults, most often because of poor nutrition. Shock may develop with smaller blood loss in this group because of decreased vascular tone and impaired cardiac function.

Pathophysiology

Iron deficiency anemia occurs when total body iron is insufficient and **erythropoiesis** (the production of red blood cells, as from the bone marrow) is diminished. The lack of iron impedes the formation of hemoglobin (Hb) ([Concept Map 16-1](#)). In **pernicious anemia**, an autoimmune disease, the intrinsic factor is missing from the gastric juices, and vitamin B₁₂ is not absorbed without it. Vitamin B₁₂ acts as a coenzyme in conjunction with folate metabolism and is important in the utilization of iron and protein for the manufacture of RBCs. The result of the missing intrinsic factor is that the red cell production is decreased, and those red cells that are produced are abnormal in their structure and function ([Concept Map 16-2](#)). To correct this condition, the provider will order the administration of vitamin B₁₂. A folic acid deficiency also contributes to anemia ([McCarron, 2013](#)).

CONCEPT MAP 16-1 Pathophysiology of anemia. *RBC*, Red blood cells.

CONCEPT MAP 16-2 Pathophysiology of pernicious anemia.

Hemolytic anemias associated with excessive destruction of RBCs are quite rare. When red cells are not normal, they break up easily or are destroyed by the body more quickly than are normal red cells. This RBC destruction causes the anemia.

Anemia occurs during end-stage renal disease when there is a deficiency of production of **erythropoietin**, a substance necessary to stimulate the creation of RBCs in the bone marrow. This problem is usually corrected by the administration of erythropoiesis-stimulating agents (ESAs), including epoetin alfa (Epogen) and darbepoetin alfa (Aranesp) (Poinier, 2013). These drugs can have severe side effects, including death, so they are used only until the hemoglobin level is high enough to prevent the need for a red blood cell transfusion. At this time, results are pending from two trials of these drugs, which are expected to provide guidelines for their administration. **Oxygen transport depends on the number and condition of the red cells and the amount of hemoglobin they contain.**

Clinical Cues

When a patient has had gastric bypass surgery or a gastrectomy, there is a risk of pernicious anemia from the resultant decrease of available intrinsic factor. Observe for signs of pernicious anemia in these patients.

Patients who take medications over a long period that suppress gastric acid secretion (histamine-2 inhibitors, proton pump inhibitors) must be watched for signs of pernicious anemia. Supplementation with vitamin B₁₂ injections or sublingual vitamin B₁₂ may help prevent this problem.

Signs and Symptoms

Signs and symptoms of anemias from causes other than rapid bleeding depend on whether the anemia is mild, moderate, or severe. Signs and symptoms of mild anemia (Hb 9.5 to 13 g/dL) are mild headache, palpitations, and dyspnea on exertion. Moderate anemia (Hb 6 to 10 g/dL) may include brittle nails, sore tongue, pallor, chronic fatigue, headache, and dizziness or faintness. Table 16-2 presents the many signs and symptoms of severe anemia. Tachypnea and tachycardia may

develop with severe anemia because of the decreased ability of the blood to transport sufficient oxygen to the tissues.

Table 16-2
Signs and Symptoms of Severe Anemia

BODY SYSTEM	SIGNS AND SYMPTOMS
General	Sensitivity to cold, lethargy, weight loss
Eyes	Blurred vision, blue sclera, yellowing of or pale conjunctiva, retinal hemorrhage
Skin	Pallor of face and palms, pruritus, jaundice, pale nail beds, pale mucous membranes, stomatitis, brittle nails, cheilitis
Cardiovascular	Palpitations, tachycardia, angina, systolic murmur, widened pulse pressure, intermittent claudication, CHF, possible MI
Respiratory	Tachypnea, orthopnea, dyspnea at rest
Gastrointestinal	Anorexia, difficulty swallowing, glossitis, enlarged liver, enlarged spleen, smooth tongue
Musculoskeletal	Bone pain
Neurologic	Headache, dizziness, impaired thinking, irritability, depression, fatigue

CHF, Congestive heart failure; MI, myocardial infarction.

Diagnosis

The microscopic appearance of the red cells in a film of blood that has been spread over a slide (a peripheral smear) gives information about abnormalities in size, shape, and color of erythrocytes circulating in the patient's bloodstream. The complete blood count (CBC) and differential cell count results are used to diagnose the presence of anemia. Measuring the quantity of hemoglobin determines whether the cells have sufficient amounts of hemoglobin to carry adequate oxygen to the body.

The prefix *normo-* refers to "normal"; the suffix *-cyte* refers to "cells"; the suffix *-chrom* refers to "color"; and the suffix *-ic* means "having the quality of" or "characterized by." Thus a normocytic, normochromic anemia is characterized by cells that are normal in size and color, but that have a deficiency in the number of RBCs and a low hematocrit. **This type of anemia usually occurs as a result of sudden blood loss.**

A hypochromic, microcytic anemia is characterized by decreased levels of hemoglobin (not enough color) and small (micro) cells. **This type of anemia is typical of an iron deficiency anemia.**

■ Common Foods High in Iron and Folic Acid

Foods High in Iron

- Beef liver
- Blackstrap molasses
- Chicken liver
- Cooked oatmeal
- Cooked prunes
- Cooked shrimp
- Dried apricots
- Egg yolks
- Kidney beans
- Lean beef
- Lima beans
- Whole grains
- Prune juice

- Raisins
- Spinach and green leafy vegetables
- Turkey

Adding raw spinach to dinner salads and snacking on raisins or dried apricots can quickly improve iron intake. Iron-enriched cereals and breads also can be added to the diet.

Foods High in Folic Acid

- Asparagus
- Beef
- Fish
- Cabbage
- Brussels sprouts
- Broccoli
- Legumes (kidney beans, etc.)
- Liver
- Eggs
- Whole grains

Note: Many of the foods high in iron also are high in folic acid.

Treatment

Correcting the underlying problem and then building up replacement blood cells treats anemia from chronic, slow blood loss. Anemia caused by inadequate iron, folic acid, or protein intake is managed with oral iron supplements, vitamins, and diet adjustment. If the anemia is serious, blood transfusions may be given, or iron supplementation may be administered intravenously (IV) with iron dextran (Imferon), sodium ferrous gluconate, or iron sucrose.

Pernicious anemia is treated by regular injections of vitamin B₁₂, or by weekly use of an intranasal form of cyanocobalamin (Nascobal), because the deficiency of intrinsic factor prevents adequate absorption of this vitamin from food. There must be sufficient folic acid in the diet or by supplement. [Table 16-3](#) presents the medications most commonly prescribed for hematologic disorders.

 **Table 16-3**

Drugs Commonly Used to Treat Disorders of the Hematologic System*

CLASSIFICATION	ACTION	NURSING IMPLICATIONS	PATIENT TEACHING
Mineral			
Ferrous sulfate (Feosol, Fer-In-Sol) Ferrous gluconate (Fergon) Ferrous fumarate (Feostat, Ircon) Iron dextran (Imferon) IM or IV Iron sucrose IV (Venofer) Sodium ferric gluconate IV	Increases elemental iron as a component in the formation of hemoglobin. Used to treat iron deficiency anemia.	May cause GI upset: nausea, diarrhea, or constipation; monitor for constipation. Tell patient that oral form will turn stool black. Do not give with milk, which reduces absorption. Dilute elixir in juice and give through a straw to prevent staining of the teeth. Do not crush enteric-coated or sustained-release tablets or capsules. For IM form, give with at least a 3-inch, 19- to 20-gauge needle and use Z-track technique to prevent staining of the skin. Change needles after drawing up the solution. When given IV, monitor closely for anaphylactic reaction. Give with epinephrine; have Solu-Medrol on hand. Flush line with 10 mL saline after infusion.	Take oral form with orange juice or other vitamin C-rich food. Avoid taking iron with milk products. Keep out of reach of children, because it is toxic. Have Hb checked according to provider's schedule to check response to medication. Eat foods high in iron. Increase fluids and roughage if constipation occurs.
Vitamins			
Folic acid (Folvite)	Promotes normal erythropoiesis; used in certain types of anemia.	May interfere with anticonvulsant blood levels. Chloramphenicol interferes with absorption. Increase foods high in folic acid.	Have blood count monitored according to provider's schedule to determine effectiveness of therapy.
Vitamin B ₁₂ Cyanocobalamin (Rubramin, Anacobin);	Acts as coenzyme for cell replication and hematopoiesis. Used in pernicious anemia, other GI	Give SC or IM daily for 5-10 days and then once monthly for maintenance. Can cause anaphylactic reaction when given IV. Deficiency more common in strict vegetarians.	Teach importance of maintaining monthly injections for life to prevent further episodes of pernicious anemia. Encourage increased intake of vitamin

methylcobalamin	disorders that decrease vitamin B ₁₂ absorption, and cases of dietary deficiency.		B ₁₂ in diet if deficiency is diet related.
Antimetabolite			
Hydroxyurea (Hydrea)	Inhibits DNA synthesis. Used to reduce episodes of sickling in sickle cell anemia. Used to eradicate abnormal cells in leukemia, myeloma, polycythemia vera, and some solid tumors.	Discontinue if WBC count is <2500/mm ³ or platelet count is >100,000/mm ³ . Capsule granules may be mixed with water if taken immediately. May cause GI problems: stomach upset, stomatitis, vomiting, diarrhea.	Use cautiously in presence of renal dysfunction. Radiation therapy increases toxicity. Monitor intake and output. Monitor for infection. Monitor blood counts for neutropenia, thrombocytopenia, and bone marrow suppression. Caution to avoid exposure to infection and to report signs or symptoms of infection promptly. Increase fluid intake to maintain adequate hydration. Give mouth care q4h to prevent stomatitis. Report bleeding to the provider.
Biologic Response Modifiers			
Epoetin alfa; erythropoietin (Epogen, Procrit)	A natural hormone produced by recombinant DNA techniques that controls rate of red cell production. Stimulates the bone marrow, functioning as a growth factor. Used to combat reduced production of erythropoietin in end-stage renal disease. Used as adjunct therapy in HIV-infected patients with anemia secondary to drug therapy.	Also used for patients with anemia secondary to chemotherapy and in rheumatoid arthritis patients who experience anemia from therapy. May be used to increase RBCs in anticipation of autologous blood transfusion before surgery.	May cause seizures. Monitor blood count closely; dosage may need to be reduced if hematocrit rises too rapidly. Monitor blood pressure closely; may cause rise. May cause pain in limbs and pelvis. Explain the purpose of the injections. Remind that the drug must be refrigerated; discard after 6 hr at room temperature.
Filgrastim (Neupogen)	Stimulates production, maturation, and activation of neutrophils.	CBC with differential before beginning therapy and twice weekly thereafter. Monitor BP; may cause transient increase.	Teach to inform provider if fever, chills, severe bone pain, chest pain, or palpitations occur.
Pegfilgrastim (Neulasta)	Regulates production of neutrophils within bone marrow. Increases phagocytic activity.	CBC and differential before therapy and routinely thereafter. Monitor for allergic reaction (i.e., peripheral edema). Assess muscle strength. Observe mouth for stomatitis, mucositis.	Inform of possible side effects and how to watch for allergic reaction. Remind that regular blood counts are important.

*Chemotherapy drugs are discussed in Chapter 8.

BP, Blood pressure; CBC, complete blood count; GI, gastrointestinal; Hb, hemoglobin; HIV, human immunodeficiency virus; IM, intramuscularly; IV, intravenously; RBCs, red blood cells; SC, subcutaneously; WBC, white blood cell.

For **hemolytic** anemia, the underlying cause is found and corrected (if possible) and then the blood volume is rebuilt with added iron and appropriate diet. If the anemia is severe, blood transfusion may be indicated.

Think Critically

Your patient who has suffered a blood loss and is now anemic complains that he is short of breath. Can you explain how blood loss might affect respiration?

Nursing Management

Assessment (Data Collection)

Whenever a patient complains of fatigue, headaches, or shortness of breath, anemia should always be considered. A CBC and data regarding physical signs and symptoms are collected.

Focused Assessment

Data Collection When Anemia Is Suspected

Health History

Ask the patient the following questions:

- Have you had any recent blood loss or trauma?
- Do you have chronic liver, endocrine, gastrointestinal, or renal disease?
- What medications, vitamins, supplements, or herbal products do you take?
- What surgeries have you had and when?
- Have you ever had radiation treatments or chemotherapy?
- Is there a history of genetic blood disorders in your family?
- Has your appetite or weight changed?

- Have you noticed any changes in your urine or stool?
- Are you experiencing shortness of breath, weakness, or fatigue?
- Have you noticed any heart palpitations?
- Do you get frequent headaches?
- Have you noticed any changes in vision or dizziness?
- Do you have pain or itching anywhere?
- Do you become cold when others are not?

Physical Assessment

Check for the following:

- *Skin:* Pale skin and mucous membranes; pale conjunctiva, yellowing of sclera; cracks in lips; brittle, spoon-shaped fingernails ([Figure 16-1](#)); jaundice; petechiae; ecchymoses; dry, brittle, thinning hair

FIGURE 16-1 Thin, concave (spoon-shaped) nails with raised edges may be seen on people with iron deficiency anemia.

- *Respiratory:* Tachypnea, orthopnea, dyspnea on exertion or at rest
- *Cardiac:* Tachycardia, systolic murmur, angina, ankle edema
- *Gastrointestinal:* Sore mouth, stomatitis, beefy red tongue, abdominal distention, enlarged liver or spleen
- *Neurologic:* Headache, dizziness, confusion, irritability, ataxia (unsteady gait), paresthesia

Pertinent Laboratory Values

- CBC, serum iron, ferritin, folate, cobalamin (vitamin B₁₂), stool for guaiac, urinalysis, serum erythropoietin

Nursing Diagnosis

Problem statements/nursing diagnoses are based on the clinical findings. Common problem statements include:

- Altered activity tolerance due to weakness and fatigue
- Altered gas exchange due to decreased hemoglobin
- Altered nutrition due to poor diet and anorexia
- Insufficient knowledge regarding nutrition and medication regimen

Specific nursing diagnoses can be chosen from the NANDA-I list (see inside the back cover).

■ Planning

Expected outcomes are written for the specific individual problem statements chosen to resolve the patient's problems. For the problem statements listed, outcomes might include:

- Within 1 month patient will be able to perform hygiene, dressing, and grooming activities without needing to rest between activities.
- Within 2 months patient will be able to carry out usual daily activities without shortness of breath or fatigue.
- Patient will eat three nutritious meals per day, containing sufficient iron, folic acid, vitamin C, and protein, daily.
- Patient will verbalize understanding of dietary and medication regimen within 1 week.

■ Implementation

Intervention is based on an understanding of the particular kind of anemia affecting the patient. Anemia from blood loss presents problems quite different from those related to chronic—and possibly incurable—aplastic or hemolytic anemia. For patients with anemia that interferes with clotting and that tends to cause bleeding episodes, nursing actions are directed toward preventing the episodes. For any patient with anemia severe enough to cause fatigue, assist with daily living activities and provide planned rest periods.

Nursing functions include administering blood, iron, vitamin B₁₂, and folic acid and monitoring for desired effects. Patients are educated about needed dietary adjustments. Patients should be taught that iron is absorbed more readily if vitamin C is simultaneously present in the gastrointestinal (GI) system. Taking iron medication with orange juice provides the necessary vitamin C.

Analgesia for headache or joint pain is given as ordered, and the patient is monitored for adverse side effects. More problem statements commonly associated with hematologic problems, including anemia, and lists of appropriate interventions are included in [Table 15-2](#).

▣ Older Adult Care Points

- Iron supplements should be taken 1 hour before or 2 hours after a meal, as long as they do not cause GI distress.
- Many older adults have chronic conditions that require daily medication. Antacids and many other drugs interfere with iron absorption.
- Check all drugs a patient is receiving to determine whether drug interactions might interfere with iron absorption.

■ Evaluation

Evaluation data are gathered to determine whether expected outcomes are being met. Laboratory values are particularly important when evaluating the care of a patient with anemia. However, equally important are data showing that the problems caused by the anemia are resolving.

Aplastic Anemia

Aplastic anemia (a rare disorder) may develop after a viral infection, as a reaction to a drug, or because of an inherited tendency. The disease is characterized by bone marrow depression and is believed to probably be an immune-mediated disease. Red cells, white cells, and platelet levels are decreased. The toxic effects of certain substances can be responsible for aplastic anemia. Some of these agents include benzene; insecticides; drugs, such as chloramphenicol (Chloromyctin), phenylbutazone (Butazolidin), and sulfonamides; some anticonvulsants; gold compounds used to treat rheumatoid arthritis; and alkylating agents or antimetabolites used in chemotherapy. Many other drugs can cause aplastic anemia, but this adverse effect is rare. Radiation exposure is another factor in the development of the disorder.

Safety Alert

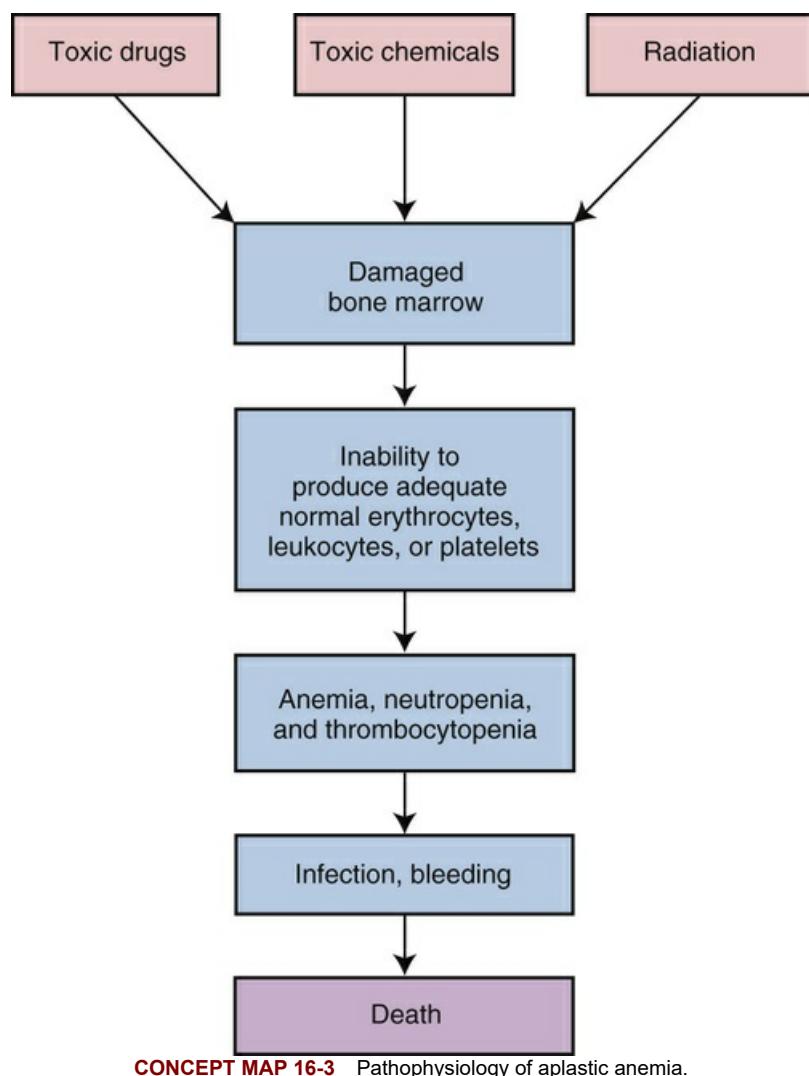

Monitor Drug Side Effects

It is your responsibility to monitor blood studies carefully for all patients who are receiving any drug that is potentially damaging to the bone marrow.

Think Critically

What chemical products in your home or garage are capable of causing bone marrow depression?

Impairment or failure of bone marrow function leading to the loss of stem cells is the cause of aplastic anemia (Concept Map 16-3). With aplastic anemia, the bone marrow has decreased cells and increased fatty tissue. In addition to the signs and symptoms of iron deficiency anemia, ecchymosis, petechiae, and hemorrhage[®] related to low platelet count also occur. Infection is common and may not cause an inflammatory response because of the very low leukocyte count. There is often frequent bleeding in the mouth.

Diagnosis is by blood count with differential, bone marrow biopsy, and ruling out other disorders. **Aplastic anemia causes an emergency situation.** Treatment must eliminate any identifiable underlying cause. Packed red cells and platelets are administered. Antibiotics are given

for identified infection; oxygen is sometimes administered to patients with low erythrocyte counts. Bone marrow transplantation (BMT) is the treatment of choice for patients younger than 45 years with severe bone marrow depression, but there must be an identical human leukocyte antigen (HLA) match. Immunosuppressive therapy with antithymocyte globulin (ATG) and cyclosporine is showing promise at improving outcomes. ATG contains polyclonal antibodies against human T cells. The 5-year survival rate for young survivors is about 70%.

Prevention of hemorrhage and infection is a top priority. Psychological support of the patient and family is important when they are faced with this life-threatening condition. Safety measures are priorities. Actions for problems of weakness and fatigue are the same as those presented for anemia earlier in the chapter. Other common nursing interventions are included in [Table 15-2](#). See [Chapter 8](#) and the Evolve website for precautions and actions for patients with disseminated intravascular coagulopathy and neutropenia and for safety measures when thrombocytopenia is present.⁸

Health Promotion

Dangers of Toxic Agents

All nurses should promote public education about the dangers of toxic agents. It is vitally important that people read and follow the label instructions on all cleaning agents, insecticides, and chemical compounds.

Sickle Cell Disease

Etiology

Sickle cell disease is a genetic disorder in which the gene is inherited⁸ from both parents (homozygous gene) ([Table 16-4](#)). Sickle cell disease is characterized by erythrocytes that contain more hemoglobin S than hemoglobin A. Sickle cell disease is found in less than 1% of African American newborns but also affects some people whose ancestors are from the Mediterranean region, the Middle East, and India. Approximately 8% of African Americans carry the gene.

Table 16-4
Comparison of Four Types of Anemia

CHARACTERISTIC RBC	ETIOLOGY	ADDITIONAL EFFECTS
Iron Deficiency Anemia		
Microcytic, hypochromic Decreased hemoglobin production	Decreased dietary intake, malabsorption, blood loss	Only effects of anemia
Pernicious Anemia		
Megaloblasts, immature nucleated cells	Deficit of intrinsic factor due to immune reaction	Neurologic damage Achlorhydria
Aplastic Anemia		
Often normal cells Pancytopenia	Bone marrow damage or failure	Excessive bleeding and multiple infections
Sickle Cell Anemia		
RBC elongates and hardens in "sickle" shape when O ₂ levels are low—short life span	Recessive inheritance	Painful crises with multiple infarctions Hyperbilirubinemia

RBC, Red blood cell.

From Gould BE, Dyer RM: *Pathophysiology for the health professions*, ed. 4, Philadelphia, 2011, Saunders.

Sickle cell trait, in which only about 50% of an individual's total hemoglobin is affected, is present in about 10% of the African American population of the United States. The trait is heterozygous, meaning that the person has an inherited gene for the trait from one parent only. People with the heterozygous trait for sickle cell are carriers; they can transmit the gene to their children even when they themselves do not show signs of the disease. Therefore genetic counseling and adequate screening for early detection of the disease are considered extremely important to control sickle cell anemia. In the United States many patients with sickle cell anemia live into their mid-40s. The most common cause of death is acute chest syndrome, in which damage occurs to the lungs.

Pathophysiology

When a patient with sickle cell disease experiences lower oxygenation than normal, the defective S

hemoglobin forms clumps in the red cells, causing them to assume a sickle shape, blocking blood vessels, breaking apart, and forming thrombi that cause organ damage. Sickle cells are destroyed by the body very quickly, causing anemia.

Sickle cell trait occurs in people who have only one gene, rather than a pair of genes, for sickle cell anemia. They usually do not have problems with cells assuming a sickle shape unless they experience severe oxygen deficiency.

Signs and Symptoms

The signs and symptoms of sickle cell disease are those that indicate lack of oxygen and blood flow, such as pallor, lethargy, and pain. The problems from interrupted normal blood flow affect many organs (Figure 16-2). Painful swelling of the hands and feet related to bone infarction from the sickled cells (hand-foot syndrome) may occur. After sickle cell crisis, signs typical of anemia occur because the abnormally shaped cells are very fragile, break easily, and are destroyed. The RBC and hemoglobin counts can drop very quickly during a crisis.

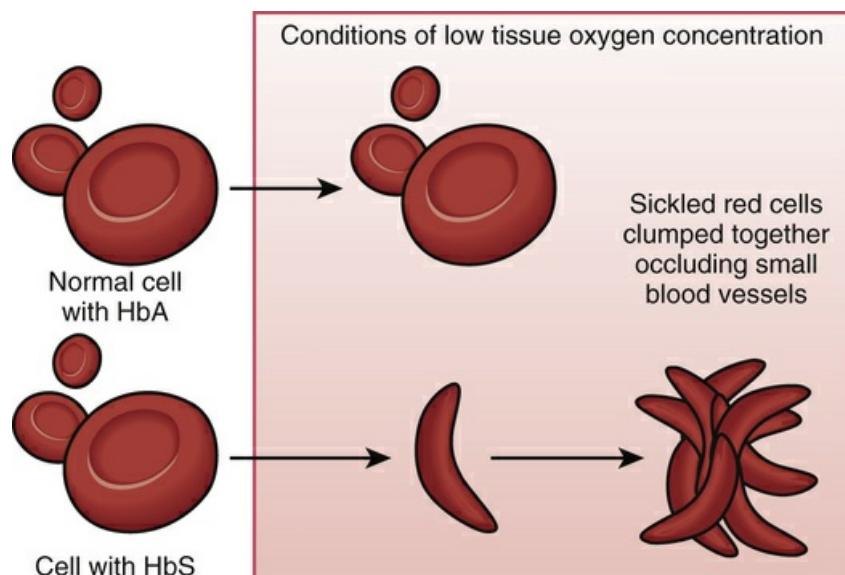

FIGURE 16-2 Sickling of red cells occurs when tissue oxygen is low. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 7, Philadelphia, 2012, Elsevier Saunders.)

Diagnosis

A peripheral blood smear can show sickled cells. The sickling test, which exposes RBCs to a deoxygenating agent, is diagnostic. Hemoglobin electrophoresis identifies the presence of abnormal hemoglobin. During crisis, there will be elevations of serum bilirubin because of the hemolysis of the abnormal red cells. Skeletal x-rays reveal bone and joint abnormalities.

Treatment

There is no cure or specific treatment for sickle cell anemia; treatment is primarily symptomatic and preventive. Patients should be taking folic acid regularly and eating a diet with sufficient protein to help build red cells. Infection is to be prevented, and the patient should receive all recommended immunizations against influenza, hepatitis A and B, pneumonia, tetanus, and other diseases.

Adequate intake of fluid on a daily basis is important to keep the blood as fluid as possible. Alcohol and recreational drugs are to be avoided, because they can cause complications. Quick attention for illness should be sought.

The drug hydroxyurea (Hydrea) has been found to reduce the frequency of sickling episodes. Patients taking this drug have shown a 50% decrease in the number of hospitalizations for crisis (SCD, 2015). If a crisis occurs, the patient may be treated at home with bed rest, adequate fluid intake, and analgesics. Pain control is important during a crisis. Narcotic analgesia with morphine is administered on a continuous basis, usually by patient-controlled analgesia pump. If the patient's

hemoglobin drops considerably or his condition suddenly deteriorates, he is hospitalized, given oxygen, and transfused with packed red cells and IV fluids are given. An attempt is made to mobilize the sickled cells and to prevent damage to major organs. Infection is treated with appropriate antibiotics.

There are many complications of sickle cell disease, including cholecystitis, stroke, congestive heart failure, and damage to all major organs (Figure 16-3). One of the most common problems is leg ulcers from impaired circulation to the legs and feet. Protecting the feet and lower legs from injury is important, because small wounds tend to develop into difficult-to-heal ulcers.

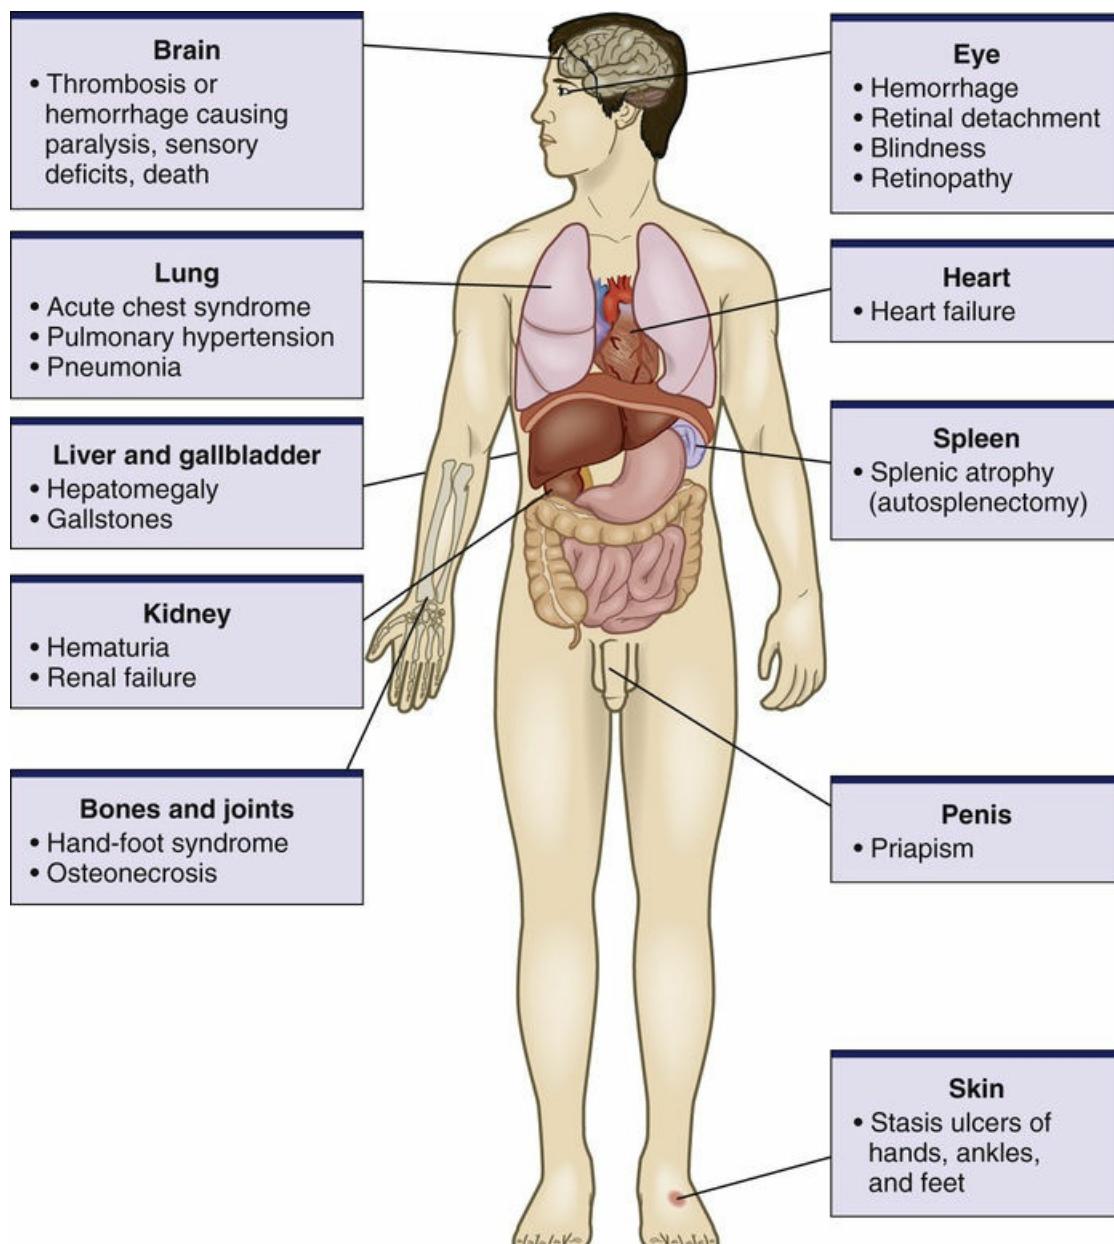

FIGURE 16-3 Clinical manifestations and complications of sickle cell disease. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Critical thinking for collaborative care*, ed. 6, Philadelphia, 2010, Elsevier Saunders.)

BMT is currently the only available treatment that can cure some patients. The scarcity of donors, the cost, and the risks involved greatly limit the use of this option. Gene therapy is offering hope for future treatment of sickle cell disease. Researchers at UCLA have discovered a technique to use hematopoietic (blood-producing) stem cells (HSC), which have had an antisickling gene introduced, from the bone marrow of patients with sickle cell disease. In early 2014, trials of this groundbreaking technique began with the hope for promising results.

Nursing Management

Nursing care is aimed at relieving the symptoms from complications of the disease and minimizing organ damage. Patients are taught to avoid high altitudes, vigorous exercise, and iced liquids. Patients are to maintain adequate fluid intake, refrain from smoking, and obtain treatment for infections promptly. Adequate rest is important, because patients with sickle cell anemia experience fatigue. **Assessment for adequate pain relief is a top priority** (Myers and Eckes, 2012). Intake and output will be monitored to prevent overloading the patient with fluid. Oxygen therapy is instituted if the patient is hypoxic (oxygen therapy helps prevent further cellular damage).

Polycythemia Vera

Excessive production of RBCs results in polycythemia vera. White cell numbers sometimes also increase, but not to the degree that they do in leukemia. The cause of polycythemia vera is unknown, but the disease is considered a neoplastic disorder. The blood becomes thick from the increased numbers of cells, blood vessels become distended, and blood flow is sluggish. Because of the sluggish flow, there is a tendency to develop blood clots. Blood pressure is elevated and the heart hypertrophies. Hemorrhage is common in areas of distended blood vessels. Signs and symptoms of polycythemia vera include a reddish face with deep-red purplish lips, fatigue, weakness, dizziness, headache, enlarged spleen (**splenomegaly**), and congested liver. Minor injury may result in excessive bleeding.

Diagnosis includes a genetic test for the JAK2V617F mutation. This mutation is positive in 95% of cases of polycythemia vera.

Treatment is aimed at reducing the number of blood cells. Phlebotomy, antineoplastic agents, and radiation therapy are all used. In phlebotomy, a blood vessel is pierced, and blood is drawn off. As much as 500 mL of blood at a time may be withdrawn every 2 to 3 months. **Increased fluid intake is essential to decrease blood viscosity, and aspirin is used to decrease platelet clumping and clot formation.**

A secondary polycythemia may develop in response to prolonged hypoxia and increased erythropoietin secretion. Secondary polycythemia does not have the same effects as primary polycythemia. In addition, 20% of patients develop acute myelogenous leukemia (AML).

Leukemia

The word *leukemia*, translated literally, means “white blood.” Actually, the white blood cells (WBCs) would have to number 1,000,000/mm³ before the blood would have a milky white appearance, and, although leukemia is characterized by an increase in the number of leukocytes, their number rarely rises above 500,000/mm³. In addition to the increase in number, however, the leukocytes of patients with leukemia are abnormal cells that do not function as normal white cells do.

Etiology

Leukemia is a cancer, and as with other types of cancers, the exact cause of leukemia is not known. There are factors considered to be closely linked with the development of leukemia. **Exposure to ionizing radiation in relatively large doses is one such factor. Another is exposure to certain chemicals, such as benzene, that are toxic to bone marrow.** Benzene is an ingredient in lead-free gasoline, and the incidence of leukemia has risen since lead-free gasoline has been in use. The amount of exposure to benzene and other chemicals that causes bone marrow suppression is unknown, and this amount possibly varies among individuals. **It is prudent to be careful about breathing gasoline fumes and using household chemicals and pesticides.** The third factor is the retrovirus known as *human T-lymphotropic virus 1 (HTLV-1)*, which causes human T-cell leukemia. People with an abnormal number of chromosomes and chromosomal translocations are at a greater risk for developing acute lymphocytic leukemia. About 90% of patients with chronic myelogenous leukemia have the Philadelphia chromosome.

Malignant production of WBCs is the actual cause of the disease. DNA becomes damaged. **Table 16-5** shows the clinical manifestations of leukemia and the factors linked to their development.

Table 16-5
Causes of Clinical Signs of Leukemia

MANIFESTATIONS	CAUSES
Severe infections	Immature and abnormally functioning leukocytes, even though there is an increased number of them.
Symptoms of anemia	Rapidly proliferating white cells apparently "crowd out" developing red cells and platelets.
Enlarged spleen, liver, and lymph nodes	Excess white cells accumulate within organs, causing distention of tissues.
Weakness, pallor, and weight loss caused by elevated metabolic rate	Increased production of white cells requires large amounts of amino acids and vitamins. Increased destruction of cells leads to more metabolic wastes that must be disposed of by the body.
Renal pain, urinary stones and obstruction to flow of urine, and urinary tract infection	Large amounts of uric acid are released when white cells are destroyed by antileukemic drugs.
Headache, disorientation, and other central nervous system symptoms	Abnormal white cells infiltrate the central nervous system.

Pathophysiology

An acute leukemia is one in which there are a large number of primitive cells, called *blasts*. In chronic leukemia, the predominant cells are more developed than blasts. Leukemias are also classified by the origin of the abnormal cells. Myeloid leukemia arises from the bone marrow, whereas lymphoid leukemia has its origin in the lymphatic system. There are four main types of leukemia: acute myelogenous leukemia (AML), chronic myelogenous leukemia (CML), acute lymphocytic leukemia (ALL), and chronic lymphocytic leukemia (CLL).

About 54,270 people will develop leukemia in 2015, and 24,450 people in the United States will die of it ([American Cancer Society, 2015](#)). In acute leukemia there is a sudden, rapid growth of immature blast or stem cells, rapid progression of the disease, and a short survival if the disease is not treated. Most leukemia occurs in adults older than 60 years.

Chronic forms of leukemia have a more gradual onset, slower disease progression, and a relatively longer survival time. CLL is common in men older than 50 years and accounts for one third of the new cases of leukemia annually. CML is most common in young and middle-aged adults. Over time CML progresses to the acute form, and eventual death is common.

Leukemia has three major effects:

1. Increased numbers of abnormal, immature leukocytes
2. Accumulations of these cells within the lymph nodes, spleen, and other organs
3. Eventual infiltration of the malignant cells throughout the organs of the body

Signs, Symptoms, and Diagnosis

Patients with chronic leukemias are often asymptomatic, and the disease is detected during a regular physical examination and routine CBC. Other signs and symptoms of leukemias include fever, malaise, frequent or persistent infections (sore throat, flu, etc.), swollen lymph nodes, enlarged spleen, bone pain, weight loss, and easy bleeding or thrombosis. Diagnosis is made by using the history, physical examination, CBC with differential, and bone marrow studies to rule out other disorders.

Treatment

Treatment is aimed at:

- Slowing down the growth of the malignant blood cells
- Maintaining a normal level of red cells, hemoglobin, and platelets
- Managing the symptoms and meeting the special needs of each patient

Acute leukemia treatment consists primarily of chemotherapy with a combination of antineoplastic agents targeted at different phases of the cell cycle. The drug therapy is divided into three phases: induction, consolidation, and maintenance. **Remission induction** therapy is initiated at the time of diagnosis and consists of an intensive combination chemotherapy aimed at achieving a complete remission of symptoms. **Consolidation** therapy is another course of the same agents, or others, at a different dosage level, and the goal is to achieve cure. **Maintenance** therapy is usually oral chemotherapy at lesser doses taken for 2 to 5 years to maintain remission.

Older Adult Care Points

Patients older than 65 years require reduced dosages of chemotherapeutic drugs (to prevent toxicity) because they have decreased kidney and liver function and the drugs are not metabolized as quickly in older adults as they are in a younger person.

Before chemotherapy is started, the patient should be well hydrated and given a drug orally to prevent hyperuricemia and kidney stones. Radiation therapy is used as a supplement to increase the success of treatment and to decrease discomfort from enlarged organs (spleen, liver). Cure is sometimes possible, as has been evidenced in children with ALL. Results in adults have not been as good. BMT is a possibility for patients who have had an initial remission with chemotherapy. Eventually it is hoped that stem cell treatment, or monoclonal antibody treatment combined with BMT, will provide lasting remission. If an enlarged spleen does not respond to radiation, splenectomy may be performed. **Chronic lymphocytic leukemia**—the most common leukemia seen in older adults—is not treated until the patient experiences symptoms. At that time a combination of chemotherapy agents is used.

Chronic myelogenous leukemia is currently treated with imatinib (Gleevec) or a combination of imatinib with other agents. Recombinant human alpha interferon has been shown to reduce the growth and division of leukemic cells in 55% to 60% of patients ([Navigating Cancer, 2015](#)). Hydroxyurea (Hydrea) may be used as a single chemotherapeutic agent. **Leukapheresis** (separation of white cells) may be done to reduce the massive number of circulating leukocytes that clog organs and cause damage. Blood is drawn, the unwanted white cells are separated out, and the remainder is returned to the patient. A small percentage of patients with CML are likely candidates for BMT.

Transfusions of blood components are prescribed for leukemia patients to maintain a near-normal blood picture. Platelet transfusion during or after chemotherapy often is necessary. Antibiotics may be given prophylactically during chemotherapy and are started immediately on signs of infection, because the body's defense mechanisms are seriously compromised. **Box 16-1** lists the chemotherapy agents used to treat the various types of leukemia.

Box 16-1

Chemotherapeutic Agents Used to Specifically Treat Leukemia

Chronic Lymphocytic Leukemia

- Chlorambucil
- Fludarabine
- Cyclophosphamide
- Vincristine
- Prednisone
- Rituximab
- Alemtuzumab
- Pentostatin
- Cladribine

Chronic Myelogenous Leukemia

- Imatinib
- Dasatinib
- Busulfan
- Hydroxyurea
- Interferon alpha

Acute Myelogenous Leukemia

- Cytosine arabinoside
- Anthracycline
- Daunorubicin
- Doxorubicin
- Anthracenedione
- Arabinosyl cytosine

Acute Lymphocytic Leukemia/Acute Lymphoblastic Leukemia

- Daunorubicin
- Vincristine
- Prednisone
- L-Asparaginase
- Cyclophosphamide
- Cytarabine
- 6-Mercaptopurine
- Methotrexate
- Cytosine arabinoside
- Clofarabine
- Doxorubicin
- Fludarabine
- Pentostatin
- Rituximab

Nursing Management

A thorough health assessment is performed, and specific problems are identified. Problem statements for a patient with leukemia include those appropriate for anemia, leukopenia, and thrombocytopenia. Patient problems to be addressed are:

- Potential for infection
- Abnormal bleeding
- Anemia
- Nutritional alteration with severe anorexia and weight loss
- Increased levels of uric acid in the urine and blood (resulting from chemotherapy)
- Psychosocial problems related to the effects of the disease, as well as the prescribed treatment

Collaboration with the dietitian and the pharmacist is a key point in nursing care of a patient with leukemia. [Nursing Care Plan 16-1](#) presents care for common problems of patients with leukemia.

Nursing Care Plan 16-1

Care of the Patient With Leukemia

Scenario

James Cathcart, a 42-year-old man, has acute myelogenous leukemia (AML). He is undergoing outpatient chemotherapy and is being followed at home by a home care agency nurse.

Problem Statement/Nursing Diagnosis

Potential for infection/*Risk for Infection related to low WBCs.*

Supporting Assessment Data

Objective: WBCs 2000/mm³.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will remain free of infection.	Monitor temperature daily. Report elevation >100.4° F (>38° C) that lasts for more than 4 hr.	Temperature elevation may indicate beginning infection.	Temp remains at 99.2° F (37.3° C).
	Teach patient and family to perform hand hygiene frequently.	Hand hygiene helps prevent infection.	Hand hygiene used consistently.
	Use meticulous hand hygiene when caring for patient.	Helps prevent transmission of microorganisms.	
	Have patient deep breathe q2h while awake.	Respiratory exercises help prevent respiratory infection from pooled secretions.	Using incentive spirometer regularly.
	Administer transfusion of granulocytes as needed.	Granulocyte transfusion provides WBCs to help fight infection.	Transfusion not ordered yet. Continue plan.
	Caution to eat only cooked fruits and vegetables.	Raw foods often carry bacteria that could cause infection.	States understands need to only eat cooked foods.

Problem Statement/Nursing Diagnosis

Fatigue/*Fatigue related to chemotherapy side effects.*

Supporting Assessment Data

Subjective: States has no energy; frequently falls asleep.

Objective: RBCs 3.2 million/mm³, Hct 33 mL/dL.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will be able to bathe and dress self without assistance.	Provide bathing assistance daily.	Conserves patient's energy.	Bathing assistance given daily.
	Encourage resting between care activities.	Prevents undue fatigue.	Is resting between activities.
	Encourage to perform ADLs in small segments.	Preserves energy.	Is combing hair and brushing teeth.

Problem Statement/Nursing Diagnosis

Altered family coping/*Disabled Family Coping related to loss of patient's income.*

Supporting Assessment Data

Subjective: Patient too weak to work; wife seeking full-time employment.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient's wife will cope effectively as primary wage earner.	Assist wife with defining alternatives for employment.	Helps focus direction for employment.	Wife is considering possible alternatives.
	Arrange consultation with social worker to coordinate patient's care when wife returns to work.	Social worker can arrange in-home assistance.	Social services appointment made.
	Suggest community resources that might help wife find employment.		Wife given list of community resources for employment. Continue plan.

Problem Statement/Nursing Diagnosis

Potential for injury/*Risk for Injury related to decreased platelets.*

Supporting Assessment Data

Objective: Platelets 106,000/mm³.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will not experience episodes of bleeding.	Monitor CBC and platelet counts.	Will detect further decrease in platelets.	CBC remaining stable, but platelets down to 104,000/mm ³ .
	Instruct to report oozing of blood from the gums.	Alerts to potential for impending bleeding episode.	No oozing of blood.

	Instruct to observe stool and urine for signs of bleeding.	
	Administer stool softener to prevent constipation.	Soft stool will not injure rectal mucosa, causing bleeding.
	Instruct to use soft toothbrush or toothettes to clean teeth.	Helps prevent small breaks in mucosa or skin that might cause bleeding.
	Instruct to use an electric razor to shave.	Using soft toothbrush and electric razor. Continue plan.

Critical Thinking Questions

- What measures are necessary for a patient who is immunosuppressed from chemotherapy and is susceptible to infections?
- How could you help boost Mr. Cathcart's self-esteem now that he has to give up his role as the family wage earner?

Infections from bacteria, viruses, and fungi are the most common cause of death in people with leukemia. Infection is a threat either because of abnormal function of bone marrow that is characteristic of the disease or because of suppression of bone marrow function as a result of therapy. Nursing measures to prevent infection are essential, as is vigilant assessment for early signs (see [Chapter 8](#) for information about risk for infection from the effects of chemotherapy or radiation).

Abnormal bleeding as a result of a very low platelet count is the second most common and dangerous complication of leukemia. Observation of the patient, awareness of the patient's current platelet count, and prevention of trauma to body tissues and blood vessels as a result of low platelets are primary concerns in nursing management.

Safety Alert

Prevent Bleeding

For a patient with a low platelet count, whenever venipuncture is performed, an injection is administered, or an intravenous catheter or needle is discontinued, pressure over the site must be maintained for 10 minutes to prevent continuous oozing.

Older Adult Care Points

- Older adult patients already have decreased immune system function. When leukemia develops, or is treated, these patients are at very high risk for infection.
- Older adult patients cannot tolerate hemorrhage, and so hemorrhage must be carefully guarded against.
- Other conditions may affect appetite. Emphasis on an appropriate diet, supplements, good nutritional status, and excellent mouth care can make a marked difference in the quality of life of an older adult with leukemia.

Anemia and its associated problems of fatigue, hypoxia, GI upsets, and cardiovascular complications affect patients with leukemia. The anemia can result from the disease itself, from excessive bleeding, or from the therapy administered. Nursing measures previously described for a patient with anemia are appropriate to the care of a patient with leukemia. Colony-stimulating factor drugs sometimes are used to counteract the anemia and neutropenia caused by treatment for leukemia. However, these drugs may stimulate the growth of abnormal cells, making the patient's condition worse, and so are used with caution.

Nutritional problems arise from any of a number of conditions. **Extreme weight loss and cachexia are nearly always seen in patients with advanced cancer.** Failure to eat sufficient amounts of nutritious foods is not the only reason this is so. As explained in [Chapter 8](#), metabolic changes that occur with the proliferation of malignant cells in the body also are responsible for weight loss and emaciation. If nursing measures to alleviate or minimize **stomatitis** (inflammation of the mouth), nausea, and vomiting are not effective, parenteral nutrition may be necessary, but

using total parenteral nutrition as a standard precaution for high-risk patients is not effective (Kim and Kim et al, 2012).

The increased level of uric acid that results from rapid cell destruction during chemotherapy often causes the uric acid crystals to settle out in the kidney structures, causing impaired renal function. Maintaining adequate hydration and administering drugs to decrease the production of uric acid are important nursing measures, as is close observation of fluid intake and urinary output. The emotional effect of a diagnosis of cancer and the psychosocial needs of the cancer patient and his family are discussed in [Chapter 8](#).

Think Critically

Why is it common for a leukemia patient to have frequent infections? What causes this problem? When caring for a leukemia patient, what parameters would you need to assess to detect early signs of infection?

Thrombocytopenia

Thrombocytopenia occurs when the platelet count drops to less than $150,000/\text{mm}^3$ and can be a life-threatening condition. Causes include bone marrow depression from chemotherapy or radiation, autoimmune diseases, bacterial and viral infections, disseminated intravascular coagulation (DIC), and overfunction[®] of the spleen. Certain drugs, such as nonsteroidal anti-inflammatory drugs (NSAIDs) and thiazides, also can result in platelet deficiency.

Immune thrombocytopenic purpura (ITP) is the most common acquired thrombocytopenia. It is an autoimmune disease in which there is abnormal destruction of circulating platelets. In ITP the platelets are covered with antibodies. In the spleen, these platelets are recognized as foreign and are destroyed by macrophages. This disorder commonly occurs in women between 20 and 40 years of age. The chronic form of ITP has a gradual onset, with transient remissions. Heparin therapy sometimes causes a type of thrombocytopenia that can be life-threatening. Porcine-prepared heparin seems to cause less of this problem than other types of heparin.

Many patients with thrombocytopenia are asymptomatic. Signs and symptoms of thrombocytopenia include **purpura** (purple spots and patches and small areas of multiple petechiae in the skin and mucous membranes) or large bruised areas caused by hemorrhage that are called **echymoses** ([Figure 16-4](#)). Bleeding can occur in any part of the body. Hemorrhage is the major danger.

FIGURE 16-4 Ecchymoses of the hand from thrombocytopenia. (From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 7, St. Louis, 2007, Mosby.)

Some patients recover spontaneously. Otherwise, transfusion of platelets is used to control hemorrhage. Splenectomy is done when the cause of the thrombocytopenia is unknown and the

patient does not respond to other therapy, with the hope that this will remove the cause of platelet destruction. The drug eltrombopag (Promacta) has been approved by the Food and Drug Administration (FDA) to treat the disease. It carries with it a risk for hepatotoxicity. Close monitoring of liver function tests is required.

Nursing care is focused on prevention of bleeding by careful handling of the patient, close observation for signs of spontaneous bleeding, and quick intervention. Invasive procedures are used only when essential. Patients are taught to avoid activities that might induce bleeding (see Chapter 8).

Multiple Myeloma

Multiple myeloma is a disease in which neoplastic plasma cells infiltrate the bone marrow and destroy bone. It occurs in about 4 in 100,000 people. Men are affected twice as often as women, and the disease occurs in African Americans twice as often as whites. The disease usually occurs after age 40 years, with the average age at diagnosis being 65 years.

Etiology and Pathophysiology

The cause of multiple myeloma is unknown. Risk factors include a family tendency toward the disease; ionizing radiation; and exposure to herbicides, insecticides, and chemicals (particularly benzene). Genetic factors and viral infections may play a role.

In multiple myeloma, abnormal plasma cells multiply out of control in the bone marrow. These abnormal cells produce excessive amounts of abnormal immune globulin and cytokines. The accumulation of the abnormal cells (tumors) in the bone marrow disrupts normal RBC, leukocyte, and platelet production. The disruption of normal cell production leads to anemia, impaired immune response with susceptibility to infection, and bleeding tendencies. The tumors disrupt normal bone marrow function and weaken the bone, predisposing the patient to frequent fractures.

Signs, Symptoms, and Diagnosis

The onset of multiple myeloma is gradual, and symptoms appear when the skeletal system is heavily involved. The patient may experience backache, bone pain that is worse with movement, or pathologic fractures and severe pain. Multiple myeloma is diagnosed by x-ray studies, bone marrow biopsy, and blood and urine tests. The appearance of light chains from the abnormal immune globulins in the urine, or Bence-Jones proteins, is a diagnostic sign. Because the bone destruction during multiple myeloma releases calcium, a hypercalcemia occurs that may lead to kidney stone formation and renal impairment. The CBC will show anemia, leukopenia, and thrombocytopenia. Bone marrow studies show large numbers of immature plasma cells.

Treatment

Chemotherapy or palliative radiation is used to combat the disease. Pain control is a primary concern. Hypercalcemia and osteoporosis often develop, and patients must be monitored and treated for these complications. Measures must be taken to prevent pathologic fractures.

The most common chemotherapy regimen is melphalan and prednisone. It is given orally for 4 to 7 days and repeated at 4- to 6-week intervals. Bortezomib (Velcade) is another successful, targeted therapy for multiple myeloma. Thalidomide (Thalomid), an immune-modulating drug, has proven very successful alone or in combined treatment. Interferon alfa may be used to prolong a remission. Bisphosphonates such as etidronate (Didronel), pamidronate (Aredia), or zoledronic acid (Zometa) inhibit bone breakdown and thereby decrease skeletal pain and hypercalcemia. The drug is given IV once a month. Measures are instituted to reduce blood calcium levels. There is no cure for multiple myeloma, but stem cell transplantation can prolong life for some patients.

Nursing Management

Supportive care for the many complications of the disease and treatment is provided. Encouraging adequate hydration with an intake of 3 to 5 L of fluid a day to minimize problems from hypercalcemia is a priority. Pain assessment and management are crucial to the quality of life for the patient. Acetaminophen and NSAIDs are used along with narcotic analgesics. Care is taken when moving the patient because of the potential for fractures.

Assignment Considerations

Assisting Patients With Blood Disorders

When enlisting the aid of a nursing assistant to help with positioning, moving, or toileting the patient, remind the person that the patient is very prone to bruising, bleeding, or fractures (as the case may be). Do not assign ambulation of a patient with multiple myeloma to assistive personnel, because any slight bump or twist of the body may cause a fracture.

Psychosocial care is essential, because the disease has remissions and exacerbations and is eventually fatal. The nursing care for a patient with a neoplastic disorder is covered in [Chapter 8](#). The patient and family must be taught about the signs and symptoms of hypercalcemia and instructed to report these signs and symptoms immediately to the provider. Measures to prevent falls must be instituted, both in the hospital and in the home. Mental status is monitored closely, and measures to protect the patient are instituted if confusion arises.

Hemophilia

Etiology

Hemophilia is an inherited X-linked disorder in which there is a deficiency of specific clotting factors. Classic hemophilia, or hemophilia A with a factor VIII deficiency, affects 1 in 5000 male births in the United States. Hemophilia B, or Christmas disease, causes a deficiency of factor IX. Christmas disease affects 1 in 30,000 male births. Both types of hemophilia are characterized by a delayed blood coagulation time that produces a prolonged period of bleeding after injury or surgery. These types of hemophilia almost always occur in males and are genetically transmitted through the mother. Although the mother does not have the disease herself, she and all her female descendants can transmit classic hemophilia to their offspring. Acquired hemophilia can affect both men and women, but the disease is rare. Hemophilia can develop as a result of formation of antibody to the clotting factors in blood transfusions, in patients with collagen vascular disease, or after a drug reaction. Idiopathic occurrence may be seen in people older than 50 years of age.

Pathophysiology

The hallmark of hemophilia is bleeding into joints, causing loss of mobility and unequal extremity lengths. In all types of hemophilia, there is a decrease in the amount of activity of 1 of the 11 different clotting factors normally present in blood and essential to the formation of clots. The blood of a hemophiliac patient forms a clot immediately after injury, but the clot breaks down and does not effectively stop bleeding. In von Willebrand disease, another type of bleeding disorder, there is a decrease in the activity of factor VIII, even though the factor is present in normal amounts in the plasma.

There are varying degrees of severity in the types of hemophilia, depending on the amount of the factor present and the role of the factor in clot formation. For patients with mild cases (those who have 25% to 50% of the deficient factor present in the serum), symptoms may not appear at all until a severe injury or surgery is followed by prolonged bleeding, and the hemophilia is thus discovered. In very severe cases (those in which less than 1% of the factor is present) the affected individuals may bleed spontaneously without injury, and severe hemorrhage can develop very quickly whenever an injury does occur.

Signs and Symptoms

The most obvious symptom of hemophilia is bleeding. Bleeding most often occurs internally, with leakage of blood into the joints, into the intestinal wall or peritoneal cavity, and into the deeper tissues of the body. **Hemarthrosis**—bleeding into the joints—produces swelling, pain, warmth, and limitation of movement similar to that experienced by patients with rheumatoid arthritis ([Figure 16-5](#)). Hemarthrosis is the primary problem for most patients with hemophilia. If the bleeding occurs in the intracranial spaces and thereby increases intracranial pressure, the patient may experience convulsions and brain damage that can be fatal. Other serious complications from internal bleeding in a person with hemophilia include obstruction of the airway as a result of hemorrhage into the

neck or pharynx and intestinal obstruction resulting from bleeding into the intestinal wall or peritoneum.

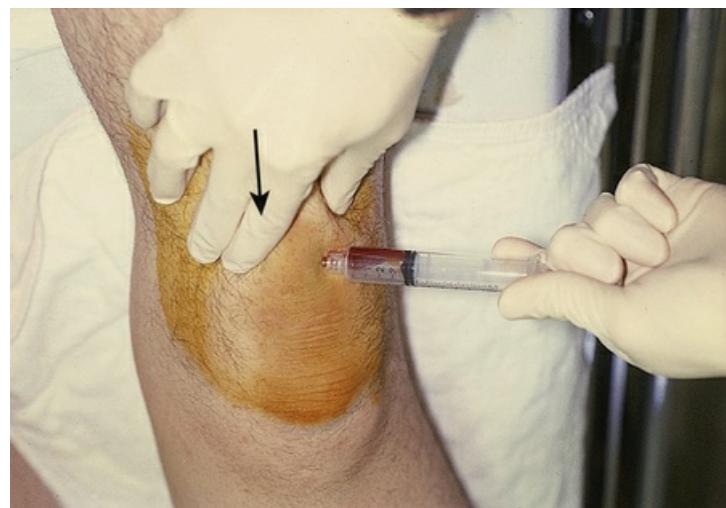

FIGURE 16-5 Aspiration of the knee to relieve the hemarthrosis common in hemophilia. (From Roberts JR, Hedges JS: *Clinical procedures in emergency medicine*, ed. 5, Philadelphia, 2009, Saunders.)

Diagnosis and Treatment

Diagnosis is by history, physical examination, CBC, and tests for the various clotting factors in the blood. In the more common types of hemophilia, transfusion of the missing blood factors prevents bleeding. Recombinant forms of factor VIII and factor IX are now available; both decrease the risk of transmitting undetected viruses and prions that can occur with donor blood.

For mild hemophilia A and for some subtypes of von Willebrand disease, desmopressin acetate (DDAVP), which is a synthetic form of vasopressin, may be given to stimulate an increase in factor VIII and von Willebrand factor. Tranexamic acid (Cyklokapron) and aminocaproic acid (Amicar) are administered to inhibit fibrinolysis by increasing clot stability.

Analgesic drugs and corticosteroids may be used to treat the joint inflammation and pain caused by hemarthrosis and by the common resultant arthritis. Safe analgesics include acetaminophen, oxycodone, propoxyphene, and pentazocine. Prophylactic factor treatment may be administered before dental procedures or in advance of other invasive diagnostic tests and unavoidable surgery.

Safety Alert

Avoid Taking Aspirin

Aspirin must never be taken by patients with hemophilia, because aspirin increases the bleeding problems. Patients must read the labels on every over-the-counter preparation to be certain that drug products do not contain aspirin or acetylsalicylic acid.

Many patients with hemophilia have been receiving blood products for a number of years. Unfortunately, many older patients have been infected with HIV or hepatitis C virus from contaminated plasma concentrates. The problem of contamination has created additional psychological stress for the patient with hemophilia. About 90% of older people with severe hemophilia are HIV positive. Death from AIDS has been common. Fortunately, adequate screening is in place now and the problem is resolving.

Nursing Management

In addition to administering the necessary clotting factors, interventions include elevating the injured body part, applying cold packs, controlling pain, observing for further bleeding, and

providing psychological support for the patient and family. You should also encourage genetic counseling for family members, if this counseling has not occurred previously.

Disseminated Intravascular Coagulation

Disseminated intravascular coagulation (DIC) is a complicated disorder that usually occurs in conjunction with tissue destruction. It accompanies serious problems, such as severe trauma, gram-negative sepsis, shock, respiratory distress syndrome, malignancy, transfusion reaction, amniotic embolus, and abruptio placentae (separation of the placenta from the uterine wall).

Damaged tissue liberates tissue thromboplastin, creating a state of excessive clotting in the microcirculation throughout the body. When excessive clotting depletes the body's clotting factors, hemorrhage follows, leading to hypotension or shock. DIC is always life-threatening.

The first signs of DIC are usually continued bleeding from an injection or IV site, extensive bruising in areas of injury, ecchymoses where there has been no trauma, and petechiae. There may be oral, vaginal, or rectal bleeding. Laboratory studies will reveal a decreased hemoglobin and low platelet count. The prothrombin and activated partial thromboplastin times will be increased. The fibrinogen level is reduced, and the fibrin degradation products level is increased. The D-dimer result is elevated.

Treatment consists of correcting the underlying problem (e.g., trauma, infection). Vascular volume is maintained with fluid replacement; vasopressor medications are given to decrease bleeding, and mechanical ventilation is needed for ventilatory support and tissue perfusion. Fresh frozen plasma—packed RBCs—and other blood coagulation factors are administered to restore blood volume and control clotting (Levi and Besa, 2012).

As a nursing priority, be alert to the possibility of the development of DIC whenever a patient has a condition that predisposes to it. Early detection of external bleeding and monitoring sensorium and vital signs for indications of internal bleeding are both extremely important.

Therapies Frequently Used in the Management of Hematologic Disorders

Transfusions

A blood transfusion involves the administration of a blood component. To minimize the risks of circulatory overload, HIV, hepatitis, transfusion reaction, and other problems related to the administration, blood usually is transfused only when there has been a large blood loss, when the patient has a deficiency of a blood component, or when there must be a total blood exchange in a newborn. **Table 16-6** shows some commonly used blood products, the usual amount given per transfusion, and reasons why each is used.

Table 16-6
Blood Products and Their Use

COMPONENT	VOLUME	INFUSION TIME	INDICATIONS
Packed red blood cells (PRBCs)	200-250 mL	2-4 hr	Anemia; hemoglobin <6 g/dL, depending on symptoms
Washed red blood cells (WBC-poor PRBCs)	200 mL	2-4 hr	History of allergic transfusion reactions Bone marrow transplantation patients
Platelets			
Pooled	About 300 mL	15-30 min	Thrombocytopenia, platelet count <20,000/mm ³ Patients who are actively bleeding with a platelet count <80,000/mm ³
Single donor	200 mL	30 min	History of febrile or allergic reactions
Fresh frozen plasma	200 mL	15-30 min	Deficiency in plasma coagulation factors Prothrombin or partial thromboplastin time 1.5 times normal
Cryoprecipitate	10-20 mL/unit	15-30 min	Hemophilia A or von Willebrand disease Fibrinogen levels <100 mg/dL
White blood cells (WBCs)	400 mL	1 hr	Sepsis; neutropenic infection not responding to antibiotic therapy

Adapted from Ignatavicius DD, Workman ML: *Medical-surgical nursing: Critical thinking for collaborative care*, ed. 6, Philadelphia, 2010, Elsevier Saunders.

Autologous (originating in one's self) blood transfusion is commonly used when the patient's own blood can be collected and reinfused. Blood is collected either during or after surgery (such as from chest drainage), or blood is donated by the patient during the weeks before surgery, for later use. Laboratory procedures that separate the various components by centrifuge or other means allow for the administration of only the particular element of blood needed by a particular patient.

Dextran—a plasma expander similar to human albumin—is often used to replenish volume quickly, until needed blood products are obtained from the blood bank. Several artificial substitutes for human blood that eliminate the need for cross-matching are being tested. So far, no artificial substitutes for human blood have been released for use by the FDA. Special precautions are always taken when any blood component is given. Blood banks have written procedures and policies for withdrawing and dispensing blood for transfusion.

Legal and Ethical Considerations

Consent for Blood Administration

The patient must have signed a consent form to receive a blood transfusion. If the patient is unable to sign, and the condition is life-threatening and no family member is reachable, the provider may make the decision to transfuse the patient.

Blood products are always checked by two nurses before administration (Figure 16-6). An LPN who is not qualified to transfuse blood may be asked to assist in checking the blood with the RN and to help monitor the patient during the infusion.

Legal and Ethical Considerations

Check the LPN/LVN Role

Some states have expanded their LPN practice act to include the administration of blood products.

Check your state's nurse practice act to see if that procedure is within legal practice in your state.

FIGURE 16-6 Two nurses must check the label on the blood product bag, the blood administration form of the blood bank, and the patient's armband and blood bracelet.

All blood bank and agency policies must be strictly followed to decrease the possibility of an adverse reaction or the administration of wrong blood to the wrong patient.

Nursing Management

Determine whether the patient has an IV site already established, and note what size catheter is in place. It is best to give blood through an 18-gauge or larger catheter. Best practices and safety require blood to be administered through a Y-type infusion set, with 250 mL of 0.9% saline on the other side of the Y. If a reaction to the blood occurs, the blood can be quickly shut off and the normal saline opened to maintain patency of the IV site. A special blood filter is included in the Y-type infusion set, and the drop factor is different from that of a regular IV tubing set. This infusion system is usually set up before the blood is obtained from the blood bank.

Older Adult Care Points

- Vessels in older adults are fragile. A 22-gauge cannula may be used for transfusion to older adults, rather than an 18-gauge cannula.
- Blood products should be transfused more slowly, to allow an older adult's body time to adjust to the added fluid.
- Careful assessment for fluid overload during and after the transfusion is essential. Signs of fluid overload are rapid bounding pulse, hypertension, and visibly swollen veins.

A lag period of 2 hours can be observed between each unit transfused to prevent fluid overload. The blood bag should be handled very gently to prevent damage to the cells. After obtaining the blood from the blood bank, immediately inform the nurse in charge of the patient that the blood is ready to be infused. The blood must be started within 30 minutes of arrival on the scene and should never be left at room temperature for more than 4 hours because blood is an excellent medium for bacterial growth; it takes between 1.5 and 4 hours for a unit of packed cells to infuse. ☎

Safety Alert

Blood Product Safety

Blood bags should never be heated in a microwave oven or placed in hot water. No other solution

or drug is ever administered through the same line or to the same site through which blood is infusing, because destruction of the cells might occur or a precipitate might be formed that could cause emboli.

Think Critically

If there has been carelessness in the proper identification method used to ensure that the right blood is given to the right patient, and the patient has a reaction, could the nurse be sued for negligence?

Transfusion Reaction

The word *reaction* means sensitivity to the blood itself, or sensitivity to the preservatives or other substances that have been added to a solution. Reactions to RBCs are the result of incompatibility between blood types. There are antigens on the surfaces of RBCs that can bring about a reaction when exposed to blood that is not the same type and is incompatible. The antigen-antibody reaction causes the cells to clump together and obstruct the flow of blood through the capillaries.

Safety Alert

Signs and Symptoms of a Transfusion Reaction

The symptoms of a transfusion reaction may be so mild that they go unnoticed, or so severe that death is the outcome (Table 16-7). In milder cases, the patient may develop a rash, hives, itching, or facial flushing. In more severe reactions, the patient may experience a variety of problems, including shock. A delayed reaction such as hepatitis, syphilis, malaria, or other infectious agents might not be evident until 4 to 6 weeks or longer after the blood has been given.

Table 16-7
Acute Transfusion Reactions

CAUSE	CLINICAL MANIFESTATIONS	MANAGEMENT	PREVENTION
Transfusion Reactions			
Infusion of ABO-incompatible whole blood, RBCs, or components containing 10 mL or more of RBCs	Chills, fever, low back pain, flushing, tachycardia, tachypnea, hypotension, vascular collapse, hemoglobinuria, acute jaundice, dark urine, bleeding, acute renal failure, shock, cardiac arrest, death	Treat shock if present. Initiate CPR, if indicated. Draw blood samples for serologic testing slowly to avoid hemolysis from the procedure. Send urine specimen to the laboratory. Maintain BP with IV colloid solutions. Give diuretics as prescribed to maintain urine flow. Give antipyretics, antihistamines as prescribed—avoid aspirin in thrombocytopenic patients. Insert indwelling urinary catheter or measure voided amounts to monitor hourly urine output. Dialysis may be required if renal failure occurs. Do not transfuse additional RBC-containing components until blood bank has provided newly cross-matched units.	Meticulously verify and document patient identification from sample collection to component infusion.
Circulatory Overload			
Fluid administered faster than the circulation can accommodate	Cough, dyspnea, pulmonary congestion, headache, hypertension, tachycardia, distended neck veins	Place patient upright with feet in dependent position. Administer prescribed diuretics, oxygen, and morphine. Phlebotomy may be indicated.	Adjust transfusion volume and flow rate based on patient size and clinical status. Have blood bank divide unit into smaller aliquots for better spacing of fluid input.
Sepsis			
Transfusion of bacterially infected blood components	Rapid onset of chills, high fever, vomiting, diarrhea, marked hypotension, or shock	Obtain culture of patient's blood and send bag with remaining blood and tubing to blood bank for further study. Treat septicemia as directed—antibiotics, IV fluids, vasoressors.	Collect, process, store, and transfuse blood products according to blood banking standards and infuse within 4 hr of starting time.

BP, Blood pressure; CPR, cardiopulmonary resuscitation; IgA, immune globulin A; IV, intravenous; RBC, red blood cell; WBCs, white blood cell.

Adapted from Lewis SL, Dirksen SR, Heitkemper MM, Bucher L: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2014, Mosby.

Clinical Cues

If there is **any** sign of reaction, the blood transfusion is stopped immediately, saline is started, vital

signs are taken, and the provider and charge nurse are notified.

Diphenhydramine hydrochloride (Benadryl) may be ordered by injection if an allergic reaction is suspected. In severe anaphylactic reactions the treatment is the same as for anaphylaxis caused by any extreme hypersensitivity. Should the patient's temperature rise above 100.4° F (38.0° C), the infusion is stopped, the saline started, and the provider notified. Follow the policies of the facility if a reaction occurs. As long as there are no signs of adverse reaction, the patient is assessed and vital signs are taken every 30 to 60 minutes until the transfusion is completed, depending on agency policy.

Think Critically

Your patient is receiving a unit of packed RBCs. When you assess him after the first hour of the transfusion, his pulse rate has increased from 78 to 84, he is slightly restless, and he is complaining of discomfort in his back. His temperature has risen from 98.4° F to 99° F. He has no skin rash and denies nausea. What would you do?

Leukapheresis

Leukapheresis is a procedure performed to clear excessive WBCs from the blood. Leukapheresis may be performed directly on the patient, or the procedure may be performed on separated blood products. When performed directly, the patient is connected to a blood separator machine. Blood is drained a bit at a time from the patient, the WBCs are washed out of the blood, and the red cells and plasma are returned to the patient. This treatment is used to lower the WBC count in patients with CML and is sometimes used to treat certain immune disorders, such as myasthenia gravis.

Biologic Response Modifiers: Colony-Stimulating Factor Therapy

Research with DNA-recombinant techniques has developed drugs that stimulate the bone marrow to produce erythrocytes or neutrophils. Erythropoietin (Epogen) is given parenterally to patients who have decreased erythropoietin resulting from end-stage renal disease or who have suppressed bone marrow from the toxicity of chemotherapy given for malignancy, rheumatoid arthritis, or HIV.

Granulocyte colony-stimulating factor (G-CSF; Neupogen, Neulasta) is given parenterally to combat neutropenia. It is used for patients with bone marrow suppression from chemotherapy, particularly for those with non-blood-related malignancies. Granulocyte-macrophage colony-stimulating factor (GM-CSF; Leukine) accelerates the recovery of bone marrow after autologous BMT in patients with ALL, Hodgkin disease, or non-Hodgkin lymphoma who have undergone total destruction of the bone marrow during therapy.

Bone Marrow and Stem Cell Transplantation

BMT is aimed at providing healthy bone marrow when the patient's own bone marrow is faulty or has been destroyed by chemotherapy or irradiation during attempts to rid the body of leukemic or other cancer cells. The bone marrow used for transplantation can be **allogeneic** (from another person) or **autologous** (from the patient).

Peripheral stem cells or stem cells from umbilical cord blood can also be used for transplant, if there is a good match with the patient. If the transplant is to be autologous, cells are taken from the patient during a period of remission of disease—either by bone marrow aspiration or by pheresis (for peripheral stem cells). Allogeneic bone marrow is harvested from an HLA-matched person. The HLA match is determined by tissue typing. Finding a good HLA match is difficult; there is only a 25% chance of matching with the patient's own sibling.

Cultural Considerations

Bone Marrow Donations

Most people willing to donate bone marrow are white. There is a 30% to 40% chance of an HLA match for a white patient and donor marrow. Far fewer African Americans have signed up at the bone marrow registry, and the chance for an HLA match for an African American patient is less than 20%. Efforts are being made to encourage African Americans to become bone marrow donors.

Bone marrow harvest is done in the operating room, where multiple aspirations from the iliac crests are performed. About 500 to 1000 mL of marrow is harvested. The marrow is filtered and may be purged to rid autologous marrow of cancer cells or to rid the allogeneic marrow of T cells. Autologous marrow is then frozen ([National Cancer Institute, 2015](#)). Nursing care after harvest consists of monitoring the dressings for bleeding and medicating the donor for pain in the hip area. Nonaspirin analgesics often are sufficient to control pain.

The patient undergoes a conditioning regimen to rid the body of malignancy or to obliterate the diseased bone marrow. This usually takes 5 to 10 days. The process involves intensive high-dose chemotherapy, and often includes total body irradiation. The patient experiences all the side effects of these treatments: bone marrow suppression, diarrhea, stomatitis, severe nausea, and vomiting. The patient is at extreme risk for infection. Meticulous supportive and preventive nursing care is essential during and after this phase.

At least 2 days after the end of chemotherapy, the BMT infusion takes place, through a central line, over approximately 30 minutes. If the bone marrow or stem cells are from an allogeneic donor, the infusion takes place right after harvest. The process of engraftment begins as the cells find their way to the marrow-forming locations in the patient's bones and establish themselves there. Engraftment takes 2 to 5 weeks and is considered successful when the patient's erythrocyte, leukocyte, and platelet counts begin to rise. Until engraftment is complete, the patient is at dire risk of infection and hemorrhage. Other complications include failure of engraftment and graft-versus-host disease, in which the cells see the patient's tissues as foreign and mount an immune attack. Thrombosis and phlebitis in the liver also can occur; either will cause liver damage if not resolved.

Oxygen Therapy

Low concentrations of oxygen may be administered to relieve severe dyspnea and hypoxia during the acute phase of a blood disorder. The treatment is mostly symptomatic, but it does offer some relief if there is sufficient hemoglobin to carry the oxygen to the tissues. With sufficient hemoglobin transportation, oxygen administration may prevent a myocardial infarction. The care of a patient receiving oxygen therapy and the need for careful monitoring of blood gases are discussed in [Chapter 14](#).

Iron Therapy

Iron is one of the principal elements in the production and maturation of RBCs. When the body lacks iron, the amount of hemoglobin is decreased in the red cells, making them very small and pale in color. In simple iron deficiency anemia, the condition is relieved by administering iron salts. The iron preparations most often used are ferrous sulfate and ferrous gluconate. Ferrous sulfate is believed to be absorbed the best.

Although iron salts are absorbed better from an empty stomach, they are irritating to the GI tract. There will be fewer gastric upsets if this medication is given in divided doses and immediately after meals. The patient should be warned that taking iron salts by mouth produces greenish black stools and that there is no cause for alarm if this change in the color of stools occurs. Because iron salts may form deposits on the teeth and gums, causing a discoloration, the liquid forms of this medication should be given through a straw. After administration of each liquid dose, the teeth should be thoroughly cleansed and the mouth well rinsed.

Some patients suffer such severe gastric disturbances from the oral intake of iron salts that the medication must be given by another route. Patients who are anemic because of gastric or intestinal bleeding cannot take iron by mouth because the irritation aggravates their condition. The drug of choice in these cases is iron dextran ([Imferon](#)), an iron preparation that is given IV or is injected deep into the muscle. Such intramuscular (IM) injections must not exceed 2 mL at each site, and the sites of injection should be rotated to allow for proper absorption and to minimize the hazards of local inflammation. The Z-track technique for IM injection is recommended. Patients receiving an IV infusion of iron dextran must be watched closely for anaphylactic and other adverse reactions.

Vitamin C usually is given with iron, because it enhances iron's absorption. If a pharmaceutical preparation of vitamin C is not prescribed, the patient can take the iron salts with orange juice or another juice that is a good source of vitamin C.

❑ Think Critically

What would you teach a home care patient who is complaining that the iron medication is causing a mild nausea, stomach discomfort, and constipation?

Vitamin B₁₂ Therapy

Vitamin B₁₂ has two main functions in the body. First, vitamin B₁₂ is needed for RBCs to develop into mature, normally functioning cells; second, vitamin B₁₂ is necessary for nerve cells to function normally. Another B-group vitamin, folic acid, also is needed for RBC maturation, but it has no effect on the nervous system. Vitamin B₁₂ is used to treat pernicious anemia.

Injections of vitamin B₁₂ are given daily for the first few weeks and later may be spaced a week apart. As the patient improves, vitamin B₁₂ injections may be necessary only once a month, but injections must continue for the duration of life for patients with pernicious anemia.

In addition to taking supplemental iron and vitamins, patients with nutritional anemia should eat nutritionally balanced, high-protein meals.

❑ Nutrition Considerations

Hints for Adding Protein to the Diet

- Mix dry skim milk into the milk called for in recipes.
- Provide between-meal shakes made with commercial protein powder available at the grocery or health food store.
- Add dry skim milk to hot or cold cereal, scrambled eggs, soups, gravies, meat loaf or meatballs, casseroles, and desserts.
- Add diced or ground meat to soups and casseroles.
- Drink commercial canned high-protein drinks (available from pharmacies) between meals, or use instant breakfast drink mix.
- Add cream cheese or peanut butter to breakfast breads.
- Eat peanut butter on crackers, apples, celery, or toast for snacks.
- Mix cooked diced shrimp, tuna, crab, or ham with sliced boiled eggs in cream sauce and serve over cooked rice, pasta, biscuits, or toast.
- Eat desserts made with eggs.
- Eat commercial high-protein bars for snacks, available at grocery, health food, or sporting goods stores.

Splenectomy

Indications for surgical removal of the spleen include:

- Severe trauma to and rupture of the spleen
- Splenomegaly caused by rapid destruction of blood cells
- Splenomegaly from blood disorders, such as leukemia

If the spleen is removed, the other organs of the monocyte-macrophage system take over many of

its functions. Individuals who no longer have a functioning spleen are at a very high risk to develop life-threatening infections, especially those caused by pneumococci. It is recommended that these persons receive the Pneumovax vaccine. They are advised to consult a provider and take preventive antibiotics as prescribed when they experience even a seemingly trivial respiratory infection.

A patient with a ruptured or torn spleen is in immediate danger of hemorrhage and shock. Whenever an accidental blow, stab wound, or gunshot wound occurs in the vicinity of the spleen, the patient must be watched closely for signs of internal bleeding, such as an expanding abdomen and increased pain. After surgery, the patient is observed for early signs of infection, abdominal distention, and other more general complications of abdominal surgery.

Community Care

Patients with blood disorders are treated in many different places in the community. Patients undergoing chemotherapy may attend an outpatient clinic to receive the doses of the drugs they need. Support groups for patients with the various disorders may meet in hospitals, clinics, churches, schools, or other community locations. Patients with sickle cell disease or hemophilia may attend ambulatory clinics.

Patients with blood disorders are commonly treated as home care patients. An older adult patient with pernicious anemia who is home-bound may need a nurse to give vitamin B₁₂ injections and draw laboratory specimens for periodic blood counts. Patients with leukemia are commonly followed at home during chemotherapy and recovery periods. Patients with sickle cell problems are more likely to be treated in the home setting, after the initial crisis period is over. In some instances blood products are administered at home. Some types of chemotherapy agents are given in the home setting, and the patient must be monitored for all of the adverse effects that such therapy can cause.

Home care nurses must do considerable patient and family teaching about prevention of infection, prevention of and treatment for bleeding episodes, appropriate nutrition, and regulation of medication. The home care nurse manager will coordinate care for patients with their provider, pharmacist, home infusion company, home health aide, and family.

Get Ready for the NCLEX® Examination!

Key Points

- Anemia results in insufficient oxygen being carried to cells for the body's needs.
- Anemias result from blood loss, failure in blood cell production, or excessive destruction of red cells.
- Hypovolemia from blood loss may result in shock.
- Blood cell production requires protein, folic acid, and iron.
- Pernicious anemia results from lack of intrinsic factor and faulty absorption of vitamin B₁₂.
- There are a variety of causes of hemolytic anemia, some of which are genetic.
- A CBC and differential (peripheral smear) are used to diagnose blood disorders.
- Sickle cell disease is a genetic inherited disorder in which the affected gene is transmitted from both the father and the mother.
- The main method of sickle cell crisis prevention is hydration; the primary treatment is rehydration and pain control.
- Abnormal hemoglobin causes red cells to sickle when oxygen tension in the blood is lowered.
- There are many signs and symptoms and problems for those with sickle cell disease (see [Figure 16-3](#)).
- Nursing care for sickle cell disease and crisis is aimed at relieving the symptoms of complications and minimizing organ damage.
- Treatment of anemia is aimed at curing the underlying disorder and providing nutrients or supplements needed for building red blood cells.
- Aplastic anemia can be life-threatening and may require a bone marrow or stem cell transplant.
- Polycythemia vera causes blood to become too thick and predisposes to blood clots.
- Thrombocytopenia affects the platelets and causes bleeding that can be life-threatening.
- Nursing care for thrombocytopenia focuses on preventing bleeding.
- There are four major types of leukemia: chronic lymphocytic, chronic myelogenous, acute lymphocytic/lymphoblastic, and acute myelogenous.
- Agents that are toxic to the bone marrow are a key factor in the development of leukemia.
- Leukemia is acute or chronic, according to the phase of cell development present and the symptoms.
- A patient with leukemia may be asymptomatic or may have fever, malaise, and frequent infections.
- Treatment for leukemia is aimed at slowing the growth of malignant blood cells and maintaining normal levels of red cells, hemoglobin, and platelets.
- Bone marrow or stem cell transplantation is an option for certain types of leukemia.
- Infection and hemorrhage are two major complications of leukemia.
- Hemophilia is mostly an inherited disorder affecting the blood's ability to clot.
- Bleeding into the joints is the major problem of hemophilia.
- Blood factor replacement is the treatment for hemophilia.
- DIC occurs in conjunction with many disorders.
- There is clotting in the microcirculation and bleeding in DIC.
- Blood transfusions must be administered very carefully, because reactions can be serious or fatal.
- Patient consent is needed before blood component transfusion.
- There are many signs and symptoms of a blood transfusion reaction (see [Table 16-7](#)).
- If there is any sign of a transfusion reaction, the transfusion is stopped immediately.
- Bone marrow transplantation requires an HLA match and is a dangerous procedure.
- Iron, vitamin C, folic acid, and vitamin B₁₂ supplementation are used to treat anemias.

Review Questions for the NCLEX® Examination

1. While reviewing the laboratory results for a patient who had gastric bypass surgery last year, the nurse notes that the amount of red blood cells has remarkably decreased. The nurse suspects that the anemia is related to:

1. vitamin B₁₂ deficiency.
2. chronic renal failure.
3. iron deficiency.
4. bone marrow suppression.

NCLEX Client Need: Physiological Integrity

2. An emergency department patient has a suspected gunshot wound to the abdomen. The nurse who finds a profusely bleeding abdominal wound should anticipate which signs(s) and symptom(s) of profuse blood loss? (*Select all that apply.*)

1. Increased blood pressure
2. Rapid, weak pulse
3. Cold, clammy skin
4. Urine output >50 mL/hr

5. Decreased blood pressure

NCLEX Client Need: Physiological Integrity

3. The patient is prescribed Feosol oral medication for a mild anemia. Which patient statement indicates a need for further teaching about this medication?
1. "The medication is absorbed best on an empty stomach."
 2. "The medication is more effective if I drink orange juice as well."
 3. "I should take the medication with milk."
 4. "I should increase fluids and fiber to prevent constipation."

NCLEX Client Need: Health Promotion and Maintenance

4. You are assessing a new admission with leukemia. You have asked her about symptoms and she replies, among other things, that she is very tired. You are concerned that this may endanger her because (*select all that apply*):
1. she will not have the energy to socialize, and because most leukemia patients are children, this will interfere with her developmental stages.
 2. the fatigue will put her at risk for increased falling and because most people with leukemia are older than 60 years she is already at increased risk.
 3. the fatigue could put her at risk for falling asleep while driving.
 4. fatigue is a sign that the leukemia is most likely incurable.

NCLEX Client Need: Safety and Infection Control

5. A nurse starts a peripheral venous access site on a patient who had multiple traumatic injuries. The nurse notes blood in the urine and the feces. Suspecting DIC, the nurse expects which laboratory result?

1. Increased hematocrit
2. Elevated platelet count
3. Increased activated partial thromboplastin time

4. Decreased D-dimer

NCLEX Client Need: Physiological Integrity

6. Your patient has been diagnosed with multiple myeloma. What are some considerations while planning nursing care for this patient? (*Select all that apply.*)

1. Be very gentle while moving the patient.
2. Encourage vigorous mobility activities.
3. Delegate the care to a nursing assistant.
4. Know that the psychosocial care is essential.
5. Place the patient in protective isolation.
6. Medicate as ordered for bone pain.

NCLEX Client Need: Safe and Effective Care Environment

7. A patient with multiple myeloma may display which signs and symptoms on assessment?

1. Ruddy complexion and elevated RBCs
2. Joint pain and low platelet count
3. Leukocytosis and frequent sore throat
4. Bone pain and a positive Bence-Jones protein test

NCLEX Client Need: Physiological Integrity

8. Which measure(s) should a patient with leukopenia institute to prevent infection? (*Select all that apply.*)

1. Avoid eating salads, raw fruits, and raw vegetables.
2. Stay within the home.
3. Wash hands after handling the mail.
4. Do not get close to pets.
5. Stay away from crowds and crowded places.

6. Do not reuse dishes or eating utensils without washing them first.

NCLEX Client Need: Safety and Infection Control

9. After the first few minutes of transfusing packed RBCs, the patient has a temperature of 101.5° F (38.6° C), heart rate 120 beats/min, and blood pressure 90/50 mm Hg with complaints of back pain. The priority nursing action would be:

1. flush the line with normal saline.
2. stop the transfusion.
3. notify the provider.
4. administer diphenhydramine (Benadryl).

NCLEX Client Need: Physiological Integrity

10. A patient with cancer who has undergone bone marrow transplant, chemotherapy, and total body irradiation is under close observation. The nurse would continue with transmission-based precautions isolation for _____ until the patient begins to show signs of improvement when engraftment takes place. (*Fill in the blank.*)

NCLEX Client Need: Physiological Integrity

Critical Thinking Questions

Scenario A

Mrs. Hutton is a young mother who has three small children. She is admitted to the hospital with a severe anemia. Her hemoglobin is 7.5 g/dL, and her red cell count also is very low. Mrs. Hutton confides in you that she has never eaten as she should, especially when she was a teenager. With the added strain of having the children to care for at home, she doesn't take the time to cook the meals she knows they should have, because she is so tired all the time. Her husband makes a fairly good salary, but Mrs. Hutton is under the impression that an adequate diet would cost more than they can afford at present.

1. How can you teach the patient the value of nutritious food and help her with shopping practices that would provide her family with food items that are not expensive?
2. Which foods that are high in iron would you suggest she include in her diet?
3. What practical suggestions could you make to help Mrs. Hutton cope with fatigue?

Scenario B

Mr. Tate is a 24-year-old who has acute lymphocytic leukemia. He is receiving chemotherapy with cyclophosphamide, vincristine, prednisone, and daunorubicin. He is experiencing many of the problems associated with a blood disorder, as well as the problems caused by the side effects of the potent drugs he is receiving.

1. Describe the physiologic problems Mr. Tate is likely to experience as a result of the disease and the therapy.
2. Identify psychosocial concerns that Mr. Tate might have.

Scenario C

Mr. Harris, a 72-year-old white man, has just been diagnosed with chronic myeloid leukemia (CML). He has started chemotherapy with hydroxyurea and imatinib. If this is unsuccessful, he will begin treatment with interferon alfa.

1. What do you need to teach Mr. Harris about the drugs he is taking? Will he be on other drugs to control the side effects of this chemotherapy?
2. His wife asks whether he would be eligible for bone marrow transplantation. What should you answer?

Scenario D

Mrs. Solter, age 82, is to receive a transfusion of packed RBCs, because she is very anemic and not responding to oral medication. You are assigned to assist with the transfusion and to monitor the patient.

1. What are the priorities of care for this patient at this time?
2. Mrs. Solter asks what this transfusion will do for her. How would you respond?
3. What is the proper sequence of actions you would take if Mrs. Solter experienced a transfusion reaction while the blood product is infusing?

UNIT VI

Cardiovascular System

OUTLINE

Chapter 17 The Cardiovascular System

Chapter 18 Care of Patients With Hypertension and Peripheral Vascular Disease

Chapter 19 Care of Patients With Cardiac Disorders

Chapter 20 Care of Patients With Coronary Artery Disease and Cardiac Surgery

CHAPTER 17

The Cardiovascular System

Objectives

Theory

1. Review the normal anatomy and physiology of the cardiovascular system.
2. Examine the risk factors and incidence of cardiovascular disease.
3. Explain ways to modify risk factors for the development of cardiovascular disease.
4. Choose ways in which nurses can contribute to the prevention of cardiovascular disease.
5. Compare the diagnostic tests, specific techniques, and procedures for assessing the cardiovascular system.
6. Present three likely problem statements for patients who have common problems of cardiovascular disease and list the expected outcomes and appropriate nursing interventions for each.

Clinical Practice

7. Teach patients about the more common diagnostic tests and procedures to diagnose and evaluate cardiovascular diseases.
8. Assist patients to form plans to modify cardiovascular disease risk factors.
9. Assess for cardiovascular abnormalities in assigned patients.

KEY TERMS

- arteriosclerosis** (är-tē-rē-ō-sklē-RŌ-sīs, p. 373)
atherosclerosis (äth-ér-ō-sklē-RŌ-sīs, p. 371)

infarct (p. 373)
intermittent claudication (in-těr-MĬT-ěnt klāw-dī-KĀ-shūn, p. 382)
ischemia (īs-KĒ-mē-ă, p. 373)
palpitations (păl-pi-TĀ-shūnz, p. 392)
pericarditis (pěr-ē-kāhr-Dī-tīs, p. 373)
rubor (RŪ-bōr, p. 386)

stroke volume (p. 370)
syncope (SĬN-kō-pē, p. 386)

Overview of Anatomy and Physiology of the Cardiovascular System

The Structures of the Heart and Their Functions

- The heart wall consists of three layers. The epicardium is the outer layer of tissue; the myocardium is the middle layer of muscle fibers that contract to pump blood; and the endocardium is the lining of the inner surface of the heart chambers.
- A membranous sac, the pericardium, surrounds the heart.
- The pericardium is a double-layered sac. The double layer helps provide a barrier to infection, prevents displacement of the heart, and contains pain and other receptors that elicit reflex changes in heart rate and blood pressure.
- The pericardial space contains a thin layer of fluid (30 to 50 mL).
- The four chambers of the heart make up two coordinated pumps: the right-side pump is a low-pressure system; the left-side pump is a high-pressure system.
- The right atrium and right ventricle receive deoxygenated blood from the vascular system and pump it through the lungs.
- The left atrium and left ventricle receive oxygenated blood from the lungs and pump it through the systemic circulation (Figure 17-1).

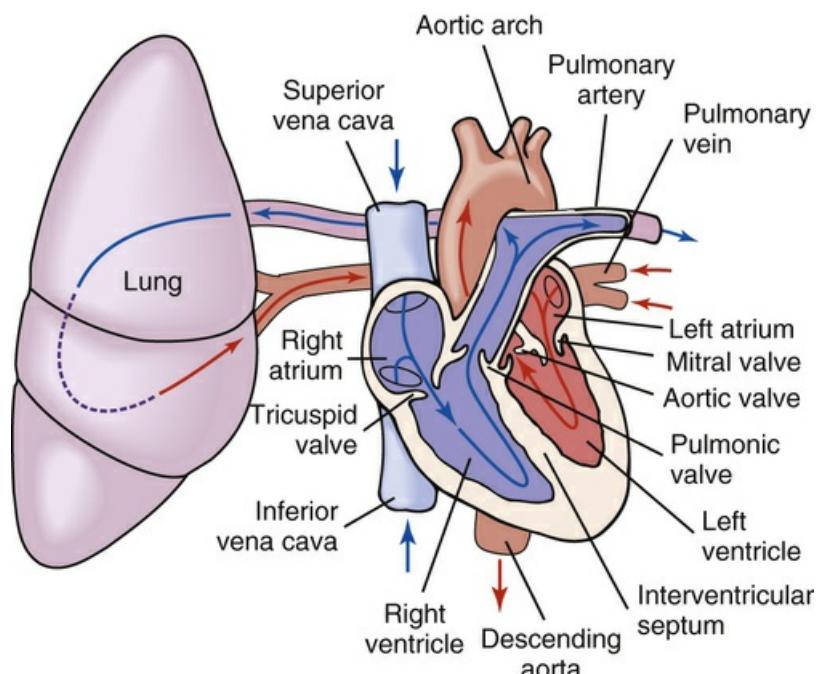

FIGURE 17-1 Heart structures and path of oxygenated blood flow out of the left ventricle and into the aorta. (From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 7, St. Louis, 2007, Mosby.)

- A septum separates the right and left sides of the heart.
- The cardiac valves direct the flow of blood through the heart chambers.
- Blood enters the right atrium via the superior and inferior vena cava and goes to the right ventricle through the tricuspid valve.
- Blood leaves the right ventricle through the pulmonic (or pulmonary) valve and goes into the pulmonary artery to circulate in the lungs, exchanging carbon dioxide for oxygen. The pulmonary artery carries blood away from the heart, so it meets the definition of *artery*, but it carries deoxygenated blood. The left atrium receives oxygenated blood from the pulmonary veins, and

the mitral valve controls the flow from the atrium into the left ventricle. Pulmonary veins carry blood toward the heart, but come from the lungs with oxygenated blood.

- The left ventricle ejects the blood through the aortic valve into the aorta and the systemic circulation.
- The coronary arteries branch from the aorta and supply the cardiac muscle with blood during diastole (Figure 17-2). Blood flow in the coronaries is restricted during systole because of muscle contraction.

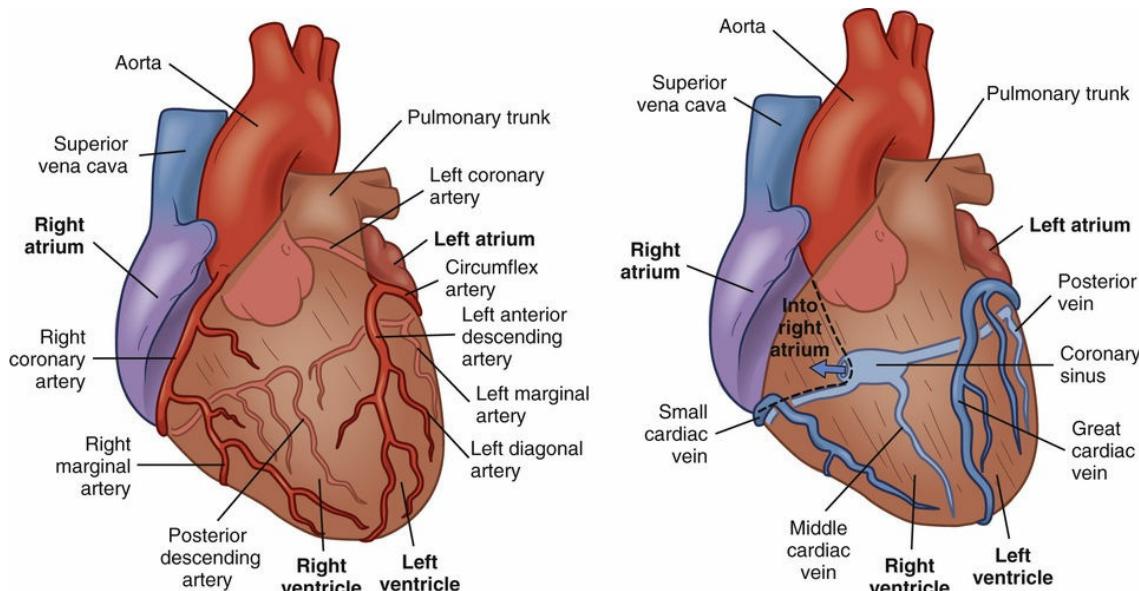

FIGURE 17-2 A view of the coronary arterial system. *Left*, Arteries. *Right*, Veins. (From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2015, Mosby.)

- The left coronary artery divides into the anterior descending and the circumflex arteries, providing blood for the left atrium and the left ventricle.
- The right coronary artery supplies the right atrium, right ventricle, and part of the posterior wall of the left ventricle, as well as the atrioventricular node of the cardiac conduction system (see Figure 17-2).
- The heart is located within the mediastinum and is tilted forward and to the left side of the chest.
- The point of maximal impulse (PMI) can normally be felt between the fifth and sixth ribs on a line dividing the left clavicle in half. Listen to the apical heart rate at this location.

Contraction of the Heart to Pump Blood

- The heart's pumping action is sparked by specialized pacemaker cells and conduction fibers that initiate spontaneous electrical activity, causing muscle contractions that result in a heartbeat.
- The conduction pathways are located in the myocardium and transmit the electrical impulse throughout the heart.
- The sinoatrial (SA) node is located in the right atrium and is called the "pacemaker" of the heart because it normally initiates the electrical impulses.
- The atrioventricular (AV) node (or junction) is located in the lower part of the right atrium. It relays the impulse from the SA node to the bundle of His and throughout the ventricles via the Purkinje fibers (Figure 17-3).

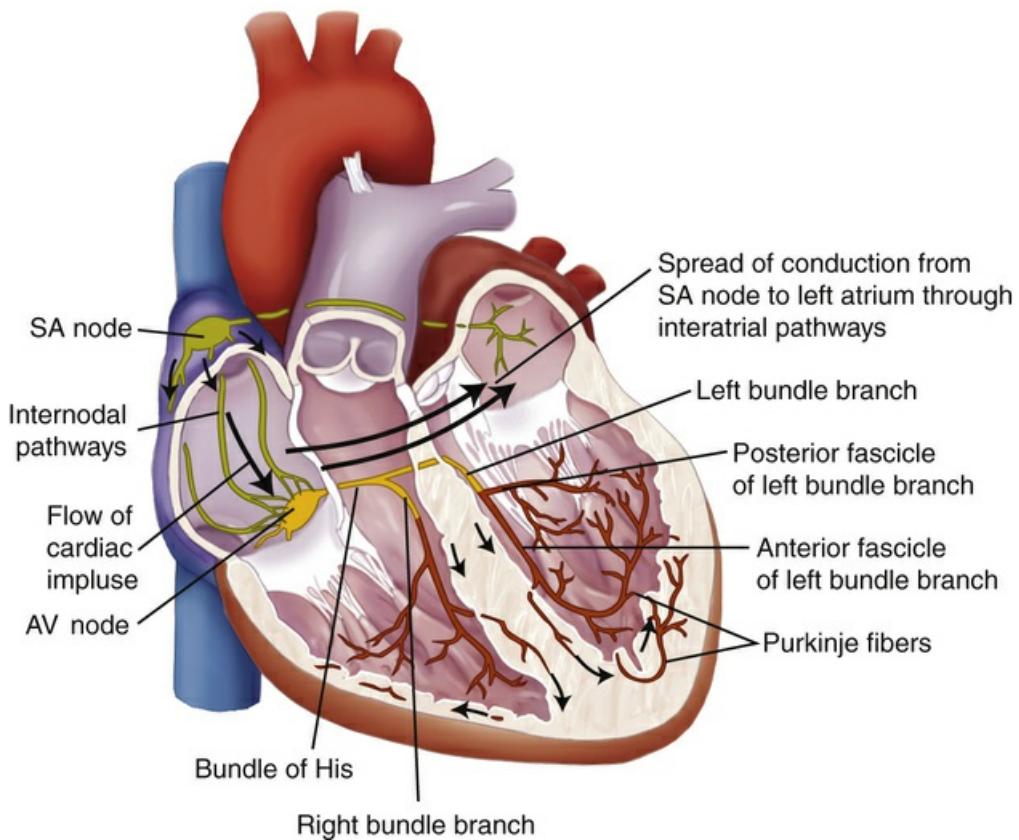

FIGURE 17-3 The cardiac conduction system. AV, Atrioventricular; SA, sinoatrial. (From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2015, Mosby.)

- The heart rate and rhythm are influenced by the autonomic nervous system; factors affecting the autonomic nervous system can speed up or slow down the heart rate.

The Cardiac Cycle

- The cardiac cycle consists of contraction of the muscle (systole) and relaxation of the muscle (diastole).
- The heart pumps out about 5 L of blood every minute.
- The amount of cardiac output depends on the heart rate, the amount of blood returning to the heart (venous return or preload), the strength of contraction, and the resistance to the ejection of the blood (afterload).
- Stroke volume** equals the amount of blood ejected by a ventricle during one contraction.
- Cardiac output** equals stroke volume multiplied by the heart rate.

The Ejection Fraction

- The **ejection fraction** is the percentage of blood that is ejected from the left ventricle during systole.
- A normal ejection fraction is 50% to 70%.
- As ejection fraction decreases with heart failure, tissue perfusion diminishes.
- A decreased ejection fraction causes backup of blood into the pulmonary vessels.
- Too much blood and the increased pressure in the pulmonary vessels can cause pulmonary edema.

Blood Flow Throughout the Body

- Three types of blood vessels make up the vascular system: arteries, veins, and capillaries; these

vessels conduct the blood from the body tissues to the heart –lung circulation and from the heart back to the tissues.

- Arteries carry oxygenated blood away from the heart (Figure 17-4). Veins carry oxygen-depleted blood back to the heart for reoxygenation by the lungs (Figure 17-5).

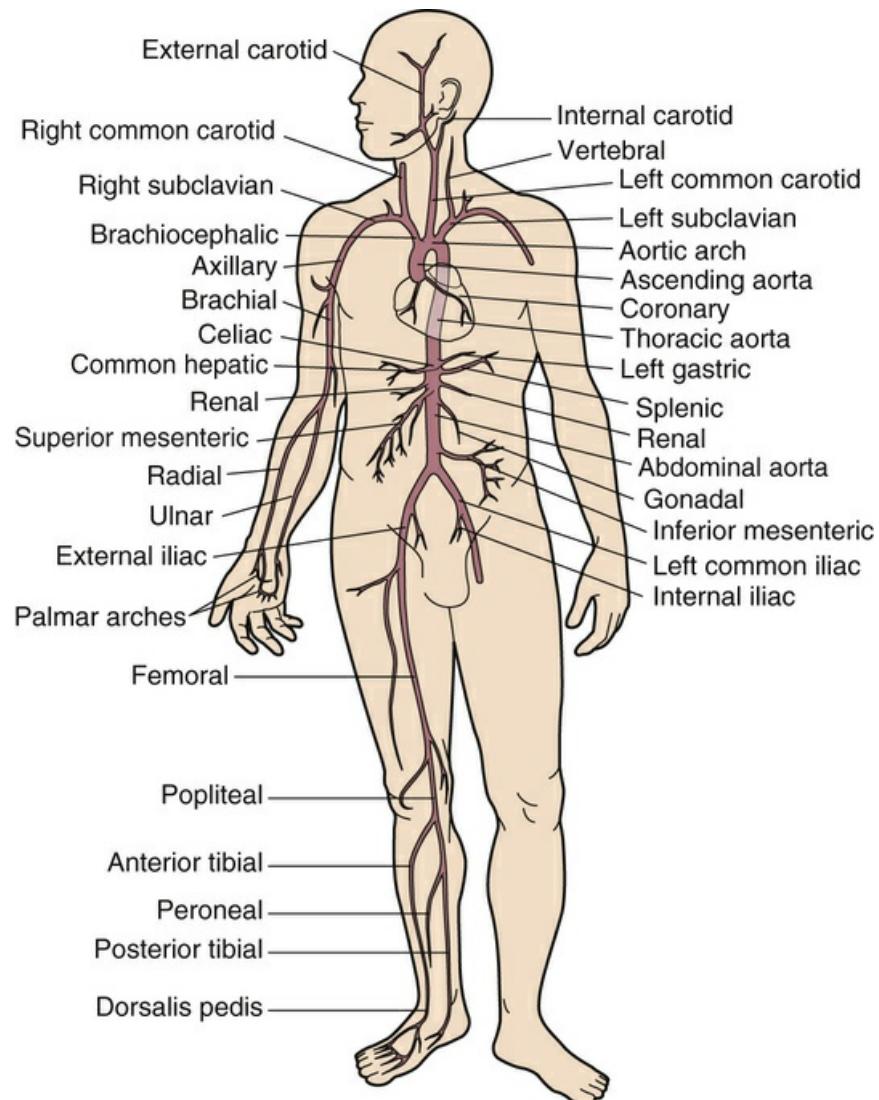

FIGURE 17-4 Major arteries in the body.

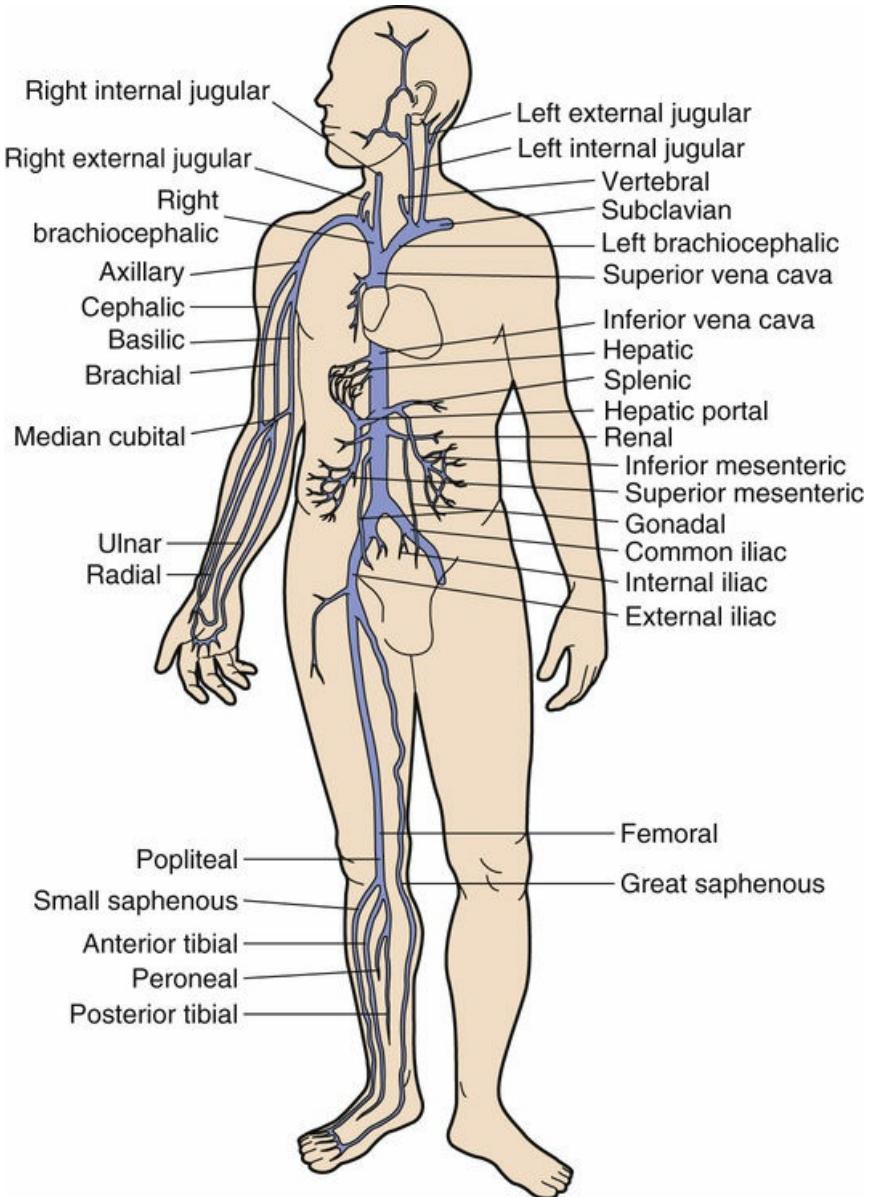

FIGURE 17-5 Major veins in the body.

- Small veins, **venules**, and small arteries, **arterioles**, are connected by the capillaries. It is in the capillaries that the oxygen is transported to cells and waste products are removed from them.
- The aorta is the largest artery in the body, and it receives blood from the left ventricle.
- The inferior and superior vena cava are the largest veins in the body and empty blood into the right atrium of the heart.
- Arteries are elastic and accommodate changes in blood flow by constricting or dilating.
- Three layers of tissue make up the artery wall: The outer layer (the **tunica adventitia**) is connective tissue; the middle layer (the **tunica media**) is smooth muscle; and the inner layer (the **tunica intima**) consists of endothelial cells.
- Veins have the same three layers but with less smooth muscle and connective tissue. The veins are thinner and less rigid and thus can hold more blood.
- The heart pumps blood through the arterial system with each contraction. Skeletal muscle contraction, respiratory movements that change pressures in the chest, and constriction of the veins propel blood back to the heart.
- Sets of valves in the medium and large veins open and close, keeping blood flowing toward the heart against gravity.

- For blood to circulate, the arteries must be unobstructed, and they must be able to dilate and constrict as necessary to regulate the blood flow. Veins also must be patent, their valves must function normally, and surrounding muscles must contract so that venous blood is continually being moved in the direction of the heart.

Blood Pressure

- Arterial blood pressure is the force that the blood exerts against the walls of the aorta and its branches.
- The blood pressure is greatest during ventricular contraction, or **systole**, when blood is ejected into the aorta.
- Diastolic pressure is the pressure when the ventricles are in the relaxation phase, or **diastole**, just before the next contraction of the ventricles.
- The difference between the systolic blood pressure and the diastolic blood pressure is called the *pulse pressure*.
- If the diameter of blood vessels becomes smaller because of atherosclerosis, blood pressure is increased with the effort of forcing the blood through the smaller opening. **Atherosclerosis** is the condition in which fibrous plaque with fatty deposits forms in the interior layers of the arteries, causing narrowing.
- If there is an increase in the volume of fluid in the blood vessels, the pressure within the vessels increases, and the heart must work harder to pump the increased volume of fluid through the vessels.
- If blood volume decreases, the kidneys secrete the enzyme renin in the blood ([Figure 17-6](#)).

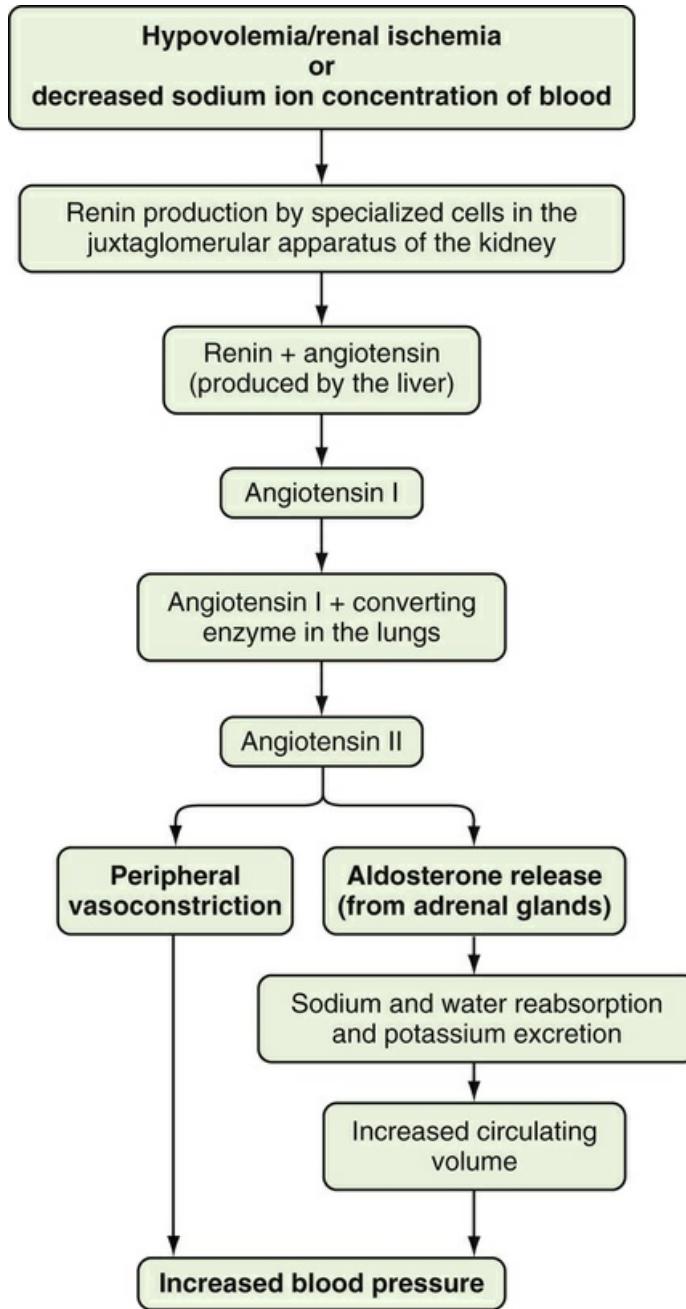

FIGURE 17-6 The renin-angiotensin-aldosterone system. (From Sole ML, Klein DG, Moseley MJ: *Introduction into critical care*, ed. 5, Philadelphia, 2009, Saunders Elsevier.)

- Renin acts on certain blood proteins to produce angiotensin I.
- Angiotensin I is converted to angiotensin II by angiotensin-converting enzyme from the lungs.
- Angiotensin II acts directly on the blood vessels, causing them to constrict, increasing resistance to blood flow in the peripheral vessels. Angiotensin II also stimulates the adrenal gland to release aldosterone, causing sodium and water retention by the renal tubules. The retained sodium and water increase the blood volume, causing blood pressure elevation and improved cardiac output.
- Blood flow is affected by the amount of resistance in the vessels and by the viscosity of the blood.
- Vascular resistance is controlled by the nervous system, hormones, blood pH, and ions that regulate the diameter of the vessels.
- **When the vessel diameter increases, resistance falls and blood flow increases. When vessel diameter decreases, resistance rises and blood flow decreases.**
- The sympathetic nervous system plays a major role in regulating vessel diameter because it prompts the release of the hormones norepinephrine and epinephrine that cause vasoconstriction.

- Blood viscosity is affected by the hydration status of the body. When dehydration occurs, blood viscosity increases; thicker blood causes an increase in blood pressure.

Cardiovascular System Changes Related to Aging

- The aging heart becomes stiffer and contractile ability decreases, resulting in decreased stroke volume.
- The coronary arteries become tortuous and dilated and have areas of calcification.
- The cardiac valves become thickened, particularly the mitral and aortic valves, which are subject to higher pressures. A systolic murmur is common in those older than age 80 years.
- The SA node loses about 40% of its pacemaker cells over time, predisposing to cardiac **dysrhythmia** (abnormal rhythm) or SA node failure.
- The aorta becomes stiffer, contributing to an increase in systolic blood pressure because the left ventricle must pump against greater resistance.
- The arterial walls thicken and lose elasticity, making them less able to adjust to changes in volume and to comply with sympathetic stimulation.
- Varicose veins develop as veins lose their elasticity, valve function decreases, and the leg muscles weaken and atrophy from decreased exercise.
- Platelet aggregation and increased coagulation potential lead to a greater incidence of thrombus formation, deep vein thrombosis, and thrombophlebitis.
- Chronic health problems and failing eyesight often lead to decreased activity, predisposing to vascular problems.

Cardiovascular Disease

Cardiovascular disease (CVD) affects one in four people in the United States, and more than 600,000 people die in the United States as a result of cardiovascular problems each year (Go et al., 2014). Cardiovascular disease is responsible for the largest portion of Medicare funds spent each year. Together with the heart, the vascular system provides the body with nutrients and oxygen needed for life. The vascular system also transports metabolic wastes that are excreted by the lungs and the kidneys. When a disorder of the cardiovascular system occurs, homeostasis is upset. Many of the disorders that afflict the cardiovascular system can be prevented or controlled.

Women and Heart Disease

Heart disease incidence in women is almost equal to that in men. More women than men die each year of heart disease. The risk factors are similar to those for men: high cholesterol, high blood pressure, and obesity. Other factors play a bigger role for women, such as diabetes, metabolic syndrome, smoking, and mental stress.

Health Promotion

Preventing Cardiovascular Disease in Women

- Participate in regular physical activity—at least 40 minutes three or four times a week.*
- Maintain cholesterol levels as indicated by risk stratification.
- Refrain from smoking.*
- Do not consume more than one alcoholic drink per day.
- Obtain and maintain a healthy weight to reduce the chance of type 2 diabetes.* Type 2 diabetes increases the risk of cardiovascular disease.
- Maintain a body mass index (BMI) below 25.
- Discontinue use of estrogen contraception/supplementation as soon as possible.
- Reduce the amount of *trans* fat in the diet.
- If diabetes is present, keep fasting blood sugar below 100 mg/dL.
- If hypertension is present, take medication regularly to keep blood pressure below 130/80 mm Hg (below 115/75 mm Hg is optimal).
- Incorporate stress reduction techniques into the daily lifestyle, because increased stress is a risk factor for cardiovascular disease.*

*These factors play an even larger role in prevention of heart disease in women than in men.

Think Critically

Can you think of two physiologic reasons why older adults are more at risk for hypertension?

Causes of Cardiovascular Disorders

Causes of cardiovascular disorders can be congenital or acquired. Narrowing of the aorta (**coarctation**), holes in the septum, or abnormal formation of a cardiac valve can occur congenitally.

Acquired defects include narrowing or hardening of the blood vessels from **arteriosclerosis** (thickening and loss of elasticity) or atherosclerosis (buildup of plaque) and aneurysms of the large vessels. Inflammation of the valve structure may cause narrowing (stenosis) or incomplete closure (insufficiency) of the valve. Alteration of the myocardial muscle tissue by extra growth with thickening (hypertrophy) or fibrosis may occur as a result of systemic **hypertension** (persistently elevated blood pressure), pulmonary hypertension, or valve problems. Lack of adequate blood supply (**ischemia**) or **infarct** (area of tissue that has died from lack of blood supply) may occur from coronary artery disease. Deterioration of the pacemaker cells and conduction fibers related to hypertrophy or inflammation of tissues may cause conduction disorders.

Several disorders involving either the heart or the vessels through which it pumps blood can eventually weaken and damage the heart muscle and lead to pump failure. This condition, called *heart failure*, is a complication of many cardiovascular diseases, as discussed in the following chapters.

Disturbances in any part of the heart's conduction system can result in an increase in heart rate (tachycardia), a slowing down of the heart rate (bradycardia), and disturbances in the rhythm of the heartbeat (dysrhythmias).

Infection and inflammation also can take their toll on the structure and function of the heart.

Endocarditis, inflammation within the lining and valves of the heart, and **pericarditis**, an inflammation of the sac surrounding the heart, can occur as primary diseases, but they are more often secondary to infection and inflammation elsewhere in the body. An example is rheumatic heart disease, which occurs after a streptococcal infection and damages heart valves.

Substances in the blood, such as excess carbon dioxide and certain drugs, can affect the rate and rhythm of the heart through their effect on the autonomic nervous system. The heart also responds to physiologic changes that indicate a need for more or less oxygen.

The arterial walls can be injured by several factors. Hypertension causes a mechanical injury by applying increased pressure continuously on the arterial walls. For each increment of 20/10 mm Hg above a pressure of 115/75, the risk of CVD doubles ([National Heart, Lung, and Blood Institute, 2012](#)). Elevated levels of total cholesterol and decreased levels of high-density lipoprotein cholesterol (HDL-c) lead to increased fatty deposits in the arterial walls, causing a narrowing of the vessels. Chemical toxins such as nicotine from tobacco and the toxins caused by renal failure cause injury to the arterial walls. Substance abuse with alcohol, stimulants, and recreational drugs are damaging to the cardiovascular system (see [Chapter 46](#)).

Physiologic disorders such as diabetes mellitus and metabolic syndrome directly cause physical changes in the vessel walls, leading to more rapid arteriosclerosis, an increased rate of atherosclerosis, and an earlier onset of hypertension.

Obesity, a sedentary lifestyle, and stress are all directly related to the increased incidence of atherosclerosis and hypertension. Smoking, and the changes it causes in the vessel walls, is directly related to arteriosclerosis of the peripheral vessels and decreased circulation in the lower extremities. Long-term hypertension causes arteriosclerosis and is a direct factor in the development of aortic aneurysm in many patients. Hypertension in some cases cannot be prevented, but it can be managed with diligent therapy and cooperation of the patient.

Prevention of Cardiovascular Disease

Cardiovascular diseases claimed 784,750 lives in 2010 in the United States ([Go et al, 2014](#)). Heart disease remains the major cause of death in the United States. Cardiovascular diseases also account for a large percentage of the chronic illnesses that disable, to some degree, a large portion of the U.S. population.

There are many kinds and degrees of heart disease. Advances in medical science have made it possible either to cure or successfully manage a large number of cardiovascular problems. Reasons for the decline in deaths from heart disease since the mid-1980s include improved emergency treatment of persons experiencing a coronary occlusion, or "heart attack," improved education of the public regarding ways to prevent cardiovascular disease, and teaching about the warning signs of a heart attack. Every nurse has a responsibility to assist with public education about heart disease.

Health Promotion

Know the Warning Signs of a Heart Attack

- **Chest discomfort:** A feeling of tightness, pressure, or a crushing or squeezing pain lasting more than a few minutes or returning after easing. In women, discomfort that radiates to the back or abdomen.
- **Pain or discomfort in other areas of the upper body:** Arms, shoulder, back, neck, jaw, or the top of the stomach. Women often have jaw or back pain.
- **Shortness of breath:** May occur with or without chest discomfort.
- **Breaking out in a cold sweat, nausea, or light-headedness** with or without chest discomfort.
- **Feeling of impending doom** that does not go away. Or unusual fatigue in women.
- **Chest pain** unrelieved by prescribed doses of nitroglycerin.

Call 911 or emergency number immediately—get help! Take an aspirin.

Nonmodifiable risk factors are those that cannot be prevented by an individual. However, control of diseases such as hypertension and diabetes mellitus and the reduction of high cholesterol are possible. Because hypertension and diabetes are factors in the development of atherosclerosis, controlling them can help prevent the early onset of heart disease. If a person with diabetes can keep the hemoglobin A_{1c} below 6% the risk of atherosclerosis is decreased ([Matsushita et al., 2010](#)).

Management of hypertension is one of the major factors for heart disease prevention.

[Table 17-1](#) presents the risk factors for cardiovascular disease. Metabolic syndrome is a strong indicator of cardiovascular risk and is diagnosed when three or more of the components in [Box 17-1](#) are present ([Wang, 2014](#)). More than 50 million Americans meet the criteria. Modifiable risk factors are the major focus for education to prevent heart disease. Cigarette smoking-related health problems are heavy contributors to heart disease, and smoking is a key factor in sudden cardiac death. The use of cocaine and methamphetamine has added to the problem of heart disease ([Figtree et al, 2012](#)). Cocaine causes vasoconstriction and is believed to speed up the atherosclerosis process. Also, cocaine has been known to cause sudden cardiac death, or stroke, in susceptible individuals. Research is finding that the ingestion of both alcohol and cocaine greatly increases the chance of cardiac death. Methamphetamine increases heart rate, causes vasoconstriction that can lead to hypertension, and speeds up electrical conduction, potentially causing dysrhythmias and myocardial infarction (MI).

Think Critically

Can you identify two risk factors you can modify to decrease your risk of heart disease?

Table 17-1
Risk Factors for Cardiovascular Disease

UNMODIFIABLE RISK FACTORS	SIGNIFICANCE
Heredity	Children of parents with cardiovascular disease are more likely to develop the same problem.
Race	African Americans experience high blood pressure two to three times more frequently than whites. Consequently the risk of heart disease in this group is higher.
Sex	Males experience more heart attacks than females earlier in life. After age 65 years, the death rate from heart disease increases in women.
Age	Four out of five people who die of a heart attack are age 65 years or older. Increasing age increases risk.
MODIFIABLE RISK FACTORS	MEANS OF MODIFICATION
Obesity	Keep weight within normal limits by diet and exercise. Reduce abdominal obesity.
High cholesterol	Implement a low-fat diet and exercise; take medication as prescribed. Target levels of cholesterol are individually set.
Hypertension	Keep blood pressure less than 120/80 mm Hg.
Diabetes	Maintain good glycemic control by keeping blood glucose within normal limits (<100 mg/dL).
Cigarette smoking	Quit smoking. Do not use smokeless tobacco; nicotine by any route affects blood vessels.
Sedentary lifestyle	Maintain an exercise program of 30-min sessions three to five times a week. Any level of increased activity is helpful.
Excessive stress	Use stress-reduction techniques regularly, such as exercise and relaxation techniques; reduce hostility; maintain a positive support system.
Excessive alcohol intake	Limit alcohol consumption to no more than recommended levels: men, 2 drinks/day; women, 1 drink/day.
Cocaine use	Do not use cocaine, methamphetamine, or other recreational drugs.

Box 17-1

Metabolic Syndrome Components

- Elevated waist circumference indicating abdominal obesity: *men*, greater than 40 inches (102 cm); *women*, greater than 35 inches (88 cm)
- Elevated triglyceride level: greater than 150 mg/dL
- Reduced high-density lipoprotein cholesterol level: *men*, less than 40 mg/dL; *women*, less than 50 mg/dL
- Elevated blood pressure: at or above 130/85 mm Hg
- Elevated fasting blood glucose level indicating insulin resistance: 100 mg/dL or greater

Although systolic blood pressure rises as a natural process of aging because arteries become less elastic, systolic hypertension should be treated in older adult patients. The *JAMA* 2014 guidelines for management of hypertension recommend implementing antihypertensive medications for individuals 60 years or older who have a systolic blood pressure at or above 150 mm Hg or diastolic blood pressure above >90 mm Hg. (James et al, 2014).

Hypertension in older adults is associated with an even higher risk of heart disease, stroke, and death from coronary thrombosis (Aronow et al, 2011). Hypertension has been associated with more rapid memory loss and loss of cognitive function in some research studies.

Nurses can play an important role in teaching others about hypertension, support patient efforts to prevent the disease and its long-term consequences, and contribute to reducing the incidence of the harmful effects of hypertension by participating in community screening programs and education. Nurses and other health care professionals have an obligation to serve as models for a healthy lifestyle.

Diagnostic Tests and Procedures

In addition to a routine physical examination and medical history, the provider has access to a number of procedures and tests to help diagnose cardiovascular disease (Figure 17-7). Noninvasive procedures usually are performed first and in general give less detailed information about cardiovascular structure and function. Specific cardiovascular diagnostic tests and their nursing implications are listed in Table 17-2.

FIGURE 17-7 Cardiac treadmill stress test.

Table 17-2**Common Diagnostic Tests for the Cardiovascular System**

TEST	PURPOSE	PROCEDURE	NURSING IMPLICATIONS
Electrocardiography (12-lead electrocardiogram [ECG])	Records electrical impulses of the heart to determine rate, rhythm of heart, site of pacemaker, and presence of injury at rest	Small electrodes are placed on the chest and extremities, to show conduction patterns in different directions of electrical flow. Signal-averaged ECG can be used for patients at high risk for serious ventricular arrhythmias. It takes longer than a standard ECG; monitoring takes approximately 10 min and signals are averaged.	Inform patient that there is no discomfort with this test. Maintain electrical safety. Normal finding: normal ECG.
Holter monitor (ambulatory ECG) Multiple devices in addition to the Holter monitor are available. All record the ECG over hours or days during regular activities of daily living.	Correlates normal daily activity with electrical function of the heart to determine whether activity causes abnormalities	Patient wears a small ECG recorder for 6, 12, or 24 hr while doing usual tasks. A diary is kept to show at what time the various activities were performed and any symptoms experienced. The record is analyzed to correlate any dysrhythmia with the activity at that time.	Remind patient that all activities must be recorded in the diary: brushing teeth, climbing stairs, sexual intercourse, bowel movements, sleeping, etc. Caution patient not to remove the electrodes and not to get the recorder or wires wet. Instruct patient to wear a loose shirt during test.
Loop recorder Implantable External	Continuously records ECG to determine if an arrhythmia is the cause of symptoms (e.g., syncope, palpitations, or dizziness)	A small device that records ECG activity for several months. The device can be implanted under the skin with local anesthesia or attached externally to the skin with long-term adhesive. The implanted device can be left in place for up to 3 yr.	The implanted device requires a small skin incision that will need assessment and care similar to any surgical incision.
Exercise ECG stress test (treadmill)	Records electrical activity of the heart during exercise Insufficient blood flow and oxygen show up as abnormal waveforms	Small electrodes are placed on the chest, and a tracing is made while the patient exercises on a treadmill, bicycle, or stairs. The degree of difficulty of the exercise is increased as the test continues to see how the heart reacts to increasing work demands. Vital signs are continuously recorded. May be combined with radionuclide imaging or echocardiograph. Provider is present.	Requires a signed consent form. Instruct patient to wear comfortable clothes and walking shoes. Light meal 2-3 hr prior, then NPO. Regular medications are given. Chest is shaved as needed for electrode placement. Inform patient that the test will be stopped if chest pain, severe fatigue, or dyspnea develops.
Chemical stress test with dipyridamole, adenosine, or dobutamine	Used for those who cannot exercise for an ECG stress test	Continuous 12-lead ECG monitoring is performed and the drug is administered. Blood pressure and pulse are taken and recorded q15min. The drug effect increases cardiac workload to identify whether cardiac ischemia results. The patient is NPO during the test.	Mild nausea or headache may occur. Explain that patient will lie on back for the test. If BP drops too low, phenylephrine is given.
Echocardiography	Useful in evaluating size, shape, and position of structures and movement within the heart Test of choice for valve problems	An ultrasound probe that emits sonar waves is guided over the chest wall while the patient is supine or turned on the left side. Test takes 30-60 min. May be done in combination with the exercise (stress) test.	Inform patient that there is no discomfort, although conduction jelly may feel cool. Normal finding: no abnormalities of size or location of heart structures; normal wall movement.
Stress echocardiogram	Detects differences in left ventricular wall motion before and after exercise	Resting echocardiogram images are obtained. The patient exercises; within 1 min, postexercise images are obtained. May be done in conjunction with a chemical stress test.	Explain the procedure and the importance of returning to the examining table immediately after exercising. Instruct patient not to consume heavy meal beforehand and to abstain from using tobacco or caffeine for 6-8 hr before test. Tell patient to wear walking shoes.
Venous ultrasound of the legs (lower extremity Doppler)	Assesses occlusion or thrombosis in a vein	A water-soluble gel is applied to bare skin in the area to be assessed. A Doppler transducer is passed over the area of the vessel. A gray-scale image of the vessel is obtained with color depicting the blood flow velocity.	Instruct patient to abstain from smoking for 30 min before the test.
Impedance plethysmography	Estimates blood flow in a limb based on electrical resistance present before and after inflating a pneumatic cuff placed around the limb Detects deep vein thrombosis	Measurements of electrical resistance are taken before and after a pneumatic cuff placed around the limb is inflated. Electrodes are placed on opposite sides of the limb.	Instruct patient to wear loose clothing. Explain that some discomfort may occur during inflation of the cuff. The patient is placed on an examination table and positioned supine in a relaxed, comfortable position. The limb is properly positioned, and electrodes and the pneumatic cuff are applied.
Nuclear imaging (myocardial perfusion scan, myocardial perfusion imaging, thallium scan, sestamibi cardiac scan, and nuclear stress test)	Evaluates blood flow in various parts of the heart Determines areas of infarction	A radioactive tracer is injected IV; radioactive uptake is counted over the heart by a gamma scintillation camera. May be done in conjunction with an exercise ECG stress test.	Explain that the radioactivity used is a very small amount and lasts only a few hours. Explain that a camera will be positioned over the heart. ECG electrodes are placed on the chest; scanning is done 10-15 min after injection; can be done as an outpatient procedure. May be done in two parts a few hours apart.
Multiple-gated acquisition (MUGA) scan (radionuclide angiography)	Determines area and extent of myocardial infarction (MI) Assesses left ventricular function	^{99m} Tc is injected IV and is taken up by areas of infarction, producing hot spots when scanned. Multiple serial images are obtained. Best results occur when done 1-6 days after a suspected MI.	Inform patient that radioisotopes will be given IV and that it will be necessary to lie still while the machine scans the heart. The patient's glucose level must be between 60 and 140 mg/dL. If scan is combined with exercise, patient will need to be NPO and must abstain from using tobacco and caffeine for 24 hr before the test.
Computed tomography (CT) scan CT angiography	Determines size and condition of aortic aneurysm Coronary vessels may be imaged	Noninvasive, unless dye contrast is used. Patient is positioned on scanning table and moved under the scanner.	Instruct patient in necessity of holding still during scan.
Magnetic resonance imaging (MRI) Magnetic resonance angiography (MRA)	Evaluates cardiac tissue integrity, detects aneurysms, determines ejection fraction and cardiac output, and determines patency of proximal coronary arteries	Noninvasive magnetic resonance is used to depict tissue images. IV gadolinium is injected as a contrast medium for the MRA.	Explain about the cylinder within which the patient will be positioned. Warn that there will be loud noises from the machine. Administer anti-anxiety medication if needed and ordered; provide ear protection.
Positron emission tomography	Evaluates myocardial perfusion	IV nitrogen-13-ammonia is injected and a scan performed to show myocardial metabolic function. Then fluoro-18-deoxyglucose is injected and a scan performed. In a normal heart, the scans will match; in an ischemic heart, the scans will differ.	Inform patient that radioisotopes will be given IV and that it will be necessary to lie still while the machine scans the heart. The patient's glucose level must be between 60 and 140 mg/dL. If scan is combined with exercise, patient will need to be NPO and must abstain from using tobacco and caffeine for 24 hr before the test.
Transesophageal echocardiogram (TEE)	Provides images of the heart, mitral valve, atrial septum, and thoracic aorta	Pharynx is anesthetized with topical agent. With patient in left side-lying position, an endoscopic transducer is placed in the esophagus and positioned behind the heart. Recordings of the images are made. Test takes about 20 min.	Patient must be NPO for 4-6 hr before test. Initiate IV access before test for sedation. Apply ECG leads for monitoring during test. Monitor pulse oximetry, end tidal CO ₂ , and BP. Observe patient after test until sedation has worn off.
Angiogram (venogram)	Identifies thrombi within the venous system	A tourniquet may be placed on the extremity, and dye is injected into the affected extremity. Radiographs are taken at timed intervals. Also used to identify venous stenosis.	Requires a signed consent form. Assess for allergies to radiopaque contrast. Hydrate patient before the procedure. Tell patient it takes 30-90 min, and that a warm flush may be felt when the dye is injected.

Arteriogram	Visualizes arterial anatomy and vascular disease in carotid, vertebral, aorta, renal, coronary, and peripheral arteries	A catheter is placed via the femoral artery into the desired artery. Radiopaque contrast is injected while x-ray (fluoroscopy) images are obtained. Digital subtraction techniques obliterate bony structures from the views. CO_2 gas may be used in place of dye if the patient is allergic to the dye. A balloon may be used during the procedure to open constricted areas. A stent may be placed in the vessel to keep it open.	Requires a signed consent form. Patient must be NPO for 2-8 hr before test. Mark peripheral pulses before procedure. Check renal function and coagulation studies before test and alert provider of abnormal values. Mucomyst may be administered a day before and after the test to prevent dye-induced nephropathy. Warn patient that dye acts as a diuretic and may cause some bladder distention during the test. Metformin must be discontinued before and after the test for several days to prevent renal damage.
Cardiac catheterization with coronary angiography; also called a <i>left heart catheterization (LHC)</i>	Assesses size and patency of coronary arteries and presence of collateral circulation Identifies pressure gradients for the aortic and mitral valves Assesses pumping action of the left side of the heart by measuring the ejection fraction of the left ventricle	Catheter is inserted into an artery. Femoral artery is commonly used, but may use radial or axillary arteries. With local anesthetic and procedural sedation, using fluoroscopy, the catheter is threaded up the aorta to the coronary arteries, which come off of the aorta just past the aortic valve. Contrast media is injected to visualize the size and shape of the coronary vessels. A separate catheter is used to pass through the aortic valve into the left ventricle. Contrast is injected into the chamber to visualize wall motion and calculate ejection fraction. Procedure is video recorded for later review.	Requires a signed consent form. Patient must be NPO for 6-8 hr before test. Assess patient for allergy to iodine, shellfish, or contrast dye. Have patient void before giving preoperative medication. Record baseline vital signs and mark location of pedal pulses. Inform patient that procedure involves being on a narrow table with a camera that rotates around to different angles, patient will have an IV, and must lie still during test. Procedural sedation is used. ECC leads, BP cuff, O_2 saturation monitor, CO_2 monitor will be in place during the test. Patient may be asked to cough or turn head during the procedure. Assess peripheral pulses with vital signs and question patient about numbness or tingling. Inspect insertion site for bleeding or sign of hematoma. If femoral insertion site was used, keep patient flat and leg extended for ordered time. If a closure device was used at the arterial puncture site, patient may be able to ambulate within 2 hr. Encourage fluids unless contraindicated to flush contrast from body.
During the procedure <i>intravascular ultrasound (IVUS)</i> may be performed.	Assesses degree of narrowing of coronary vessels and the type of material causing the narrowing (e.g., calcium, clot, or plaque)	An ultrasound catheter may be advanced into the coronary artery to image the lumen of the vessel. This is accomplished through the existing vascular access and through the catheters already in place. It is done as an adjunct procedure to the LHC.	Patient may be asked to cough or turn head during the procedure. Assess peripheral pulses with vital signs and question patient about numbness or tingling. Inspect insertion site for bleeding or sign of hematoma. If femoral insertion site was used, keep patient flat and leg extended for ordered time. If a closure device was used at the arterial puncture site, patient may be able to ambulate within 2 hr. Encourage fluids unless contraindicated to flush contrast from body.
Electrophysiology studies	Measures and records electrical activity from within the heart to determine the area of origin of the dysrhythmia and the effectiveness of the antidysrhythmic drug for the particular dysrhythmia	Three to six electrodes are placed in the heart through the venous system. Electrodes are attached to an oscilloscope that records the intracardiac and external ECG waveforms simultaneously. After baseline tracings are taken, the cardiologist tries to trigger the dysrhythmia that is to be studied by programmed electrical stimulation through the electrodes. Once the dysrhythmia is triggered, an antidysrhythmic drug is administered to determine its effectiveness in stopping the abnormal rhythm. Studies may take 1½ -4 hr; serial studies may be done on different days.	Provide psychological support for the patient, who is commonly fearful of having dysrhythmias induced. Antidysrhythmic drugs may be stopped 24 hr or more before the test to eliminate them from the patient's system. Assure the patient of constant monitoring and that emergency equipment and staff will be on hand. Keep patient NPO after midnight. Patent IV line is required. Electrodes are placed using fluoroscopy. Patient will be supine on an x-ray table. The femoral vein is most commonly used; the groin is shaved, and local anesthesia is used. Post-test care: much the same as for cardiac catheterization.
Hemodynamic monitoring via pulmonary artery (PA) (Swan-Ganz) catheter Placement of a PA catheter for diagnostic purposes is called a <i>right heart catheterization</i> .	Determines pressure, flow, and oxygenation within the right side of the heart and pulmonary vessels	A special catheter, infusion system, transducer, and a monitor are prepared, and the catheter is placed by the provider, usually under fluoroscopic guidance.	The system must be calibrated to perform properly. Readings are taken in the right atrium, right ventricle, and pulmonary artery, including pulmonary wedge pressures. Cardiac output may also be measured. Other data can then be calculated.
Laboratory Tests*			
B-type natriuretic peptide (BNP)	Determines degree of HF	Obtain 5-7 mL of venous blood; use an EDTA lavender-top tube.	No fasting is required.
C-reactive protein (CRP)	Assesses cardiac risk Level increased with inflammation	Obtain one tube of venous blood; use red-top tube.	Some laboratories require fasting; water is permitted. Low risk: <1 mg/dL High risk: >3 mg/dL
Serum lipids	Elevation of cholesterol is a risk factor for atherosclerotic heart disease	Use red-top serum separator tube (SST). Upon collection, the tube is inverted 6-12 times to accelerate the clotting process and separate the serum from the clot.	Patient is NPO except for noncaloric liquids for 12 hr. Normal ranges: Cholesterol: 150-200 mg/dL HDL: 30-80 mg/dL LDL: 60-180 mg/dL (with two or more risk factors, <73 mg/dL) Triglycerides: 40-150 mg/dL
Myoglobin	Is released by all damaged muscles, including the heart	Obtain 5 mL blood; use a red-top tube. Apply pressure to venipuncture site.	Explain procedure. No fasting is required. An elevated level can help confirm an MI. A nonelevated level rules out an MI. Normal value: <90 mcg/L
Troponin I (Tn I) Troponin T (Tn T)	Specific to heart muscle damage	Troponin I and T require different tubes for collection. Serial samples are usually drawn.	Levels may elevate within 4-6 hr after MI, peak within 10-24 hr, and return to normal within 10 days Normal values: Tn I: <0.3 mcg/L Tn T: <0.1 mcg/L
Creatine phosphokinase (CPK)	CPK is an enzyme found mainly in the heart, brain, and skeletal muscle	Serial samples are drawn over a 2-day period.	Elevated within 4-8 hr after heart attack (may also rise with injury to other muscles). Peaks within 12-24 hr; returns to normal levels within 3-4 days. Normal ranges: Men: 55-170 International Units/L Women: 30-135 International Units/L
CK-MB (creatinine kinase)	Isoenzyme of CPK that is primarily found in the heart	Serial samples may be evaluated.	Elevates within 2-6 hr after an MI, peaks within 12-24 hr, and returns to normal within 3 days. CK-MB is specific to myocardial injury. Normal value: <3 ng/mL
Homocysteine	An amino acid (a building block of protein) usually present in the blood as a result of eating meat	Obtain blood sample; use a blue- or purple-top tube.	10- to 12- hr fast is required. Normal ranges: Men: 5.2-12.9 $\mu\text{mol/L}$ Women: 3.7-10.4 $\mu\text{mol/L}$ Elevated level is considered an independent risk factor for ischemic heart disease. There are no current guidelines that recommend use of the test and most insurance will not cover the significant cost.
Myeloperoxidase (MPO)	Found in heme and is an antimicrobial enzyme biomarker for predicting risk for cardiovascular disease	Obtain 0.5-mL blood; use a yellow-top tube.	No fasting required. Normal value: <6 U/mL Detects or assists in ruling out microangiitis of the arteries.

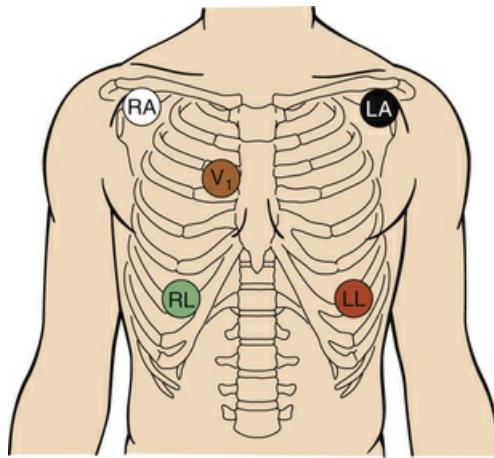

*Electrolyte values are listed in Table 3-3.

BP, Blood pressure; CO_2 , carbon dioxide; EDTA, ethylenediaminetetraacetic acid; HDL, high-density lipoprotein; HF, heart failure; IV, intravenously; LDL, low-density lipoprotein; MAP, mean arterial pressure; NPO, nothing by mouth; PADP, pulmonary artery diastolic pressure; PAWP, pulmonary artery wedge pressure; RAP, right atrial pressure; VLDL, very-low-density lipoprotein.

Cardiac Monitoring

Continuous monitoring of cardiac rate and rhythm often is done by **telemetry**. Disposable electrodes and wire leads are applied to the patient and are connected to a battery-operated transmitter unit. The wave pattern signals are sent to a monitor in a central station, where they are continually observed. This allows patients to walk around the nursing unit while being monitored. The wave pattern signals may also be displayed on a bedside monitor when continuous observation of the electrocardiogram (ECG) by the nurse is needed.

Cardiac monitors can detect specific **dysrhythmias** (abnormal variations of heart rhythm), automatically store the wave pattern, and alert the nurse to the abnormality with an alarm. Cardiac monitoring is used for patients experiencing an acute cardiac disorder, after cardiac surgery, after pacemaker insertion, and for patients with a potential for developing dysrhythmias. [Figure 17-8](#) shows proper placement for telemetry leads.

Five-electrode placement

FIGURE 17-8 Placement of the most commonly used telemetry leads. *RA*, Right arm; *LA*, left arm; *RL*, right leg; *LL*, left leg; *V1*, chest lead corresponding to the *V1* on a 12-lead electrocardiogram.

Specific Tests for Vascular Disorders

Diagnosing a vascular problem begins with a history and physical examination that includes a variety of tests for risk factors for vascular disorders. A complete blood count (CBC); urinalysis; blood lipid and cholesterol assessment (including high-density lipoprotein [HDL] and low-density lipoprotein [LDL]); or sequential multiple analyzer (SMA, also called a *metabolic panel*) panel that screens liver and kidney function, electrolytes, and blood glucose are ordered. If blood pressure is elevated, tests of thyroid, adrenal glands, kidneys, and renal arteries are done to rule out the possibility of another disease that might cause secondary hypertension. Hyperthyroidism, Cushing syndrome, pheochromocytoma, nephrosclerosis, and renal arterial stenosis all elevate blood pressure.

Doppler flow studies are performed to detect a venous thrombus when one is suspected and to assess the patency of the carotid arteries. Angiography may be performed to determine areas of narrowing in arteries or to detect a blockage. Nuclear medicine scans or CT angiography are performed to detect emboli in the lungs.

The ankle-brachial index (ABI) is an inexpensive, noninvasive bedside screening test to evaluate arterial status in the lower extremities ([Figure 17-9](#)). A regular blood pressure cuff is placed above the malleolus. Another blood pressure cuff is positioned over the brachial artery. A Doppler probe is used to check the systolic end point at the dorsalis pedis and the posterior tibial sites. The brachial blood pressure is measured. The ABI is calculated by dividing the systolic ankle pressure by the systolic brachial pressure. An ABI of 1 or more is considered normal. An abnormal ABI indicates arterial disease and can confirm a vascular cause for ischemic pain in the legs at rest and **intermittent claudication** (cramping pain in the muscles brought on by exercise and relieved by

rest). This pain is most common in the calves of the legs, but it also can affect the muscles of the thighs and buttocks. Chronic occlusive arterial disease commonly causes pain described as burning and tingling, with numbness of the toes. It is most noticeable at night when the patient is in bed.

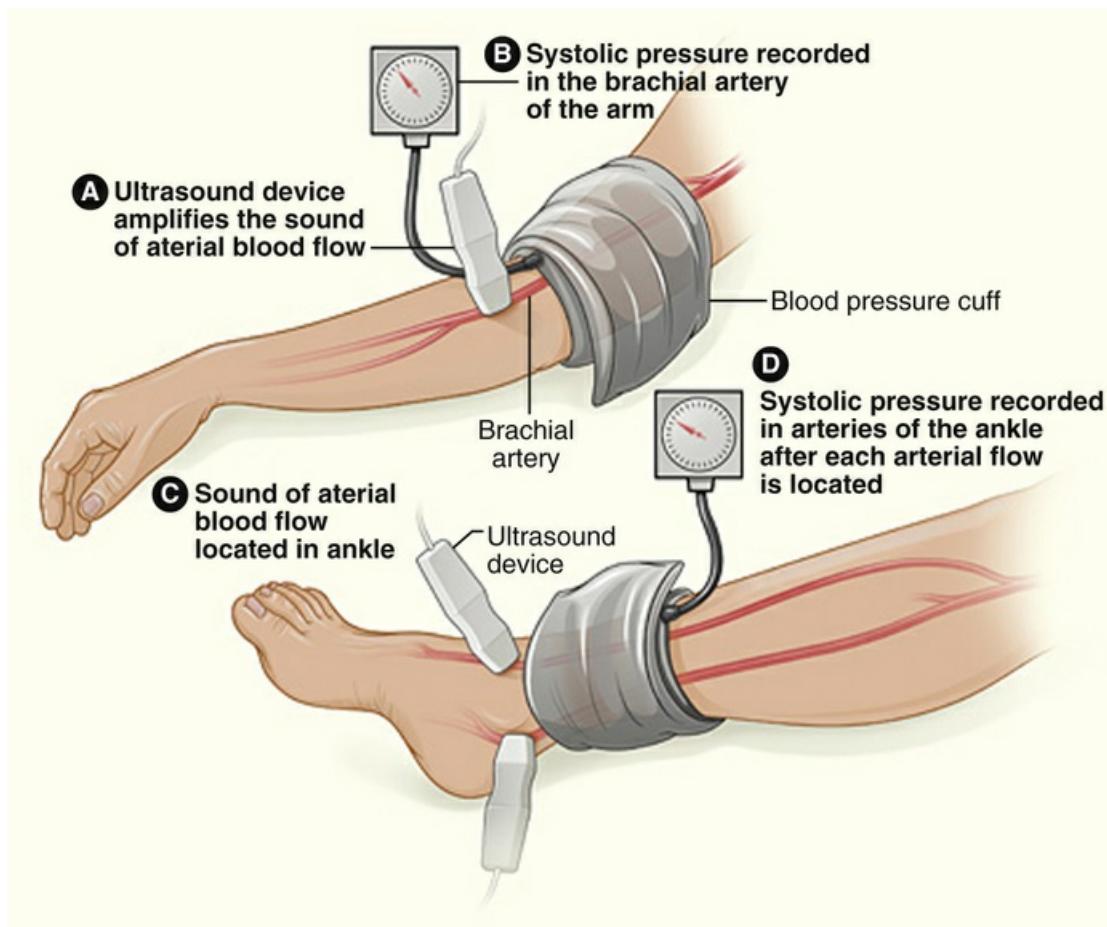

FIGURE 17-9 Ankle-brachial index. (From National Heart, Lung, and Blood Institute; National Institutes of Health; U.S. Department of Health and Human Services.)

See [Table 17-2](#) for diagnostic tests used to detect other problems in the vascular system. Serum cholesterol and lipids are also discussed in [Chapter 18](#).

Think Critically

Can you identify four teaching points to be covered for the patient who is to undergo an arteriogram?

Nursing Management

Assessment (Data Collection)

History Taking

It is important to determine whether the patient has risk factors for cardiovascular disease. Much of this information is obtained by the physician or nurse practitioner during history taking and by the admitting nurse during a complete nursing assessment. Some additional information, however, will be gathered in less formal interactions when the patient becomes more relaxed and comfortable with the nurses providing care.

Focused Assessment

Data Collection for the Cardiovascular System

History Taking

Ask the following questions:

- Do you ever have any chest discomfort or pain? What does it feel like? What, if anything, seems to bring it on? What makes it worse? How long does it last? Is it worse when you breathe in deeply? What gives relief? Does the pain radiate (spread) to other parts of the body, for example, down the arm or up into the neck or jaw, or to the upper abdomen? Is it localized, or does it cover a large area? On a scale of 1 to 10, with 10 being the worst and 1 being the least, how do you rate your pain? Do you have numbness, tingling, nausea, sweating, shortness of breath, anxiety, or dizziness when you have chest pain?
- Have you or any member of your family ever been told that you have diabetes mellitus; cardiovascular, thyroid, or renal disease; arteriosclerosis; hyperlipidemia; atherosclerosis; peripheral vascular disease; a blood disorder; gout; kidney disease; or an immune disorder such as lupus erythematosus?
- Do you become easily fatigued? Dizzy or light-headed?
- Do you become short of breath? When? Do you sleep on more than one pillow? Is your shortness of breath worse after physical activity? What kind of activity? When walking up steps? Does it occur when you are at rest? Does resting relieve it? Do you wake up at night short of breath or feeling like you are suffocating? Does sitting up on the side of the bed or getting up give you relief?
- Do you have a cough? What kind? Dry and hacking, or wet and productive? What does the sputum look like? Is there ever any blood in your sputum?
- Do you notice your heart beating very fast or pounding in your chest (palpitations)? Does it skip a beat?
- Have you ever fainted or felt like you were going to faint?
- Do you get up in the night to urinate? How many times do you get up each night?
- Have you noticed any sudden weight gain or swelling in the feet and legs?
- Do you experience pain in your legs when walking?
- Are your feet always cold?
- Have you ever had a bad injury to either leg?
- Have you ever had a deep vein thrombosis (DVT) or thrombophlebitis?
- What medications do you take that are prescribed by your provider? What over-the-counter medications do you take? Do you take herbals? Do you use recreational drugs?
- Do you smoke? Have you ever smoked? How much and for how long?
- Do you drink alcohol? What do you usually drink? How many drinks do you have? About how many times a week do you drink something alcoholic?
- What do you usually eat? Can you tell me what you generally eat for breakfast, lunch, and dinner? Do you have a midmorning, midafternoon, or evening snack? What do you eat for a snack? Do you eat fast food often? What type of fast food? What do you usually drink at meals? Do you drink liquids between meals?

- Do you regularly add salt to your food?
- Do you have leg pain at night?
- Have you ever had a sore on your foot or lower leg that was slow to heal?
- How would you rate your stress levels? What do you do to cope with or reduce stress?

Information concerning the patient's actual eating habits, such as snacking on "junk" food or daily consumption of several drinks containing caffeine, is more likely to be obtained during nursing care activities than during the initial assessment. Data concerning stressors in the patient's life and her response to them are more easily assessed while interacting over time.

An understanding of the patient's perception of her disorder and overall health is necessary to plan appropriate teaching. The effectiveness of your communication with the patient will determine the quality of subjective data obtained. Many over-the-counter (OTC) drugs can cause vasoconstriction and elevate blood pressure. Cold remedies, decongestants, and diet pills are particularly noted for having this effect. Patients sometimes do not consider OTC items as medications and do not report their use. Prescription medications also may affect the heart, including bronchodilators, anticoagulants, contraceptives, and psychotropic medications. Street drugs also alter blood pressure. A careful, specific diet history should be gathered. Fast-food intake is significant because it is often high in fat and sodium. **Excessive alcohol intake is a factor in the development of hypertension and cardiomyopathy.** Questions are asked to identify symptoms that might indicate that cardiovascular function has been impaired.

💡 Think Critically

How would you phrase questions about alcohol intake or drug use so that the patient would answer the questions honestly?

Physical Assessment

Significant findings include abnormal or extra heart sounds, crackles in the lungs, or pink frothy sputum indicating pulmonary edema.

🌐 Cultural Considerations

Dyspnea as the Major Symptom

African Americans often experience dyspnea as the most acute symptom during an MI. Dyspnea is more common than the more classic chest discomfort in this group. For this reason, they may delay seeking assistance.

Chest pain, if present, should be further assessed using the "PQRST" memory device ([Table 17-3](#)). Other significant findings might be a bluish cast to skin; pallor or diaphoresis (sweating); clubbing of the fingers; or pitting edema of the feet, ankles, or sacral area (see [Chapter 3, Figure 3-4](#)). There may be distended jugular veins, an abnormal rate or volume of pulses, or a pulse deficit. A pulse deficit is the difference between the apical and radial pulse rate when they are counted at the same time.

☒ Focused Assessment

Physical Examination of the Cardiovascular System

When assessing the cardiovascular system, check for:

- Skin color, temperature, and texture
- Facial expression: signs of pain or anxiety

- Vital signs
- Heart sounds: S_1 , S_2 , abnormal sounds, murmurs
- Apical pulse rate and rhythm; presence of pulse deficit
- Quality of peripheral pulses; compare them bilaterally
- Breath sounds: presence of crackles in lung bases
- Shape of fingers: presence of clubbing (see [Chapter 12, Figure 12-9](#))
- Appearance of neck veins: presence of venous jugular distention
- Abdomen: presence of distention; abdominal pulsation
- Ankles and feet: presence of edema and degree
- General body appearance: presence of edema
- Weight: gain of 2 lb or more over a few days
- Varicosities in lower extremities

Clinical Cues

Chest pain should be considered cardiac in origin until another cause can be ruled out. Many things can cause chest pain, but it is important to always think “cardiac first.”

Table 17-3
“PQRST” for Pain Assessment*

FACTOR	QUESTIONS TO ASK
Precipitating events	What events or factors precipitated or caused the pain or discomfort?
Quality of pain or discomfort	What does the pain or discomfort feel like? Is it aching, dull, sharp, tight, heavy pressure, etc.?
Radiation of pain	Where is the pain located? Does it radiate to the back, arms, jaw, teeth, shoulder, or elbow?
Severity of pain	On a scale of 0-10, with 10 being the most severe, how do you rate the pain?
Timing	When did the pain or discomfort begin? Has it changed since it started? Has this type of pain occurred before?

*This memory device is used to assist in obtaining information from any patient experiencing chest pain or discomfort.

An apical pulse rate should be taken for all patients on admission. Privacy should be provided before baring the chest, and the room should be warm. Heart sounds are auscultated at least every 8 hours on all patients who have a known dysrhythmia or a potential for dysrhythmia, a valve problem, or heart failure ([Figure 17-10](#)). The diaphragm of the stethoscope is placed over the bare skin at the mitral area to listen to the apical pulse. S_1 (lub) and S_2 (dub) should be distinguished. S_1 occurs with the closing of the AV valves during systole. S_2 is the closure of the pulmonic and semilunar (aortic) valves during diastole. Extra sounds or gallops may occur as S_3 sounds. Splitting of the S_2 sound may be normal in children and young adults, but may be abnormal in adults. S_4 is usually heard just before S_1 and can indicate various heart diseases.

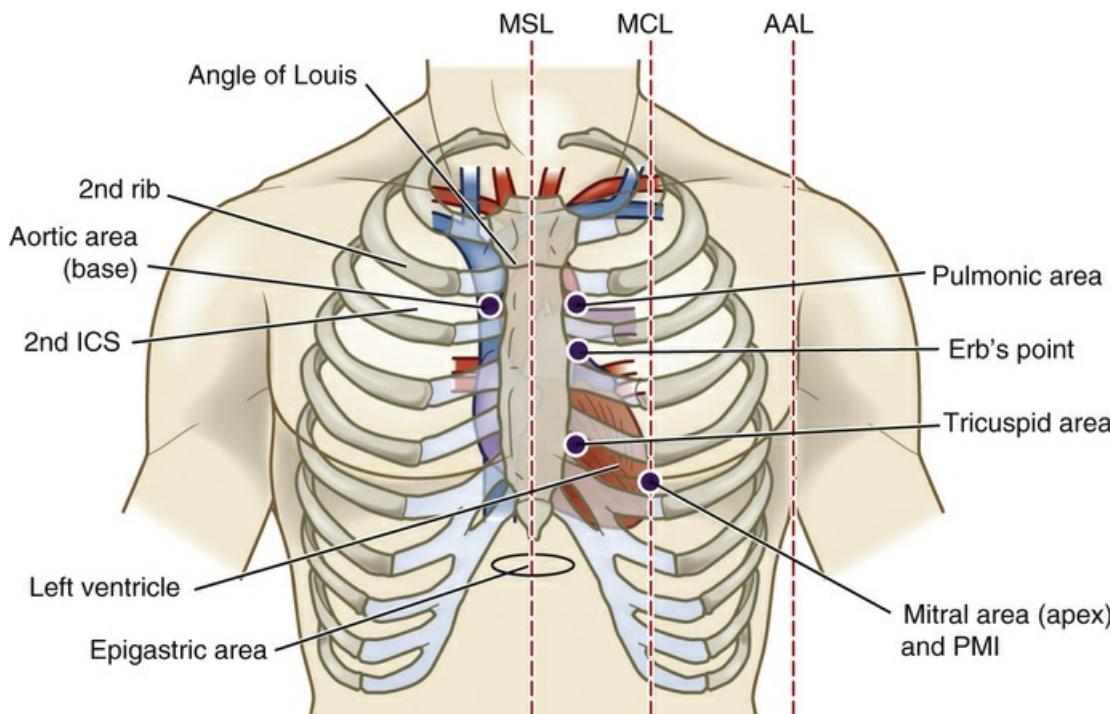

FIGURE 17-10 Sites for auscultation of heart sounds. S₁ is loudest at mitral and tricuspid areas. S₂ is loudest at aortic and pulmonic areas. Listen in the mitral area for S₃ and S₄ sounds. AAL, Anterior axillary line; MCL, midclavicular line; MSL, midsternal line; PMI, point of maximal impulse. (Modified from Price SA, Wilson LM: Pathophysiology: clinical concepts of disease processes, ed 6, St Louis, 2003, Mosby, and Kinney MR: Andreoli's comprehensive cardiac care, ed 8, St Louis, 1996, Mosby.)

The bell of the stethoscope is used to listen for heart murmurs. **It must be placed lightly on the skin for the sounds to be heard.** Murmurs usually have a “swooshing” sound from turbulent blood flow. Murmurs are commonly the result of damaged valves, causing abnormal blood flow in the heart. Because heart sounds typically are very soft, ask the patient to refrain from talking, and turn off the television or radio while listening. (Just remember to turn it back on.) Having the patient roll to the left side or lean forward may make the sounds louder and clearer.

Older Adult Care Points

The thickening of valve leaflets with age may cause a systolic murmur common in persons older than age 80 years.

Pulses. Check the arterial pulses and determine the pulse rate, rhythm, and character (force) of the pulse (Box 17-2). When performing a cardiovascular assessment, the radial pulse should be assessed and compared with the apical pulse. The apical pulse should be counted for a full minute. The carotid, femoral, popliteal, and pedal pulses should also be palpated and compared bilaterally, noting quality and character (Figure 17-11). The quality of pulses are graded as to their intensity. The character of the pulse is its regularity (see Box 17-2).

Box 17-2

Scale for Grading Pulse Quality

0 Absent

+1 Weak, thready

+2 Light volume

+3 Normal volume

+4 Full, bounding

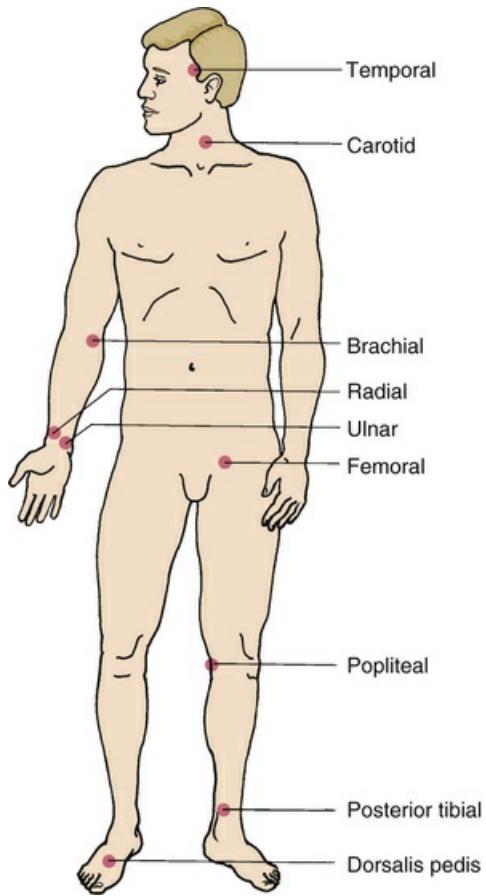

FIGURE 17-11 Palpation sites for arterial pulse.

If pulsations are weak or undetectable, use a Doppler device to check them. A Doppler measures the velocity of blood flow through a vessel with ultrasound waves. It can sense weak pulsations even in severely narrowed arteries. Dopplers may have a stethoscope or handheld probe attachment (Figure 17-12).

Think Critically

Can you recall the correct way to locate a dorsalis pedis and a posterior tibial pulse? Could you demonstrate the technique to a classmate?

FIGURE 17-12 The Doppler stethoscope is used to detect a faint pulse. (From Jarvis C: *Physical examination and health assessment*, ed. 5, Philadelphia, 2008, Saunders.)

Examine the abdomen with the patient lying supine to observe for a visual abdominal pulsation from the aorta. This sometimes indicates the presence of an aneurysm.

Bruits. A whooshing or purring sound (a **bruit**) is made when blood passes through a partially obstructed artery. To detect bruits, listen with the bell of the stethoscope applied lightly over the skin of the carotid arteries, abdominal aorta, and femoral arteries.

Blood pressure. For more accurate readings, be certain the patient has not had a cigarette or any caffeine for the past 30 minutes. Blood pressure should be carefully measured with the correct size cuff. The cuff should fit the upper arm with the lower edge 2.5 cm (1 inch) above the antecubital space. If the cuff is too narrow, the pressure will be falsely elevated. Cuffs are available in child, normal adult, and large adult sizes. The bladder must be centered over the brachial artery, and its length should cover at least 80% of the extremity's circumference when positioned correctly. The pressure should be taken lying supine, sitting, and standing for a thorough assessment. Standing blood pressure measurements also are important when a patient is started on a new medication, particularly an angiotensin-converting enzyme (ACE) inhibitor. Blood pressure should be measured on both arms. The arm on which the cuff is placed should be supported at heart level, and the feet should be supported or be on the floor. The patient should be resting quietly for 5 minutes before the measurement is taken. The equipment used should be calibrated, and the valve should open and close smoothly. The cuff should be deflated slowly and smoothly to obtain a correct diastolic reading. Automatic blood pressure machines must regularly be calibrated and checked for accuracy.

Orthostatic or postural hypotension occurs when the blood pressure drops when a person stands. Orthostatic or postural hypotension is a common cause of **syncope** (fainting) in older patients. A decrease of 20 mm Hg systolic pressure or a drop of 10 mm Hg diastolic pressure within 3 minutes of standing is orthostatic hypotension.

Older Adult Care Points

The blood pressure of older adult patients is usually lower right after a meal. For accurate readings, assess blood pressure between meals.

Skin. Tissues in light-skinned people who are receiving an adequate supply of oxygenated blood

appear pink and rosy, whereas tissues deprived of normal amounts of arterial blood appear pale and mottled. In dark-skinned people, the mucous membranes will be rosy and pink if oxygenation is adequate. However, the environment must be taken into account. Pale and mottled skin also can indicate that the patient is cold. Reddish-blue color can indicate venous insufficiency.

One way to assess arterial blood flow more accurately is by having the patient elevate her feet and legs above the level of the heart for 1 to 3 minutes until pallor occurs. Have the patient lower the legs to a dangling position while sitting. Compare both feet, noting the time necessary for pinkness to return (usually about 10 seconds). Note the time it takes for the veins of the feet and ankles to fill (usually about 15 seconds). For those with dark skin, inspect the soles of the feet for color change and use a light shining at an angle to visualize vein filling.

Return of color to the lowered feet is delayed in arterial insufficiency. If there is severe peripheral arterial disease, the dangling feet soon take on a dusky red color (**rubor**). The skin may be shiny and taut.

A cold environment and immobility will cause the extremities to feel cold to the touch. However, when a patient experiences persistent coldness of an extremity in a warm environment, peripheral arterial disease should be suspected. When observing a patient for signs of arterial disease, note differences in skin temperature in various areas of the same limb, as well as differences between limbs.

Skin that is chronically malnourished because of decreased blood supply has a characteristic appearance: the skin appears smooth, shiny, and thin, and there is little or no hair on its surface. The nails are thick with deposits of cornlike material under them.

If there is severe blood flow restriction of the tissues for several days, the tissues become necrotic. This causes the skin to assume a purple-black color. This is a deep cyanotic condition indicative of gangrene. Gangrene of the toes is a likely complication in the diabetic patient who has poor circulation in the feet.

Chronic venous insufficiency is accompanied by chronic edema. This in turn leads to inflammation of the tissues and eventually to the formation of ulcers. Edema is either present, absent, pitting, or nonpitting. Pitting means that a fingertip pressed into the area for 5 seconds leaves an indentation. Pitting is graded on a scale from 1+ to 4+ depending on how deep the skin can be depressed and how long the indentation remains. Review [Chapter 3](#) for assessment and staging of edema. Increased pigmentation of the skin, dryness and scaling, and excoriations are objective signs of venous insufficiency.

The capillary refill test has traditionally been used to check peripheral circulation. A fingernail or a toenail is squeezed over the bed of the nail sufficiently to cause blanching; the pressure is removed and an observation is made of how quickly the color returns. Normally the color returns immediately. Although it is a good gross assessment of circulation to the extremity, this test may be unreliable, because many factors can cause a decrease in time for color to return. This test is most useful for determining whether circulation is occluded by constriction or thrombosis above the area and has been shown to be a “red flag” warning in the assessment of children. A new device is available that squeezes the finger and uses optical sensors to identify color change, eliminating the subjectivity of human interpretation.

Nursing Diagnosis, Planning, Implementation

[Table 17-4](#) presents general problem statements/nursing diagnoses, expected outcomes, and nursing interventions for patients experiencing cardiovascular problems. Problem statements/nursing diagnoses may be added to the care plan for problems secondary to treatments, such as drug side effects or complications from surgery or preexisting diseases of other body systems. Specific NANDA-I diagnoses may be chosen from the NANDA-I list (see inside back cover).

Table 17-4
Common Problem Statements, Expected Outcomes, and Interventions for Patients With Heart Disorders

PROBLEM STATEMENT/NURSING DIAGNOSIS	GOALS/EXPECTED OUTCOMES	NURSING INTERVENTIONS
Cardiac Disorders		
Altered activity tolerance due to decreased perfusion	Patient will not experience undue fatigue performing activities with changes in vital signs.	Space activities of daily living and nursing procedures to prevent undue fatigue. Encourage use of oxygen as ordered. Implement actions to promote rest.
Potential for injury due to dysrhythmia or complications of myocardial infarction (MI) or heart failure (HF)	Patient will not experience serious dysrhythmia and will have a stable ECG. Patient will not experience complications from MI	Monitor ECG or telemetry tracings, observing for changes and life-threatening dysrhythmias. Assess for complications.

	or HF.	<p>Monitor lungs for crackles. Check for jugular venous distention. Auscultate for changes in heart sounds, extra sounds, changes in rhythm. Assess respirations for increasing dyspnea. Assess for signs of inflammation or infection; check temperature trend, white blood cell (WBC) level. Assess for chest pain on exertion or at rest. Monitor for central and peripheral edema. Assess trends in daily weight. Assess trends in 24-hr intake and output. Monitor vital signs.</p>
Potential for altered cardiac output due to dysrhythmia or ineffective cardiac muscle action	Patient will demonstrate adequate cardiac output with normal pulses, vital signs, skin color, and urine output.	<p>Assess apical pulse every shift. Administer antidysrhythmic and cardiotonic medications as ordered. Observe for side effects of medications. Assess for adequate perfusion: Check peripheral pulses. Assess color of extremities and around mouth. Assess mentation. Monitor urine output (related to perfusion of kidneys). Auscultate lungs for crackles every shift. Assess level of fatigue. Treat impaired oxygenation and fluid imbalance. Give stool softeners or laxatives, as ordered, to prevent straining at stool (Valsalva maneuver) and slowing of pulse or stopping of heart.</p>
Altered gas exchange due to cardiac failure	Patient will not experience impaired oxygenation; SpO ₂ within normal limits and PO ₂ between 80 and 100.	<p>Place in high Fowler position. Administer oxygen, as ordered. Feed frequent small meals to decrease oxygen demand. Administer diuretics as ordered. Monitor intake and output. Enforce fluid restrictions. Assist with activities of daily living (ADLs). Promote relief of anxiety. Give morphine, as ordered, to ease breathing and decrease anxiety. Monitor lung sounds, pulse oximetry, and blood gases. Assist to use incentive spirometer q2h as ordered.</p>
Altered self-care ability due to fatigue, weakness, or dyspnea	Patient will increase performance of own ADLs of 1-3 metabolic equivalents (METs) within 1 wk.	<p>Assist with all ADLs as needed. Plan nursing treatments to provide rest periods. Encourage to do small tasks of ADLs as condition improves. Assist to turn in bed q2h. Assess skin every shift and when turning. Provide mouth care before meals to stimulate appetite.</p>
Fear due to life-threatening illness	Patient will verbalize feelings and fears regarding life-threatening condition. Patient will identify own best coping mechanisms.	<p>Perform a spiritual assessment. Determine usual coping style. Support in coping mechanisms. Obtain clergy if patient desires contact. Provide privacy for prayer and devotions. Assist to express fears to reduce anxiety. Keep informed of what is being done for treatment and what to expect. Inform of positive gains toward wellness. Allow state of denial in acute stage; denial may be protective. Provide time with loved ones. Provide therapeutic touch if patient is accepting. Assess cultural meanings of events to patient. Actively listen to the patient's fears and concerns. Offer realistic reassurance as appropriate.</p>
Decreased ability for home maintenance due to fatigue, dyspnea, and activity intolerance	Appropriate home services will be in place before discharge.	<p>Refer for social services consultation. Consider home health care services. Offer information on homemaker aide services. Consult with family regarding ongoing care of patient at home. Collaborate with patient regarding plans for home care.</p>
Vascular Disorders		
Altered tissue perfusion due to vascular damage from elevated blood pressure	Patient's blood pressure will be within normal range within 3 mo.	<p>Assess blood pressure; determine effectiveness of therapy. Administer medications to lower blood pressure. Discourage intake of caffeine and excess sodium. Discourage smoking. Teach to arise slowly and stabilize before walking to counteract postural hypotension effect from medication. Teach anxiety- and tension-reduction techniques to decrease blood pressure. Encourage regular rest, relaxation, and exercise program.</p>
Potential for injury due to obstructed blood flow	Patient will not develop thrombosis or emboli. Thrombosis will resolve within 10-14 days.	<p>Assess for signs and symptoms of deep vein thrombosis and impaired blood flow. Maintain activity restrictions as ordered. Elevate affected extremity as ordered. Increase fluid intake to 3000 mL/day unless contraindicated. Administer anticoagulants as ordered; monitor for side effects. Teach to prevent future episodes by encouraging not to sit with legs crossed, not to sit for long periods, and not to put pressure on the back of the knees. Apply elastic stockings or sequential pneumatic devices to promote venous return.</p>
Potential for injury due to surgical revascularization	Patient will not develop bleeding or decreased perfusion.	<p>Check incisions for bleeding q1-2h × 24 hr, then q4h × 6, then every shift. Assess for internal hematoma by checking sensation below surgical area. Assess for adequate blood flow by checking pulses distal to incision on same schedule. Assess skin color and temperature above and below incision when checking for bleeding. Reinforce dressing as needed; change dressing per orders, using strict aseptic technique.</p>
Pain related to decreased blood flow and edema	Patient will verbalize adequate pain control attained from analgesics and comfort measures provided.	<p>Assess type and location of pain experienced. Handle gently and avoid jarring the bed. Use a bed cradle or footboard to prevent pressure from bed linens. Administer analgesics and anti-inflammatory agents as ordered. Apply heat as ordered; monitor closely to prevent burns. Teach relaxation techniques, imagery, or distraction to decrease pain. Elevate edematous extremity. Apply elastic stockings or sequential pneumatic devices to encourage venous return and decrease edema. Medicate for sleep as ordered if discomfort is interfering with rest.</p>
Altered activity tolerance related to pain in legs when walking	Patient will develop own activity program within 3 wk. Patient will exercise regularly according to devised program.	<p>Collaborate with physical therapist to encourage prescribed exercises. Assist to plan walking, swimming, or cycling program.</p>
Altered body image related to: Diagnosis of chronic illness Edema and dilated veins in the legs Loss of limb by amputation Inability to maintain former lifestyle	Patient will verbalize feelings regarding diagnosis, body changes, and needed lifestyle changes. Patient will identify personal strengths and coping mechanisms within 3 wk. Patient will become as independent as possible in tasks of daily living within 2 mo.	<p>Allow to express feelings about illness and disease process. Assist through the grief process. Assist to identify personal strengths. Reinforce coping mechanisms that have been helpful before. Be with patient for first dressing change. Clarify misconceptions about physical limitations after amputation. Involve patient in care of the wound after initial period of adjustment. Foster independence in tasks of daily living. Assist to explore lifestyle changes. Encourage significant others in their support of the patient. Teach ways to decrease risk of further amputation.</p>
Altered tissue integrity related to: Ulcer from decreased circulation Surgical wound (Risk for infection may be used here also.)	Patient will not develop a wound infection.	<p>Use strict aseptic technique for wound care. Treat and dress wound per provider's orders. Promote adequate nutrition to promote healing. Administer medication, as ordered, to prevent infection.</p>

		Position affected limb as ordered. Maintain correct body alignment.
Potential for altered tissue integrity related to bed rest and impaired circulation	Patient will not develop impaired tissue integrity.	Inspect pressure points q2h. Turn at least q2h. Maintain smooth linens on bed; provide appropriate padding to prevent pressure areas. Keep skin clean and dry. Refrain from raising the knee section of the bed. Encourage foot and ankle exercises every hour while patient is awake. Prevent shearing when patient is moving in bed by using a lift sheet and two people to turn the patient. Use mechanical lifts when indicated and special beds for complicated skin lesions. If skin breakdown occurs, notify provider immediately and provide appropriate wound care.
Insufficient knowledge due to inadequate information about disease process, medications, and self-care	Patient will verbalize knowledge of disease process and ways to prevent further damage. Patient will verbalize how to take medications and side effects to report. Patient will demonstrate self-care techniques.	Explain what is happening in the body to cause the decreased blood flow. Allow time for questions. Instruct in ways to decrease risk factors. Teach self-care methods, including exercises, skin care, foot care, dietary changes, and lifestyle changes. Teach about medications, including schedule of administration, action, side effects, and what to report to the provider. Encourage regular visits to the provider.
Absence of compliance due to refusal to follow treatment regimen	Patient will verbalize frustrations and problems in complying with treatment regimen and lifestyle changes. Patient will demonstrate compliance with treatment regimen.	Reinstruct about disease process. Explore problems with treatment regimen. Allow patient to express feelings about lifestyle changes. Explore ability to obtain and afford medications. Explore any difficulty in swallowing medications. Explain progression of disease and consequences of poor control; discuss complications and effect on lifestyle. Seek support system for compliance with treatment program. Give praise for each attempt at compliance. Respect the patient's right to make decisions about compliance.
Potential for injury due to: Embolus or bleeding from anticoagulant medication Circulatory occlusion from embolus	Coagulation times will remain within safe therapeutic range. Patient will have no signs of bleeding. Patient will have no signs of embolus.	Do not massage affected extremity. Encourage activity restrictions as ordered. Monitor laboratory values: international normalized ratio (INR) or activated partial thromboplastin time (APTT); notify provider when values are outside of accepted therapeutic limits. Assess urine and stool for signs of blood. Assess patient for excessive bruising, bleeding gums, nosebleeds, or bleeding at puncture sites. Check injectable anticoagulant dosages and IV admixtures with another nurse before administration to verify correct ordered dosage and rate of infusion. Assess for signs of embolus: chest pain, shortness of breath, change in level of consciousness, sudden headache, or other neurologic signs.

ECG, electrocardiogram; IV, intravenous.

A goal of community nursing is the promotion of healthful living to prevent cardiovascular disease. A concerted effort is being made to decrease childhood obesity as a method of decreasing risk for cardiovascular disease in adulthood. Blood sugar management in patients with diabetes and blood pressure control in those with hypertension are important for preventing vascular complications.

When planning care for cardiovascular patients, it is important to schedule nursing activities to conserve the strength of the patient and prevent excessive fatigue. Patients undergoing telemetry monitoring should not be disconnected from their monitor for any extended time. Check whether the patient may shower before disconnecting the telemetry device. **Reconnect the leads immediately afterward.**

Clinical Cues

Know what the patient's last blood pressure and pulse measurements were before going to the room with cardiovascular medications. Often you will need to take an apical pulse rate and blood pressure reading before administering certain medications. You need to know what those measurements were previously to properly evaluate the patient's status. Plan time to take these measurements and record them.

When a patient has a history of thrombosis, plan measures to prevent recurrence regardless of what patient problem is currently the focus of treatment. If the patient has peripheral arterial disease, be alert to prescribed medications that may cause further vasoconstriction. Understanding of the patient's overall condition allows for individualized care specific to the patient.

A large part of what the nurse does for a patient with a cardiovascular disorder is to monitor the condition and determine whether treatment is effective. Considerable time is spent on teaching patients about the disease, self-care, and medications. It is very important to monitor side effects or adverse effects of medication and teach the patient what effects to report.

Remember that any patient experiencing fatigue or weakness takes longer to accomplish the tasks of daily living. Space nursing actions appropriately. Watch the patient receiving cardiac drugs for postural hypotension; have her hold on to the bed rail and steady herself for a couple of minutes after arising before beginning to walk. This will help prevent falls. Specific nursing interventions are discussed with the various disorders in the following chapters.

Collaboration

Cardiovascular patients often are being treated by the physical therapist, dietitian, and respiratory therapist, as well as by the provider and nurse. It is important that the nurse consult with the other health professionals involved in the patient's care. Early collaboration with the discharge planner is important to provide continuity of care after discharge. Providing others on the health care team with information useful to them promotes a good working relationship and provides the patient with a team working toward the same goals.

■ Evaluation

Evaluation involves both subjective and objective data. Use good communication skills to ask the right questions to gather the required information from the patient. Ask the patient to describe any "different" feelings she has experienced. Inquire about changes in appetite and bowel movements that could indicate possible medication side effects. Check laboratory values for therapeutic drug levels before giving doses of medication, and note the latest blood levels of electrolytes. Assess for signs and symptoms of drug toxicity and for fluid or electrolyte imbalance. Ask yourself whether the patient is showing signs indicating that the medication you are giving is effective. The nursing care plan should be checked daily to evaluate whether each nursing action is effective. If an action is ineffective, it should be stopped and a new action should be devised to resolve the problem.

It is important to look at serial blood pressure readings to evaluate the effectiveness of treatment and of nursing interventions. Pressures that are consistently higher than normal between medication doses indicate a need to change either the dosage schedule or the medication. Trends in assessments give more information than isolated information.

Carefully evaluating pulses and comparing them bilaterally are important parts of nursing care for patients with problems of the cardiovascular system. Writing a good description of the quality and character of the pulses monitored in the nurse's notes will give coworkers an accurate assessment baseline on which to evaluate changes.

It is important to determine whether skin color and temperature have changed since the last assessment. Accurately measure and document areas of discoloration in the medical record. Monitor ulcerated areas closely and measure and photograph the areas to determine whether healing is occurring. Evaluate the color of the healing tissue and presence of exudate. If the wound is growing or not improving, the nursing actions or treatment must be changed.

Often the nurse must rely on subjective data from the patient to evaluate whether treatment and nursing actions are effective. Increases in peripheral circulation may be evident only by a decrease in pain or an ability to walk farther without pain.

Common Problems of Patients With Cardiovascular Disorders

Fatigue and Dyspnea

When the coronary arteries fail to supply adequate oxygen to the cells of the heart muscle, the heart is unable to perform as it should, especially when extra demands are placed on it. The result is a general hypoxia of the tissues throughout the body, which causes fatigue and dyspnea on exertion. In the early stages of heart disease, the patient may be only slightly aware of the inability to do as much physical work as she formerly could.

Activity may be restricted for MI and severe congestive heart failure (CHF). The patient may feed herself and assist with her sponge bath, with the nurse monitoring for shortness of breath or return of admitting symptoms. She should be cautioned against any strenuous activity, and response to activity should be monitored via telemetry units to watch for dysrhythmias or excessive heart rate changes. The amount of energy used in activity is expressed in **metabolic equivalents** (METs). [Box 20-4](#) shows the metabolic equivalents for various activities. The MET level and exercise tolerance are assessed, and targets are set for the rehabilitation process.

Criteria used to determine whether a cardiac patient is tolerating an activity include the following:

- The heart rate does not rise more than 20 beats per minute over the baseline rate.
- Systolic blood pressure does not drop.
- There is no complaint of chest pain, dyspnea, or severe fatigue.
- There is no abnormal heart rate or rhythm.

The progress of activity often is jointly supervised by a physical therapist and a nurse. More information on cardiac rehabilitation is presented in [Chapter 9](#).

Edema

Edema is an accumulation of fluid in the interstitial fluid compartment. It becomes a problem in heart disease when blood flow into or out of the heart is inhibited, causing a slowing down of the normal movement of body fluids between fluid compartments and their eventual excretion.

Continually assess the fluid balance of a patient with cardiac disease by looking for signs of abnormal collections of fluid in the body tissues. Daily weight change is considered the best indicator of fluid buildup. Check the feet and ankles of ambulatory patients for signs of dependent edema, and watch patients on bed rest for signs of swelling in the area of the sacrum, buttocks, and thighs. Observe for progressive signs of shortness of breath, and auscultate lung fields each shift to detect crackles—a sign of beginning pulmonary congestion. Observe the jugular veins for prominence when the patient is in an upright position; prominent veins may indicate fluid overload and CHF.

Clinical Cues

A weight gain of 3 lb or more in a 24-hour period indicates fluid retention.

Nursing responsibilities include recording the patient's weight daily before breakfast, supervising fluid restriction, accurately measuring intake and output, and assessing for signs of both fluid deficit and fluid overload. Older adult patients on fluid restriction and diuretics can easily become dehydrated.

Therapeutic measures to control edema include the administration of diuretics and restriction of sodium and, possibly, the restriction of fluid. You must observe for adverse effects of medication, such as electrolyte imbalance and postural hypotension. Potassium supplementation may be ordered for a patient who is experiencing hypokalemia or to prevent hypokalemia in patients taking non-potassium-sparing diuretics.

Safety Alert

Signs of Hypokalemia

Be alert for the following signs of hypokalemia: fatigue, muscle weakness, muscle cramps, drowsiness, confusion, new onset of bradycardia, or postural hypotension. Hypokalemia may cause life-threatening dysrhythmias.

Pain

Chest pain can be a symptom of a life-threatening heart event. Each episode of pain is carefully assessed by noting when it started; the location and radiation pattern; degree of pain on a scale; activity before onset; associated symptoms such as nausea, diaphoresis, or **palpitations**; and vital signs.

Severe pain is most often associated with heart disease of an acute nature (e.g., MI). Anginal pain caused by narrowed coronary arteries can interfere with the patient's lifestyle, as well as cause discomfort. Acute anginal pain is treated with nitroglycerin, oral nitrates, oxygen, reassurance, and careful monitoring for relief. Nitrates and other medications that dilate coronary arteries to promote better blood flow and decrease ischemia are used to control or prevent anginal pain.

Clinical Cues

If chest pain is not relieved after administering three nitroglycerin sublingual tablets (or spray) 5 minutes apart, notify the provider. Institute oxygen therapy according to agency protocol, monitor vital signs, and stay with the patient. The patient may be experiencing an MI. (Do check to make certain that the nitroglycerin causes tingling under the tongue. If not, the tablets may be too old and will not work. The tablets are very light sensitive.) Nitroglycerin can cause a significant decrease in blood pressure and mild to severe headache. Monitor for these side effects. At home, 911 should be called if the first nitroglycerin dose has not relieved the pain within 5 minutes.

If pain is not relieved, the analgesic drug used most often in an emergency situation is IV morphine sulfate. The goals of treatment are to restore oxygen supply to the heart and relieve the symptoms. Morphine, nitroglycerine, and oxygen are given as well as low dose aspirin—not to decrease pain but to decrease the stickiness of platelets to prevent further clot occlusion of coronary arteries (Zafari, 2015). For chronic chest pain not related to acute MI, oral pain medications may be used in addition to other interventions. The patient's pain may be increased because of nervousness and anxiety, and you can do much to help relieve pain by providing a restful environment, interacting therapeutically with "active listening," and balancing rest with prescribed physical activity.

Sleep deprivation and fatigue can increase the pain. Turning, administration of medications, visiting, exercise, and procedures should be coordinated so that the patient is not disturbed more than necessary.

Determining those factors that seem to trigger an attack can identify stressors that the patient may be able to avoid. Relaxation and other noninvasive techniques to manage pain are discussed in [Chapter 7](#).

Altered Tissue Perfusion

In **peripheral vascular disease**, **blood flow may be sluggish or altered by constriction of the vessels**. The smooth muscles of the arterial walls respond to temperature by constricting in the presence of cold and extreme heat and relaxing in the presence of warmth. Therefore the nurse's care plan should include (1) providing a warm environment for the patient; (2) covering the hospitalized patient with warm blankets or dressing her in warm clothing; and (3) instructing the patient to avoid extremes of cold and heat.

The constricting effect of extreme heat rules out the use of local applications of heat therapy. In addition to the danger of burning the patient because of decreased sensitivity to extremes of temperature, local heat increases metabolic activity in the tissues to which it is applied and

therefore further disrupts the balance of supply and demand for blood flow to all the tissues.

Think Critically

What would you recommend to an older adult home care patient to keep her lower extremities warm during the winter? The patient does not have the funds to keep the house heated above 68° F (20° C).

A second consideration is that of **pressure** against the walls of the blood vessels. Constricting clothing, elastic materials in underclothing, tight socks, and other form-fitting clothing is avoided. Frequent position changes are essential; position must be changed at least every 2 hours.

Patients with poor venous circulation can benefit from periodic elevation of the lower extremities above the level of the heart to facilitate venous return of blood to the heart. Well-distributed support of the vessels near the surface of the body will help improve venous return. To provide this kind of support, the provider may prescribe an elastic bandage or fitted elastic stockings. The stockings or elastic bandage should be applied early in the morning, before the legs are placed in a dependent position, because the blood vessels are less congested after a prolonged rest. Bandages and hose should be applied by beginning at the feet and working upward to avoid trapping blood in the lower leg. To stay in place the stockings have a band at the top. The skin under this area should be assessed to make sure the stockings are not constricting blood flow. The patient should have two pairs of elastic hose and should wash the hose after each day's wearing. Elastic hose should be replaced every 6 months, because they lose their elasticity. When stockings are removed, the heels should be checked for pressure areas. **Elastic stockings are not used for patients with arterial disorders.**

Exercise is especially beneficial to patients with decreased blood flow. Flexion of leg muscles helps "pump" venous blood back up to the heart against gravity. Walking is ideal exercise for ambulatory patients. Bedridden patients will need range-of-motion (ROM) exercises and the other kinds of muscular movements described in [Chapter 31](#). Use of a treadmill for patients who cannot exercise by walking outside is very beneficial. A stationary bicycle is another alternative.

In addition to mechanical factors, certain chemical factors affect the constriction of blood vessels. **Nicotine**, which is inhaled with tobacco smoke, has the effect of producing spasmodic narrowing of the peripheral arteries. Patients with arterial insufficiency are encouraged to stop smoking. Used in conjunction with a community smoking cessation support program, the booklet *You Can Quit Smoking*, available from the Agency for Health Care Research and Quality at <http://www.ahrq.gov/patients-consumers/prevention/lifestyle/index.html>, can be very helpful.

Alcohol is a mild vasodilator when taken in moderate amounts. Unless the patient has moral or religious convictions against its use, the provider may approve a daily intake of a specific, small amount of wine or liquor. It is important to find out whether alcohol will interfere with the action of medications being taken or cause problems for other coexisting diseases.

Health Promotion

Drink in Moderation

Promote proper use of alcohol for those who consume alcoholic beverages. Moderate alcohol intake for a man is two drinks in any 1 day. For a woman, the appropriate amount is one drink per day. One drink is $1\frac{1}{2}$ ounces of alcohol, 4 ounces of wine, or 12 ounces of beer.

Drugs that are helpful to relieve vasoconstriction and improve blood flow are prescribed. These drugs are of value only when the arteries are still capable of dilating. Severely sclerosed vessels respond very poorly to therapy of this kind.

Impaired Tissue Integrity

Tissues that have a diminished blood supply are subject to severe and permanent damage from the slightest injury, because the normal processes of healing and repair are impaired. Arterial and venous stasis often lead to chronic leg ulcers.

These ulcers are particularly distressing to patients, because they heal very slowly and many never completely heal. Patients must be taught to avoid conditions that contribute to injury of the extremities and to report any injury, no matter how minor.

Prevention of leg ulcers includes (1) wearing elastic bandages or support hose; (2) proper positioning and exercise; (3) preventing injury to the feet and legs; and (4) avoiding extremes of heat and cold and other mechanical and chemical factors that contribute to obstruction of blood flow. Information on care of a patient with a venous stasis ulcer is provided in [Chapter 18](#).

Get Ready for the NCLEX® Examination!

Key Points

- Cardiovascular disease is the leading cause of death in the United States.
- The heart and vessels become stiffer with age, and older adults have less cardiac reserve.
- Atherosclerosis and arteriosclerosis are major contributors to cardiovascular disease.
- Close to one third of the population in the United States has elevated blood pressure.
- Control of hypertension and obesity could lower the incidence of cardiovascular disease.
- Peripheral pulses should be compared bilaterally.
- Blood pressure should be taken—using correct technique—lying, sitting, and standing.
- Comprehensive nursing care plans should be holistic and may need to include problems secondary to the cardiovascular disease.
- Planning should include time management, because many heart medications need to be given as close to the prescribed time as possible to maintain a steady blood level of the drug.
- Collaboration with other health care team members assists in providing consistent, thorough care for patients with cardiovascular disorders. Evaluation involves ECG monitoring, checking blood levels of electrolytes, obtaining laboratory values for cardiac drugs to determine adequate dosing or toxicity, and monitoring blood counts for adequate red cells and hemoglobin to carry sufficient oxygen to the tissues of the body.
- Fatigue and dyspnea occur when the heart cannot pump sufficiently to carry adequate oxygen and nutrients to the tissues.
- Activity during cardiac rehabilitation is measured in metabolic equivalents; activity is started slowly and may progress according to the body's response.
- Heat therapy is applied cautiously to the extremities of patients with peripheral vascular disease.
- When blood volume is more than the heart can handle, there is a slowing of normal movement of body fluids and changes in concentration and pressure, causing edema.
- Daily weight change is the best indicator of fluid buildup.
- Watch patients who have fluid imbalances for accompanying electrolyte imbalances.
- Measures to reduce or prevent edema are often needed for patients with peripheral vascular disease.
- Pain from an MI may be acute or described as discomfort.
- Nitroglycerin, morphine, aspirin, and oxygen are the drugs of choice for myocardial pain.
- Anginal pain is treated with nitroglycerin and other drugs to promote arterial vasodilation.
- Decreasing anxiety and promoting rest may decrease anginal pain.
- It is very important to encourage patients with cardiovascular disease to quit smoking, because nicotine is a vasoconstrictor.
- Patients with peripheral vascular disease have difficulty healing lower leg and foot wounds.

Review Questions for the NCLEX® Examination

1. Which statement(s) regarding drug use and the risk of cardiac disease is/are true? (Select all that apply.)

1. The vasodilation effects of cocaine hasten atherosclerosis.

2. Sudden cardiac death is associated with cocaine use.
3. Methamphetamine dilates blood vessels.
4. Cigarette smoking contributes heavily to heart disease.
5. Methamphetamine can cause myocardial infarction.

NCLEX Client Need: Health Promotion and Maintenance

2. The ankle-brachial index test is ordered for a patient experiencing signs of peripheral vascular disease. Which patient statement indicates that further teaching about the test needs to occur?

1. "I'll be lying down for this examination."
2. "The test is noninvasive."
3. "My brachial and pedal pulses will be checked and compared."
4. "My brachial and ankle blood pressure will be taken."

NCLEX Client Need: Reduction of Risk Potential

3. Morphine 6 mg is ordered for a man admitted with chest pain and a probable myocardial infarction. On hand is morphine 10 mg/mL. The nurse should give ____ mL to the patient. (*Fill in the blank.*)

NCLEX Client Need: Pharmacological Therapies

4. During initial assessment of an older adult, the nurse finds that the skin appears smooth, shiny, and thinned with little or no hair on the surface. Which nursing diagnosis should be on the care plan?

1. *Altered peripheral tissue perfusion.*
2. *Potential for infection.*
3. *Acute Pain related to decreased perfusion.*
4. *Fluid volume deficit.*

NCLEX Client Need: Physiological Adaptation

5. When providing care for a patient with cardiac disease, the nurse understands that the patient is at risk for alteration in cardiac output. Which of the following has the most potential to affect cardiac output?

1. Antihypertensive medications

2. Dysrhythmias

3. Chest pain

4. Atherosclerosis

NCLEX Client Need: Reduction of Risk Potential

6. The nurse weighs a patient with congestive heart failure and determines that there is a net weight gain of 3 lb within the last 24 hours. The patient states that she is short of breath. Place in priority order the nursing actions to take.

1. Listen to lung sounds.
2. Place nasal cannula O₂ starting at 2 L/min.
3. Raise the head of the bed.
4. Notify the provider.
5. Take vital signs, including pulse oximetry.

NCLEX Client Need: Physiological Adaptation

7. The nurse administered two consecutive sublingual nitroglycerin tablets to a patient complaining of moderate chest pain. If the patient's blood pressure is 148/88 mm Hg with continued chest pain, the next nursing action would be to:

1. administer morphine sulfate.
2. get an IV cannula inserted.
3. give another sublingual nitroglycerin.
4. provide emotional support.

NCLEX Client Need: Pharmacological Therapies

8. When interviewing a patient complaining of moderate chest pain, what question(s) should be asked? (*Select all that apply.*)

1. Who witnessed the pain?
2. What does the pain or discomfort feel like?

3. What relaxation strategies were implemented?
4. Where is the pain located?
5. To where does the pain radiate?

NCLEX Client Need: Physiological Adaptation

9. A nurse assesses an 83-year-old patient and finds a diastolic murmur on auscultation of the heart. The priority action for the nurse should be to:

1. stop the examination and call the provider.
2. document the finding in the chart.
3. inquire if other members of the family have a murmur.
4. realize that such a murmur is normal in this age group.

NCLEX Client Need: Physiological Adaptation

10. A patient is receiving a drug that may cause postural hypotension. For safety, the nurse should instruct the patient to do what? (*Select all that apply.*)

1. Increase fluid intake to prevent dehydration.
2. Arise slowly from a lying to a sitting position.
3. Sit on the side of the bed until not light-headed before standing.
4. Stand holding on to the bed rail to stabilize before walking.
5. Always ask for assistance when up and moving around.

NCLEX Client Need: Pharmacological Therapies

Critical Thinking Questions

Scenario A

Debra Johnson, a 20-year-old African American college student on your campus, comes to the health center complaining of frequent headaches. The assessment data show that she is 5'4" tall, weighs 170 lb (77 kg), temp 98.8° F (37° C), P 82, RR 14, and BP 154/90 mm Hg. She smokes about half a pack of cigarettes per day. She has a heavy academic schedule and rarely exercises. She eats a lot of "food on the run" at the local fast-food places. Her mother and uncle both have hypertension.

1. Which of her data is abnormal for her age?

2. What risk factors does she have for cardiovascular disease?

3. Which risk factors are modifiable?

Scenario B

Akio Sukura, a 64-year-old man, comes into the emergency department after experiencing chest pain and diaphoresis. His ECG is abnormal. He is scheduled for a cardiac catheterization.

1. Is a consent required for this procedure? If so, would he be able to sign it?
2. What questions would you need to ask him when preparing him for this diagnostic test?
3. What would be the priorities of care related to this diagnostic test after the procedure is finished?

Scenario C

Jackson Smith, a construction worker, comes into the clinic. The provider suspects that he has peripheral vascular disease.

1. What are the risk factors for this type of cardiovascular disease?
2. What diagnostic tests might be ordered for him?
3. Why would it be important to assess for signs of diabetes mellitus as well?

CHAPTER 18

Care of Patients With Hypertension and Peripheral Vascular Disease

Objectives

Theory

1. Explain the pathophysiology of hypertension.
2. Identify the complications that can occur as a consequence of hypertension.
3. Briefly describe the treatment program for mild, moderate, and severe hypertension.
4. Contrast the pathophysiology of arteriosclerosis with that of atherosclerosis.
5. List four factors that contribute to peripheral vascular disease.
6. Explain the signs, symptoms, and treatment of aneurysm.
7. Prepare a teaching plan for a patient with Raynaud syndrome.
8. Discuss the etiology and care for thrombophlebitis and deep vein thrombosis.
9. Summarize how venous insufficiency may lead to a venous stasis ulcer.
10. Compare venous stasis ulcer with arterial leg ulcer.
11. List types of surgery performed for problems of the peripheral vascular system.

Clinical Practice

12. Develop and implement a teaching plan for a patient who has hypertension.
13. Choose the points to be included in the teaching plan for a patient who has experienced thrombophlebitis.
14. Institute a teaching plan for a patient undergoing anticoagulant therapy.
15. Differentiate between venous and arterial insufficiency during a physical assessment.
16. Prepare a nursing care plan for a patient with arterial insufficiency.
17. Identify three likely problem statements for patients who have vascular disease and list the expected outcomes and appropriate nursing interventions for each.

KEY TERMS

bruit (brū-Ē, p. 411)

cellulitis (sēl-ū-LĒ-tēs, p. 406)

embolus (ĒM-bō-lüs, p. 405)

gangrene (găng-GRĒN, p. 412)
hypertension (hī-pĕr-TĒN-shūn, p. 396)
intermittent claudication (ĭn-tĕr-MĬT-ĕnt klăw-dĭ-KĀ-shūn, p. 406)
rubor (RŪ-bōr, p. 406)
scleropathy (sklér-ÖP-ā-thē, p. 419)
stent (stĕnt, p. 408)
thrombophlebitis (thrōm-bō-flĕ-BĪ-tīs, p. 406)
thrombus (THRÖM-būs, p. 408)
varicose veins (VÄR-ĕ-kōs VÄNZ, p. 418)

Hypertension

Hypertension is defined as persistently high blood pressure. This means a systolic pressure that is equal to or greater than 140 mm Hg and a diastolic pressure that is equal to or greater than 90 mm Hg when taken at least twice and averaged on two different occasions 2 weeks apart. The diastolic pressure is the main focus of treatment. It reflects the amount of pressure being exerted against the vessel walls while the heart is in its phase of relaxation and there is no added pressure from blood being forced out of the left ventricle and into the arteries. [Table 18-1](#) presents ranges for the classification of hypertension.

Table 18-1
Blood Pressure Classification

CLASSIFICATION	SYSTOLIC	DIASTOLIC	PATIENT ACTION
Normal	Less than 120	Less than 80	Monitor if risk factors are present.
Prehypertension	120-139	or 80-89	Modify diet, increase exercise, lose weight, stop smoking.
High			
Stage 1	140-159	or 90-99	Antihypertensives and diuretics may be prescribed.
Stage 2	160 or higher	or 100 or higher	Additional antihypertensive drug(s) may be prescribed. Continue lifestyle modifications.

Hypertensive individuals usually die of long-term damage to the end organs or target organs, that is, from damage to the brain, heart, and kidneys. More than half of the deaths associated with persistent and unrelieved hypertension are caused by myocardial infarction. Immediate causes of death related to high blood pressure include cerebral hemorrhage and heart failure.

Older Adult Care Points

Can you think of two physiologic reasons why older adults are at greater risk for hypertension?

Etiology

The etiology of hypertension is unknown, but it is believed to be related to alterations in the immune system ([Madhur, 2014](#)). Although the exact cause has not been identified, there are several known contributing factors. Secretion of excess sodium-retaining hormones and vasoconstriction substances, high sodium intake, obesity, diabetes mellitus, excessive alcohol intake, and sympathetic nervous system activity all contribute to elevated blood pressure.

There are two major types of hypertension: primary (idiopathic or essential) and secondary hypertension. Persons with a family history of hypertension are at risk for developing primary hypertension. Approximately 90% to 95% of all cases of hypertension are primary.

In 5% to 8% of patients, the hypertension is secondary to another disorder. Acute stress, excessive alcohol intake, sickle cell disease, arteriosclerosis, coarctation of the aorta, eclampsia of pregnancy, renal disorders, endocrine disorders, and neurologic disorders are examples of secondary causes. Amphetamine use, chronic nonsteroidal anti-inflammatory drug (NSAID) use, and tyramine-containing foods such as beer and wine taken with monoamine oxidase inhibitors (MAOIs) contribute to secondary hypertension. Female hormone therapy and nicotine use appear to be contributing factors in some people. If the underlying disorder can be detected and treated successfully, the problem of secondary hypertension is eliminated or more easily controlled. If no underlying disease can be identified as elevating the patient's blood pressure, the patient is considered to have primary hypertension.

[Table 18-2](#) presents the nonmodifiable and modifiable risk factors for hypertension. In many cases a loss of excess weight alone can return a slightly elevated blood pressure to normal. A moderate reduction of salt intake has been effective in lowering the blood pressure of some patients with mild or moderate hypertension. There is continuing research on the relation of race, gender, and ethnicity on the incidence and effects of hypertension.

Cultural Considerations

Hypertension and African Americans

African Americans tend to have a higher incidence of hypertension than do other minority groups and whites; African Americans also have higher noncompliance, complication, and mortality rates. Economic issues, access to health care, dietary practices, weight, and diabetes have been identified as possible reasons for the disparities ([American Heart Association, 2011](#)).

Table 18-2
Nonmodifiable and Modifiable Risk Factors for Primary Hypertension

Nonmodifiable Risk Factors	
Age	Systolic blood pressure (SBP) rises with age. After age 50 years, SBP >140 mm Hg is a cardiovascular risk factor.
Gender	Until age 55 years, hypertension is more prevalent in men; after age 55 years, it is more prevalent in women.
Ethnicity/race	Incidence is much higher in African Americans.
Family history	A close relative with hypertension increases a person's risk for developing it.
Modifiable Risk Factors	
Alcohol	Excessive alcohol intake is strongly associated with hypertension. Daily intake should be limited to 1 oz for those with hypertension.
Cigarette smoking, smokeless tobacco	Nicotine contributes to arteriosclerosis and thereby to hypertension. People with hypertension who smoke are at greater risk for cardiovascular disease.
Diabetes	Diabetes accelerates atherosclerosis and leads to damage of the large vessels. Hypertension is twice as prevalent in diabetics as nondiabetics.
Obesity	Central body obesity in particular is associated with the development of hypertension. When combined with other factors in metabolic syndrome, the risk of hypertension is increased even more.
Stress	Stress increases peripheral vascular resistance and stimulates sympathetic nervous system activity. If stress responses become excessive, they can contribute to the development of hypertension.
Elevated serum lipids	Elevated cholesterol and triglycerides are risk factors for atherosclerosis. Atherosclerosis contributes to hypertension in many individuals.
Excess dietary sodium	High sodium intake contributes to hypertension in some patients.
Decreased kidney function	Hypertension is more prevalent with an estimated glomerular filtration rate (GFR) less than 60 mL/min.

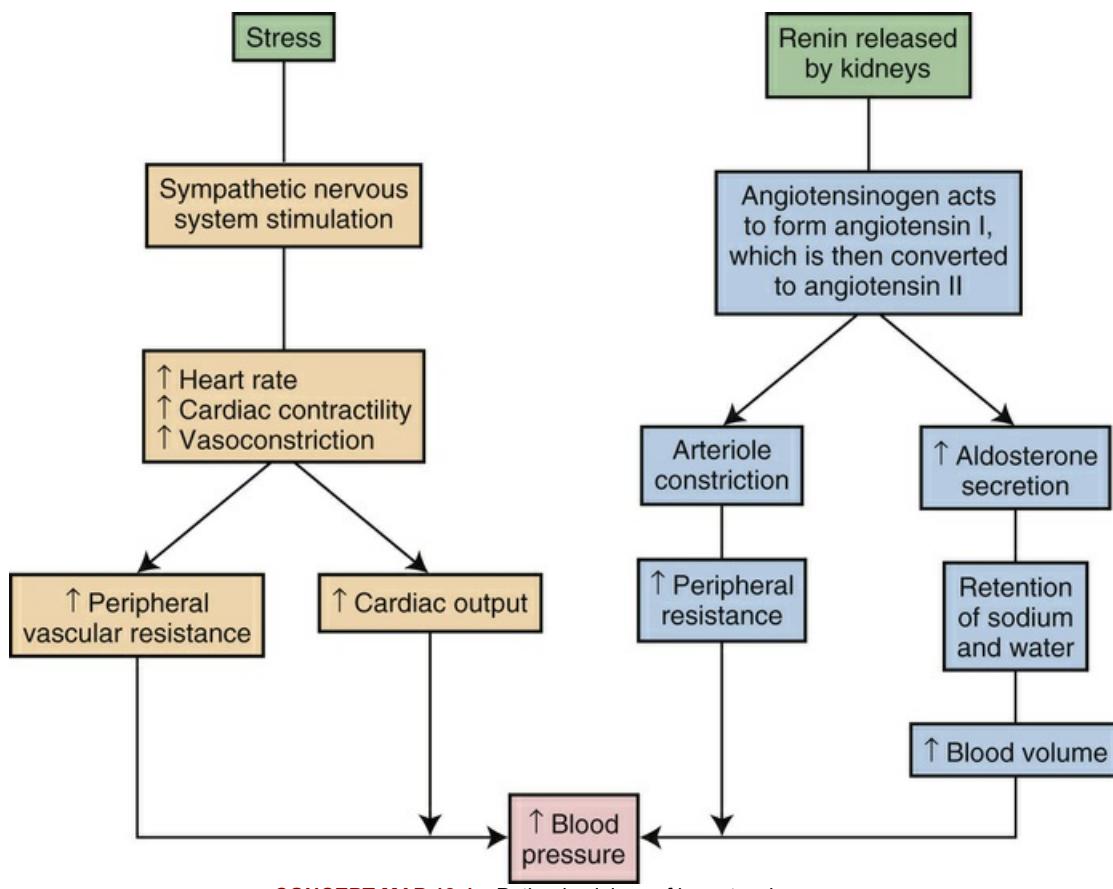

The rising incidence of childhood obesity has resulted in an increase in the incidence of hypertension. Health promotion activities targeting nutrition and exercise habits of children are increasing.

Pathophysiology

Blood pressure equals the amount of blood pumped out of the heart (cardiac output) multiplied by the systemic vascular resistance. If the diameter of blood vessels becomes smaller because of atherosclerosis or vasoconstriction, blood pressure increases with the effort to force the blood through the smaller opening. If there is an increase in the volume (amount) or viscosity (thickness or consistency) of fluid in the blood vessels, the pressure within the vessels increases and the heart must work harder to pump the fluid through the vessels. A pathologic response to stress can result in an elevation in blood pressure by stimulating the sympathetic nervous system and causing peripheral vasoconstriction and increased heart rate. Insulin, glucose, and lipoprotein abnormalities related to metabolic syndrome are common in primary hypertension. In some instances of hypertension, an excess of renin is secreted by the kidneys. Renin acts on a substance called *angiotensinogen*, converting it to angiotensin I. Angiotensin I is converted to angiotensin II by angiotensin-converting enzyme (ACE). Angiotensin II acts directly on the blood vessels, causing them to constrict, and stimulates the adrenal gland to release aldosterone. Angiotensin thereby increases resistance to blood flow in the peripheral vessels and causes retention of sodium and water by the renal tubules through the influence of aldosterone (see [Figure 17-6](#)). The retained sodium and water increase the blood volume, causing increased cardiac output and elevation of blood pressure. [Concept Map 18-1](#) shows the pathophysiology of hypertension.

Older Adult Care Points

The stiffening of arteries occurring with arteriosclerosis is a natural part of aging. The baroreceptors that normally help adjust blood pressure become less sensitive with age. The lack of elasticity of the vessels and the decreased sensitivity of the baroreceptors cause older adults to be at risk for orthostatic (postural) hypotension when changing position. An elevation of systolic pressure above normal should still be treated in this age group.

Signs, Symptoms, and Diagnosis

Hypertension has been called the “silent killer,” because in early stages it does not usually cause discomfort or any other subjective signs and symptoms to indicate its presence. About one third of those who have hypertension are not aware of it. Signs may appear only in the later stages when damage has been done to the target organs—that is, the kidney (renal ischemia and nephrosclerosis), brain (arteriosclerosis and microaneurysm), aorta (aortic aneurysm), eyes (retinal damage), and heart (left ventricular hypertrophy and reduced cardiac output). **Patients with symptoms may complain of headache, dizziness, blurred vision, blackouts, irritability, angina, dyspnea, or fatigue.**

Hypertensive patients develop coronary heart disease at a rate two to three times greater than that of persons with normal blood pressure. Examination of the blood vessels of the retina will reveal any damage to the retinal vessels. This retinal assessment gives an indication about how much damage the high blood pressure has done to vessels throughout the body. If retinal damage has occurred, it is an indication that the person's hypertension is moderate to severe.

Diagnosis is based on blood pressure readings on at least two occasions 2 weeks apart. An electrocardiogram (ECG), echocardiogram, and cardiac stress test may be ordered to determine whether any damage has been done to the heart muscle.

Treatment

The goals of treatment are (1) reduction of high blood pressure and (2) long-term control to decrease the risk of stroke, heart attack, loss of vision, and kidney disease. The target is to control blood pressure at or below 120/80 mm Hg. Treatment is individualized, using a stepped-care approach. For mild hypertension, smoking cessation, weight reduction, sodium restriction, alcohol restriction, exercise, a low-fat diet, and stress control are instituted. Sodium should be kept to less than 2400 mg/day with the DASH (Dietary Approaches to Stop Hypertension) eating plan. Alcohol intake should not exceed one serving of liquor, wine, or beer per day for women or two servings

per day for men. Aerobic exercise of 30 to 45 minutes most days of the week is recommended. If blood pressure is still high, a diuretic is added. If the blood pressure does not fall within normal limits, the second step is initiated, and an antihypertensive drug is prescribed.

Other drugs are added, if needed, to keep the blood pressure consistently within normal limits. Patients with more severe hypertension often require more than two drugs to attain control. The third step is to add additional drugs. The dose of each drug is increased as needed to achieve the desired blood pressure level unless side effects occur. In the event of side effects, another drug is substituted. Newer blood pressure medications are very expensive, and cost is a concern for many patients. Some drug companies have programs to help patients who cannot afford their medications. If a potassium-wasting diuretic is prescribed, the patient is taught to increase dietary potassium intake. A potassium supplement is added to treatment, and electrolyte levels are monitored regularly.

Patients should monitor their blood pressure at home and keep records of the readings. Periodic visits to the provider's office for regular examinations are necessary. The better the blood pressure is controlled and kept within normal limits, the less damage there will be to the target organs.

Safety Alert

Licorice that is found in herbal teas as well as black licorice candy, if consumed in large amounts, can increase blood pressure. If non-potassium-sparing diuretics are taken together with licorice, dangerously low potassium levels may result ([National Center for Complementary and Alternative Medicine, 2012](#)).

Antihypertensive Therapy

The drugs prescribed to reduce blood pressure work by decreasing blood volume, cardiac output, or peripheral resistance. [Table 18-3](#) and [Box 18-1](#) list examples of the drugs most commonly prescribed for hypertension and relevant nursing interventions.

 **Table 18-3**

Drug Classifications Used for Patients With Vascular Disorders

TYPE OF DRUG	ACTION
Diuretics	
Thiazides and Related Drugs	
Hydrochlorothiazide (Esidix, HydroDIURIL, Dyazide) Metolazone (Zaroxolyn) Indapamide (Lozol)	These drugs increase the excretion of water, sodium, potassium, and chloride by blocking the reabsorption of sodium and chloride.
Loop Diuretics	
Bumetanide (Bumex) Furosemide (Lasix) Torsemide (Demadex)	These drugs work in the loop of Henle to block reabsorption of sodium and chloride. This prevents passive reabsorption of water and promotes its excretion. These drugs produce the greatest amount of diuresis.
Potassium-Sparing Diuretics	
Amiloride hydrochloride (Midamar) Spironolactone (Aldactone) Triamterene (Dyrenium)	These drugs block the action of aldosterone in the distal nephron. This prevents the promotion of sodium uptake in exchange for potassium secretion usually caused by aldosterone, and potassium is "spared" (not secreted) and sodium is excreted. These drugs cause very little diuresis.
Antihypertensives	
Adrenergic Inhibitors	
Beta Blockers	
Atenolol (Tenormin) Propranolol (Inderal) Metoprolol (Lopressor, Toprol XL) Timolol (Apo-Timol) Bisoprolol (Zebeta) Carvedilol (Coreg)	It is not certain how these drugs work to reduce blood pressure. Blockade of the beta ₁ receptors lowers cardiac output by decreasing heart rate and contractility. Action on the beta ₁ receptors in the kidney decreases the release of renin, which is a factor in rising blood pressure.
Alpha Blockers	
Doxazosin (Cardura) Prazosin (Minipress) Terazosin (Hytrin)	These drugs block alpha ₁ stimulation on arterioles and veins, preventing sympathetic vasoconstriction. This action results in vasodilation, reducing peripheral vascular resistance and venous return to the heart.
Alpha-Beta Blocker	
Labetalol (Normodyne, Trandate)	This drug blocks both alpha ₁ and beta ₁ receptors, producing decreased heart rate, contractility, peripheral vascular resistance, and venous return.
Angiotensin-Converting Enzyme (ACE) Inhibitors	
Benazepril (Lotensin) Captopril (Capoten) Enalapril (Vasotec) Fosinopril (Monopril) Lisinopril (Prinivil) Quinapril (Accupril)	These agents lower blood pressure by inhibiting the conversion of angiotensin I into angiotensin II, thereby preventing vasoconstriction. They also restrict volume expansion mediated by aldosterone.
Angiotensin II Receptor Blockers	
Candesartan (Atacand) Eprosartan (Teveten) Irbesartan (Avapro) Losartan (Cozaar) Olmesartan (Benicar) Telmisartan (Micardis) Valsartan (Diovan)	These agents lower blood pressure by blocking the action of angiotensin II, thereby preventing vasoconstriction.

Calcium Channel Blockers	
Amlodipine besylate (Norvasc, Lotrel) Diltiazem (Cardizem) Nicardipine (Cardene) Nifedipine (Procardia) Verapamil (Calan, Isoptin)	These drugs reduce blood pressure by causing dilation of arterioles. Calcium channels are blocked, preventing the influx of calcium that promotes constriction.
Central-Acting Agents	
Clonidine (Catapres) Guanabenz (Wytensin) Methyldopa (Aldomet)	These agents act within the brainstem to suppress sympathetic impulses to the heart and blood vessels. This action decreases the release of norepinephrine by sympathetic nerves, reducing activation of peripheral adrenergic receptors, and promotes vasodilation. The agents also decrease heart rate and cardiac output.
Peripherally Acting Adrenergic Blockers	
Guanethidine (Ismelin) Reserpine (Serpaline)	These agents reduce blood pressure by blocking adrenergic receptors in the postganglionic sympathetic neurons and causing decreased sympathetic stimulation of the heart and blood vessels.
Direct-Acting Vasodilators	
Hydralazine (Apresoline) Minoxidil (Loniten)	These agents reduce blood pressure by promoting arteriole vasodilation.
Direct Renin Inhibitors	
A lisinopril (Tekturna)	This new class of drugs inhibits renin secretion from the kidney, reducing angiotensin I and angiotensin II, inhibiting vasoconstriction.

Box 18-1

General Nursing Interventions for the Administration of Diuretics and Antihypertensive Drugs

Diuretics

- Follow the “Six Rights” and “six rules” of medication administration to prevent errors and injury to the patient: **right** patient, **right** drug, **right** dose, **right** route, **right** time, **right** documentation; instruct the patient, take a drug history, assess for drug allergies, check for possible interactions, document after administration, and assess effectiveness.
- Check for sulfa allergy. Thiazide and thiazide-like diuretics are related to sulfonamides. Patients allergic to sulfas may have adverse reactions.
- Monitor intake and output to determine amount of diuresis and the drug's effectiveness.
- Track the patient's weight daily to determine the drug's effectiveness; evaluate for decreased edema.
- Check all drugs the patient is receiving for drug interactions with the diuretic drug to prevent toxicity or lack of absorption. Several diuretics are ototoxic, and this adverse effect may be potentiated by other ototoxic drugs.
- If possible, administer diuretic dose in the morning; if a second dose is required, give it mid-afternoon to avoid sleep interference by need to urinate.
- Provide assistance with urination in a timely manner (answer call bell quickly).
- Assess for signs of dehydration and hypotension; take blood pressure on a set schedule. Older adults are prone to excessive diuresis and can quickly become dehydrated.
- Monitor diabetic patients for increased blood glucose levels when taking loop or thiazide diuretics, because these drugs may cause hyperglycemia.

Regarding possible side effects or adverse effects of the drug, the nurse should:

- Monitor potassium levels frequently if the patient is taking a potassium-wasting diuretic; assess for signs of hypokalemia: weakness, tremor, muscle cramps, change in mental status, cardiac dysrhythmia.
- If the patient also is taking digoxin, consult the provider before administering the dose if the potassium level is below 3.5 mEq/L or if the patient exhibits signs of hypokalemia, because hypokalemia increases risk of fatal cardiac dysrhythmia in patients taking digoxin.
- If a patient is taking a potassium-sparing diuretic and potassium level is above 5 mEq/L, or if signs of hyperkalemia develop (abnormal cardiac rhythm), consult the provider before administering the dose.

- Monitor blood pressure. If blood pressure drops considerably, speak with the provider before giving another dose of the drug.
- Monitor the patient for signs of constipation, which is a possible side effect of diuresis.
- Monitor patients with a history of deep venous thrombosis (DVT) for recurrence, because diuretics reduce circulating fluid volume.
- Monitor and educate the patient for side effects or adverse effects of the particular drug taken. The most common general side effects are constipation, electrolyte disturbance, gastric upset, and hypotension. Adverse effects are dehydration, ototoxicity, hyperglycemia, and hyperuricemia.
- Monitor the patient for signs of allergic reaction, such as rash or itching.

Teach patients taking a diuretic to:

- Expect a frequent need to urinate, and an increased volume of urine.
- Report any new heartbeat irregularity.
- Report any signs of ringing of the ears, roaring sounds, a feeling of fullness in the ears, or decreased hearing.
- Eat foods high in potassium, such as bananas, orange juice, cereals, meats, tomatoes, potatoes, and raisins, daily, unless taking a potassium-sparing diuretic.
- If taking a potassium-sparing diuretic, restrict foods high in potassium.
- Take potassium supplement regularly if one is prescribed.
- Increase fiber in the diet if prone to constipation; consult provider if constipation occurs. Older adult patients who are inactive are more prone to constipation.
- Watch for signs of postural hypotension, such as dizziness or light-headedness, when changing position. Encourage patients to arise slowly from a supine position and to sit a minute before standing. (Older adults are particularly prone to this side effect.)
- Avoid the sun or take precautions; do not use a sunlamp when taking a loop or thiazide diuretic, because the medication may cause photosensitivity.
- Watch for signs of gout (tenderness or swelling of joints) when taking a loop or thiazide diuretic and notify the provider if these occur. Loop diuretics may cause an increase in uric acid levels.
- When taking spironolactone, menstrual irregularities or impotence may occur; report these occurrences to the provider.

Antihypertensive Drugs

- Establish that the patient is not hypotensive before giving a dose of an antihypertensive drug. If the patient's blood pressure is below normal levels, consult the provider before giving the dose.
- Monitor the heart rate for bradycardia or tachycardia. Follow specific parameters for administration of the specific drug; some drugs may cause bradycardia, and others may cause tachycardia.
- Follow the "Six Rights" and " six rules" of medication administration, and check the patient's identification by two methods before **each** dose.
- Inquire about any dizziness. If dizziness has been occurring, measure blood pressure standing and sitting to determine whether the patient is experiencing orthostatic hypotension; several antihypertensives may cause orthostatic hypotension.

- Note contraindications and precautions for each specific drug the patient is taking. Angiotensin-converting enzyme (ACE) inhibitors are contraindicated during pregnancy.
- Check all drugs the patient is receiving for drug interactions to prevent toxicity or increased severity of side effects. Many antihypertensive drugs have a depressant effect on the heart.
- Monitor blood pressure readings to evaluate effectiveness of the drug.

Regarding possible side effects or adverse effects of the drug, the nurse should:

- Monitor the patient for the side effects of each drug administered.
- Monitor serum glucose levels in patients with diabetes who are taking a beta-blocker drug, because the drug may mask hypoglycemia.
- Monitor lipid levels for changes in patients taking beta blockers, because these drugs interfere with lipid metabolism.
- Observe for hypersensitivity reactions such as rash; ACE inhibitors may cause hypersensitivity.
- Monitor patients for signs of congestive heart failure, such as edema; beta blockers, calcium channel blockers, and other drugs that decrease cardiac output may precipitate heart failure in patients with borderline cardiac function.
- Check the skin of patients using a clonidine patch for signs of irritation, a potential side effect of the patch. Be certain the old patch is removed when applying a new one.
- Give the first dose of an ACE inhibitor at bedtime, because it often causes hypotension.
- Monitor the potassium level of patients taking an ACE inhibitor. Because it suppresses the release of aldosterone, it increases potassium retention.
- Monitor liver function tests for patients taking centrally acting drugs, such as clonidine, because these drugs may cause liver damage in some patients.
- Monitor renal function tests in patients taking hydralazine, because this drug may cause renal impairment.

Teach the patient taking an antihypertensive to:

- Monitor blood pressure regularly and record the readings.
- Alter lifestyle factors that contribute to hypertension, such as smoking, excess weight, excessive stress, excessive alcohol ingestion, high-salt diet, and lack of exercise.
- Rise slowly from a lying position and stabilize before standing for a couple of minutes.
- Report alteration in sexual response, because some of the antihypertensive drugs may cause impotence.
- Report persistent side effects and any adverse effects of the drug.
- Monitor for weight gain from retention of sodium and water by weighing at least twice a week; report weight gain of more than 2 lb to the provider.
- Report signs of ankle edema, because several of the antihypertensive drugs can precipitate congestive heart failure.
- Be aware that methyldopa may cause dark urine for the first few weeks of therapy.
- Avoid abruptly discontinuing centrally acting antihypertensives, such as clonidine, because

rebound hypertension may occur.

- Check with the provider before taking over-the-counter drugs, because many are contraindicated in hypertension.
- Comply with medication therapy even when blood pressure is normal, because long-term compliance is the key to preventing the organ damage that hypertension can cause.
- Set own goals for lifestyle changes and medication therapy; a patient-directed program has a better chance of success.
- Notify the provider if a persistent dry cough develops after starting on an ACE inhibitor medication.

The blood pressure of older adult patients who are taking antihypertensive medications should be measured when they are sitting and when standing. Many of these medications can cause orthostatic hypotension; measuring blood pressure with the patient standing will reveal whether the medication is reducing the blood pressure too much. Assess patients receiving antihypertensives for dizziness, confusion, syncope, restlessness, and drowsiness, which may indicate hypotension.

Patient Teaching

Safety Measures to Prevent Falls for Patients With Orthostatic Hypotension

Teach patients who experience the side effect of orthostatic hypotension from medication to:

- Rise slowly from a lying to a sitting position; do not hold the breath while arising. Sit for 1 minute before standing; stand slowly holding on to a stable object. Stand for 1 minute before walking.
- While seated, flex and rotate the feet several times before attempting to stand; have feet firmly planted on the floor before standing.
- When walking, do not turn the head or body abruptly.
- When feeling unsteady while standing, call for assistance before walking.
- Report light-headedness or sudden dizziness.
- Use the bathroom before meals and try to avoid getting up for 30 to 60 minutes after meals.

Complications

Malignant hypertension is an older term for a hypertensive crisis that describes rapid onset of severe hypertension that causes symptoms. The term is no longer used except for billing and coding purposes.

Hypertensive Crisis

Hypertensive emergency is a life-threatening situation in which the blood pressure rises higher than 180/120 mm Hg and there is indication of target organ damage. Symptoms may include severe headache, blurred vision, seizures, nausea, and change in level of consciousness. It may occur if a patient has stopped taking antihypertensive medication, or it may be secondary to another disease process such as renal stenosis. The patient is placed in the intensive care unit and treated with intravenous (IV) emergency drugs, such as IV sodium nitroprusside (Nipride), nicardipine (Cardene IV), nitroglycerin, or labetalol (Normodyne), to lower the blood pressure. A reduction in blood pressure to 160/100 mm Hg is desired over the first 2 hours. Blood pressure is monitored every 5 to 15 minutes. Medication is adjusted to reduce the pressure slowly to prevent renal, cerebral, or coronary ischemia. **Hypertensive urgency** occurs when the blood pressure rises to

180/110 mm Hg but there are no signs or symptoms of target organ damage. This is a more common occurrence. The patient is observed in the emergency department and treated with oral medication. The patient is directed to follow up with the primary care provider.

Nursing Management

■ Assessment (Data Collection)

The patient should be assessed for indications of modifiable and nonmodifiable risk factors for cardiovascular disease. Physical assessment of the cardiac system should be performed. Assessment of blood pressure and documentation of levels and potential influences on values is an important aspect of nursing care. The patient's blood pressure should be taken lying supine, sitting, and standing for a thorough assessment. Standing blood pressure measurements also are important when a patient is started on a new medication, particularly an ACE inhibitor, because orthostatic hypotension may occur.

■ Older Adult Care Points

The blood pressure of older adult patients can be affected by other coexisting diseases. As people live longer, more chronic illnesses develop. Blood pressure management must take into consideration all medical conditions.

■ Nursing Diagnosis and Planning

Common problem statements for a patient with hypertension include:

- Potential for injury due to complications of hypertension.
- Insufficient knowledge (disease process, medications) due to new diagnosis of hypertension.
- Altered nutrition due to obesity, high-fat diet, or high sodium intake.
- Anxiety due to potential complications of disease process. Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

Expected outcomes for a patient with hypertension may include:

- The patient will not experience retinopathy.
- The patient's blood pressure will return to normal limits.
- The patient will verbalize an understanding of teaching related to medications and disease process.
- The patient will lose 10% of body weight in a designated period.
- The patient will be able to choose low-fat and low-sodium items from a variety of menus.

■ Implementation

Nursing interventions consist of assisting the patient to make necessary lifestyle changes that will help control the blood pressure and slow further atherosclerosis. Diet changes are often the most difficult for the patient. It is best to work with the patient's current dietary likes and dislikes, modifying methods of food preparation to decrease sodium and fat content.

Sources of hidden sodium should be identified, and the patient should be taught how to read food labels. A dietitian referral or providing contact information to community groups that encourage healthful eating and promote exercise may be helpful.

■ Nutrition Considerations

Decreasing Sodium in the Diet

Instruct a patient who must reduce sodium in the diet to:

- Avoid "convenience" foods: ready-mixed sauces, frozen dinners, cured or smoked meats (including lunch meats), canned soups, and prepared salad dressings, unless the label truly indicates low sodium content.

- Be aware that regular canned vegetables often contain a large amount of sodium; in some instances rinsing will greatly decrease the sodium content. Use fresh or frozen vegetables or those canned without sodium when possible.
- Check soft drink labels for sodium content; avoid those that contain more than 140 mg of sodium.
- Check cereal box labels for sodium content; switch to a lower-sodium cereal, such as shredded wheat.
- Use one fourth to one half the amount of salt that a recipe calls for.
- Avoid adding salt to food after cooking.
- Make a salt-substitute seasoning of $\frac{1}{2}$ tsp garlic powder mixed with 1 tsp each of basil, black pepper, marjoram, onion powder, parsley, sage, savory, and thyme; or use a product such as Mrs. Dash or lemon pepper instead of salt.
- Fast-food and other restaurants are required to supply nutrition information, including sodium content. Make wise choices.
- Do not eat preserved or commercially prepared smoked meats, such as bacon, hot dogs, salami, pastrami, ham, smoked turkey, or sausage.
- Read all labels on food containers, looking for the words *salt* and *sodium*, and the letters *NaCl*.
- Check condiments for amount of sodium. Catsup, soy sauce, steak sauce, and others are high in sodium.

Cultural Considerations

Cultural Diet Variations

Working with patients from diverse cultures who have very different diets can be a challenge. Encouraging fat and sodium restriction in a cultural diet requires working with the patient to discover food preferences and food preparation patterns inherent in the family.

Patients who need to increase potassium intake are taught to include citrus fruits and juices, bananas, dried beans, tomatoes, and potatoes in their diet. The person who does the shopping and food preparation must be included in the diet instruction process. **Weight loss is the most important lifestyle change for obese patients.** The goal is a weight that is within 15% of ideal body weight.

If caffeine restriction is recommended, teach the patient to gradually decrease his caffeine consumption so that he will not experience withdrawal symptoms, such as headache and nervousness. Remind the patient that many types of soft drinks, as well as coffee, tea, and chocolate, contain caffeine. Most of these beverages are available in decaffeinated formulas. Because it produces vasoconstriction, nicotine has a major effect on blood vessels and blood pressure. Stopping smoking or use of smokeless tobacco products can be a difficult task for many patients. Core Measures call for counseling and an information packet on smoking cessation to be given to the patient. An exercise program that fits the patient's personality, ability, and preference should be designed. Walking to work from a parking lot a few blocks away, climbing stairs instead of using elevators, and a daily walk in the neighborhood often are sufficient. Other patients might prefer to use a stationary bicycle or treadmill. The object is to work on something that the patient will continue to do for the rest of his life.

Weight loss will begin to occur if the patient is faithful to the prescribed diet and exercise program. As his weight decreases, remind the patient of the direct effect these efforts have had on the blood pressure. Even a moderate weight loss of 7 to 12 lb (3 to 5 kg) can reduce blood pressure. Positive reinforcement should be given for even small amounts of weight loss.

Stress reduction requires an evaluation of lifestyle. Meditation, yoga, leisure activities, or just

saying no to extra obligations can all decrease stress. Help the patient determine where his stressors are and what can practically be done to manage them. Lifetime compliance with diet, exercise, stress reduction, and medication plans is difficult for most patients. Alternative therapy may help.

Complementary and Alternative Therapies

Grapeseed Extract for Hypertension

Grapeseed extract is an alternative medicine treatment for hypertension that also helps decrease cholesterol.

Many patients do not understand or accept that it is up to them to control their disease. They do well for several months or a few years, but then, because they feel well (while their blood pressure has been controlled), they stop taking their medication and gradually return to previous lifestyle patterns. By teaching them what high blood pressure does to the blood vessels and the heart, brain, eyes, and kidneys, you can do much to encourage patients to follow the treatment plan for life. Instruct patients on how to monitor their blood pressure at home to engage them in their care and track effectiveness of treatment. Each patient needs continuing encouragement for maintaining blood pressure control.

Patient Teaching

Complications of Uncontrolled Hypertension

The following information should be included in the teaching plan of a patient at risk for noncompliance with treatment of hypertension:

- Hypertension can cause damage to arteries, making them less elastic. This places an increased workload on the heart. This may cause MI, left ventricular hypertrophy, aortic aneurysm, and congestive heart failure.
- Small vessel damage to the brain disrupts circulation and may lead to dementia, transient ischemic attacks (TIAs) and ischemic stroke.
- Hypertension may cause an already weakened area in a blood vessel to rupture. This may cause an intracranial bleed known as a *hemorrhagic stroke*.
- Hypertension may cause damage to the small vessels of the kidney and may lead to kidney failure.
- Hypertension damages the arteries of the eye, causing the formation of clots or occurrence of hemorrhage that may lead to blurred vision or blindness.

There are many resources to help hypertensive patients manage their illness more effectively. The American Heart Association, Heart Center Online, the National Institutes of Health, and many others offer educational materials for patients with hypertension. *Healthy People 2020* goals and objectives have been written for hypertension. [\(e\)](#)

Health Promotion

Assessment for and Management of Hypertension

Blood pressure should be assessed every time there is contact with a health care provider. All adults should have their blood pressure assessed at least once a year, even if it has always been within normal limits. A patient with hypertension requires intense teaching to assist in achieving health management goals. Blood pressure should be monitored regularly at home with an

automatic blood pressure cuff that can be purchased at any pharmacy or most department stores. Ensure that the patient understands the needed lifestyle changes and how to accomplish behavior modification. The patient may be referred to a local support group as a resource in the management of his health.

■ Evaluation

Consistent maintenance of blood pressure within prescribed limits is a primary indicator of effectiveness of disease management. Evaluate the patient's knowledge of prescribed medications, including use, side effects, and administration. Knowledge of dietary management, exercise activities, stress management, and smoking cessation should be discussed at follow-up sessions. The patient's compliance with the management of hypertension is critical to preventing or minimizing complications of the disease process.

Arteriosclerosis and Atherosclerosis

Arteriosclerosis (hardening of the arteries) is a general term for a variety of arterial changes. Arteriosclerosis occurs with aging as degenerative changes occur in the small arteries and arterioles. The disorder is characterized by thickening of the artery walls that progresses to hardening as calcium deposits form. Vessel elasticity is lost. The thickening and calcification reduce the diameter of the vessels and cause slowing of blood flow. This may lead to ischemia and necrosis in various tissues. *Atherosclerosis* is another form of artery narrowing. Lipids are deposited within the vessel walls and combine with cells, fibrin, and cell debris to form plaques. The plaque grows and extends into the lumen of the artery, where inflammation or erosion causes the plaque to be exposed to the blood. This triggers clotting and subsequent blocking of the vessel by a clot (see [Figure 20-1](#)).

Atheromatous plaque with thrombi form primarily in the larger arteries, the carotid and coronary arteries. Diabetes mellitus, particularly when uncontrolled, speeds the development of arteriosclerosis and atherosclerosis. Hypertension is a major factor in arteriosclerosis. Any artery in the body can develop atherosclerosis. When vessels delivering blood to the extremities, heart, and brain narrow because of plaque formation, serious consequences can result.

Peripheral Vascular Disease

Peripheral vascular disease (PWD) involves narrowing or obstruction of peripheral blood vessels and loss of function. These vessels may be in the arms, neck, abdomen, or lower extremities (Figure 18-1). Peripheral blood vessels include all blood vessels except those in the heart and brain. Diabetes, particularly when uncontrolled, contributes to vascular disease.

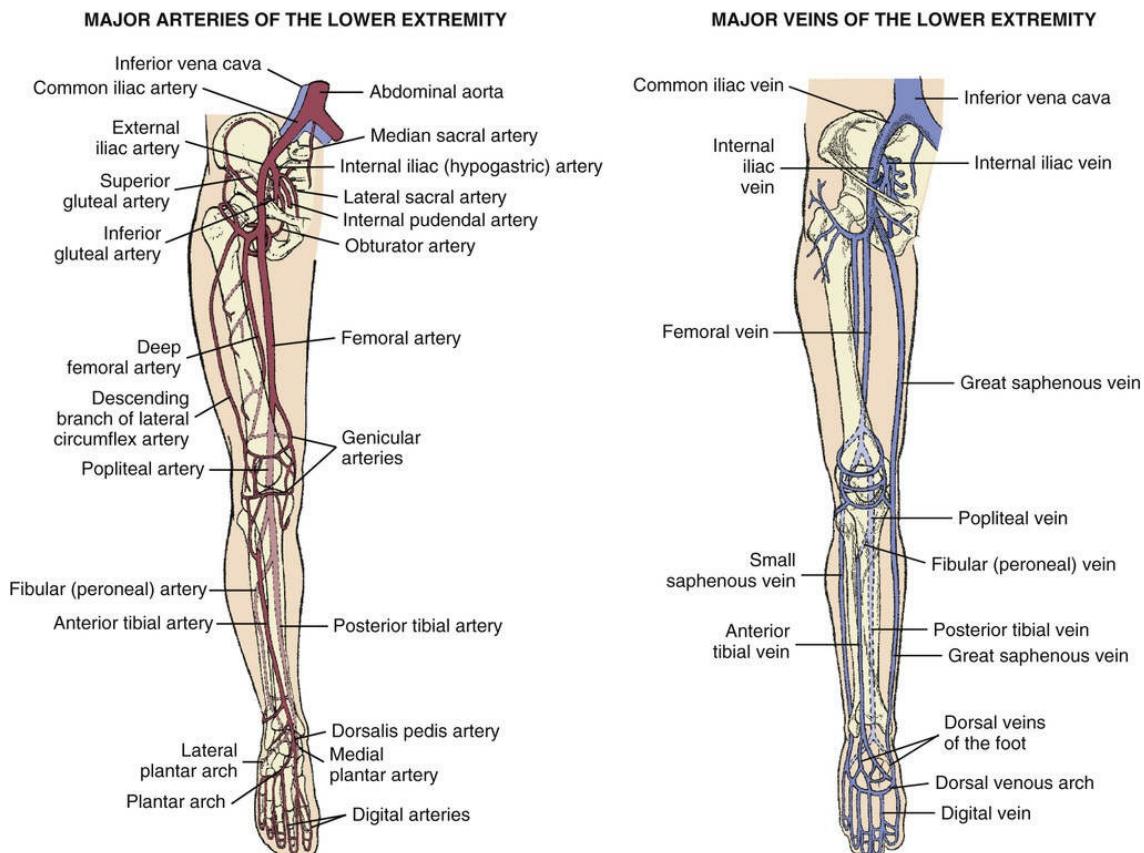

FIGURE 18-1 The peripheral vascular system: veins and arteries of the lower extremities. (From Mosby's dictionary of medicine, nursing, and health professions, ed. 8, St. Louis, 2009, Mosby.)

Other causes of peripheral vascular problems include spasm of the smooth muscles in the arterial walls (e.g., Raynaud disease), structural defects in the arteries (aneurysms), trauma, or **embolus** (blood clot or debris that travels and lodges in a blood vessel) that causes occlusion. Peripheral venous problems are caused by defective valvular function and formation of **venous thrombosis** (blood clots), which may be accompanied by **thrombophlebitis** (inflammation of a vein).

Prevention of PVD is focused on decreasing atherosclerosis and arteriosclerosis, controlling diabetes mellitus, controlling hypertension, and preventing smoking. Smoking cessation is important because nicotine causes vasoconstriction, resulting in elevation of blood pressure and decreased blood flow through the vessels.

Peripheral Arterial Disease (Arterial Insufficiency)

Etiology and Pathophysiology

The most common etiology of peripheral arterial disease (PAD) is atherosclerosis. The vessel walls become narrowed or the lumen obstructed, leading to loss of blood flow to the extremity. Restriction of arterial blood flow may cause arterial ulcers. Cessation of blood flow in the arteries leads to ischemia and tissue death (necrosis). PAD may be acute or chronic. Embolism is the most common cause of acute interruption of arterial blood flow. PAD may occur in any peripheral artery

and frequently occurs in the carotid arteries.

Signs, Symptoms, and Diagnosis

Obtain a complete history and physical examination of the patient. Table 18-4 compares the signs and symptoms of arterial and venous disorders to help identify which part of the vascular system is affected. Signs and symptoms of PAD of the lower extremities include **intermittent claudication** (pain when walking that diminishes at rest), pain at rest, tightening pressure in calves or buttocks, and ischemic changes. Blood pressure in the extremity affected by PAD is lower.

Table 18-4
Differences in Signs and Symptoms of Arterial and Venous Disease

CHARACTERISTIC	ARTERIAL DISEASE	VENOUS DISEASE
Pulses	Diminished, weak, or absent	Strong and symmetrical; may be difficult to palpate if edema is present
Skin	Pallor, dependent rubor; thin, dry, shiny, cool	Mottling with brown pigmentation at ankles; veins may be visible; legs or feet bluish when dependent; dermatitis; warm at ankle
Edema	Absent or mild	Present, particularly around ankle and in foot
Ulceration	On toes or at pressure points on feet	At bones of ankle
Necrosis and gangrene	Likely	Unlikely
Pain	Intermittent claudication when walking; sharp, stabbing, gnawing; lessens when at rest	Aching, cramping, particularly when dependent; may have nocturnal cramps
Nails	Thick, brittle (normal in older adults)	Normal
Hair	Hair loss distal to area of occlusion (hair loss normal in older adults)	Normal

Patients with PAD have pallor in the affected extremity when the leg is elevated and **ruber** (dark redness) when the leg is dependent. The skin may appear tight and shiny. Hair is usually absent on the affected extremity and the toenails are thickened. Pulses are diminished or absent. There also is a temperature change distal to the occlusion. Wounds on the lower leg are difficult to heal. The severity of these symptoms depends on the extent of the lesion, degree of occlusion, and amount of collateral circulation that has been established.

If severe ischemia occurs from occlusion of arterial blood flow, tissue distal to the occlusion blanches, becomes cold, hurts, and eventually becomes numb as necrosis occurs. Ischemic areas of the lower leg and foot may develop skin breakdown without injury. **Arterial ulcers** with a sharp edge and a pale base may form that are quite painful. These ulcers are very slow and difficult to heal (Figure 18-2). This is particularly true for diabetic patients. The affected part may develop **cellulitis** and edema and become gangrenous, necessitating amputation (Figures 18-3 and 18-4). The toes and foot are most often affected.

FIGURE 18-2 Patient with peripheral arterial disease who has arterial ulcers of the lateral malleolus and distal and lateral portion of the leg. Note the round, smooth shape. (From Black JM, Hawks JH: *Medical-surgical nursing: Clinical management for positive outcomes*, ed. 8, Philadelphia, 2009, Saunders.)

FIGURE 18-3 Patient with cellulitis of the legs. (From *Mosby's dictionary of medicine, nursing, and health professions*, ed. 8, St. Louis, 2009, Mosby.)

FIGURE 18-4 Patient with gangrene of the toes. (Courtesy Cameron Bangs, M.D.)

An arterial thrombosis can occur as a vessel is narrowed by atherosclerosis. Atherosclerotic plaque ruptures, platelets aggregate at the roughened area, and a clot forms. If the clot breaks loose and travels, it becomes an arterial embolus and may cause acute occlusion of an artery. **Signs and symptoms of embolus occlusion of an extremity artery are the five Ps: pain, pulselessness, pallor, paresthesia, and paralysis.** Acute arterial occlusion may be treated with percutaneous intravascular procedures. The artery is accessed and the clot can be removed by special catheters, balloon angioplasty may be performed to open the lumen of the vessel, and stents may be placed to keep the vessel open. Many procedures that previously required surgery can now be done in a procedure room with fluoroscopy and the patient given procedural sedation rather than general anesthesia. Thrombolytic therapy may be given directly into the clot within the artery if it cannot be removed successfully.

Older Adult Care Points

Hair loss is a natural occurrence with aging, as is thickening of fingernails and toenails. These signs alone are not reliable indicators of vascular problems on the extremities in older adults.

Diagnosis of PAD is made using the ankle-brachial index (ABI) (see [Figure 17-9](#)). The normal value is 1 (i.e., the systolic pressure is the same at the ankle and brachial artery sites). Radiographic and ultrasound procedures also may be performed.

Treatment

The best treatment for arterial occlusive disease is regular exercise. A regular walking program results in substantial improvement. Patients are instructed to walk until the claudication pain starts and then rest until the pain goes away. This cycle is repeated until patients are able to walk 45 to 60 minutes daily. Smoking cessation is also a key factor in improvement of peripheral arterial occlusive disease (Rowe, 2014). Some dietary supplements have proven helpful in increasing circulation.

Complementary and Alternative Therapies

L-Carnitine

Several research studies have shown that L-carnitine, a natural substance found in muscle, heart, brain, and nerve cells, may be beneficial in improving the exercise capacity of individuals with peripheral artery disease. L-Carnitine, especially in the form of propionylcarnitine, improves muscle recovery after exercise. L-Carnitine can be found in many foods, with higher concentrations in red meat and dairy products. It is supplied as a dietary supplement in 50- to 500-mg tablets. Recommended dosage for individuals with PAD is 600 to 1200 mg three times per day or 750 mg twice daily. Side effects are few; however, these dosages in the upper range may cause diarrhea, hyperactivity, and insomnia.

Areas of ulceration are kept clean and free from pressure. Bed rest may be initially prescribed but walking has been shown to help circulation. Dry eschar is left in place. Debridement is performed only by a qualified health professional. Moist interactive dressings are used on the clean and granulating ulcer to promote healing. The goal of treatment of PAD is directed toward increasing blood flow through the peripheral arteries and decreasing the risk of clot formation in the vessels. Antiplatelet agents and platelet inhibitors may be used alone or in combination with other drugs. Aspirin is the most commonly used antiplatelet agent. It prevents the aggregation of platelets in the arteries. Platelet inhibitors, such as clopidogrel (Plavix), may be prescribed. Patients experiencing intermittent claudication may achieve relief of symptoms when prescribed pentoxifylline (Trental) or cilostazol (Pletal). These drugs increase blood flow by inhibiting clot formation in the vessel. Patients experiencing acute ischemia may receive thrombolytic therapy. Alteplase (t-PA, Activase) and tenecteplase (TNKase) are the drugs of choice for thrombolysis. Cholesterol-lowering drugs (e.g., atorvastatin [Lipitor], simvastatin [Zocor], ezetimibe [Zetia]) have been shown to be effective by decreasing low-density lipoprotein (LDL) and increasing high-density lipoprotein (HDL) levels, thus reducing plaque deposits in the arteries.

Clinical Cues

Medications to treat PAD or thrombosis may cause serious adverse reactions. The major adverse reaction is bleeding. Observe the patient for and report immediately evidence of excessive bruising or bleeding, prolonged clotting after a needle stick, hematuria, changes in vital signs, or changes in neurologic signs.

Percutaneous transluminal angioplasty (PTA) may be performed to open an artery to reduce claudication symptoms and improve extremity perfusion. A catheter is introduced into the artery, and when the proper spot is reached, a balloon is inflated multiple times to dilate the vessel, promoting better blood flow. A metal or mesh **stent** (tubular device to give support to a vessel interior) may be placed to prevent narrowing or closure of the artery (see [Figure 20-4](#) for a similar stent illustration). If the plaque has a significant calcium component, it may be difficult to dilate the vessel. Atherectomy with a Rotablator may be used to improve blood flow to a limb. It can scrape hardened plaque from the arterial wall.

Surgical treatment of PAD is a palliative measure only. It does not cure the disease or halt the atherosclerotic process. It can, however, relieve ischemic pain, help prevent amputation, and add years to a patient's life. The purpose of vascular surgery is to revascularize and nourish cells in the affected area.

An aortoiliac bypass or a femoropopliteal bypass is performed to correct arterial occlusion of the

leg to prevent the need for amputation. A synthetic graft is placed to divert blood around the obstructed area. [Figure 18-5](#) shows a schematic of a femoropopliteal bypass graft surgery. Postoperative care is the same as for other operative procedures but includes careful assessment of pulses distal to the graft to detect **thrombus** (clot) formation. As with any vascular surgery, extra attention is paid to assessment for signs of bleeding. An aortoiliac bypass requires both an abdominal and a groin incision. Blood pressure management is extremely important to maintain blood flow in the graft. Hypotension will cause slowing of the blood flow and potential thrombosis formation, whereas hypertension puts significant stress on the graft sutures, risking bleeding. Because of the condition of the patient's cardiovascular system, the very patients who need the grafting are the poorest surgical candidates. Percutaneous interventions are used more frequently for this patient population. A hyperbaric oxygen chamber is sometimes used for patients with severely compromised circulation to a lower extremity to increase tissue oxygen and prevent amputation.

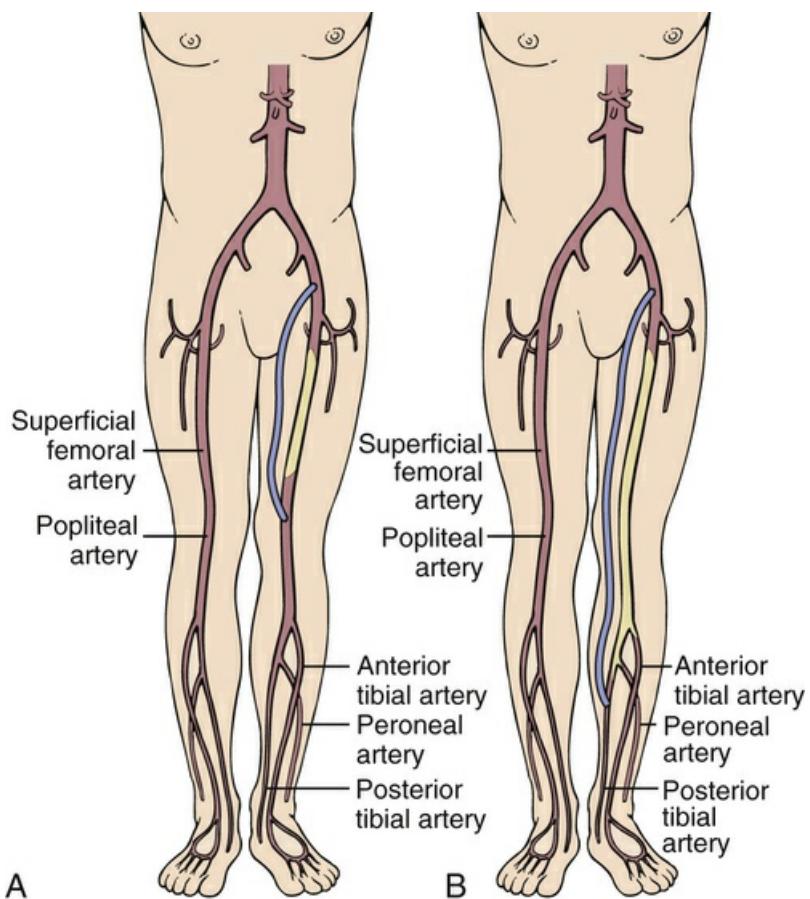

FIGURE 18-5 Femoropopliteal bypass graft. **A**, Femoropopliteal bypass graft around an occluded superficial femoral artery. **B**, Femoropopliteal bypass graft around occluded superficial femoropopliteal and proximal tibial arteries. ❖Nursing Management

■ Assessment (Data Collection)

Perform a physical assessment of the patient's affected extremity at least every 4 hours or per facility protocol. Feet should be assessed for warmth, paresthesia, pain, and pulses. All findings must be documented, including any changes. If ulcers are present, assessment and documentation of skin integrity should be included. A major role of the nurse is early detection and prevention of complications. Acute changes in assessment of patients with arterial insufficiency are unlikely; however, maintain a record of the patient's condition in the event of complications.

■ Nursing Diagnosis and Planning

The major nursing care goals for patients with PAD are (1) maintaining arterial blood flow to the lower extremities; (2) protecting tissues from further injury from pressure and constriction of blood flow; and (3) preventing wound infection.

Problem statements for a patient with PAD may include:

- Altered peripheral tissue perfusion due to narrowed vessels.
- Altered skin integrity due to ulcers on lower extremities.
- Potential for injury due to loss of peripheral circulation.
- Acute pain due to ischemia to lower extremities. Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

Expected outcomes may include:

- The patient will not experience loss of skin integrity.
- Peripheral pulses will remain palpable.
- The patient will report reduction in pain level in the lower extremities.

Rehabilitation of the patient requires instruction and guidance in special exercises to increase collateral circulation to the legs. See [Table 17-4](#) for other common problem statements and interventions appropriate for patients with peripheral arterial occlusive disease.

■ Implementation

Encourage blood flow by keeping the patient and the environment warm. Constricting clothing is to be avoided, and the bed should not be raised at the knees to prevent added pressure on the back of the knees and further occlusion of blood flow. Encourage the patient to change position frequently while awake. The lower extremities should be positioned below heart level to facilitate arterial blood flow. The legs are elevated only if edema is impeding circulation. See Evolve for a nursing care plan for a patient [with PAD](#).

▣ Clinical Cues

Assess the affected extremity; document and report significant changes in pain level, pulses, sensation, and skin temperature. Additional medical intervention may be needed to prevent complications that could result in amputation of all or part of an extremity.

Encouraging exercise is especially beneficial to patients with decreased blood flow. Walking regularly every day is best for the ambulatory patient. Swimming also is good because it applies light pressure to the surface of the legs and requires muscle action that encourages venous return. Patients on bed rest should be encouraged to do foot and leg exercises at least once each hour.

▣ Think Critically

Rhonda, a 63-year-old executive, is experiencing worsening intermittent claudication. Describe how you would interact with her to develop an exercise program that could lessen her symptoms.

Patients should dress in warm, nonrestrictive clothing and should avoid becoming cold. Blankets may be added for additional warmth. The room temperature should be maintained at the patient's comfort level.

▣ Older Adult Care Points

Older adults are less tolerant of cold temperatures because of decreased subcutaneous fat tissue as a result of the aging process. Room temperatures must be maintained at the patient's comfort level. Chilling can result in vasoconstriction and contribute to discomfort for patients with vascular disorders.

Tobacco use, especially smoking, contributes to PVD because of the vasoconstrictive effect of nicotine. There are other chemicals in cigarettes that directly damage blood vessels, accelerating the

development of atherosclerosis. If appropriate, patients should be referred to a smoking cessation program. Information concerning the effects of alcohol on vascular disorders, surgical interventions, patient teaching, and interventions to prevent leg ulcers can be reviewed in [Chapter 17](#).

Think Critically

Can you describe the specific actions you would take to help a patient recognize the need to establish a smoking cessation program?

Evaluation

Evaluation of the effectiveness of the plan of care involves assessing changes in peripheral pulses and skin integrity. Improvement or extension of vascular ulcers should be documented in writing and photographed periodically (e.g., weekly). Note changes in color, sensation, and temperature of the lower extremities. The patient's perception of pain level should be documented using a scale of 0 to 10. Evaluate the patient's level of compliance with establishing an exercise routine. Include type, frequency, and tolerance of exercise activities. Evaluate the patient's ability to meet established goals and revise the plan as needed.

Aneurysm

Etiology

Aneurysms—outpouching of the wall of an artery resulting from a structural defect in the layers of the arterial wall—occur in a weakened area of a blood vessel. Aneurysms usually are the result of plaque formation, genetic predisposition, or hypertension. Aneurysms may also occur in areas weakened by trauma or surgical procedures. Aortic aneurysms can occur in the area below the diaphragm (abdominal aneurysm) or on the ascending aorta in the chest (thoracic aneurysm). An abdominal aortic aneurysm is usually located below the kidneys. Long-term hypertension and smoking are risk factors, particularly in men.

Congenital malformations, diabetes mellitus, and hyperlipidemia predispose to various types of aneurysm. However, atherosclerosis and hypertension are believed to be the major factors in their development. Atherosclerotic plaque weakens the vessel wall, and hypertension puts extra pressure on the weakened walls. Cerebral aneurysm is covered in [Chapter 23](#).

Pathophysiology

An aneurysm can occur along any artery. Blood flow may become stagnant along the wall of the aneurysm, and clots can form. The clots can cause occlusion by thrombosis; alternatively, a clot may break away from the thrombosis to become an embolus that travels and lodges elsewhere. Once an aneurysm develops, it continues to grow larger. Aneurysms may eventually rupture if not repaired. **Aortic dissection** of the medial layer of the arterial wall can occur, causing bleeding between layers of the wall and increasing pressure on surrounding structures. As the dissection extends, blood flow through the arterial branches of the aorta become blocked. Blood flow slows to the organs those branches feed. Dissection occurs more frequently than aneurysm, particularly in men who are hypertensive.

Signs, Symptoms, and Diagnosis

Aneurysms often cause no obvious symptoms. Patients with an abdominal aortic aneurysm (AAA) may report back pain or a feeling of pressure and may have a visible pulsation of the abdomen. An aortic aneurysm in the thoracic area may cause substernal or tracheal pressure and difficulty with breathing. Diagnosis of aneurysms is difficult because of lack of symptoms during formation.

Physical examination and screening of patients with a family history may be the best means of early detection. The presence of an aneurysm can be verified by chest or abdominal radiograph, ultrasound, magnetic resonance imaging (MRI), or computed tomography (CT) scans. Men who have hypertension and a smoking history should undergo ultrasound screening for AAA. Many times abdominal or thoracic aneurysms are discovered when the patient has a scan or x-ray for some other reason.

Aortic dissection or rupture causes abrupt, excruciating pain. The pain radiates to the back, chest, abdomen, or extremities. Peripheral pulses are diminished. The patient may be in hypotensive shock because of blood loss. About 65% of patients with a ruptured AAA die before reaching the hospital (O'Conner, 2013). Emergent surgery to stop the hemorrhage and repair the aneurysm is indicated for patients who present to the emergency department.

Treatment

If an aortic aneurysm is detected early, it usually can be surgically repaired before it dissects or ruptures. The size and location of the aneurysm guides the need for surgical intervention. Thoracic and abdominal aneurysms do not warrant surgical intervention until the risk of rupture is higher than the risk of the surgery. The patient is evaluated every few months with ultrasound tracking of the size of the aneurysm. Surgery may be performed when AAAs are approximately 6 to 8 cm in diameter and thoracic aneurysms 5.5 to 6.5 cm. Patients may be prescribed antihypertensive drugs, such as beta blockers, to reduce the pressure on the arterial walls. If symptoms occur, surgical intervention may be necessary to prevent rupture of the aneurysm.

Surgery for aortic aneurysm involves replacing the area of the vessel wall that is weakened with a graft (open abdomen or chest surgery) or inserting a stent graft into the vessel (percutaneous intravascular insertion). The open surgery requires access to the aorta, where the aneurysm is opened and graft material placed, then the vessel is closed around the graft material. The use of a stent graft is a minimally invasive procedure and is used for patients who are not good candidates for open surgical repair of the aneurysm. A wire mesh stent covered with fabric is percutaneously placed in the area of the aneurysm. Small incisions in the groin are used to access the femoral artery. The stent grafts are positioned in the abdominal aorta and usually down the right and left femoral arteries. The graft provides support to the vessel wall and allows blood to flow through the stent, thus reducing pressure on the vessel wall. The aneurysm is then monitored frequently.

❖Nursing Management

■ Assessment (Data Collection)

Careful physical assessment is needed to detect the presence of an aneurysm. Immediately report findings of pulsations in the abdomen or other structures in which this is abnormal. Information concerning family history of aneurysm should be gathered during the patient history interview. Assessment of pain patterns—especially changes in intensity and location—is needed to identify progression of the patient's condition, which may be life-threatening.

■ Nursing Diagnosis and Planning

The main goal for a patient with an aneurysm is the prevention of rupture. Rupture of an aneurysm is a medical emergency and causes rapid hypovolemic shock, which can lead to death. Advise the patient to report any change in symptoms, such as pain intensity, apprehension, light-headedness, or any unusual sensation. Problem statements for a patient with an aneurysm may include:

- Potential for injury from possible rupture or dissection of aneurysm.
- Acute pain due to pressure of aneurysm on body structures and nerves.
- Insufficient knowledge due to management of medical condition.

Other problems will depend on the location of the aneurysm and whether there is leaking. Expected outcomes might be:

- The patient will not experience rupture or dissection of the aneurysm.
- The patient will report absence of pain.
- The patient will verbalize understanding of management of medical condition.

■ Implementation

Presurgical patient education is important. The patient must be taught signs and symptoms that should be reported to the health care provider immediately. Teaching concerning the medical and surgical treatment regimen should be included along with what to expect postoperatively.

?

Think Critically

You detect a pulsation in a patient's abdomen during physical examination. He states that it has been present for several years and the health care provider is "watching it." List signs and symptoms that could indicate a need for surgical intervention.

The surgical procedure and nursing care depend on the location of the aneurysm and the procedure performed. If aortic aneurysm is treated by thoracotomy or abdominal surgery, the care is similar to that of other types of thoracic and abdominal surgery. The main difference is that you must also carefully assess pulses and function distal to the repair site. Renal function must be watched closely, because blood flow to the kidneys is briefly cut off when the aorta is clamped for surgical repair.

Clinical Cues

Attentive postsurgical care is very important. Monitor urinary output at least every 30 minutes in the immediate postoperative period, then every 2 hours. The urinary output should be at least 30 mL/hr. Report falling urinary output immediately.

The patient may spend 24 to 48 hours in an intensive care unit postoperatively. Assist the patient to deep breathe and use an incentive spirometer every 1 to 2 hours if not intubated. Coughing is not encouraged, but should it occur the incision should be splinted with a pillow or folded bath blanket. Paralytic ileus may occur for a few days after abdominal surgery, and a nasogastric tube may be in place. Auscultate the abdomen every shift for the return of bowel sounds. Adequate pain medication is needed.

A patient undergoing thoracic aortic aneurysm repair will have chest surgery that uses a cardiopulmonary bypass machine. The care is the same as for other chest surgery patients. Chest tubes will be in place. These patients are especially at risk for atelectasis and pneumonia. Pain management is necessary to promote adequate respiratory effort. Cardiac dysrhythmias may be a problem, depending on the location of the repair.

A patient having an endovascular repair may be placed on a telemetry or medical-surgical unit. Observation for bleeding from the procedure site is the priority assessment.

■ Evaluation

Objective data—including vital signs, neurologic status, distal pulses, and respiratory status—should be assessed. Subjective data—including pain level and loss of sensation—should also be determined. Evaluation of the patient's understanding of teaching related to the disease process, potential complications, follow-up appointments, medications, and recommended lifestyle changes should be assessed and appropriate revisions made to the nursing care plan.

Carotid Artery Disease

When atherosclerosis has narrowed the carotid arteries leading to the brain, the signs and symptoms include carotid **bruit** (a purring sound heard with a stethoscope), confusion, transient vision loss, fainting, extremity weakness or paralysis, or other strokelike signs of decreased blood flow to the brain. The condition is treated by carotid endarterectomy or carotid artery angioplasty with stenting. Surgery is performed when the artery is 70% occluded (Singh, 2014). The goal of both procedures is to prevent the occurrence of stroke (see Chapter 23).

Specific postoperative care for endarterectomy includes assessing for signs of bleeding, for pressure from hematoma on the trachea (evidenced by increasing hoarseness), and for neurologic problems caused by thrombosis or embolus. Neurologic signs are monitored every 2 to 4 hours.

Clinical Cues

There is risk for cerebrovascular accident (stroke) after carotid endarterectomy. Assess the patient for signs of disorientation, hoarseness, impaired speech, impaired swallowing, hemiparesis, facial asymmetry, aphasia, and hypertension. These findings should be reported immediately to the surgeon. Because there may be swelling in the neck that may occlude the airway, observe for difficulty breathing.

If surgery is not indicated, the patient is taught to maintain adequate hydration and to comply with drug therapy for hypertension and diabetes, if applicable. Teaching is provided regarding prescribed antiplatelet or anticoagulant drugs. Signs and symptoms of further problems are reviewed, and the patient is advised to call 911 for emergency assistance if sensory or motor deficits appear.

Buerger Disease (Thromboangiitis Obliterans)

Etiology and Pathophysiology

Thromboangiitis obliterans, or Buerger disease, is not caused by atherosclerosis, but involves inflammation and thickening of small and medium-size arteries. Occlusion of the vessels in the hands and feet is usually noted first. The disease occurs more often in men than women and is commonly found in people from the Middle East, the Far East, India, and Southeast Asia. There is increasing incidence of the disease in women older than age 50 years. Moderate to heavy cigarette smoking is directly linked to the progression of the disease. It may be classified as an allergic response in some people in whom the body reacts to properties in nicotine.

Signs, Symptoms, Diagnosis, and Treatment

The signs and symptoms include numbness and tingling of the toes or fingers in cold weather, pain in the feet, and intermittent claudication that progressively becomes more severe. The pain is intense. Ulcerations and **gangrene** (death of tissue) may occur. Diagnosis is made through patient history and symptoms. **Cessation of smoking is the single most important treatment factor.** Cigarette smoking must be stopped immediately. Those who do not stop smoking are at great risk for gangrene and amputation of fingers or toes. Exercise may be used to increase circulation in the legs and feet.

❖Nursing Management

■ Assessment (Data Collection), Nursing Diagnosis, Planning, and Evaluation

The most important role of the nurse is patient teaching and reinforcement of the need for smoking cessation. Assessment of the extremities for skin impairment is essential. Nursing care and teaching is the same as for PAD.

Raynaud Disease and Raynaud Phenomenon

Etiology and Pathophysiology

The etiology of Raynaud disease is unknown. Raynaud disease is characterized by spasm of the arteries of the upper and lower extremities. The body has an exaggerated response to cold and stress, resulting in bilateral vasospasm. The disease occurs most commonly in young women. It mostly affects the fingers and toes. Raynaud disease can be a primary disorder or may occur secondary to another disease such as lupus erythematosus, rheumatoid arthritis, or scleroderma. In the latter instance it is known as Raynaud phenomenon and often occurs on only one side of the body.

Blood vessels normally constrict in cold environments; however, with Raynaud disease, this process is excessive. The affected body part changes color. When the spasm stops, there typically is burning pain and throbbing. In about 10% of those affected, the disease progresses to the point at which ischemia from arterial spasm is so severe that gangrene occurs and amputation is necessary.

Signs and Symptoms

Signs and symptoms of Raynaud disease include:

- Fingers and toes may display a series of color changes from white to blue to red; these changes are evident on the dorsal surface of the hands and feet ([Figure 18-6](#)).

FIGURE 18-6 Raynaud disease. (From Kamal A, Brockelhurst JC: *Color atlas of geriatric medicine*, ed. 2, St. Louis, 1991, Mosby.)

- The patient may experience numbness or a prickly sensation on warming and relief of stress.
- There may be decreased sensory perception.
- Edema may be present.
- Discomfort may occur in the extremity.

Diagnosis and Treatment

Diagnosis of Raynaud disease is usually made by evaluation of patient symptoms. The provider may order laboratory studies such as antinuclear antibody (ANA) test to determine the presence of autoimmune disorders. Medical therapy consists of stress control, avoidance of exposure to cold, and smoking cessation. Calcium channel blockers may be used to dilate capillaries in the hands and feet. The synthetic prostaglandin iloprost (Ventavis) dilates arterial beds throughout the body and extremities. Other drugs such as alpha blockers and vasodilators may be used to achieve vasodilation in the small blood vessels in the hands.

Nursing Management

The major nursing intervention for Raynaud disease is teaching the patient to protect extremities and prevent injury. The patient should be taught to dress warmly when in cold environments. Clothing should be layered and nonrestrictive. Hat, gloves, and warm socks should be worn. The patient should be taught to wear protective gloves when reaching into ovens and when handling extremely cold items. Teach the patient to avoid cold temperatures when possible, to manage stress, and to stop tobacco use. Caffeine intake should be limited. If appropriate, the patient should be referred to a smoking cessation program.

Health Promotion

Smoking Cessation

Encourage smokers with vascular disorders to seek smoking cessation programs in their communities. The American Lung Association's program "Freedom from Smoking" is offered free of charge online at the American Lung Association website (see Online Resources). Discuss other programs such as nicotine replacement therapy. Group programs are offered in many communities, hospitals, American Lung Association affiliates, and community-based health programs. A variety of products are available to decrease and prevent nicotine cravings during the cessation process. Assessment of progress with smoking cessation should occur at each visit with a health care provider.

Evaluate the progression of symptoms, including changes in skin color and sensation. Any changes in skin integrity should be noted. The patient's compliance with recommended lifestyle changes should be evaluated and the plan revised as needed to assist the patient to meet established goals.

Venous Disorders

Venous Thrombosis and Phlebitis

Superficial or deep veins can become inflamed, resulting in thrombosis. Superficial thrombophlebitis that occurs in a patient receiving IV therapy may be caused by chemical or mechanical irritation of the vessel. If not identified and treated, bacteremia may occur, resulting in *septic thrombophlebitis*. Decreasing hospital-acquired bloodstream infections is a Patient Safety Goal. Deep vein thrombosis (DVT) occurs most commonly in the iliac and femoral veins. DVT occurs in about 5% of all surgical patients. Because DVT can lead to embolization from the thrombus to the lungs. DVT prophylaxis is recommended for all hospitalized patients and is included in The Joint Commission's Patient Safety Goals.

Etiology and Pathophysiology

Three factors (Virchow's triad) that increase risk for venous thrombosis are (1) venous stasis, (2) damage of the inner lining of the vein (endothelium), and (3) hypercoagulability of the blood. Venous stasis occurs when the vein valves are damaged or when muscles of the extremities are inactive. People who are immobile for a long time are very susceptible to DVT. Prolonged surgeries, spinal cord damage and paralysis, and chronic heart failure all contribute to venous stasis. Immobility with the legs dependent in car or airplane travel for long periods also promote venous stasis. Trauma or external pressure or internal pressure from hypertension may damage the endothelium. Inflammation of the vessel leads to aggregation of blood components at the site of the inflammation. A clot forms at the inflammation site, leading to obstruction of blood flow. If not treated, the clot may become an embolus that may travel from the legs to the lungs, resulting in pulmonary embolus.

Smoking, female hormone replacement, estrogen-based contraceptives, corticosteroids, and various blood disorders are contributing factors to blood hypercoagulability. Obesity and dehydration also contribute to increased coagulability.

Older Adult Care Points

Older adult patients who have problems with mobility or stress incontinence tend to drink less fluid so that they do not have to visit the bathroom as often. This can lead to dehydration and more viscous blood, which in turn can predispose to thrombus formation in those susceptible to this disorder. Encourage adequate fluid intake to promote circulation, and provide a means for convenient toileting for these patients. The occurrence of DVT or thrombophlebitis increases with advanced age.

Patients particularly at risk for DVT are those having orthopedic surgery; those who smoke; and those who have diabetes, lung disease, blood disorders, PVD, sepsis, or cancer. If DVT is not resolved, the interaction of the clot with the vessel wall results in destruction of venous valves and development of venous insufficiency. **Embolism** may develop when a portion of a DVT in a leg breaks loose and travels to the lungs. The embolus lodges in small vessels, especially those in the pulmonary system. Blood flow is interrupted, and loss of oxygenation to the lung may occur. The condition can be life-threatening (see Chapter 14). When a pulmonary embolus is suspected, place the patient in a high Fowler position, provide oxygen and reassurance, notify the provider, and stay with the patient. Medication for pain and anxiety may be ordered; tests to determine whether a pulmonary embolus has occurred will be ordered.

Superficial Thrombophlebitis

Continuous IV therapy and contaminated IV drug needles are common causes of superficial thrombophlebitis. Phlebitis also occurs in patients with diseases associated with vasculitis. It can also occur spontaneously in the lower extremities or as a complication of a medical intervention.

Signs, Symptoms, and Diagnosis

Signs and symptoms of thrombophlebitis include swelling, redness, warmth, and considerable tenderness and pain on touching. Diagnosis is usually by ultrasound studies and rarely by venography. If venous imaging is needed, CT venography can be performed. Physical examination, patient history, and evaluation of signs and symptoms are important in diagnosing thrombophlebitis.

Treatment and Nursing Management

Treatment for thrombophlebitis includes discontinuing the source of irritation and modifying risk factors; applying warm, moist heat; elevating the extremity; and administering NSAIDs and antibiotics if infection is present. Patients are encouraged to stay off their feet and to elevate their legs. Support stockings are to be worn after the acute phase. If the IV is implicated as a cause, the IV catheter site will be changed to a new location.

Nursing management of a patient with thrombophlebitis includes assessment and documentation of the color, warmth, circumference, and pulses of the affected extremity. Explain the importance of adhering to the prescribed level of physical activity, and explain the potential complications of noncompliance. Make certain that the patient receives medications as prescribed. Warm, moist compresses to the affected extremity may be ordered. Emphasize the importance of this treatment. Develop a discharge teaching plan related to the disease process, medications, activity level, home care, and follow-up. Components of teaching may include:

- Avoidance of sitting for long periods with the legs down
- Avoidance of standing in one place for long periods
- Management with NSAIDs
- Application of compression stockings
- Activity limits
- Preventive measures

Think Critically

What teaching points would you cover for a 52-year-old female hair stylist who is being discharged after hospitalization for thrombophlebitis of the right leg?

Decreased redness, swelling, and pain indicate resolution of the thrombophlebitis. Evaluation of patient success in meeting goals would include compliance with medications and demonstrated evidence of understanding of discharge teaching. Often, subjective data from the patient must be relied on to evaluate whether treatment and nursing actions are effective.

Deep Vein Thrombosis

Signs, Symptoms, and Diagnosis

The main sign of a DVT is edema in one extremity ([Figure 18-7](#)). The area over the thrombosis may feel warm. Never rub or vigorously palpate the area, because this can dislodge the clot and send it into the circulation, which can cause severe damage or death.

FIGURE 18-7 Patient with deep vein thrombosis. (From Kamal A, Brockelhurst JC: *Color atlas of geriatric medicine*, ed. 2, St. Louis, 1991, Mosby.)

The most common method of diagnosing DVT is ultrasonography. Sound waves detect blood flow through the veins and identify areas of abnormality. If sonography is not clear, an MRI may be performed. Activated clotting time (ACT), activated partial thromboplastin time (aPTT), international normalized ratio (INR), hemoglobin (Hgb), hematocrit (Hct), and D-dimer laboratory tests are performed to detect blood dyscrasias or abnormal clotting times. A venogram sometimes is performed, but it requires injection of a dye to identify areas of obstruction, which may further irritate the vessel. Obtain the patient's allergy history before this procedure.

Clinical Cues

Whenever a patient has a known DVT, watch for signs of pulmonary embolus: dyspnea, hemoptysis, tachypnea, tachycardia, chest pain, decrease oxygen saturation, a feeling of impending doom, cyanosis, and possibly coughing and altered mental status. These signs indicate an emergency situation.

Treatment

Inpatient medical treatment for DVT usually consists of IV heparin. Low-molecular-weight heparin (LMWH), such as enoxaparin (Lovenox) by injection, may be used for inpatient management and is increasingly being used for outpatient treatment. Fondaparinux (Arixtra), a factor Xa inhibitor, may be used instead of enoxaparin. After initial IV or subcutaneous injection anticoagulation treatment, oral anticoagulation is started with warfarin sodium (Coumadin), rivaroxaban (Xarelto), edoxaban (Lixiana), dabigatran (Pradaxa), or apixaban (Eliquis). Anticoagulation is continued for 3 to 6 months for the first episode of DVT and a year for recurrent episodes (Patel, 2014). Anticoagulants will not dissolve the clot but may prevent new ones. The body dissolves the clot on its own over time.

Thrombolytic therapy may be used to dissolve the thrombus if vessel obstruction is severe; the agents used are the same as those listed for arterial thrombolysis. There is a high risk of bleeding with these drugs, and a compelling reason must be present for use, because in time the body will dissolve the clot without intervention. Sequential compression devices (SCDs) may be prescribed, or compression stockings may be fitted for daily use. Stockings must fit properly and be kept smooth. The compression forces blood from the superficial veins into the deep veins, decreasing venous stasis. Compression stockings are only removed for bathing and are changed and laundered daily. They must be replaced after 6 months, because the elastic quality decreases. Ambulation as soon as it is not prohibited by pain and swelling is recommended. There is no evidence that ambulation will dislodge a DVT and cause a pulmonary embolus as has been believed for many years (Patel, 2014).

If a patient is considered at risk for further embolus formation from DVT and is not a candidate for anticoagulation, a **vena cava filter** will be inserted. The device is placed in the inferior vena cava

(IVC) below the kidneys to prevent pulmonary emboli. With the use of a special catheter threaded into the vena cava, the device is positioned and deployed. The metal cage device catches the emboli and the body slowly dissolves and disposes of them. IVC filters come in different shapes and configurations but all do the same thing.

Post-thrombotic syndrome (PTS) is a potential complication for 50% of patients with DVT. While the body is dissolving the clot, there is continued inflammation at the site. This causes permanent damage in the vessel, called PTS. Some studies have shown that use of compression stockings relieves symptoms for some patients. A 2014 study reported in *The Lancet* found that use of elastic compression stockings after DVT did not prevent PTS ([Kahn et al, 2014](#)). Current research is focusing on more aggressive DVT treatment to remove the clot so it does not remain in contact with the vessel wall. Thrombolytic therapy delivered directly into the clot, percutaneous thrombectomy, angioplasty, and stenting are all being examined with the goal of preventing PTS.

Heparin-induced thrombocytopenia (HIT) may occur when unfractionated or low molecular weight heparin is used for several days to weeks. It is heralded by a sudden decrease in platelet count. If HIT occurs, heparin administration must be stopped.

❖Nursing Management

■ Assessment (Data Collection)

Assess patients at risk for DVT each shift for signs and symptoms. Assessment should include:

- Observation of the extremity for asymmetrical size
- Areas of warmth and redness over a vein
- Calf pain and/or tenderness
- Pitting edema of the affected extremity
- Measurement of calf circumference
- Body temperature greater than 100.4° F (38° C)

■ Nursing Diagnosis, Planning, and Implementation

Early ambulation postoperatively helps promote circulation and reduces the risk of clot formation. Encouraging patients on bed rest to change position and perform leg and ankle exercises each hour while awake can do much to decrease the incidence of DVT. Venous thrombosis occurs fairly commonly during long plane flights or car trips. Staying well hydrated, exercising the leg and calf muscles frequently during the trip, and walking every 1 to 2 hours help prevent clots from occurring. Wearing support hose while standing aids venous return and helps prevent thrombosis in those who have varicose veins ([Lew, 2013](#)).

Problem statements/nursing diagnoses, expected outcomes, and interventions are presented in [Nursing Care Plan 18-1](#).

✳ Nursing Care Plan 18-1

Care of a Patient With a Deep Vein Thrombosis

Scenario

Mrs. Hanson, age 72, fainted at the airport after returning from a cross-country plane trip of 6 hours. She was unconscious at the scene and woke up when medical personnel arrived. She had a heart rate of 20 when checked by the paramedics, and her heart rate returned to a normal range before she arrived at the hospital. She was admitted to a telemetry floor for observation.

She has now developed pain in her right calf, and her lower leg is swollen, with a hot, tender area in the midcalf region. She has been placed on a continuous heparin drip.

Problem Statement/Nursing Diagnosis

Insufficient tissue perfusion/*Ineffective tissue perfusion due to presence of clot in vein and inflammation.*

Supporting Assessment Data

Subjective: "My leg really hurts." Complains of pain in right calf.

Objective: Reddened, warm, tender area on midcalf. Temperature 101.2° F (38.4° C). Leg circumference increased compared with left leg.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Thrombus will resolve within 2 wk as evidenced by Doppler flow studies.	Encourage ambulation as tolerated; keep right lower leg elevated when in bed.	To prevent formation of further clot.	Up to the bathroom several times during the day. Right leg elevated when in bed.
Thrombosis will begin to resolve by discharge as evidenced by normal temperature and no calf tenderness, redness, or swelling.	Early ambulation. Administer analgesia for aching and tenderness. Warm packs to right leg; handle right leg gently. Auscultate lung sounds every shift; check pulse oximetry; be alert for signs of pulmonary emboli.	Maintain venous circulation. Promotes comfort. Provide comfort, decrease edema. Early detection of pulmonary emboli for immediate intervention.	Walking as much as tolerated. Analgesic administered x 2. States is more comfortable. Leg circumference decreased by 0.5 cm. Lung sounds clear to auscultation. Oxygen saturation 98%-100% on room air.

Problem Statement/Nursing Diagnosis

Potential for injury/*Risk for injury related to heparin drip, thrombus formation, or embolus.*

Supporting Assessment Data

Objective: Heparin drip 50,000 U in 500 mL at 25 mL/hr. Deep venous thrombosis (DVT) in right leg.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will not experience embolus or other DVT during hospitalization.	Maintain heparin drip on IV pump at ordered rate; assess IV site qhr for infiltration. Caution not to rub leg. Encourage increase in fluid intake. Apply compression stockings smoothly, removing only for bathing.	Prevent formation of additional thrombi. Rubbing may dislodge a clot and cause an embolus. Assists in reducing blood viscosity. Assists with venous return and prevents blood pooling.	Heparin drip continuous; IV site without redness or swelling. States understands not to rub the leg. Intake 2000 mL this shift. Compression stockings in place.
Patient will have no hemorrhage from heparin as evidenced by no sign of bleeding internally or externally.	Observe for bleeding of gums, excessive bruising, blood in urine or stool, nosebleeds, and abdominal pain with rigidity. Monitor Hgb and hematocrit to detect blood loss. Monitor ACT or aPTT and advise provider immediately if values rise above $2\frac{1}{2}$ times the control value or above therapeutic range.	Heparin can cause bleeding. May indicate need to change infusion rate or administer protamine sulfate if excessive blood loss occurs. Allows for adjustment of heparin dosage to keep it within therapeutic range.	Slight bleeding of gums. Bruising from previous needle sticks. No evidence of blood in urine or stool; bowel sounds present all four quadrants, abdomen soft. No change in Hgb and hematocrit. aPTT two times control value.
	Hold pressure over any needle stick for 5 min. Begin warfarin (Coumadin) or other drug therapy as ordered 3 days before heparin is stopped. Handle patient very gently.	Heparin extends bleeding time. Anticoagulant therapy will continue when discharged home. Prevents bruising.	No excessive bleeding with laboratory draws. Coumadin administered today. No new bruising.

ACT, Anticoagulant therapy; aPTT, activated partial thromboplastin time; Hgb, hemoglobin; IV, intravenous.

Problem Statement/Nursing Diagnosis

Insufficient knowledge/*Deficient knowledge due to precautions necessary when taking warfarin and about treatment regimen.*

Supporting Assessment Data

Objective: Will take warfarin at home for at least 6 to 12 months. Has never taken this medication.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will verbalize danger signs to report to provider, proper dosage of medications, and dietary considerations before discharge.	Teach the following: Avoid foods high in vitamin K (give list). Avoid over-the-counter medications and drugs that might extend clotting time or interfere with action of warfarin (e.g., aspirin, etc.). Move around carefully, trying not to hit head on anything or bump into things. Observe urine and stool for signs of bleeding.	Vitamin K counteracts the action of warfarin. Some over-the-counter drugs have anticoagulant actions that may increase risk of complications of drug therapy. Injury could cause bruising and hematoma formation. May indicate international normalized ratio (INR) higher than therapeutic range.	Patient identified foods high in vitamin K that are in her routine diet and states "I will be consistent in the amount of these foods in my diet." States understands to check with provider before using over-the-counter medications. Slight bruising noted on buttocks. No signs of bleeding in urine or stool.
Patient will verbalize understanding of need for regular medical follow-up and periodic laboratory clotting times before discharge.	Instruct her to maintain close contact with provider to monitor clotting times. Explain dosage schedule. Give written instruction sheet.	Monitoring of INR important to evaluate effectiveness of warfarin therapy. Provides reference for safe administration of drug.	Verbalizes need to keep appointments for follow-up laboratory studies. Given written instructions to be followed when taking warfarin. Verbalized understanding.
Patient will completely stop smoking within 1 mo.	Give smoking cessation information. Get order for nicotine patch or other assist product. Refer to support group.	Cigarette smoking constricts vessels and contributes to blood coagulability.	Is willing to work with a smoking cessation counselor.
Patient will establish a walking program when acute stage has resolved.	Assist to establish walking schedule. Caution not to sit with legs crossed or to sit for long periods without elevating legs. Caution not to wear constricting clothing.	Walking promotes venous return by calf muscles compressing the veins. Crossing the legs decreases venous return and promotes blood pooling in the extremity. Sitting causes dependent pooling in legs. Tight clothing can decrease venous return and cause pooling in extremities.	Is thinking about a walking schedule. States understands not to sit with legs crossed or for long periods with legs dependent. States she understands not to wear tight clothing items.

Critical Thinking Questions

1. List the signs and symptoms of pulmonary embolism.
2. What assessment data would you expect to find indicating that the treatment of a patient with deep vein thrombosis was successful?

■ Evaluation

Decrease in leg circumference and adequate blood flow to the extremity as evidenced by color, warmth, and lack of edema indicate that interventions for DVT are working. Evaluation of interventions for thrombophlebitis include checking for decreased redness and swelling.

Varicose Veins

Varicose veins are enlarged and tortuous veins that are distorted in shape by accumulations of pooled blood. Veins that develop varicosities have incompetent valves that allow reflux of blood from the deep to the superficial veins. The increased blood flow and resultant pressure on the vein walls cause the vessels to dilate and become tortuous.

Varicosities usually occur in the saphenous veins and perforator veins in the ankle. Congenital or family disposition that leads to loss of vessel wall elasticity is a primary cause. Standing for long periods, obesity, and pregnancy are contributing factors. Trauma, DVT, and inflammation that results in vein valve damage are secondary causes. Individuals who must be on their feet a great deal are encouraged to wear support stockings to promote venous return.

■ Think Critically

Can you identify two lifestyle changes you could personally make that would decrease your risk of a vascular disorder later in life?

■ Older Adult Care Points

Varicose veins develop in older adults as the veins lose their elasticity and the leg muscles weaken and atrophy from decreased exercise.

Signs and symptoms of varicose veins include dilated, twisted-appearing, superficial vessels on the legs. Swelling of the foot and ankle on the affected leg may occur by the end of the day, and swelling is often accompanied by aching. The patient may complain of pain, itching, or both along varicose veins (Figure 18-8). The legs may feel full and heavy during walking or exercise. Diagnosis is made by thorough physical assessment and patient history.

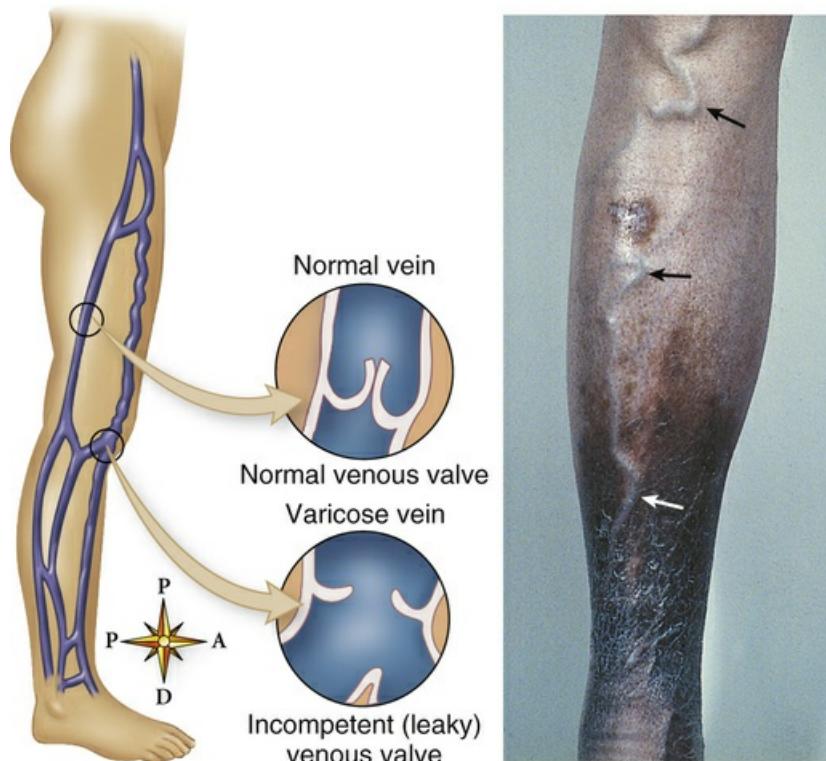

FIGURE 18-8 Varicose veins. (From Patton KT, Thibodeau GA: *The human body in health and disease*, ed. 6, St. Louis, 2014, Mosby.)

Treatment

Treatment of varicose veins includes using elastic support hose, exercising the legs and feet periodically throughout the day, and elevating the legs whenever possible. Prolonged standing, sitting, or crossing the legs is to be avoided. Weight reduction is recommended for patients who are obese. Exercises such as walking or swimming are beneficial, because the muscle contraction encourages venous return to the heart. Some herbs are helpful for varicose veins.

Complementary and Alternative Therapies

Herbs for Varicose Veins

Several herbs have been found to be helpful for patients with varicose veins (but should not be used during pregnancy and lactation):

Bilberry: May cause constipation; affects blood glucose levels, may increase the action of anticoagulants; check drug and herbal interactions

Butcher's broom: Not to be used for patients with hypertension or prostatic hypertrophy

Gotu kola: Also helpful for hypertension

Horse chestnut: Check for interactions with other drugs the patient is taking; do not use with hypoglycemics, salicylates, or anticoagulants

Patients need to be aware of potential side effects of herbs, as well as prescribed medications.

Knee-high elastic stockings or elastic wraps should be used to support venous circulation. See Chapter 17 for correct use and application of support garments.

Clinical Cues

Follow directions carefully and measure the patient's calves and legs before choosing a pair of elastic stockings. Accurate fit is crucial to effective treatment. If standard sizes do not coincide with the measurements, custom stockings may need to be purchased.

Exercise is especially beneficial to patients with decreased blood flow. Walking is the ideal exercise for ambulatory patients. If a patient is unable to ambulate, promote venous return through range-of-motion (ROM) exercises and other kinds of muscular movements. Any activity that causes contraction of the leg muscles will help move venous blood from the legs to the heart.

Medications such as NSAIDs (e.g., aspirin, ibuprofen) may be used for aching. Surgical procedures may be used when medical treatment is ineffective. Small varicosities can be treated by **scleropathy**, which involves injecting an agent that will sclerose the vessel, causing it to dry up and wither. Endovenous occlusion using a laser is performed by placing a catheter within the vein under duplex ultrasound guidance; a laser heats the vessel, causing it to collapse and close off. It can be performed in an office setting or outpatient ambulatory surgery site. Compression stockings are worn for 1 to 2 weeks after the procedure. Patients ambulate immediately after the procedure for 30 to 60 minutes and 1 to 2 hours per day for 1 to 2 weeks. A similar procedure uses radiofrequency energy for closure of the vessel. Vein stripping may be performed for severe cases; a less invasive technique is called *PIN (perforate invaginate) stripping*. In this procedure only two small incisions are used, and the vein is removed much like pulling a sock off inside out. It can be done in an office setting but may also be performed in an operating room.

Chronic Venous Insufficiency

Etiology and Pathophysiology

Chronic venous insufficiency is common among older adults. Many cases are caused by congenital absence of the valves in the veins. It can also occur when the venous valves are damaged and can affect the superficial low pressure vessels or the higher pressure deep venous system, such as occurs with severe cases of DVT. When valves are damaged or absent, there is retrograde venous blood flow, and blood pools in the legs. Swelling results with increasing venous pressure and stasis of blood flow. The condition may lead to venous stasis ulcers.

Venous return occurs by the pumping action of the calf muscles against the venous walls. When valves are incompetent, venous return is compromised, and flow goes both ways in the vessel. The increased pressure leads to leakage of red blood cells into the tissues. The breakdown of the red cells releases hemosiderin, which causes a brownish skin color (Weiss, 2014). Fibrous tissue replaces subcutaneous tissue around the ankle. The skin becomes thick and hardened.

Signs, Symptoms, and Diagnosis

Signs and symptoms of chronic venous insufficiency include chronically swollen legs; thick, brownish skin around the ankles; and itchy, scaly skin (Figure 18-9). Stasis dermatitis is common. Venous stasis ulcers often occur (Figure 18-10). Infection and cellulitis occur if an ulcer is untreated. Diagnosis is made through physical assessment and patient history.

FIGURE 18-9 Characteristic skin changes in a patient with venous insufficiency. (From Swartz M: *Textbook of physical diagnosis: History and examination*, ed. 6, Philadelphia, 2009, Saunders.)

FIGURE 18-10 Venous stasis ulcer. (From Black JM, Hawks JH: *Medical-surgical nursing: Clinical management for positive outcomes*, ed. 8, Philadelphia, 2009, Saunders.)

Treatment and Nursing Management

Treatment is the use of knee-high elastic support stockings and elevation of the legs for 8 out of 24 hours each day. Teach the patient to avoid prolonged standing or sitting and to sleep with the foot of the bed elevated 6 inches. Legs should not be crossed when sitting and tight, restrictive clothing should be avoided. Legs should be elevated above heart level whenever possible.

Venous Stasis Ulcers

Diabetic patients with venous insufficiency are at high risk for venous stasis ulcers because of compromised circulation in the extremities and a slow rate of healing. The ulcers may extend

deeply into the tissue and are very slow and difficult to heal because of tissue congestion and edema that prevent nutrients from reaching the cells. The ulcer may begin as a small, tender, inflamed area and becomes very painful. With the slightest trauma, the skin breaks and the ulcer enlarges. It is imperative that patients with venous insufficiency be taught the extreme importance of good foot and leg care. An inflamed skin area can be preventively treated with a clear occlusive dressing, such as Tegaderm or OpSite, to help prevent ulcer formation. These transparent dressings allow monitoring of the site for signs of infection or complications of healing. Teach the patient about proper self-care and signs of beginning skin breakdown. The slightest injury to an ischemic area can take a very long time to heal and can easily become infected, because the blood supply is inadequate to provide the usual leukocyte defenses. Any injury to an affected extremity, no matter how minor, should be reported to the provider immediately.

Treatment for an ulcer consists of leg elevation, a moist dressing, and compression. A culture is performed to determine whether infection is present. Saline or mild soap is used to clean around the ulcer. A lanolin-type lotion is used to keep skin moist and supple. The dressing to be used depends on the condition of the ulcer and the amount of exudate produced. A vacuum-assisted drainage device may be needed for excessive drainage. The wound may need a graft to heal completely. Venous stasis ulcers can take weeks to months to heal. Compression dressings are not used if arterial insufficiency is also present. Compression therapy options include compression stockings, elastic tubular support bandages, intermittent compression devices, a paste bandage such as Unna boot, or placement of two to four layers of compression dressings to the affected area. Venous return is accomplished as the patient moves his leg and achieves pressure on the calf muscles. Compression dressings can be placed over wound dressings. The dressings help to reduce ulcer pain, keep the wound moist, and assist debridement. The dressing is changed from every 2 to 3 days to every few weeks depending on the type of dressing applied.

For success, the underlying venous problem must be treated. A graft may be necessary to heal the ulcer. A split-thickness graft or bioengineered skin may be used. Advise the patient to avoid injury to the graft site. Patients are placed on bed rest for several days after grafting to protect the site. Give the patient considerable support, because treatment is long, recurrent, and tedious. Patients with stasis ulcers commonly become depressed. Praise for compliance with instructions and for any small gains made toward healing can do much for a patient's morale.

❖ Nursing Management

■ Assessment (Data Collection)

Subjective information is gathered during history taking. A nutritional assessment is essential. Objective assessment data should include status of the skin, noting color, warmth, and moisture. Stasis dermatitis may be present, and pruritus and edema are common. Document the location, size, and presence of exudate and its color and odor, and include a photograph. Obtain a patient statement of pain at the site on a scale of 0 to 10. Assess the patient's experience with pain, including intensity, when pain occurs, and how it is relieved. Assess arterial pulses and determine the pulse rate, rhythm, and character (force) of the pulse. For diagnostic tests, refer to [Table 17-2](#).

☒ Focused Assessment

Data Collection for Vascular Disorders

Gather data on the following while interviewing the patient.

Health History

- Family history of hypertension, cardiovascular disease, stroke, hyperlipidemia, aortic aneurysm, diabetes mellitus, or PVD
- History of trauma to the lower extremities
- Personal history of any PVD
- All medications taken on a regular basis (prescribed and over-the-counter medications)

- History of tobacco use, especially smoking
- History of alcohol use
- Dietary practices, especially sodium and fat intake
- Current or history of central nervous system occurrences, such as dizziness, headaches, or loss of consciousness
- Occurrence of edema in the legs, feet, or ankles
- Occurrence of leg pain during walking (When? How is it relieved?)

Physical Assessment

- Color of skin of the neck
- Observe for jugular vein distention
- Auscultate carotid arteries for presence of bruit
- Auscultate heart sounds and note any abnormalities
- Assess for any visible abdominal pulsation over aorta
- Auscultate over aorta in abdomen for presence of bruit
- Assess peripheral pulses and compare bilaterally
- Assess blood pressure on both arms, sitting and standing
- Assess skin for temperature, color, appearance, lesions, dryness, presence or absence of hair on legs
- Note presence of varicosities
- Assess capillary refill

Nursing Diagnosis and Planning

Problem statements are chosen based on those assessment data that indicate problems for the patient. Common problem statements associated with vascular disorders are listed in [Table 17-4](#). Nursing diagnoses may be added to the care plan for problems secondary to treatments, such as drug therapy or surgery. Other problem statements sometimes used include:

- Insomnia related to pain in the legs while at rest.
- Decreased self-esteem related to inability to perform usual roles because of chronic leg ulcers.

Appropriate exercise is important to treat vascular disease. Collaborate with the provider and physical therapist about activity, exercises, and the reinforcement of teaching. Work with the dietitian to promote the patient's adequate nutrient intake for healing ([White-Chu and Conner-Kerr, 2014](#)). Specific expected outcomes must be written on an individual basis (see [Table 17-4](#)).

Implementation

A major role of a nurse caring for a patient with venous insufficiency is to monitor the condition and determine whether treatment is effective. [Table 17-4](#) lists helpful interventions for the most common problem statements associated with problems of the vascular system. Nursing interventions for selected problems in a patient with a venous stasis ulcer are summarized in [Table 17-4](#).

Evaluation

Evaluate the patient's response to treatment to determine effectiveness and potential development of complications. Carefully evaluating pulses and comparing them bilaterally are important parts of nursing care for patients with problems of the vascular system. Documenting a good description of the quality and character of the monitored pulses in the nurse's notes will give coworkers an accurate assessment baseline on which to evaluate changes in the pulse (see **Box 17-2**).

It is important to determine whether skin color and temperature have changed since the last assessment. Ulcerated areas are monitored closely, measured, documented in writing, and photographed to determine whether healing is occurring. The color of the healing tissue and presence of exudate also are evaluated. Documentation of the characteristics of any exudate should be included. If the wound is enlarging or not improving, the nursing actions or treatment must be changed.

Subjective data from the patient help evaluate whether treatment and nursing actions are effective. Increases in peripheral circulation may be evident only by a decrease in pain or an ability to walk farther without pain. The patient should be able to demonstrate understanding of the disease process, preventive measures, medications, signs and symptoms to report to the health care provider, and follow-up care.

Community Care

Many patients with vascular disease are treated in outpatient clinics and their homes. Patients who have venous stasis ulcers are often treated by a home health nurse. With early discharge after surgery, many patients receive postoperative care in the home. Patients with arterial bypass may be referred for rehabilitation exercise programs at a rehabilitation center. Your role in these settings is focused on ongoing assessment, coordination of care with other members of the health care team, monitoring progress and compliance with treatment, and patient education.

Include careful monitoring of the blood pressure for the presence of hypertension. Patients should be aware of expected blood pressure levels and critical levels to report to the health care provider. Evaluate the home care patient's understanding of medication, diet, and exercise to accomplish optimal management of hypertension.

Some patients may have the capability of monitoring their coagulation status through home monitoring devices. This is especially important for patients who are taking drugs such as warfarin. There are multiple devices on the market for home testing of INR. The patient then has more information to manage his coagulation status and prevents missed laboratory appointments. Be aware of patient use of these devices and ensure that the patient is using them correctly.

Get Ready for the NCLEX® Examination!

Key Points

- Hypertension is more prevalent and more severe in African Americans than in other minority groups and whites.
- Treatment of hypertension involves measures to assist the patient to maintain blood pressure at or below 120/80 mm Hg.
- Antihypertensive drugs work by decreasing blood volume, cardiac output, or peripheral resistance.
- Nursing care of patients with hypertension includes counseling and education about lifestyle changes, diet, weight control, stress relief, and exercise.
- Noncompliance with the medical regimen for hypertension can result in heart problems, dementia, blindness, stroke, and kidney failure.
- Obesity, stress, and sedentary lifestyle contribute to the incidence of atherosclerosis and hypertension.
- Atherosclerosis is the most common cause of PVD.
- Arterial wall injury may be caused by hypertension, deposit of fatty plaque, chemical toxins, or diabetes mellitus.
- Disorders of peripheral arteries lead to ischemia.
- Quitting smoking, maintaining a low-fat diet, controlling diabetes mellitus, and following an exercise program decrease the incidence of PAD.
- Signs and symptoms of PAD include intermittent claudication, pain at rest, and ischemic changes. The five *Ps* are pain, pulselessness, pallor, paresthesias, and paralysis.
- The best treatment for arterial insufficiency is exercise—specifically, walking.
- Long-term hypertension and atherosclerosis are factors in the development of aneurysms.
- Aneurysms in the aorta may be repaired by surgical resection and graft or stent insertion.
- An aortic aneurysm rupture often causes death.
- The etiology of Raynaud disease is an exaggerated response to cold environment and stress.
- Carotid occlusion is signified by a carotid bruit, confusion, blackouts, extremity weakness or paralysis, temporary loss of vision, or other neurologic symptoms.
- Treatment for carotid stenosis includes carotid endarterectomy or stenting.
- Thrombophlebitis is the development of a clot and inflammation of a vein.
- DVT is a clot in a deep vein occluding blood flow.
- The effects of a thrombus depend on the location and size of the clot and the degree of obstruction to blood flow.
- The etiology of DVT includes immobility, trauma, surgery, cancer, dehydration, and abnormal clotting.
- Treatment of DVT may include IV heparin, subcutaneous agents, oral anticoagulants, and hydration.
- Medical management of DVT includes elevation of the extremity when seated, compression stockings, ambulation, warm moist packs, NSAIDs, and sometimes antibiotics.
- Varicose veins are enlarged, tortuous veins engorged with pooled blood.
- The symptoms of varicose veins include fatigue, a feeling of heaviness in the legs after prolonged standing or sitting, pain, and itching along the course of the blood vessel.
- Medical management of varicose veins involves compression stockings, treatment of obesity, and exercise.
- Surgical treatment of varicose veins may include sclerotherapy, vein stripping or PIN stripping, ligation, or endovenous laser treatment.
- Venous insufficiency occurs from damaged valves in veins and pooling of blood.

- Venous stasis ulcers are skin lesions, usually on the lower leg, from venous insufficiency.
- Treatment for venous stasis ulcers includes acute debridement, dressings, compression, and prevention of infection.

Review Questions for the NCLEX® Examination

1. A 40-year-old woman complains of leg pains that are associated with fullness during walking. She describes itching on the lower leg and on inspection has a twisted-appearing swelling in her legs. The patient most likely will be treated for:

1. venous stasis ulcers.
2. deep vein thrombosis.
3. arterial insufficiency.
4. varicose veins.

NCLEX Client Need: Physiological Adaptation

2. A nurse reinforces discharge instructions to a patient who is diagnosed with chronic venous insufficiency. Which instruction(s) should be included? (*Select all that apply.*)

1. "Take a low-dose aspirin every day."
2. "Consider swimming for exercise."
3. "Avoid wearing tight clothing."
4. "Reapply elastic wraps in the afternoon."
5. "Decrease fluid intake to help prevent edema."
6. "Elevate the legs above the level of the heart as much as possible."

NCLEX Client Need: Health Promotion and Maintenance

3. If a patient complains of intermittent claudication, the nurse would expect which clinical finding?

1. Strong, symmetrical peripheral pulses
2. Skin mottling
3. Rubor when legs are dependent
4. Continual pain

NCLEX Client Need: Reduction of Risk Potential

4. A patient diagnosed with peripheral arterial disease complains of a sudden onset of pain in his right foot. Identify in priority order the actions of the nurse.

1. Notify the provider.
2. Note the color, temperature, and capillary refill of the foot.
3. Check for pedal and posterior tibial pulses.
4. Check vital signs.

NCLEX Client Need: Physiological Adaptation

5. A patient is started on antihypertensive medications. Which patient statement indicates effectiveness of teaching?

1. "I will be able to perform sit-ups in the morning."
2. "I need to take the medication when I feel dizzy."
3. "It helps reduce the incidence of a blood clot."
4. "Sudden changes in position may cause dizziness."

NCLEX Client Need: Pharmacological Therapies

6. The nurse is receiving a patient who had angioplasty and stenting of his right femoral artery. Which nursing intervention would take priority in the immediate postoperative period?

1. Assessing the right femoral artery pulse

2. Monitoring for signs of fluid overload
3. Determining range of motion
4. Checking right pedal pulses

NCLEX Client Need: Reduction of Risk Potential

7. The nurse is reinforcing the provider's instructions to an older adult woman who is newly diagnosed with hypertension. The patient does not speak the nurse's language and is legally blind. What is the best nursing action?

1. Use a certified translator to provide instructions.
2. Speak slowly and use hand motions to describe information.
3. Use a loud voice and speak directly into the patient's ear.
4. Provide written instructions for the family.

NCLEX Client Need: Health Promotion and Maintenance

8. A 54-year-old man complains of pain when walking and numbness of his lower extremities. On examination, the nurse notes that both extremities are pale and cool to touch. The highest priority nursing diagnosis would be:

1. *Altered peripheral tissue perfusion.*
2. *Altered activity tolerance.*
3. *Altered fluid volume.*
4. *Potential for injury.*

NCLEX Client Need: Reduction of Risk Potential

9. A patient with PAD is prescribed a daily dose of aspirin. The nurse accurately explains the prescription by stating:

1. "Aspirin controls the body temperature to reduce vasoconstriction."
2. "Aspirin helps prevent formation of clots."
3. "Aspirin protects the blood vessels from injury."

4. "Aspirin reduces pain associated with inadequate tissue perfusion."

NCLEX Client Need: Pharmacological Therapies

10. The nurse promotes lifestyle modifications to a 39-year-old man who is diagnosed with prehypertension. Which lifestyle modification(s) should be recommended? (*Select all that apply.*)

1. Smoking cessation
2. Restrict sodium intake to 4000 mg/day
3. Exercise 30 minutes per day most days of the week
4. Limit alcohol intake to two drinks per day
5. Low-fat diet
6. Stress reduction measures

NCLEX Client Need: Reduction of Risk Potential

Critical Thinking Questions

Scenario A

Mrs. Dunn is being discharged from the hospital after being treated for arterial insufficiency in both lower extremities. Her provider requests that Mrs. Dunn receive instruction in the care of her feet and legs before discharge.

1. What findings do you expect on physical examination of Mrs. Dunn's legs?
2. What medication and treatment do you expect the provider to prescribe? Why are these prescribed?
3. List five priority teaching points for Mrs. Dunn.

Scenario B

Ms. Yao, age 27, developed a DVT in her left thigh after surgery to repair a fractured right femur. She is receiving IV heparin and will transition to warfarin starting tomorrow.

1. Describe the pathophysiology of DVT. How does Ms. Yao's diagnosis relate to development of DVT?
2. Identify essential information you need to safely administer the medications prescribed.
3. Develop a teaching plan for Ms. Yao.

Scenario C

Mr. Tompkins, age 66, who is hypertensive and only recently quit smoking, has been diagnosed with a 3-cm AAA.

1. What treatment would you expect for him?
2. What signs and symptoms of complications would you teach him?
3. What measures could he take to help prevent the aneurysm from growing and rupturing?

CHAPTER 19

Care of Patients With Cardiac Disorders

Objectives

Theory

1. Contrast left-sided and right-sided heart failure.
2. Discuss treatment of systolic and diastolic heart failure.
3. Apply the nursing assessment specific to a patient who is admitted with heart failure.
4. Identify life-threatening heart rhythms from a selection of cardiac rhythm strips.
5. Examine usual treatment for atrial fibrillation, third-degree heart block, and ventricular tachycardia.
6. Explain nursing responsibilities in the administration of cardiac drugs.
7. Determine under what circumstances cardiac surgery is appropriate treatment.
8. Analyze the nurse's role in caring for patients with heart disorders in a long-term care facility or in their home.
9. Develop a teaching plan with dietary recommendations for heart disease.

Clinical Practice

10. Develop a plan of care for a patient who has heart failure.
11. Perform a basic physical assessment on a patient who has a mitral valve stenosis and dysrhythmia.
12. Use the nursing process to care for assigned patients who have cardiovascular disorders.
13. Safely administer medications for patients with cardiac disorders.
14. Provide support to patients undergoing diagnostic testing and treatment for cardiac disorders.
15. Develop a teaching plan for patients with a newly implanted pacemaker or implantable cardioverter-defibrillator (ICD).

Disorders of the Heart

Heart Failure

There are more than 5 million Americans with heart failure (HF), and approximately 670,000 are newly diagnosed each year. Approximately 1 in 100 people will develop HF. The prevalence of HF is increasing, and it is a major chronic condition. Half of patients diagnosed with HF will die within 5 years. African Americans have a higher incidence of HF and have higher mortality rates than other populations. HF can occur at any time the heart muscle is prevented from fulfilling its function as a pump and circulator of blood. HF may be acute or chronic, mild or severe. The New York Heart Association scale identifies four stages of HF, classed according to exercise tolerance ([Table 19-1](#)). The American Heart Association (AHA) has identified stages of HF from A-D. The "A" stage includes individuals who have no structural heart problems but are at high risk for HF. Early recognition of risk factors and prevention of HF is being promoted. ([Yancy et al, 2013](#))

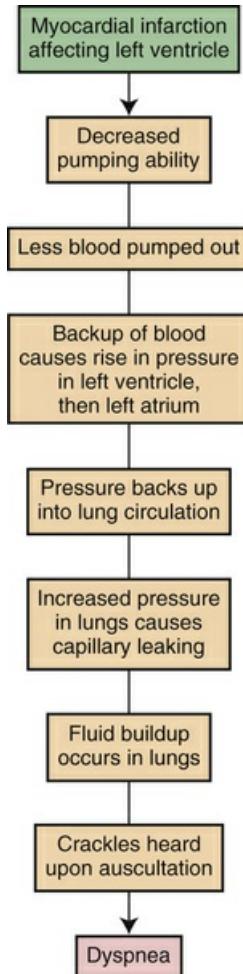

Table 19-1
Classification of Heart Failure

Class	Activity Tolerance
I	Ordinary physical activity with no symptoms
II	Dyspnea with long-distance walking, climbing two flights of stairs, or strenuous activity
III	Dyspnea and fatigue with short-distance walking or climbing one flight of stairs
IV	Dyspnea at rest or with very little activity

Adapted from the New York Heart Association Heart Failure Symptom Classification System. Retrieved from www.clevelandclinicmeded.com/medicalpubs/diseasemanagement/cardiology/heart-failure/Default.htm.

Etiology

The most common causes of HF are coronary artery disease and uncontrolled hypertension. Other factors that contribute to weakness of the heart muscle are toxins, infection, anemia, myocarditis, dilation from blood backup behind diseased valves, and damage from myocardial infarction (MI) ([Concept Map 19-1](#)). Toxins include cocaine, excessive alcohol, certain chemotherapy drugs, nonsteroidal anti-inflammatory drugs (NSAIDs), and thiazolidinediones used for diabetes. Cardiac dysrhythmias also can contribute to HF. (Coronary artery disease [CAD] and MI are covered in [Chapter 20](#), with cardiac surgery.)

CONCEPT MAP 19-1 Pathophysiology of heart failure after a myocardial infarction.

Older Adult Care Points

Heart failure is the most common reason for hospitalization among adults age 65 years or older. As life spans continue to extend, more and more older adults will develop HF related to hypertension and CAD.

Pathophysiology

The key words to understanding HF are *congestion* and *increased pressure*. Congestion develops because the heart is unable to move the amount of blood it receives efficiently through the system. This may occur because the heart muscle is too weak or because the blood vessels throughout the body are narrowed and constricted (because of atherosclerosis or arteriosclerosis). Therefore the vessels cannot accommodate a normal supply of blood, causing the heart muscle to become exhausted trying to overcome the resistance (pressure) in the vessels. Poorly functioning valves may cause the chambers to dilate from blood backup, further decreasing pumping ability. A myocardium damaged by infarct, infection, ischemia, or other factors is not an efficient pump and cannot manage the volume of blood in the circulation. [Box 19-1](#) lists factors that precipitate HF.

Older Adult Care Points

Aging processes also contribute to arteriosclerosis and stiffening of the heart muscle. The combination of high blood pressure, diabetes, and age greatly contributes to the number of older patients who develop HF.

Box 19-1**Factors That Can Precipitate Heart Failure**

- Anemia
- Systemic infection (sepsis)
- Myocardial infarction/ischemia
- Pulmonary embolism
- Uncontrolled hypertension
- Thyroid disorders
- Dysrhythmias
- Pericarditis, myocarditis, or endocarditis
- Chronic pulmonary disease
- Physical, emotional, or environmental stress

HF may be classified as right-sided HF or left-sided HF. The heart has two pumps: a right-sided and a left-sided pump. The right-sided pump receives blood from the body and pumps it to the lungs for oxygenation. The left-sided pump receives blood from the lungs and pumps it out to the body. Although the terms *right-* and *left-sided failure* are used to explain the physiology, clinically it is rare to see pure right or left failure. The circulatory system is a continuous circle and eventually all congestion or increased pressure affects both sides of the heart. Left-sided failure typically occurs first. If the muscle wall of the left ventricle cannot contract effectively, not enough of the blood is ejected from the ventricle; this residual blood prevents part of the blood from the lungs from entering the left side of the heart. This causes fluid to back up into the pulmonary vessels. The pressure within those vessels increases, and fluid leaks into the lung tissue—producing congestion and, eventually, pulmonary edema. If not corrected, left-sided failure, because of the backup of blood and increased pulmonary artery pressure, will soon lead to failure of the right side of the heart. [Table 19-2](#) compares the signs and symptoms of left-sided and right-sided HF.

Table 19-2
Left-Sided and Right-Sided Heart Failure comparison

	Right-Sided Heart Failure	Left-Sided Heart Failure
Selected etiology	Pulmonary stenosis, pulmonary hypertension, severe emphysema, right ventricular MI	Hypertension, coronary artery disease, MI, mitral or aortic valvular disease
Pathophysiology	Increased pump pressure is needed to eject blood into pulmonary arteries. The myocardium of the right atrium and ventricle becomes thickened, and contraction strength weakens.	Weakness of the left ventricle results in reduced cardiac output and backup of blood into the atrium and the pulmonary system.
Signs and symptoms	Fatigue; edema in sacrum, legs, feet, ankles; hepatomegaly; abdominal distention as a result of ascites; weight gain; dyspnea	Fatigue; dyspnea; wheezing; orthopnea; sleep apnea; pulmonary edema (pink, frothy sputum); pallor; clammy skin

MI, Myocardial infarction.

Primary right-sided HF is commonly caused by chronic pulmonary disease. The right ventricle does not usually have to generate a lot of pressure to pump blood to the lungs. Normal systolic pressure in the right ventricle is about 25 mm Hg. Chronic lung disease causes scarring, which makes it harder for the ventricle to eject blood into the pulmonary circulation. This increased resistance requires the right ventricle to squeeze harder, generating more pressure and causing inadequate ejection. This makes it difficult for entry of the venous blood returning to the heart. As pressure in the peripheral vessels increases, the fluid from the intravascular fluid compartment begins to leak into the interstitial compartment. This produces edema. When the right side of the heart fails, the edema is first evident in the lower extremities (**dependent edema**) ([Figure 19-1](#)). There also is an accumulation of fluid in the liver and abdominal organs, as the portal circulation becomes involved. Alteration of blood flow to the kidneys may lead to impaired renal function, preventing normal excretion of urine and causing more accumulation of body fluids. Inadequate

circulation to and from the brain may cause mental confusion and irritability.

FIGURE 19-1 Dependent, pitting edema. (From Bloom A, Watkins PH, Ireland J: *Color atlas of diabetes*, ed. 2, St. Louis, 1992, Mosby.)

The systemic backup of blood that occurs in right-sided HF will eventually lead to left-sided HF, because the heart will have to pump against increasing pressure in the aorta and systemic circulation. The circulatory system is exactly that: a system. Failure of one component affects the entire system.

Think Critically

Can you describe the changes that occur with chronic hypertension that may cause HF?

Left-sided HF is subdivided into systolic and diastolic HF. In the cardiac cycle, diastole is the part of the cycle in which the heart is resting and filling with blood. During this time the valves between the atria and ventricles (tricuspid and mitral) are open. Most of the blood entering the ventricles does so passively by the pressure in the system during diastole. Right before the ventricles are ready to contract, the atria contract and “top off the tank,” contributing about 20% of the volume. Systole occurs, and the exit valves open in the ventricles (pulmonic and aortic), allowing ejection of blood into the circulation. Different problems cause failure of this process. Here the problems occur in either the filling or ejection phase of the cycle.

Systolic failure.

Systolic failure is caused by anything that interferes with ejection of blood from the ventricles. Muscle dysfunction, problems from MI, dilated cardiomyopathy, and aortic or pulmonic stenosis may lead to systolic failure. Inability of the heart to pump an adequate amount of blood to meet the needs of the body can lead to problems in other organs. **Ejection fraction** is the percentage of the filling volume pumped out with each ventricular contraction. In a normal heart, ejection fraction is 55% to 70%. This means that 30% to 45% of the blood is left in the ventricle, which allows the body to increase cardiac output when needed by increasing the force of contraction (through release of epinephrine, responsible for the fight or flight response) and ejecting more blood. An ejection fraction of 40% or less is a marker of systolic HF.

Diastolic failure.

Diastolic failure occurs when conditions prevent the filling of the heart with blood. Tricuspid and mitral stenosis, cardiac tamponade, or constrictive cardiomyopathy can cause diastolic failure. Decreased filling results in decreased stroke volume and cardiac output. Ejection fraction is normal in primary diastolic failure. Medical literature refers to *diastolic failure* as HF with preserved ejection fraction (HFpEF). A hallmark of diastolic failure is neck vein (jugular) distention.

Evidence is emerging that HF with a reduced ejection fraction (HFrEF) and HFpEF are separate

clinical conditions that require very different treatments. Determination of ejection fraction can be done with echocardiography or left heart catheterization and is a key feature in determining the correct treatment.

Think Critically

Can you explain to a patient in simple terms what happens in the body when systolic HF occurs?

Signs, Symptoms, and Diagnosis

Initially, compensatory mechanisms prevent symptoms of HF. Heart rate rises to increase output, and the ventricles hypertrophy to pump out more blood with each contraction. In left-sided failure compensatory mechanisms eventually weaken the heart, and the blood backs up into the pulmonary vessels, pressure within those vessels increases, and fluid leaks into the lung tissue, producing congestion. Fatigue and shortness of breath (SOB) are first noticed with activity and when lying down. If failure progresses, pulmonary edema occurs. There is no single diagnostic test for HF, and diagnosis is made primarily on clinical signs and symptoms and careful history.

Diagnostic tests that are helpful include chest x-ray, echocardiogram, electrocardiogram (ECG), magnetic resonance imaging (MRI), electrolytes, complete blood count (CBC), and brain natriuretic peptide (BNP). BNP measures the level of a protein released when myocardial cells are stretched. A level greater than 500 pg/mL is consistent with HF when other symptoms are present (see [Table 19-2](#)).

Advanced systolic HF signs are S₃ and S₄ heart sounds. Weight gain of 2 lb in 24 hours or 5 lb in 1 week occurs as fluid is retained. Dyspnea is present, and crackles or wheezes are heard in the lungs.

Think Critically

You auscultate the lung sounds of a patient with HF. You hear crackles in the bases and up to mid-chest. What is the significance of this finding?

Treatment

There are multiple causes of HF, but the clinical signs and symptoms are the same. Identification and treatment of the underlying cause of HF should be initiated. Dysrhythmias are controlled. Surgical correction of valve or septal abnormalities may reverse HF. Medical treatment is largely symptomatic and depends on the type and degree of HF present. Drugs and other therapies are used to reduce or eliminate the symptoms and complications of HF, but they only control the condition; they do not cure it. AHA 2013 Heart Failure Guidelines outline strategies for early identification of patients at risk for HF and implementation of interventions to prevent the disease or decrease its effects. For patients experiencing HF, efforts are made to (1) reduce the demand for oxygen and the workload of the heart, (2) strengthen the heart's pumping action, (3) relieve venous congestion in the lungs, and (4) minimize sodium and water retention in the tissues. Some clinical trials have shown that early intervention with appropriate drug therapies can reverse some of the ventricular dysfunction found in HF ([Zile and Gaasch, 2014](#)).

To accomplish the goals of medical intervention, the following may be prescribed:

- Angiotensin-converting enzyme (ACE) inhibitors and angiotensin-receptor blockers (ARBs) decrease the workload of the heart by causing vasodilation; as a result, blood pressure is reduced ([Table 19-3](#)). ACE inhibitors and ARBs also play a role in reducing fluid retention.

Table 19-3

Drugs Used to Treat Heart Failure*

Classification	Examples	Use
Diuretics		
Loop	Furosemide (Lasix), bumetanide (Bumex)	Remove excess fluid
Potassium sparing	Triamterene (Dyrenium), amiloride (Midamor)	Remove fluid but not potassium
Thiazide	Hydrochlorothiazide	Removes fluid but wastes potassium
Angiotensin-converting enzyme inhibitors	Enalapril (Vasotec), captopril (Capoten), lisinopril (Zestril)	Prevent vasoconstriction
Angiotensin-receptor blockers	Losartan (Cozaar), valsartan (Diovan), irbesartan (Avapro)	Produce vasodilation and salt and water excretion
Beta-adrenergic blockers	Atenolol (Tenormin), metoprolol (Lopressor), nadolol (Corgard)	Reduce blood pressure, slow heart rate
Calcium channel blockers	Amlodipine (Norvasc), diltiazem (Cardizem), nifedipine (Procardia), verapamil (Calan)	Produce vasodilation and reduced heart rate

Vasodilators (nitrates)	Nitroglycerin (Nitrostat, Nitro-Bid), isosorbide (Isordil), nitroprusside (Nipride)	Dilate blood vessels; decrease preload and relieve shortness of breath; relieve myocardial ischemia
BNP analog	Nesiritide (Natrecor)	Alleviates dyspnea
Inotropics		
Beta-adrenergic agonists	Dobutamine (Dobutrex), dopamine (Intropin)	Increases cardiac contractility and cardiac output
Phosphodiesterase inhibitors	Milrinone (Primacor)	Reduces preload and afterload; causes vasodilation; increases cardiac contractility
Digitalis	Digoxin	Increases cardiac contractility
Hyperpolarization-activated cyclic nucleotide-gated (HCN) channel blocker	Ivabradine (Coralan) <small>(approved for use in the United States, April 15, 2015)</small>	Directly acts on the sinoatrial node (SA) to reduce heart rate, reduce myocardial work load, and prevent angina.

*The choice of drugs depends on the type of heart failure and whether the left ventricle function is normal.

BNP, Brain natriuretic peptide.

See [Table 18-3](#), [Box 18-1](#), and [Table 19-4](#) for further information and nursing implications for these drugs.

- Beta-adrenergic blockers (e.g., metoprolol [Toprol XL]) are used if tachycardia is causing the HF to slow the heart rate, thereby decreasing oxygen demand. Beta blockers are used cautiously as they can also cause HF.
- Diuretics, especially loop diuretics, are prescribed to reduce fluid retention in the lungs and lower extremities. Watch for ototoxicity with these drugs. Thiazide diuretics such as hydrochlorothiazide (HydroDiuril) may also be prescribed. Measures are taken to prevent electrolyte imbalances from the use of these drugs.
- Digitalis is occasionally used to increase the force of heart contraction (i.e., an inotropic agent) and slow the rate, thereby increasing cardiac output. The most commonly used drug in this category is digoxin (Lanoxin). Several large doses of the drug are given initially, followed by a lower, regular-maintenance dosage. This drug is not recommended for older adult white women, because it increases mortality rates in this group.
- Venous vasodilators such as isosorbide dinitrate (Isordil) and nitroglycerin (NTG), which relax and dilate blood vessels, allow the vessels to accommodate larger percentages of the total blood volume.
- Morphine is prescribed if pulmonary edema is present to relieve anxiety and make breathing easier.
- Benzodiazepines may be used for anxiety and reduction of emotional stress.
- Limited physical activity or bed rest in semi-Fowler or high Fowler position will decrease the workload of the heart and help breathing.
- Oxygen therapy will optimize the amount of oxygen available to be delivered to the tissues.
- Dobutamine (Dobutrex) may be used intravenously (IV) for acute systolic HF to improve cardiac contractility.

Nutrition Considerations

Guidelines for a Heart-Healthy Diet

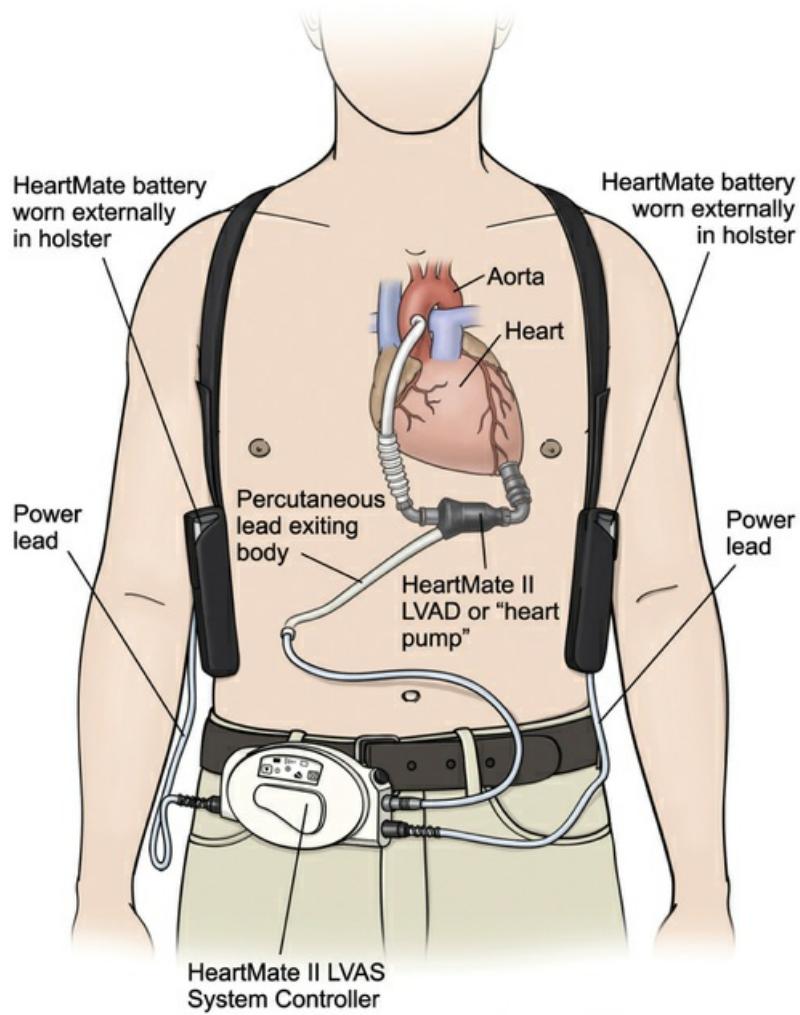

- Limit foods high in saturated fat, *trans* fat, and cholesterol. Limit meat intake to no more than 6 oz of cooked **lean** meat and skinless poultry (singly or in combination) per day. Fix main dishes with pasta, rice, beans, or vegetables mixed with small amounts of lean meat, poultry, or fish to create "low-meat" dishes. Restrict intake of organ meats, such as liver, brains, chitterlings, kidney, gizzards, and sweetbreads, because they are very high in cholesterol.
- Avoid *trans* fat as much as possible. Read product labels. Limit food high in saturated fat, including tropical oils and partially hydrogenated vegetable oils.
- Cook using little or no fat; broil, bake, roast, poach, stir fry, microwave, or steam foods rather than frying them.
- Eliminate as much fat as possible by trimming meat and skinning poultry before cooking. After browning meats, drain off all fat. Chill soups, stews, and so on, and then skim off fat before reheating to serve.
- Use fats with no more than 2 g of saturated fat per tablespoon. Olive, canola, corn, or safflower oil and liquid and tub margarines are good choices.

- Eat fish at least twice a week. Fatty fish such as salmon, mackerel, and tuna are best.
- Eat five to seven servings of fruit and vegetables per day. Use fresh or frozen vegetables and fresh fruit or fruit canned in juice rather than high-fructose corn syrup.
- Increase intake of fiber and carbohydrates by eating six or more servings of whole-grain products, such as cereals and breads, per day. Check labels to see that the product really contains **whole** grains.
- Use skim or 1% fat milk and nonfat or low-fat yogurt, cheeses, and ice creams.
- Limit consumption of egg yolks to three or four per week, including those in baked or cooked items. Check store packages for listing of eggs or egg yolk as an ingredient.
- Eat less than 1500 mg of salt (sodium chloride) per day.
- Have no more than one alcoholic drink per day if you are a woman and no more than two per day if you are a man. Examples of one drink are 12 oz of beer, 4 oz of wine, or $1\frac{1}{2}$ oz of 80-proof spirits.

Note: The heart-healthy diet is promoted by the American Heart Association.

Other treatments may include:

- The pumping action of the atria and ventricles may be synchronized for more efficient pumping by use of a **biventricular pacemaker**. This procedure is called *cardiac resynchronization therapy (CRT)*; pacing wires attached to a pulse generator are placed in the heart to send electrical impulses to the right and left ventricles so they contract at the same time. In a standard pacemaker, only the right ventricle is stimulated to cause ventricular contraction. CRT is the treatment of choice when drug therapy does not control HF.
- A left ventricular assist device (LVAD) may be used to help with the heart's pumping action. This device is implanted in the patient's abdomen or chest and attached to the heart. These devices have proven to be beneficial to adults diagnosed with severe HF. The device may be used while the patient is awaiting transplant and, with continued research, may potentially eliminate the need for transplant in some patients ([Figure 19-2](#)).

Copyright 2008 Thoratec Corporation

FIGURE 19-2 HeartMate II left ventricular assist device (LVAD). (Courtesy Thoratec, Pleasanton, CA.)

- Surgery to reduce the size of an enlarged heart (ventricular restoration surgery) may be effective for some patients. The less effective portions of the left ventricle are removed, and the remaining muscle is reattached and shaped to form a more efficient pump. Sometimes the heart enlarges again.
- Heart transplant may be the only alternative for patients with advanced HF who do not respond to other medical or drug treatment. Heart transplant is discussed in [Chapter 20](#).

Complementary and Alternative Therapies

Hawthorn Use in Heart Failure and Coronary Artery Disease

The herb hawthorn is believed to improve performance of damaged myocardial tissue and to improve myocardial perfusion. Hawthorn is said to reduce the symptoms of mild to moderate HF. Hawthorn should be used cautiously in older adults. Hawthorn may increase hypotension when used in combination with antihypertensive drugs. This herb may increase the effects of cardiac glycosides. Cardiovascular status should be monitored closely ([Reilly and Janson-Sand, 2012](#)).

Short-term treatment for severe HF can be accomplished with an intraaortic balloon pump (IABP). The IABP is positioned in the descending aorta and is designed to increase blood supply to the myocardium and decrease the workload. The balloon inflates during diastole, thus increasing perfusion to the coronary arteries. The balloon deflates during systole, making it easier for the left ventricle to eject blood ([Figure 19-3](#)).

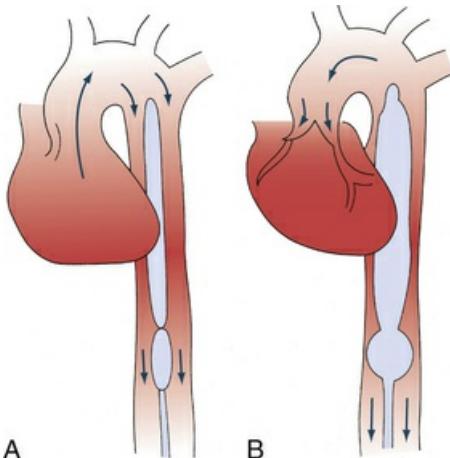

FIGURE 19-3 Intraaortic balloon pump. **A**, The balloon is deflated at the beginning of systole to decrease afterload. **B**, The balloon is inflated during diastole, increasing coronary perfusion. (From Sole ML, Klein, DG, Moseley MJ: *Introduction to critical care nursing*, ed. 6, Philadelphia, 2013, Elsevier Saunders.)

Acute pulmonary edema.

Acute pulmonary edema (acute left ventricular failure) is a medical emergency that must be treated promptly. A patient with this condition has severe dyspnea; a cough productive of frothy, pink-tinged sputum; tachycardia; and moist, bubbling respirations with cyanosis. Nursing interventions for acute pulmonary edema include placing the patient in high Fowler position to relieve the dyspnea; administering oxygen, diuretics, morphine, and other prescribed drugs; limiting and monitoring activity; and assessing cardiopulmonary status.

❖Nursing Management

■ Assessment (Data Collection)

The effects of HF can range from very mild to extremely serious. A thorough nursing assessment can help identify specific patient care problems. Data guide the provider in the evaluation of the patient's response to medical treatment and the decision to continue or change prescribed drugs and other therapies. It is important to ask the patient if her clothes, rings, or shoes fit tighter than previously, indicating edema. Is pedal edema worsening or improving? Obtain an accurate weight. What has the trend of weight been? Feelings of breathlessness or having to catch the breath in midsentence may indicate fluid in the lungs and left-sided HF. Are crackles present in the lungs? Inquire how much activity causes SOB. Does the patient have paroxysmal nocturnal dyspnea (PND) (wakes up at night with SOB) or onset of nocturia (being awakened by the need to urinate)? Ask about medication compliance and any problems or side effects noted. Assess the diet to determine usual sodium, fat, and calorie intake, and obtain a smoking history.

☒ Clinical Cues

It is important for patients who have been diagnosed with HF that is well controlled (**compensated**) to weigh themselves daily at home and to write down the weight. If the patient can see that fluid weight gain is occurring, she may be able to avert a trend back into **decompensated** HF by adjusting diuretic medication, decreasing sodium intake, treating infection, and decreasing activity and resting more.

Significant Findings Indicating Heart Failure Is Occurring

Left-sided failure

- Increasing fatigue.

- Dyspnea and a dry, hacking cough.
- Crackles heard on auscultation of the lungs.
- Pale, cool, and clammy skin, which are signs of poor peripheral circulation.
- Diminished peripheral pulses.
- Dizziness, confusion, restlessness, and difficulty concentrating and remembering because of diminished blood flow to the brain.
- Gradually increasing heart rate, even when the patient is at rest; increased heart rate occurs when the heart attempts to increase cardiac output.
- Extra heart sound (S_3 , S_4).
- Decreased blood pressure as the ventricles fail.

Right-sided failure

- Weight gain without a change in caloric intake
- Dependent, pitting edema (assess feet and ankles in an ambulatory patient or one sitting up most of the time). Assess thighs and sacral region in a patient confined to bed. Patient may feel “bloated” and experience a loss of appetite and nausea because of diminished venous return from abdominal organs, liver enlargement resulting from increased pressure in the portal veins, edema in the intestine, and accumulations of fluid in the abdominal cavity.
- Jugular venous distention; visible jugular vein pulsation more than 4.5 cm above the clavicle when the patient is in a semi-Fowler position.
- Reduced urinary output, which reflects the kidney's response to poor perfusion by retaining sodium and water; need to urinate at night (nocturia).
- Blood pressure increased from fluid overload.
- Waking up at night after a few hours of sleep because of PND.

Older Adult Care Points

Older adult patients who have little cardiac reserve can be at risk for HF from any condition that increases the body's demand for blood or oxygen. Pneumonia, generalized infection, severe trauma, or other conditions that increase the metabolic rate and demand for oxygen can be the precipitating factor, because a heart that is already having difficulty meeting normal body oxygen demands cannot respond. When an older adult patient has an infection, carefully assess the lungs for signs of crackles that might indicate beginning HF. Your quick action can save the patient from considerable problems. Assess urinary output of older adult patients. Renal function is decreased because of the aging process. Loss of perfusion related to HF will place the patient at greater risk of renal insufficiency or failure. Treatment for infection can further compromise kidneys because of the nephrotoxic effect of many antibiotics.

Nursing Diagnosis and Planning

The main problem statements/nursing diagnoses for patients with HF are listed in [Nursing Care Plan 19-1](#) (see also [Table 17-4](#)). Plan extra time when caring for patients with HF because fatigue, possible lack of mobility, and oxygen deficit cause these patients to move slowly and need more time to accomplish the activities of daily living. For each patient outcome criteria are written for each nursing problem statement specific to the patient.

Nursing Care Plan 19-1

Care of a Patient With Heart Failure

Scenario

Miguel Garcia, age 60 years, is admitted to the nursing unit with exacerbation of left- and right-sided heart failure. Physical examination reveals 3+ pitting edema of the right lower extremity and 4+ pitting edema of the left lower extremity. He is in acute respiratory distress and is positioned in high Fowler position to facilitate breathing. He is receiving oxygen with a simple mask at 8 L/min. T 98° F (36.6° C), P 96, R 28, BP 160/90, SpO₂ 90%, Wt. 255 (20-lb increase).

Problem Statement/Nursing Diagnosis

Altered gas exchange/*Impaired gas exchange due to fluid in lung tissue.*

Supporting Assessment Data

Subjective: States has difficulty breathing while lying down.

Objective: SpO₂ 90% on 8 L oxygen, elevated respiratory rate, sitting up to facilitate breathing.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
SpO ₂ 95% on room air.	Assess vital signs and SpO ₂ q2h. Report increase in respiratory rate or decrease in oxygen saturation.	Change in vital signs and oxygen saturation may indicate improvement or deterioration of condition.	SpO ₂ remains within 93%-95%. The respiratory rate is 12-22/min. The heart rate remains between 60 and 100.
	Increase oxygen to maintain SpO ₂ at level specified by provider.	Maintain oxygen saturation at levels that indicate effective gas exchange.	SpO ₂ 94%. O ₂ at 5 L/min by nasal cannula
	Assess lung sounds at least q4h.	Changes in lung sounds indicate positive response to therapy or need to modify treatment plan.	Lung sounds clear on right, fine crackles on left.
	Maintain Fowler position as needed for comfort. Teach patient pursed-lip breathing.	Promotes optimum expansion of thoracic cavity to facilitate breathing and improve gas exchange.	Head of bed at 45 degrees. Continue plan.

Problem Statement/Nursing Diagnosis

Altered activity tolerance/*Activity intolerance due to fluid in lungs, fluid retention in lower extremities.*

Supporting Assessment Data

Subjective: States feet have become more swollen over the past 3 days.

Objective: Pitting edema both lower extremities, dyspnea on exertion, crackles in bases bilaterally.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will be able to complete activities of daily living	Assess activity tolerance.	Provides guidelines for planning care	Able to complete partial bath. Becomes

and personal hygiene without fatigue.	Assist with personal hygiene initially. Monitor oxygen saturation. Provide frequent rest periods. Coordinate care with other health care providers to conserve energy.	activities. Conerves patient energy. Scheduling activities to maximize energy use prevents overexertion. Prevents fatigue.	fatigued, requires assistance. Patient remains fatigued. Continue plan; reassess readiness to meet goals.
---------------------------------------	--	--	---

Problem Statement/Nursing Diagnosis

Fluid volume excess/*Fluid volume excess due to pulmonary and venous congestion.*

Supporting Assessment Data

Subjective: Patient reports nonproductive cough.

Objective: 3 to 4+ edema both lower extremities; crackles in lung bases on auscultation.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Lung fields will be clear, pitting edema in lower extremities 0-1+.	Assess lung sounds q4h.	Identifies changes in condition.	Fine crackles on auscultation. Less distress.
	Assess lower extremities each shift.	Identifies effectiveness of drug therapy.	2+ pitting edema bilaterally.
	Elevate legs	Helps move fluid from the tissues back into the circulation so it can be removed by the kidneys.	2+ pitting edema bilaterally—less than on admission.
	Administer diuretics as prescribed by the provider.	To reduce fluid retention through diuresis.	Urinary output 2500 mL q8h.
	Maintain accurate intake and output.	Identify positive or negative response to treatment.	Continue plan. Weight 245 lb.
	Daily weights.		

Critical Thinking Questions

1. List three additional problem statements that are appropriate for this patient.
2. List five items to be included in the discharge teaching plan for this patient.
3. What assessment data might indicate a worsening of this patient's condition?
4. What assessment data might indicate improvement of this patient's condition?

■ Implementation

HF is a chronic disease. Patients with mild HF may not be hospitalized, but they do require instruction in self-care. Instruction includes balancing rest with physical activity, limiting sodium intake, and following other dietary restrictions. The entire family should be included in dietary teaching. Teach self-administration of medications and awareness of adverse side effects that must be reported. Review the dangers of drug-drug interaction when taking nonprescription drugs, particularly NSAIDs. Reconcile medications. Immunize the patient against seasonal flu and pneumonia. Modify lifestyle according to patient needs (diet, smoking, physical activity). Teach symptoms that should be reported to the provider if they become worse or appear for the first time.  An objective of *Healthy People 2020* is to reduce hospitalizations of older adults with HF as the principal diagnosis.  Thorough patient teaching and nursing follow-up helps achieve this objective.

Patient Teaching

Instructions for Patients Taking Warfarin (Coumadin)

Teach the patient who has been prescribed warfarin to:

- Take the medication at the same time every day.
- Keep appointments for international normalized ratio (INR) blood tests or perform the test at home.
- Take a missed dose as soon as it is remembered on the day it is due. Do not double up on the dose the next day if the previous dose was totally forgotten.
- Check all medications, all over-the-counter preparations, and all herbs for possible interactions with warfarin.

- Wear a medical alert bracelet and carry a wallet ID card indicating warfarin use.
- Tell all medical personnel that warfarin is being taken.
- Foods containing vitamin K should be eaten in consistent amounts weekly; asparagus, beans, broccoli, cabbage, spinach, cauliflower, brussels sprouts, kale, and mustard greens are high in vitamin K and should not be eaten in large quantities. Fish, rice, and yogurt also contain vitamin K.
- Avoid consuming more than one or two alcoholic drinks per day.
- Use an electric razor if prone to nicking the skin when shaving.
- Use a soft toothbrush.
- Blow the nose gently.
- Report unusual bleeding or bruising to the provider.
- Report signs of intestinal bleeding (blood in the stool) and blood in the urine.

Older Adult Care Points

An older adult patient who is experiencing HF often is taking many medications. With decreased kidney function, it is especially important to look for drug interactions and to monitor for signs and symptoms of toxicity. Loop diuretics continue to work even after excess fluid is eliminated. Monitor older adult patients for signs of dehydration such as decreased urine output and confusion.

It is of vital importance to monitor patients with HF for electrolyte imbalances, especially imbalance of sodium or potassium. **Electrolyte imbalances may cause serious cardiac dysrhythmias.**

Patients with chronic HF will need encouragement to follow the prescribed regimen. A chronic disease management program is advised based on multiple studies over the past decade indicating better outcomes ([Hanson et al, 2013](#)). If treatment does not stop the progress of the disease, the patient may be admitted to the hospital for reevaluation and a change in therapies. Sometimes the patient's heart continues to fail despite aggressive therapy, and pulmonary edema, liver, and renal failure occur.

Think Critically

Why does weighing the patient daily help you evaluate the treatment for HF? How would you know that the treatment is not effective?

Assisting hospitalized patients with activities of daily living will decrease oxygen demand. Scheduling all activities to promote as much rest as possible is a high priority. Activity is alternated with rest throughout the day. Several pillows may be required to achieve a comfortable bed position. Monitoring intake and output is very important. Daily weight is recorded at the same time each day, preferably before breakfast. Careful attention to frequent repositioning and skin care is essential, because edematous tissue breaks down easily. Particular attention should be given to the sacral area as a pressure point susceptible to skin break down for a patient on bed rest. Bed rest causes venous pooling, and DVT prophylaxis should be implemented. Elastic stockings or sequential compression devices and leg exercises should be used. Careful ongoing physical assessment is essential. Nursing interventions for selected problems in a patient with HF are summarized in [Nursing Care Plan 19-1](#). Instructional materials regarding smoking cessation are sent home with **all** smokers, and they are counseled about the importance of quitting smoking ([The Joint Commission, 2014](#)). *Tobacco treatment*, the term used by The Joint Commission, is a stand-alone core measure and is not specific to any one diagnosis because smoking cessation is key to control of many diseases. Discharge instructions include (1) activity level, (2) diet, (3) discharge medication,

(4) follow-up appointment, (5) weight monitoring, (6) what to do if symptoms worsen, and (7) when to notify the health care provider.

HF patients with left ventricular dysfunction (ejection fraction less than 40%) should receive a prescription for an ACE inhibitor or an ARB medication. Providing education about warning signs of worsening condition (decompensation), exercise needs, diet compliance, and lifestyle changes greatly helps symptom control ([Yancy et al, 2013](#)).

Evaluation

Patients with HF require extensive treatment with medication and lifestyle changes. Evaluate objective and subjective data to determine whether expected outcomes are being met. Note subjective data related to activity tolerance, respiratory status, comfort, and understanding of teaching related to the disease process and self-management. Understanding of the medication regimen is key to the patient's progress. The cardiovascular system should be monitored for improvement of status. Observe the patient for the improvement of symptoms, including edema, respiratory quality, and activity tolerance. Improvement is an indication of patient progress.

Cardiac Dysrhythmias

A normal heart generates electrical impulses and sends them through an electrical conduction system signaling the atria and ventricles to contract. An abnormal heart rhythm occurs when the conduction system or heart muscle is not functioning normally. The goal for a beginning nurse is to be able to determine when the tracing is not a normal sinus rhythm.

Etiology

Alterations in the conduction of cardiac electrical impulses that create heart rate and rhythm may be the result of congenital abnormalities, electrolyte disturbances, too much caffeine, illegal drug use, stress, or medication side effects. Valvular disorders, damage to the heart from **infarct** (area of necrosis caused by ischemia), thyroid problems, infective endocarditis, and problems in the autonomic nervous system also cause rhythm disturbances. Abnormal rhythms are called **arrhythmias** or **dysrhythmias**.

Pathophysiology

The sinoatrial (SA) node generates electrical impulses 60 to 100 times per minute. Each impulse travels through the atria to the atrioventricular (AV) node (or junction), which delays the impulse slightly then relays it via the bundle of His and the Purkinje fibers to the ventricles, causing them to contract ([Figure 19-4](#)). [Box 19-2](#) describes the procedure for evaluating an ECG strip. If the SA node fails to produce an electrical impulse, the AV node will initiate an impulse at 40 to 60 beats per minute. If neither the SA nor the AV node is functioning, the Purkinje fibers in the ventricles will initiate an impulse at a slower rate. When there is disruption of the normal electrical conduction in the heart, an abnormal heart rhythm occurs.

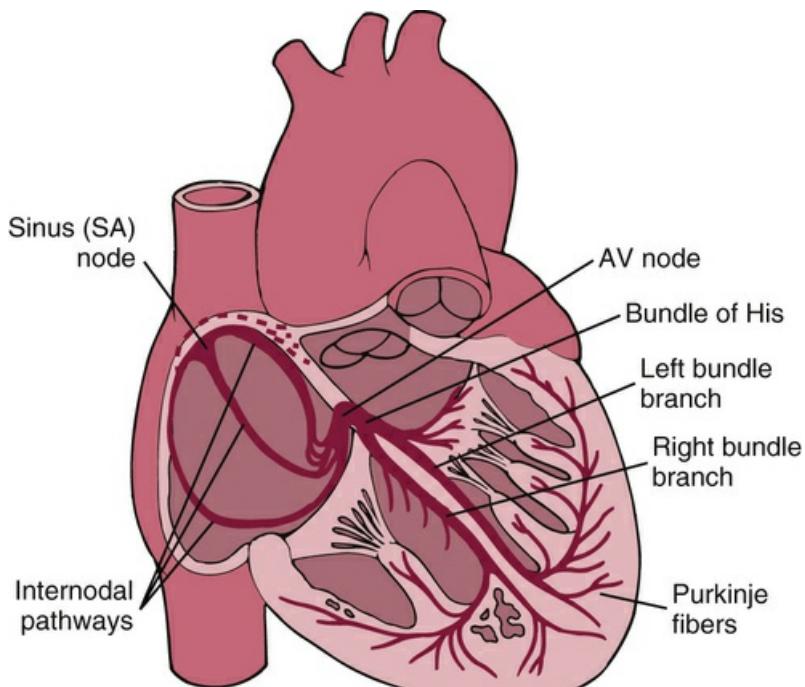

FIGURE 19-4 Cardiac conduction system. SA, sinoatrial; AV, Atrioventricular; (From Aehlert B: *EKGs made easy*, ed. 2, St. Louis, 2002, Mosby.)

Box 19-2

Evaluating an Electrocardiogram Rhythm Strip

- Obtain a 6-sec strip (35 large graph squares).
- Find the QRS. If the rate is too slow or too fast, check the patient before proceeding. Calculate the rate. Count the number of QRS complexes in the 6-sec strip and multiply by 10. Measure with calipers from R wave to R wave throughout the tracing to determine whether the rate is regular. Do all the QRS complexes look the same?
- Look directly in front of the QRS for the P wave. Is there a P wave in front of every QRS? Do the P waves all look alike? Measure the P-R interval. Is it normal (0.12 to 0.20 sec or 3 to 5 little boxes)? Does it vary?
- Measure the QRS duration. Is it normal (0.04 to 0.12 sec or 1 to 3 little boxes)?
- Are there any abnormal beats? Is the QRS wide or normal? Do the beats come in early?

Signs and Symptoms

Normal pulse rate is 60 to 100 beats per minute (bpm). Figure 19-5 shows the ECG pattern of normal sinus rhythm. A pulse below 60 is labeled *bradycardia*. Bradycardia may or may not be a problem. Athletes often have a bradycardia without a pathologic condition because their hearts are so well conditioned they are very efficient. Whether or not a bradycardia requires treatment depends on whether the patient has symptoms of decreased blood flow. Symptomatic bradycardia is treated with atropine or pacing. In an emergency, external pacing pads may be used until a different mode of pacing can be implemented.

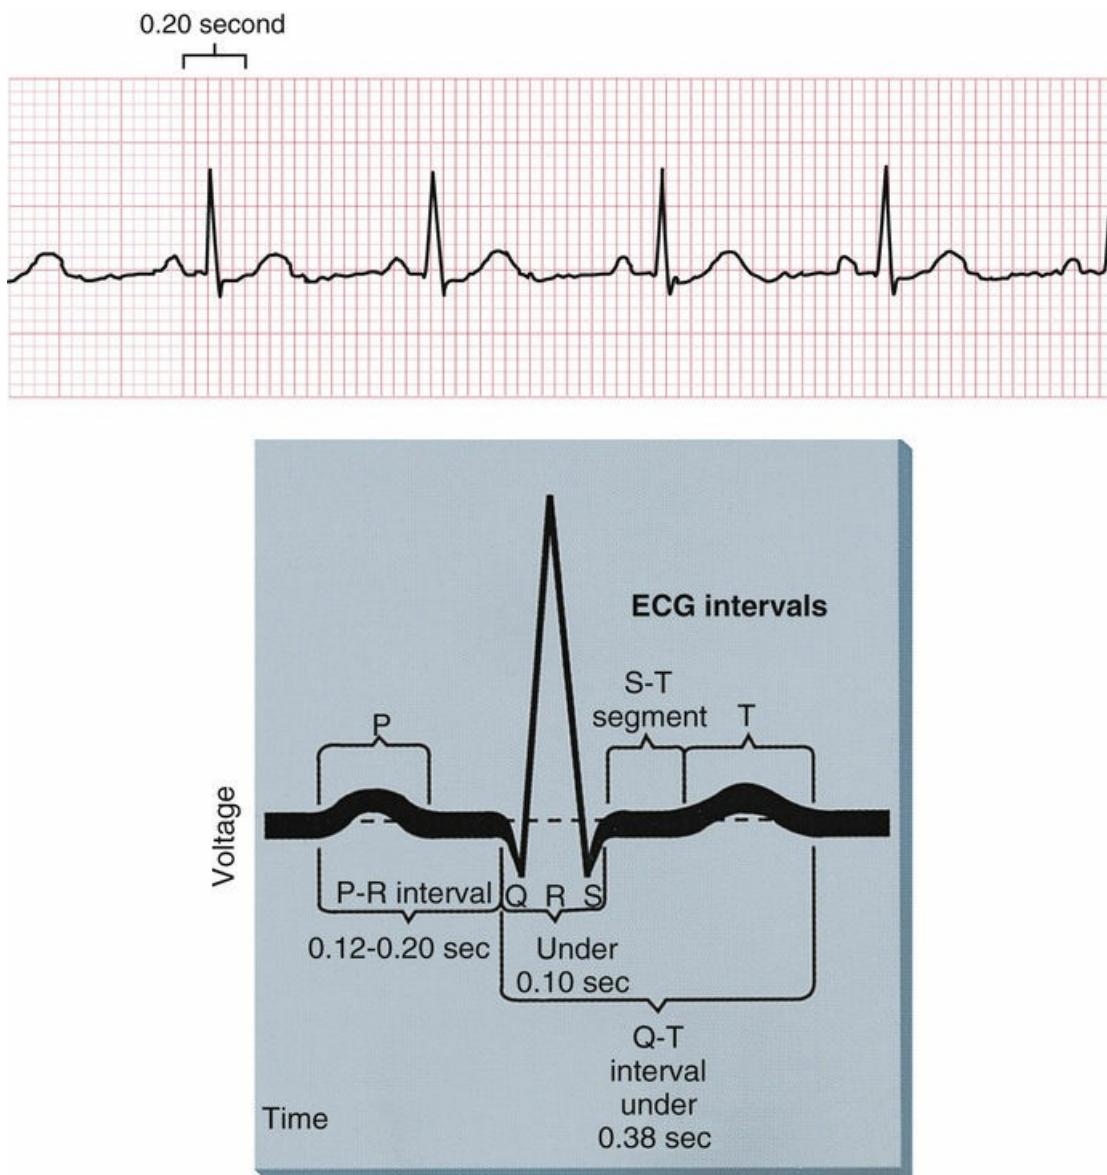

FIGURE 19-5 Electrocardiogram tracing of normal sinus rhythm. (From Aehlert B: *EKGs made easy*, ed. 2, St. Louis, 2002, Mosby.)

If the heart rate rises above 100, the patient has a dysrhythmia known as *tachycardia*. Sinus tachycardia with a rate of 100 to 150 bpm is usually caused by pain, fever, stress, hypovolemia, or hypoxia. Increasing heart rate is the body's response to the need for increased blood flow. It is managed by treating the underlying condition.

When the heart beats too fast, the ventricles do not have adequate time to fill with blood and therefore cannot pump effectively. As a result, cardiac output falls. Heart rates over 150 bpm are considered "too fast" for most patients. Again signs and symptoms of decreased blood flow determine how urgently treatment needs to be administered. When the heart is not stimulated to contract at the correct rate or in an effective manner, adequate blood is not pumped out to the body. Symptoms the patient may experience include dizziness, **palpitations** (abnormally rapid throbbing or fluttering of the heart), fatigue, chest pain, and loss of consciousness; death may occur. The severity of the symptoms depends on whether the abnormal rhythm significantly decreases cardiac output and whether the dysrhythmia is persistent.

It is important to be able to recognize a normal heart rhythm so that abnormalities can be quickly identified (see Box 19-2). The most important component in delivering appropriate treatment is assessment of the patient. The overall health of the patient will determine whether a specific dysrhythmia requires immediate reporting or treatment. Some rhythms are more likely than others to cause decreased cardiac output. The heart rate is the single best indicator as to how the patient

may be tolerating a heart rhythm. The ECG will give additional information about the specific source of the problem, but bedside assessment is key in delivering the correct therapy. The name of the rhythm indicates where the electrical impulse originated to cause the QRS. Sinus rhythms originate in the sinus node; for ventricular rhythms, an impulse starts in the ventricles.

As stated previously, a pulse rate below 60 is a bradycardia. The only time a bradycardia is treated is if the patient has symptoms of decreased cardiac output. The heart fills during diastole, which is the flat line part of the ECG. The amount of blood in the ventricles pumped out multiplied by the number of times per minute the heart pumps is cardiac output. If the heart does not beat enough times per minute to generate enough blood flow, then symptoms occur. Slow heart rates can be caused by hypoxia, electrolyte imbalances, infection, drugs, hypoglycemia, and other treatable conditions. There also may be disease of the conduction system causing the “pacemaker” of the heart—the SA node—to malfunction. **Sinus bradycardia** is the most common form of bradycardia. The rhythm looks like a normal sinus rhythm except for the rate. Conduction problems that produce bradycardia are heart blocks. Normally when the SA node fires it sends the electrical signal through the atria and then to the ventricles through the AV node (also called the AV junction). In heart block the signal is stopped either temporarily or permanently at the AV junction. Heart block is either first, second, or third degree. The higher the degree, the more significant the block and more likely it is to produce bradycardia.

In **first-degree heart block**, impulse conduction between the atrium and the ventricle is consistently lengthened beyond 0.2 seconds. First-degree block can be temporary or permanent. It often occurs after open heart surgery or an MI. Digoxin, calcium channel blockers, and beta blockers may cause this arrhythmia. It usually does not cause hemodynamically significant symptoms.

Second-degree heart block has two types. The first is Mobitz I or Wenckebach, which displays a normal R-R interval on the ECG and increasingly lengthened P-R intervals until a P wave appears without a QRS complex because the impulse was not conducted to the ventricles. This causes a “pause” in the rhythm. The cycle then begins again after the AV node has rested for that one beat. Parasympathetic tone or drug effect from digoxin, calcium channel blockers, beta blockers, or disorders such as electrolyte imbalance, Addison disease, and endocarditis are a few of the possible causes. The arrhythmia is most often transient and rarely progresses to third-degree heart block; it is considered benign.

Type II second-degree block (Mobitz II) is a more severe heart block. The AV node blocks certain beats from traveling through to the ventricles. P waves are seen without a following QRS. There may be a single or multiple P waves without a QRS. The P-R interval is constant throughout. The rhythm can be regular or irregular. This rhythm is dangerous, because it may progress to third-degree heart block and is most often caused by ischemia. This arrhythmia often occurs after open heart surgery. Bradycardia may be the result, and the patient may or may not be symptomatic depending on the ventricular rate. If the patient is symptomatic, a temporary transvenous pacemaker may be inserted, followed by a permanent pacemaker if needed.

In **complete heart block** (third-degree heart block; [Figure 19-6, B](#)) the AV node does not conduct atrial impulses to the ventricles. The atria contract on their own, and an “escape” stimulus from the ventricle provides a slow ventricular rhythm. Cardiac output falls drastically. This dysrhythmia can be life threatening, but it depends on the rate and how the patient is tolerating it.

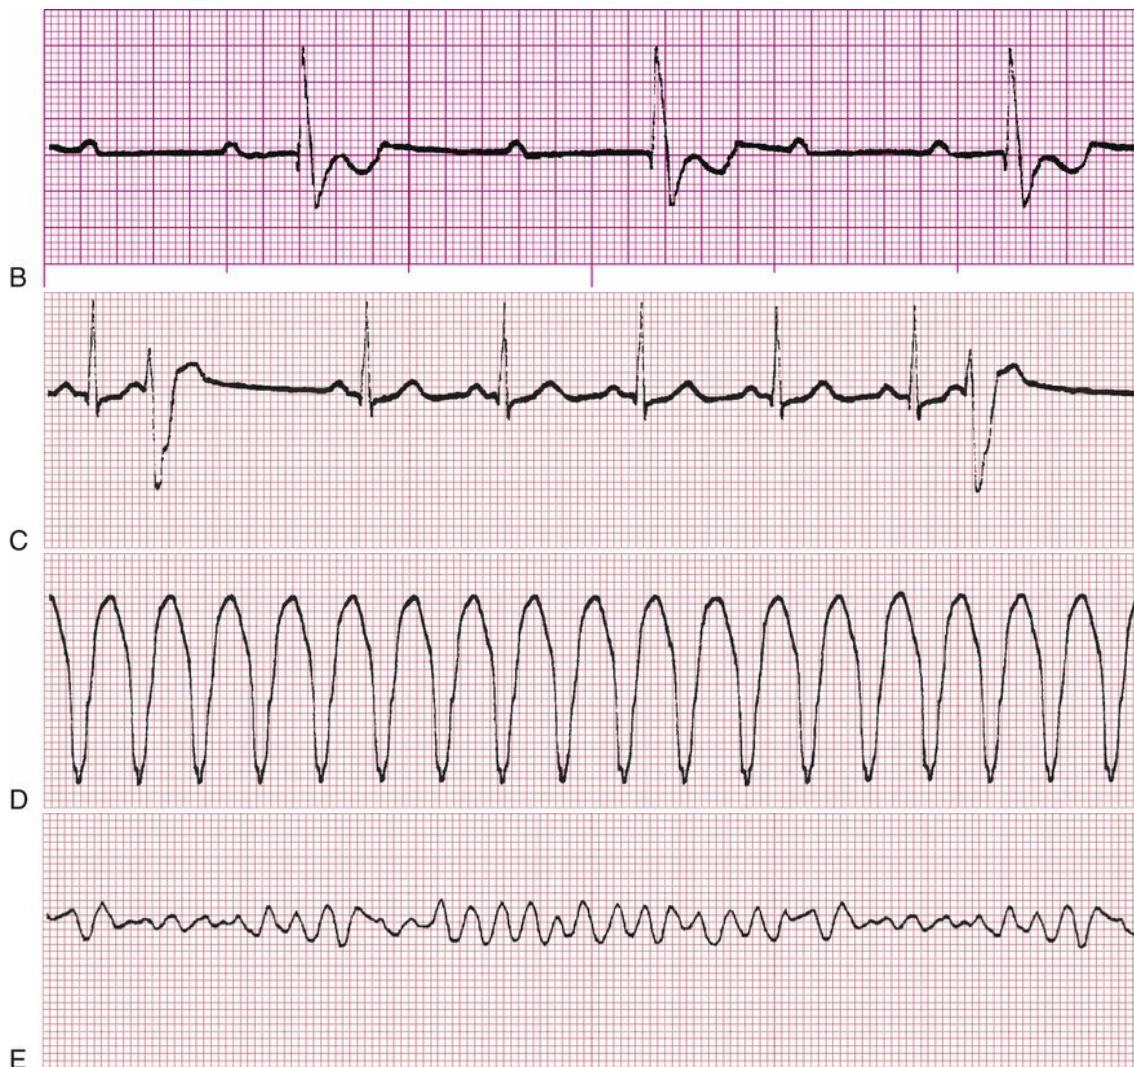

FIGURE 19-6 ECG patterns of abnormal and life-threatening dysrhythmias. **A**, Supraventricular tachycardia. **B**, Complete (third-degree) heart block. **C**, Sinus rhythm with premature ventricular contractions **D**, Ventricular tachycardia. **E**, Ventricular fibrillation. (From Aehlert B: *EKGs made easy*, ed. 2, St. Louis, 2002, Mosby.)

If a rhythm strip has more P waves than QRS complexes, the rhythm is Type I or Type II second-degree block or third-degree heart block. All bradycardia is treated the same, so initially, specific identification is not necessary to implement correct therapy.

Clinical Cues

Any time a person states she has noticed an irregular or rapid heartbeat, ask how much caffeine is being consumed each day. If consumption is minimal, ask about medications being taken, such as decongestants. Ask about the person's stress levels. The problem may disappear when the precipitating factor is removed.

Life-Threatening Cardiac Dysrhythmias

Any fast heart rate has the potential to be clinically significant. It is during diastole that the heart fills with blood. When heart rate increases, the time spent in diastole significantly shortens, reducing the time for filling to occur.

Supraventricular tachycardia (SVT) (see Figure 19-6, A) is a rhythm that originates in or above the bundle of His. (“above” the ventricles) SVTs include sinus tachycardia, atrial flutter or fibrillation, atrial tachycardia, and junctional tachycardia. The rate will be greater than 150 bpm and the QRS will be of normal duration. At this heart rate the origin of the impulse is almost impossible to identify, so the term *SVT* communicates that the rhythm is not ventricular tachycardia.

Ventricular tachycardia.

Ventricular tachycardia (VT) is a potentially life-threatening dysrhythmia that is generated from one or more focal points in the ventricle at a very fast rate (usually 120 to 200 bpm) (see [Figure 19-6, D](#)). The patient may be awake and alert without symptoms or just not feeling well. Or the patient may be pulseless. **The ECG tracing will not tell if the patient has a pulse; feel for the pulse.** VT occurs in bursts, short runs, or as a sustained rhythm. The length of time this rhythm continues and the underlying condition of the heart determine how well the body can tolerate it. The atria do not have a chance to contract and push blood into the ventricles. The ventricles contract too fast to allow for adequate filling with blood. Cardiac output falls drastically, and death may occur. VT can quickly deteriorate into ventricular fibrillation or cardiac standstill. Treatment depends on whether the dysrhythmia is sustained and how well the patient is tolerating the rhythm. Intervention with drugs such as amiodarone (Cordarone) is used to stabilize VT. If the patient is symptomatic with changes in BP, pulse, and level of consciousness, the VT is unstable; synchronized cardioversion starting at 100 joules (biphasic) is the treatment. If the patient is not unstable, treatment is with oxygen and amiodarone. It is usually caused by cardiac ischemia or one of the same causes as for PVCs. Cocaine use is another cause.

Atrial flutter/fibrillation.

New onset **atrial fibrillation** or flutter usually presents with a very rapid heart rate. In a normal heartbeat, the atria provide the “atrial kick,” which is about 20% of the blood volume for the ventricles to pump out. When atrial fibrillation happens, the atrial kick is lost, and the fast heart rate decreases filling time. Some patients are light-headed, have a decreased blood pressure, and are clammy. Atrial flutter may occur with HF, coronary artery disease, hyperthyroidism, or chronic obstructive pulmonary disease (COPD). Instead of atrial contraction there is quivering. P waves are not visible on the ECG tracing. There are only a lot of tiny, erratic spikes visible. Because the AV node cannot respond to the huge number of impulses, it conducts impulses to the ventricle in an erratic manner, resulting in irregular heart rhythm. The rhythm is **irregularly irregular**. Treatment is with loading doses of diltiazem or digoxin, amiodarone, or a beta blocker. If drug treatment is unsuccessful, synchronized cardioversion is performed to convert to a normal sinus rhythm.

Atrial fibrillation predisposes the patient to clot formation in the atria. The quivering rather than pumping of the atria allows blood to pool, leading to formation of clots. Patients with chronic atrial fibrillation are usually placed on oral anticoagulant therapy. Teach the patient the importance of taking the medication as directed by the provider. Dislodged clots from the right atrium can cause pulmonary embolus, and clots from the left side can travel to the brain, resulting in stroke or possibly death.

Premature beats (ectopic beats).

An extra heart beat that interrupts the regularity of the rhythm can be caused by an impulse coming from the atria, junction, or ventricles. Because they occur outside of the normal location, they are considered *ectopic*. They are usually beats that come in early and are labeled according to which part of the heart is responsible for the QRS.

Premature ventricular contractions.

The premature ventricular contraction (PVC) appears on the ECG as an early beat without a P wave and with a wide QRS complex. A ventricular impulse causes a ventricular contraction; it is labeled *premature* because it comes in early (see [Figure 19-6, C](#)). A pause usually occurs after the premature beat. The patient perceives a PVC as a skipped beat, because the PVC is not efficient at pumping blood and may not generate enough blood flow to be felt at a pulse point. An apical and radial pulse deficit may be detected. The ventricular irritability causing PVCs may be from caffeine, drugs, or increased emotional stress. Hypoxia, hypokalemia, and myocardial ischemia also may trigger PVCs. A few PVCs are not abnormal, but when there are more than six or seven in a minute, cardiac output may fall. If PVCs are persistent and symptomatic, antidysrhythmic drugs are used to control them ([Table 19-4](#)). Three or more PVCs in a row are considered to be ventricular tachycardia. PVCs may not all look alike. This indicates more than one area of irritability in the heart muscle. PVCs should be reported to the health care provider when they occur frequently or have multiple shapes or the patient has several in a row or shows signs of decreased cardiac output.

Table 19-4**Drugs Commonly Used to Treat Dysrhythmias**

Examples	Action	Nursing Implications	Patient Teaching
Class I Antidysrhythmics			
1A Quinidine sulfate Procainamide (Pronestyl, Procan) Disopyramide (Norpacing) 1B Lidocaine (Xylocaine) Phenytoin (Dilantin) Tocainamide (Tonocard) Mexiletine (Mexitil) Moricizine (Ethmozine) 1C Flecainide (Tambocor) Propafenone (Rythmol)	Uses: Atrial and ventricular dysrhythmias Actions: Slows the sodium channel, prolongs time of depolarization, and increases refractory period	<i>Quinidine:</i> Monitor for cinchonism: tinnitus, headache, nausea, vertigo, and disturbed vision. Observe for changes in ECG pattern. If patient is taking digitalis , monitor for digitalis toxicity; quinidine can double digoxin levels. Cimetidine increases effects of quinidine . Quinidine may enhance action of anticoagulants. Monitor for diarrhea. Monitor drug level. <i>Procainamide:</i> Monitor for systemic lupus erythematosus-like syndrome: joint pain; hepatomegaly; unexplained fever; soreness of the mouth, throat, or gums. Discontinue medication if this occurs. Observe for side effects or adverse effects of particular drug administered. Monitor electrolyte levels; watch for postural hypotension, especially if patient is taking antihypertensives.	Instruct to report signs of adverse effects of the drug. Report noticeable changes in cardiac rhythm to the provider. Advise to take quinidine with meals to prevent gastrointestinal (GI) upset. Advise to minimize citrus fruit intake; it changes the urine pH and decreases excretion of quinidine. Procainamide is absorbed best on an empty stomach; if GI upset occurs, instruct to take immediately after a meal.
Class II Antidysrhythmics (Beta Blockers)			
Propranolol (Inderal) Acarbose (Sectral) Atenolol (Tenormin) Carvedilol (Coreg) Esmolol (Brevibloc) Nadolol (Corgard) Sotalol (Betapace) Metoprolol (Lopressor, Toprol XL) Esmolol (Brevibloc)	Uses: Atrial and ventricular dysrhythmias Action: Slow sinoatrial nodal impulses	Monitor for signs of congestive heart failure (CHF); monitor pulse and blood pressure, watching for bradycardia and hypotension. Monitor electrolytes. Carefully monitor blood sugar in diabetic patients.	Instruct not to discontinue the drug abruptly. Notify provider if skin rash, confusion, fever, sore throat, or unusual bleeding or bruising occur. Monitor weight and report gain of >2 lb/wk. Report edema or shortness of breath.
Class III Antidysrhythmics (Potassium Channel Blockers)			
Amiodarone (Cordarone) Dofetilide (Tikosyn) Ibutilide (Corvert)	Uses: Supraventricular and ventricular dysrhythmias Actions: Increase the refractory period and action potential duration	Check for drug interactions and for side or adverse effects of specific drug administered. Monitor heart rhythm, blood pressure, and pulse. Monitor renal function.	Instruct to report adverse reactions to specific drug being taken. Advise of need for provider supervision. Report any new heart rhythm irregularities.
Class IV Antidysrhythmics (Calcium Channel Blockers)			
Verapamil (Calan, Isoptin, Verelan) Diltiazem (Cardizem)	Use: Paroxysmal supraventricular tachycardia (PSVT) Action: Converts PSVT to normal sinus rhythm by slowing conduction time through the nodes	Monitor heart rate and rhythm; watch for signs of CHF. Observe for hypotension and edema. Use very cautiously with beta blockers.	Instruct to report signs of edema, shortness of breath, or weight gain of >2 lb in 1 wk. Notify provider of new changes in heart rhythm.
Other Agents			
Atropine		Used to raise the heart rate, monitor rate and rhythm.	Explain goal of use.
Digoxin (Lanoxin)		Monitor heart rate for expected decrease.	Teach signs and symptoms of toxicity: visual changes, anorexia, nausea, vomiting, diarrhea, headache, confusion, new dysrhythmia.
Adenosine (Adenocard)		Monitor for expected decreased heart rate.	Monitor for dizziness, blurred vision, facial flushing, nausea, dyspnea, bronchospasm, new dysrhythmia, and chest pressure.
Magnesium		Used to correct digitalis toxicity, to aid in correction of ventricular dysrhythmias, and in cardiac arrest.	Monitor for muscle weakness, flushing, confusion, nausea, cramps, diarrhea, and circulatory collapse.

Premature atrial contractions.

Premature atrial contraction (PAC) happens when an ectopic electrical focus fires before the next SA node impulse is due, thereby depolarizing the atria. An abnormally shaped P wave appears on the ECG before the QRS wave. The impulse is routed to the AV node and then to the ventricles causing normal ventricular contraction. PACs are common and do not often produce symptoms. PACs result from sympathetic nervous system stimulation, such as occurs with anxiety, hypoxia, or ischemia. Early junctional beats can also occur and are called *premature junctional contractions (PJC)s*. They look much like PACs and are not within the scope of this text to discuss fully. They do not cause hemodynamic compromise and are difficult to distinguish from PACs.

Older Adult Care Points

With increased age the left ventricle and cardiac valves thicken and the amount of fibrous tissue and fat in the SA node increases, which decreases the number of pacemaker cells the SA node

contains. These changes make individuals older than 75 years more prone to cardiac dysrhythmias. Failure of the SA node and the need for a pacemaker are common. Thyroid studies should be performed for patients older than 65 years who have atrial fibrillation, because thyroid problems can be a cause. Hypothyroidism or hyperthyroidism may also aggravate HF.

Absent Pulse

Ventricular fibrillation.

Ventricular fibrillation (VF) is a chaotic random firing of all the ventricular cells. The ventricles quiver rather than contract; there is no cardiac output, and without cardiopulmonary resuscitation (CPR) and defibrillation, death will occur (see [Figure 19-6, E](#)). There is no pulse and no blood pressure. The ECG shows coarse electrical waveforms varying in size and shape, and no intervals can be determined. Immediate intervention is required.

Pulseless Electrical Activity

Sometimes the heart muscle is not capable of responding to the electrical signal with an effective contraction. Severe acidosis, electrolyte imbalances, profound hypovolemia, and other disorders keep the myocardium from contracting because of the toxic environment. The signal is sent and a QRS appears on the ECG, but there is no pulse. The rhythm on the monitor can be anything that would normally be expected to have a pulse generated. The most common rhythm displayed is sinus tachycardia. CPR and correction of the underlying disorder is the only way to regain a pulse.

There are many types of cardiac dysrhythmias. Nurses assigned to a critical care or telemetry unit take a special course in dysrhythmia recognition to learn the patterns, significance, and treatment of each type. All nurses should be able to recognize life-threatening dysrhythmias.

Diagnosis and Treatment

Disorders of the cardiac conduction system are diagnosed by a 12-lead ECG, by continuous ECG monitoring, and by patient history (see [Table 17-2](#)). Drug therapy is effective in correcting or controlling dysrhythmias in many cases. A variety of antiarrhythmic agents may be used alone or in combination to regulate the heartbeat (see [Table 19-4](#)). Oxygenation, acid-base status, and electrolyte balance are watched carefully and corrected as needed. Early recognition and correction of abnormalities decreases life-threatening dysrhythmias.

Synchronized cardioversion.

Patients who experience tachycardia or rhythms that do not respond to drug therapy may be treated with **synchronized cardioversion**. A mild electrical shock is delivered to the heart at a specific time in the cardiac cycle to interrupt the abnormal rhythm and begin a new, normal rhythm of electrical impulse and contraction. The patient is given a sedative before the procedure. Signed consent is required. The procedure may be performed in the cardiac catheterization laboratory or in the emergency department by the provider. Resuscitation equipment must be at hand. The patient must be monitored for response to treatment, including heart rate, rhythm, and blood pressure. If the rhythm has a sudden onset and the patient is unstable, synchronized cardioversion may be done emergently.

Cardiac pacemakers.

Cardiac pacemakers may be used to manage chronic and life-threatening dysrhythmias and are used to support heart rate when bradycardia occurs. Advances in pacemaker technology have led to units that are programmable for single- and dual-chambered control. A pacemaker can be used to pace the atria and one or both ventricles. Some units can override a dysrhythmia and keep the heart at a more steady rhythm. There are rate-responsive pacemakers, in which the pacemaker automatically adjusts to the patient's level of activity. When the patient exercises, the heart rate increases (similar to the normal SA node response).

Pacing can be a temporary measure if the problem is an emergent, transient condition, such as drug toxicity. An external pacemaker often is used in the emergency department. Electricity is passed through the chest wall via external pads. It causes uncomfortable muscle contractions as current passes through the chest, so it is only used until another mode of pacing is available.

A temporary transvenous pacemaker is placed if a transient rhythm such as heart block develops after an MI or drug toxicity. Transvenous pacemakers are inserted by fluoroscopy with local anesthesia. The leads are attached to an external power source. Patient consent is required, and a sedative is given to the patient before the procedure. Epicardial pacemaker wires are often placed during cardiac surgery for quick use should the patient need pacing in the postoperative period. The wires are brought through the chest wall and are attached to an external power source. When the wires are no longer needed, the surgeon will pull them out.

Clinical Cues

Patients are at risk for cardiac tamponade when the epicardial pacer wires are pulled. Monitor patients for signs and symptoms of bleeding into the pericardial sac, including sharp chest pain, dyspnea, hypotension, cyanosis, tachycardia, paradoxical pulse, and distended neck veins.

A permanent pacemaker is implanted for SA node dysfunction, heart block, or treatment of chronic HF. All pacemakers have the same function: to produce effective heartbeats. A permanent pacemaker is inserted in the operating room or cardiac catheterization laboratory to ensure an aseptic environment (Figure 19-7). The pulse generator is placed in a skin pocket below the right or left clavicle.

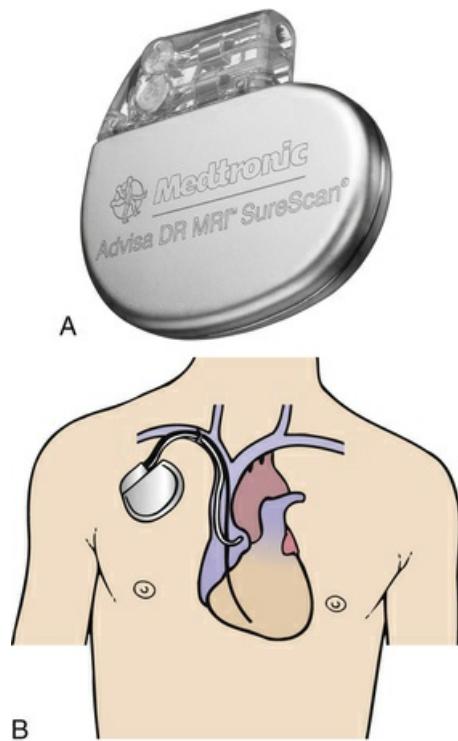

FIGURE 19-7 Thoracic placement of permanent pacemaker and transvenous pacing wires. **A**, Pacemaker. **B**, Placement of pacemaker and wires. (**A**, Reproduced with permission of Medtronic, Inc. **B**, From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 8, St. Louis, 2011, Mosby.)

Nursing Management

If inserting a pacemaker is not an emergency procedure, there will be opportunities to assess the patient's knowledge of and feelings about having her heart rate regulated. Assess the patient's learning needs, seek to identify the source of any fear, and gauge the level of anxiety.

Think Critically

How would you approach discussion with an older adult patient who is fearful of getting a permanent pacemaker?

Both the American Heart Association and the manufacturers of pacemakers provide illustrated booklets to help patients learn more about their cardiac pacers. You can go over these booklets with the patient and perhaps show her a demonstration model and explain how it works to her advantage.

Older Adult Care Points

Older patients who have SA node disease and resulting cardiac dysrhythmias can achieve a far better quality of life with an implanted pacemaker. Many patients are fearful of the surgery required and can benefit from talking to another patient who has had a successful pacemaker implantation.

Postoperative nursing care for patients with a permanent pacemaker includes continuous monitoring of heart rate, rhythm, blood pressure, and temperature. Patients are also monitored for hematoma formation at the site of insertion. Prophylactic antibiotic therapy may be prescribed for a short time. The battery in a pacemaker should last 6 to 9 years, depending on how frequently pacing is required.

Patient Teaching

Instructions for a Patient With a Permanent Pacemaker

A patient who has had a permanent pacemaker implanted should receive these instructions before discharge:

- Avoid lifting the arm away from the body on the pacemaker side until your provider says you may progress to normal activity. Lifting may dislodge the leads from their positions.
- Keep the incision dry for at least 4 days after the surgery.
- Check for redness, swelling, drainage, or fever and report such findings to your provider immediately.
- Refrain from activities that might cause a direct blow to the pacemaker.
- Use cellular or cordless phones on the ear opposite the pacemaker.
- Stay away from high-output electrical generators or large magnets such as a magnetic resonance imager. Such devices can interfere with pacemaker function.
- Monitor your pulse daily and report to the provider if it drops below the set rate.
- Carry a pacemaker information card with you at all times.
- Wear a medical alert bracelet or necklace at all times.
- Keep follow-up appointments with your provider to check the insertion site and to check pacemaker function.
- **Microwave ovens are safe to use, and airport security screening should not cause a problem with the function of the pacemaker. Travel is not restricted.**

The patient must understand the importance of periodic evaluations of her condition for the rest of her life. Some pacemakers have a telephone monitoring device that allows calling a monitoring station to have the pacemaker checked or a telemetry device that sends a report automatically every

night. Instructions for the use of the pacemaker and monitoring device are included in the owner's manual.

Implantable cardioverter-defibrillators.

Implantable cardioverter-defibrillators (ICDs) are used for patients who have an episode of a life-threatening dysrhythmia. They are also indicated in some patients with cardiomyopathy and decreased ejection fraction that are at increased risk of lethal dysrhythmias. The defibrillator is implanted in the same way as a pacemaker. The pulse generator is slightly larger than that for a regular pacemaker because it requires a high-capacity battery. ICDs monitor the heartbeat and provide an electrical shock similar to that delivered in cardiac defibrillation or cardioversion when a life-threatening rhythm is detected. Most ICDs have the ability to pace as well as defibrillate. The patient is warned to avoid exposure to strong magnetic fields such as microwave towers, transformers and electrical transmitters, electrical generators, handheld security devices at airports, and arc welding equipment. The patient should not lean over the alternator of a running car or boat motor. A magnetic field will temporarily inactivate the device. Moving away from the magnetic source will restore normal function.

Radiofrequency catheter ablation.

When drugs will not control supraventricular or ventricular tachydysrhythmia, the irritable focus can sometimes be destroyed with radiofrequency catheter **ablation**. Electrophysiologic studies are completed in a specially equipped cardiac catheterization laboratory to pinpoint the irritable focus. A specially trained provider then uses radiofrequency waves to destroy the irritable focus via heat and subsequent scarring. The procedure may affect the normal conduction system, requiring the implantation of a permanent pacemaker.

Inflammatory and Infectious Diseases of the Heart

The tissues of the heart are subject to the same inflammatory conditions that affect other parts of the body. The inflammation may be present in the inner lining (**endocarditis**), the heart muscle (myocarditis), or the sac surrounding the heart (pericarditis). Inflammation may be from an infectious source or from a noninfectious cause.

Infective Endocarditis

Etiology

Infective endocarditis (IE) is an infection of the endocardial surface of the heart. It may affect the heart valves, the walls, or a septal defect in the heart. IE was formerly called *bacterial endocarditis* (BE), or *subacute bacterial endocarditis* (SBE), but it can be caused by organisms other than bacteria. When the wall of the heart is affected, **myocarditis** is present. Myocarditis is most often caused by the Coxsackie virus but can be caused by a toxin or inflammation from an autoimmune disorder.

Infective endocarditis may be caused by bacteria, viruses, or fungi. Ports of entry are the oral cavity, particularly with dental procedures; the skin, from surgery or invasive procedures; and from infections in the body. Intravenous drug use with unclean needles is a major cause of endocarditis. Patients with irregularity or injury to the endocardium are at risk for organisms to stick to the surface and grow. Rheumatic fever causes injury to the heart valves. The heart valves are covered by the endocardium.

Older Adult Care Points

Systemic infections of the respiratory tract, urinary tract, gastrointestinal tract, or skin often are the causes of endocarditis in older adults. The immune system function decreases with age, making older adults more susceptible to IE. Diagnosis is difficult because symptoms are usually vague. The aortic valve is most often affected.

Although antibiotics—particularly penicillin—have decreased the incidence of rheumatic fever, the danger is still present. Throat culture should be performed any time there is a question whether group A beta *Streptococcus* is the organism responsible for a sore throat. If the streptococcal infection is treated early with antibiotics, inflammation in the heart and heart valve injury is usually prevented.

Pathophysiology

The inflamed tissues of the heart become rough and swollen. The inflamed tissue traps organisms. The bacterial growth on the valves are called *vegetations*. Vegetations decrease the effectiveness of the valve. Damage to the valve from bacteria may require valve replacement. The mitral valve is the most common location of infection (Figure 19-8). Arterial emboli may occur if pieces of the vegetation break off and travel. As mentioned previously, where an embolus lodges depends on the side of the heart from which it emerges: Emboli from the right side of the heart become pulmonary emboli; those from the left side of the heart can lodge in the brain or coronary vessels or can affect other organs of the body.

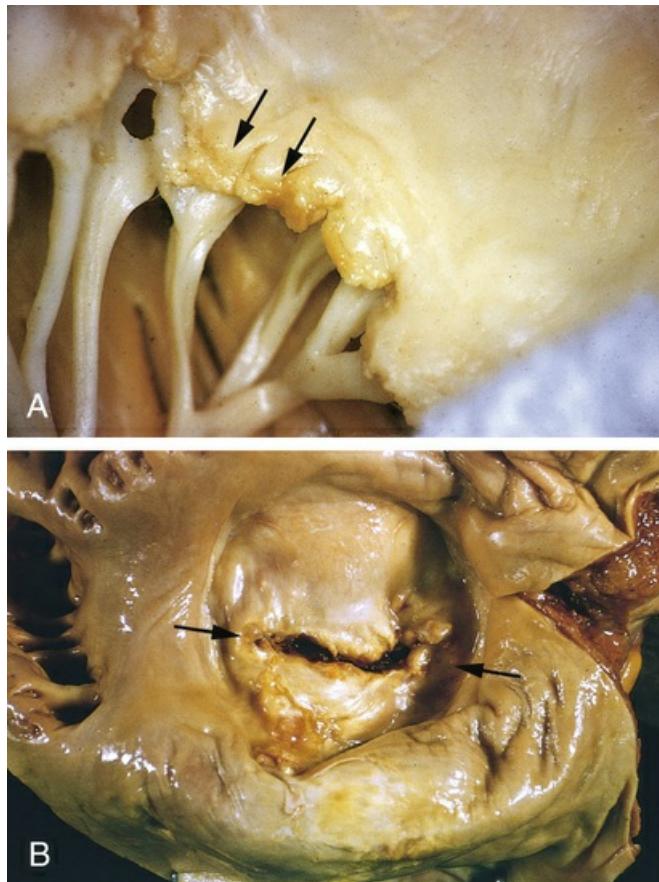

FIGURE 19-8 **A**, Thickening and valve leaflet distortion from infection and inflammation of the endocardium. **B**, Mitral stenosis. (From Kumar V, Abbas A, Fausto N: *Robbins & Cotran's pathologic basis of disease*, ed. 7, Philadelphia, 2005, Saunders.)

Signs, Symptoms, Diagnosis, and Treatment

The signs and symptoms of IE vary considerably. The sedimentation rate or C reactive protein and leukocyte count are elevated, and signs of low-grade intermittent fever are evident. A blood culture will be positive. The spleen becomes enlarged. Splinter hemorrhages (thin black lines) can occur under the nails, and there may be petechiae (pinpoint red spots) inside the mouth, in the conjunctivae, and above the clavicles. Echocardiography or transesophageal echocardiography (TEE) confirms the diagnosis. Fatigue, chills and sweats, malaise, anorexia, muscle aches, and headache may occur.

An existing cardiac murmur may worsen, or a new murmur may appear as a valve is damaged. Cardiac dysrhythmia may appear. There may be complaints of sharp, stabbing chest pain. Each instance of endocarditis further damages the heart valves. The scar tissue that occurs as the inflammation subsides may cause the valve to leak, resulting in regurgitation (lack of closure), or the valve leaflets may become thickened and calcified, causing narrowing or stenosis. The mitral and aortic valves are most commonly affected. When mitral or aortic stenosis or regurgitation causes symptoms sufficient to interfere with the patient's usual lifestyle, surgery becomes necessary. Stenosis and regurgitation of cardiac valves may eventually cause HF.

Older Adult Care Points

The valve leaflets thicken with age; this gives rise to the common systolic murmur heard in persons older than 80 years. This murmur does not indicate cardiac inflammation.

Treatment for IE is with antibiotics for underlying infection. NSAIDs are used to decrease inflammation. Pain medication is provided. Medications for dysrhythmia and HF are administered for those complications. Repair of congenital cardiac problems, such as atrial or ventricular septal

defect, may be performed.

Safety Alert

Infective Endocarditis

Streptococcus viridans, a bacterium found in the mouth, is responsible for about 50% of cases of infective endocarditis. Regular dental care is very important. The health care provider should be advised of all cardiac history before any invasive procedure so that appropriate prophylactic treatment can be provided.

Pericarditis

Pericarditis is inflammation of the pericardium (the sac that encloses the heart). Pericarditis may be caused by cancer and its treatment, systemic connective tissue disease, infectious organisms, renal failure, trauma, or tissue damage from an MI. The serous fluids that typically are produced by inflammation may cause an **effusion** (accumulated fluid) in the pericardium. If the effusion becomes large, it can affect the filling of the heart and the cardiac output. Should the fluid become excessive, **cardiac tamponade** may occur as the fluid restricts the filling and pumping of the heart (Figure 19-9). If unresolved, the heart cannot supply the body with needed oxygen and nutrients and death occurs.

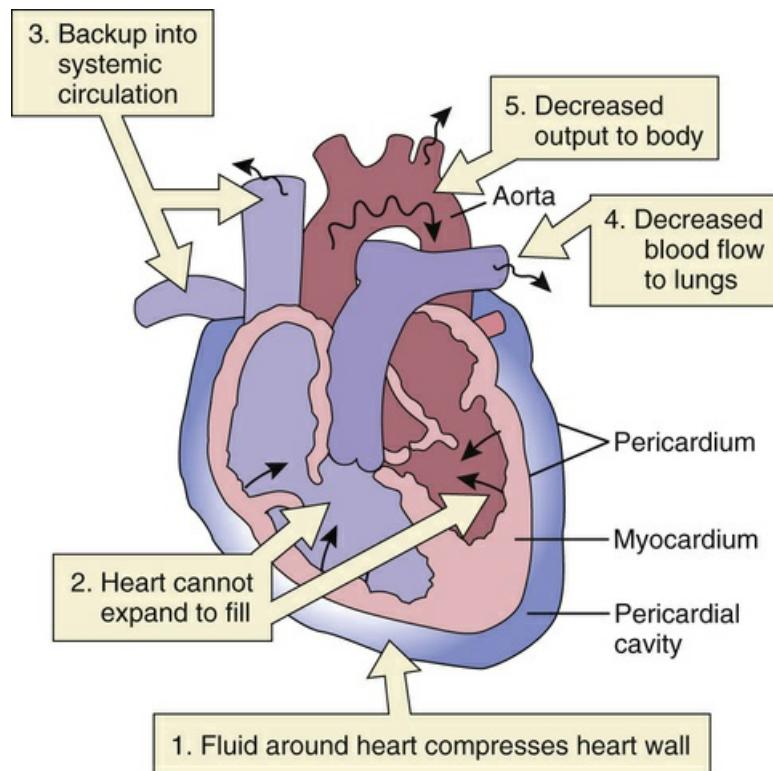

FIGURE 19-9 Effects of pericardial effusion. (From Gould BE: *Pathophysiology for health professions*, ed. 2, Philadelphia, 2002, Saunders.)

Symptoms of pericarditis include fever, tachycardia, chest pain eased by sitting up and leaning forward, dyspnea, and a pericardial **friction rub**. The rub is a high-pitched scratchy sound heard with the diaphragm of the stethoscope placed at the left sternal border at the third intercostal space. The ECG will show changes.

Dressler syndrome is pericarditis with effusion occurring from inflammation after an MI. It appears 1 to 12 weeks after infarct. When effusion is present, there may be malaise and fatigue related to decreased cardiac output and decreased perfusion of the tissues with oxygen. Assess for

fever, muffled heart sounds, tachycardia, restlessness, anxiety and confusion, distended neck veins, and **pulsus paradoxus**—a drop in systolic blood pressure greater than 10 mm Hg on inspiration. This can be noted when measuring the blood pressure.

Diagnosis of pericarditis is made by history and physical examination and confirmed by ECG, echocardiogram, computed tomography (CT) scan or MRI, and laboratory studies of C-reactive protein (CRP), CBC, and erythrocyte sedimentation rate (ESR). **Pericardiocentesis** will be performed at the bedside if effusion is interfering with cardiac output. The fluid extracted is analyzed to determine a cause of the inflammation. Restrictive pericarditis may be treated by **pericardiotomy** and creation of a window in the pericardium. Pain is controlled with medication.

Think Critically

Which patients should you watch for signs of pericarditis?

Cardiomyopathy

Cardiomyopathy is a group of diseases that affect the structure or function of the heart. The risk of cardiomyopathy is increased in systemic hypertension, with chronic excessive alcohol intake, during pregnancy, and in those who have had a systemic infection. The heart enlarges and becomes an inefficient pump. There are three main types of cardiomyopathy: dilated, hypertrophic, and restrictive (Box 19-3).

Box 19-3

Three Main Types of Cardiomyopathy

Dilated

Characterized by extensive enlargement of the ventricles with impairment of contraction. Causes include chemotherapy, alcohol abuse, infection, inflammation, poor nutrition, and connective tissue disorders. Advances to heart failure.

Hypertrophic

Increased growth of left ventricle muscle. May be hereditary as an autosomal dominant gene or be caused by hypertension or hypoparathyroidism. Sudden death may occur.

Restrictive

Stiffened ventricles prevent adequate relaxation after systole, affecting ventricular filling. Caused by systemic diseases such as amyloidosis or sarcoidosis. Progresses to right-sided heart failure. Is the least common of the three types of cardiomyopathy.

The major problems exhibited by patients with cardiomyopathy are HF and dysrhythmias. Signs and symptoms of cardiomyopathy include dyspnea, activity intolerance, angina, dizziness, hypertension, and palpitations. Diagnosis is made through history and chest x-ray, cardiac catheterization, echocardiography, ECG, or MRI/CT scans. Medical treatment for cardiomyopathy includes drugs to increase contractility (such as digoxin), antihypertensive drugs, diuretics, antiarrhythmic drugs, and anticoagulants. Severe cardiomyopathy can be rapidly fatal. These patients are possible candidates for a heart transplant. Because of the possibility of cardiac arrest, families are taught CPR. In later stages, an LVAD may be used to rest the heart or as a bridge to heart transplant. An LVAD can be external or can be implanted. The patient may have an ICD implanted.

Clinical Cues

Takotsubo cardiomyopathy, also known as *broken heart syndrome* or *stress cardiomyopathy*, can occur abruptly in patients with no underlying cardiac disease. Signs and symptoms are similar to an acute MI and can only be diagnosed when a left heart catheterization is performed. No coronary blockages are found, the ejection fraction is reduced, and there is evidence of dysfunction of the left ventricle. The images obtained of the left ventricle show a similar shape to a Japanese ceramic

octopus trap, a takotsubo. The dysfunction is believed to be caused by increases in circulating hormones such as adrenaline that are released with stress. Most patients recover without long-term consequences.

Nursing Management for Infectious and Inflammatory Heart Disease

Complete a thorough history and physical examination and document all data as a baseline assessment. Any abnormalities should be noted and included in the nursing care plan. Assess heart sounds carefully. Assess vital signs on a regular basis and note abnormalities. The patient may experience an elevation in temperature in addition to changes in heart rate and rhythm. Adherence to the prescribed medication regimen is essential to care. Ordered medications must be given on schedule. The teaching plan should include information about the drugs, as well as detailed information about the specific disease process. Activity restrictions are determined by patient tolerance. Make the patient as comfortable as possible and reinforce the rationale for the prescribed activity level. Oxygen administration may be required; discuss the importance of this treatment with the patient. Include evaluation of the patient's physical status, assessment of the patient's understanding of the home care requirements, and teaching related to medications and treatment in discharge planning. Home IV antibiotics may be required for weeks after discharge. Advise that prophylactic antibiotic therapy is necessary before dental procedures that involve gingival manipulation or bleeding. If the patient is at high risk for IE, prophylaxis may be needed before other invasive procedures.

Think Critically

Can you describe why it is important to assess a patient with IE for lung, brain, and abdominal organ abnormalities?

Cardiac Valve Disorders

Mitral and aortic valve disorders are the most common cardiac valve disorders. Tricuspid and pulmonic valve problems are rare. Tricuspid problems are usually from IV drug abuse or rheumatic fever. Pulmonic stenosis is congenital. In addition to congenital abnormalities, untreated hypertension, MI, and IE can cause cardiac valve disorders. The AHA published guidelines for valvular heart disease in 2014. Valve disorders are staged, and treatment recommendations are made according to the severity of the disease.

Mitral valve prolapse (MVP) occurs when the valve leaflets and tendonlike cords supporting the valve weaken and prolapse into the left atrium during systole. This is most often a benign condition. MVP is typically asymptomatic but can cause chest pain, palpitations, exercise intolerance, or fainting. A mid-systolic click heard at the apex is characteristic of MVP.

Mitral Stenosis

Mitral stenosis is most commonly caused by rheumatic fever. This disorder is occurring less frequently as the incidence of rheumatic fever from Group A *Streptococcus* declines. Other causes are systemic lupus erythematosus, rheumatoid arthritis, and related conditions. Valve leaflet thickening and calcification cause stiffening. Left atrial pressure rises, and the left atrium dilates, causing back-up pressure in the lungs. Pulmonary pressure increases, pulmonary congestion occurs, and over time the right ventricle hypertrophies.

The first symptom may be dyspnea on exertion. Paroxysmal nocturnal dyspnea (sudden dyspnea at night), palpitations of atrial fibrillation, and a dry cough may occur. If untreated, right-sided HF may eventually occur. Atrial fibrillation may be present. A diastolic murmur that is rumbling is heard on auscultation. Treatment is based on the stage of mitral stenosis identified by intracardiac pressures and clinical symptoms.

Mitral Regurgitation (Insufficiency)

Rheumatic heart disease is the main cause of mitral regurgitation. Papillary muscle rupture from ischemic heart disease, a congenital anomaly, and infective endocarditis are other causes. Fibrosis and calcification, other causes or insufficiency, prevent the valve from closing completely during systole. Backflow of blood into the left atrium occurs as the ventricle contracts. In diastole, the blood flows back into the left ventricle along with the normal blood flow. This increased volume must be ejected with the next contraction. The left ventricle and left atrium dilate and hypertrophy to accomplish the ejection. More women than men develop mitral regurgitation.

Symptoms take decades to emerge. Fatigue and weakness from reduced cardiac output are early signs. Dyspnea on exertion and orthopnea are later developments. There may be complaints of palpitations, anxiety, and atypical chest pain. Atrial fibrillation may occur. Right-sided HF causes jugular venous distention, hepatomegaly, and pitting edema. Auscultation at the apex reveals a high-pitched systolic murmur. A third heart sound occurs when regurgitation is severe.

Aortic Stenosis

Aortic stenosis is the most common valve disorder in the United States. Atherosclerosis with degenerative calcification of the valve is a common factor in older adults. Congenital valve malformations and rheumatic fever are causes in younger patients. The aortic valve opening narrows and obstructs left ventricular outflow during systole. The increased pressure required to eject the blood causes left ventricular hypertrophy. Eventually cardiac output is decreased to the point that the body's demands cannot be met during exertion. Systolic HF begins, and pulmonary congestion produces symptoms. When the pressure gradient across the valve is significantly increased and the ejection fraction decreases, aortic valve replacement is recommended (Nishimura et al, 2014).

Dyspnea, angina, and syncope on exertion are classic symptoms of aortic stenosis. Later, extreme fatigue, weakness, and peripheral cyanosis become apparent. A narrowed pulse pressure is found when blood pressure is measured. Auscultation reveals a systolic crescendo-decrescendo murmur.

Older Adult Care Points

Older adults with long-term hypertension are at risk for aortic stenosis because of increased atherosclerosis and stiffening of the aorta. Carefully assess the aortic valve sounds of older adult patients, especially if hypertension is not well controlled.

Aortic Regurgitation (Insufficiency)

Infective endocarditis, congenital abnormalities, long-term hypertension, and Marfan syndrome (a rare genetic connective tissue disease) are factors in aortic regurgitation. The valve leaflets do not close properly during diastole, allowing backflow of blood from the aorta into the left ventricle. The left ventricle dilates and hypertrophies from the greater blood volume.

Symptoms do not appear until left ventricular failure happens. Dyspnea on exertion, orthopnea, and paroxysmal nocturnal dyspnea begin. Nocturnal angina with diaphoresis and palpitations particularly when lying on the left side occur late in the disease. The pulse is bounding, and pulse pressure is widened with increased systolic pressure and decreased diastolic pressure. On auscultation there is a high-pitched, blowing diastolic decrescendo murmur.

Treatment of Valve Disorders

Treatment depends on the valve affected and the degree of impairment. Yearly monitoring and drug therapy for symptoms is standard when disease is not severe. Later, heart surgery for valve replacement may be needed. Newer techniques allow for an endovascular approach to some valve replacements or repair.

Medical Treatment

Diuretics, beta blockers, digoxin, and oxygen along with rest are used to improve symptoms of HF and dysrhythmias. Prophylactic antibiotics are no longer recommended for aortic valve stenosis. Atrial fibrillation is corrected with drug therapy and/or cardioversion. If atrial fibrillation cannot be converted to a normal sinus rhythm, drugs such as amiodarone (Cordarone), procainamide (Pronestyl), or a beta-blocking agent may be prescribed to slow ventricular response rate. Patients with chronic atrial fibrillation are prescribed regular anticoagulant therapy. Medical treatment is not the treatment of choice. Interventional procedures are the only effective treatment for the problem.

Surgical Treatment

When valvular disease becomes severe, surgery is required to correct the problem. Reparative procedures are becoming more common. Balloon valvuloplasty is sometimes used to open stenosed valves. It is performed with a balloon-tipped catheter. The catheter is threaded via the femoral artery into the heart and to the diseased valve. The balloon is inflated to enlarge the opening, then is deflated and removed. However, it is questionable as to how long the valve will stay open. Often the stenosis recurs within 6 months.

Direct commissurotomy occurs during cardiopulmonary bypass with open heart surgery. Thrombi are removed from the atria and the leaflets are incised, along with calcification debridement. This opens the valve orifice.

Mitral valve annuloplasty (reconstruction) is performed for acquired mitral regurgitation. The valve ring (annulus) that attaches to the leaflets and supports them is made smaller with sutures or tucks. Leaflets are repaired as well to provide good closure of the valve at systole.

Valve Replacement

Replacement may be performed as an open heart procedure with cardiopulmonary bypass or as minimally invasive surgery. Many mechanical (prosthetic) and biologic (tissue) valves are available (Figure 19-10). Mechanical valves require lifetime anticoagulation postoperatively because of the possibility of clot formation. Biologic valves may be from a pig (porcine), from a cow (bovine), or from a human cadaver. Biologic valves do not require postoperative anticoagulation therapy. Biologic valves tend to wear out in about 15 years, requiring replacement. Mechanical valves are more durable. The aortic valve is always replaced with a mechanical valve because of the high

pressure in the aorta.

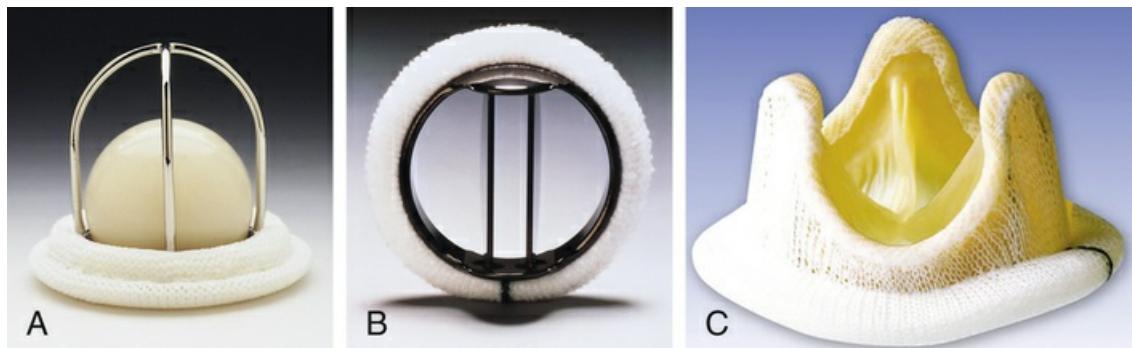

FIGURE 19-10 Examples of mechanical and biologic tissue valves for valve replacement. **A**, Starr-Edwards caged ball valve. **B**, St. Jude bileaflet valve. **C**, Carpentier-Edwards porcine valve. (From Bonow RO, Mann DL, Zipes DP, Libby P: *Braunwald's heart disease: A textbook of cardiovascular medicine*, ed. 9, Philadelphia, 2012, Saunders.)

Transcatheter aortic valve replacement is an emerging technology that allows for replacement of the aortic valve via a percutaneous approach rather than a thoracotomy. A catheter is threaded from the groin (or other arterial access site) through the aorta to the aortic valve. A valvuloplasty is performed on the stenotic valve. The replacement valve is then carefully positioned and deployed. The patient is sedated and the procedure is performed in a hybrid operating room/cath lab suite.

Nursing Management for Cardiac Valve Disorders

The primary nursing goals for patients with cardiac valve disease are to maintain adequate cardiac output, to control dysrhythmias, and to prevent or control HF. Assessing the patient for signs of developing HF, teaching the patient about prescribed medications, and preparing the patient for surgical procedures should all be included in the nursing plan of care. See [Chapter 17](#) for common problems and interventions for complications related to valve problems.

Valve surgery is most often an elective procedure. Preoperative and postoperative care is very similar to that of coronary artery bypass graft surgery (see [Chapter 20](#)). Patients taking anticoagulation drugs preoperatively must stop taking them about 72 hours before the procedure. Any needed dental work is obtained before the valve replacement to decrease the chance of infective endocarditis.

Patients with mitral stenosis may have pulmonary hypertension and stiff lungs. Postoperatively, respiratory status must be monitored very closely during weaning from the ventilator. Patients undergoing aortic valve replacement are at higher risk of postoperative hemorrhage. Be particularly alert for bleeding. Monitor cardiac output closely and watch for signs of HF. Fatigue is a common problem during convalescence. Rest and activity must be balanced carefully. For those with a mechanical valve, teach about the care needed when taking an anticoagulant.

Common Therapies and Their Nursing Implications

The medical treatments most commonly used to manage heart disease include (1) oxygen therapy, (2) pharmacologic agents, (3) surgical and interventional procedures, and (4) dietary controls.

Education and rehabilitation of the cardiac patient also must be included in the plan of care.

Surgical treatment of cardiac conditions most often is used to correct structural defects of the heart and great vessels. Interventional procedures correct blockages, repair structures, or are for implantation of therapeutic devices.

Oxygen Therapy

Administering supplemental oxygen to relieve the dyspnea and hypoxemia of a cardiac patient is a routine therapeutic measure. Any patient experiencing chest pain is started on low-dose oxygen. Responsibilities regarding oxygen therapy for a cardiac patient are primarily concerned with observation to determine a patient's need for supplemental oxygen, maintenance of the ordered flow rate, and the response to therapy once oxygen has been initiated. It is important to be alert for signs of changing oxygen needs, such as increased pulse rate and symptoms of cerebral anoxia, including irritability, confusion, and disorientation. The patient's oxygen saturation can be monitored by pulse oximetry or by blood gas analysis.

Clinical Cues

The patient's PO_2 should be maintained between 95% and 99%. If PO_2 falls lower than 93% consistently, notify the provider. Oxygen saturation by blood gas determination should be 94 to 100 mm Hg. Patients with a history of pulmonary disease such as emphysema may normally exhibit an oxygen saturation between 89% and 92%.

Pharmacologic Agents

Many types of drugs are used to treat heart disorders (see Tables 19-3 and 19-4). Digitalis in its various forms is a widely prescribed drug. However, it is a potent drug that can produce serious toxicity. **Classic symptoms of digitalis toxicity are yellow-green halos around lights, nausea, diarrhea, and confusion.** Digitalis can be very effective in treating certain kinds of cardiac disorders, but its therapeutic range is quite narrow. A therapeutic dose is only about one third less than the dose that will induce toxicity. A recent study (Freeman et al, 2013) suggests that use of digoxin in systolic HF may be contraindicated. Moreover, physiologic changes resulting from age, electrolyte imbalances (particularly hypokalemia or hypercalcemia), renal impairment, metabolic disturbances, and certain heart conditions can predispose a patient to digitalis toxicity. Other drugs given simultaneously, including erythromycin, also can alter the effects of digitalis and make it more toxic. Both beta blockers and calcium channel blockers will lower the heart rate, and beta blockers may cause pedal edema.

Clinical Cues

Remember that digitoxin has a slower and more prolonged action and is 10 times more potent than digoxin. **For this reason, digitoxin and digoxin are not interchangeable.**

Some providers may not want a dose of digitalis held if the patient's pulse rate is below 60 bpm, as long as there are no signs of digitalis toxicity. If the pulse rate is less than 60, check the provider's order before administering the medication.

When life-threatening complications arise from digitalis toxicity, digoxin immune Fab is given to counteract the excess digitalis. This drug is used cautiously, because side effects include hypotension, hypokalemia, worsening of HF, and rapid ventricular rates if the patient is experiencing atrial fibrillation.

Think Critically

Can you list four signs and symptoms that might indicate your patient is experiencing digitalis toxicity?

Anticoagulants are prescribed to inhibit the formation of clots within blood vessels and the heart. Anticoagulants do not dissolve clots that have already formed, but they can prevent existing ones from growing larger and can interfere with the development of new clots. Long-term anticoagulant therapy is necessary for patients with chronic atrial fibrillation or mechanical valve replacement.

Dietary Control

The National Heart, Lung, and Blood Institute cites obesity as a risk factor for cardiac disorders. When obesity is present in conjunction with other factors, such as metabolic syndrome, hypertension, high cholesterol levels, diabetes mellitus, smoking, or family history of heart disease, the likelihood of cardiovascular problems is increased.

Many health professionals consider self-help groups to be most successful in assisting people to lose pounds and then to keep their weight within normal range once the excess is lost. These groups include Weight Watchers, TOPS (Take Off Pounds Sensibly), and Overeaters Anonymous. Results of studies have shown that the behavior-modification techniques these groups use are very successful. To prevent heart disease and decrease the factors that predispose one to cardiovascular disease, the American Heart Association recommends the following measures.

Health Promotion

Heart-Healthy Lifestyle Recommendations

- With daily activities plus exercise, use up as many calories as you consume. To calculate, multiply current weight by 15 if moderately active; if sedentary, multiply weight by 13.
- Follow a heart-healthy diet (see Guidelines for a Heart-Healthy diet).
- Limit portion sizes to recommended amounts.
- Exercise with physical activity at least 30 minutes a day.
- Avoid inhaled smoke and smokeless tobacco products.

Increased fiber will lower cholesterol even without cutting down on dietary fat. Adults should consume about 35 g of fiber per day; the national average consumption is about 12 g. Increasing fiber in the diet also lowers the risk of cancer and helps with weight control by maintaining a feeling of fullness for longer.

Foods containing *trans* fats increase the cholesterol level, especially low-density lipoprotein. A tub of soft-style margarine that lists water or liquid vegetable oil as its first ingredient contains less *trans*-fatty acids than other types (AHA, 2012). Patients should be taught to read food labels for the presence of *trans* fat. Many community hospitals sponsor weight management programs. Local chapters of the American Heart Association provide pamphlets and other sources of information about diet. AHA resources can also be found on the website www.heart.org.

A high intake of sodium is believed to contribute to the development of high blood pressure. Limiting sodium intake is an important part of preventing and treating hypertension. Several cookbooks that make low-sodium, low-cholesterol meals easier to plan and prepare are sponsored by the AHA and organizations. The fact that the tendency to develop cardiovascular disease is familial gives the patient and the family good reason to develop good eating habits and to change to more heart-healthy foods. Restriction of sodium, prescribed because of sodium's association with retention of water in the tissues, is discussed in Chapter 3.

Think Critically

How could you specifically change your eating habits in a way that would help you follow a more heart-healthy diet?

Community Care

Patients with infectious and inflammatory disease of the heart are sent home after a few days in the hospital. A home care nurse is usually assigned to supervise any ordered IV antibiotic infusion and to carefully assess the patient on a regular basis. The importance of taking prescribed NSAIDs for inflammation is discussed. A thorough heart and lung assessment is performed at every visit. The nurse teaches the patient or family how to infuse the antibiotics and how to care for the IV or peripherally inserted central catheter (PICC) line. The importance of tracking temperature daily is stressed. Signs and symptoms to report to the provider are reviewed, including new or increased chest pain, dysrhythmia, fatigue, shortness of breath, change in level of consciousness, sharp abdominal pain, or dependent edema. Assessment for signs and symptoms of adverse reactions is performed. Repeat blood cultures and CBCs are drawn at intervals to determine effectiveness of treatment.

Nurses in long-term care settings must be vigilant for beginning signs of HF, because many older adult residents have had chronic hypertension, previous MIs, or previous episodes of HF. Whenever a resident has an infection, an increased demand is placed on the heart and HF can develop quickly if the heart is already compromised. Episodes of vomiting or diarrhea or of dehydration cause electrolyte imbalances that can lead to dysrhythmias. Heart rates and rhythms should be monitored closely, and fluid and electrolyte replacement should begin early in the course of the illness.

Get Ready for the NCLEX® Examination!

Key Points

- HF is the inability of the heart to pump as it should, and pressure changes cause blood to back up into lungs and systemic circulation.
- Systolic HF is identified by an ejection fraction of 40% or less.
- Diastolic HF results when filling of the ventricles is impaired. A primary sign is JVD.
- Medical treatment of HF includes limited activity initially; oxygen therapy; medications such as ACE inhibitors or ARBs, digoxin, loop diuretics, and antihypertensive drugs; restricted sodium intake; and smoking cessation.
- Recording daily weight and keeping accurate intake and output records are essential.
- Assist the patient to maintain fluid restrictions as required.
- Disruption of normal SA node conduction leads to dysrhythmias; lack of normal regular myocardial contraction decreases cardiac output.
- Life-threatening dysrhythmias include ventricular tachycardia, ventricular fibrillation, pulseless electrical activity, and asystole.
- Dysrhythmias causing decreased cardiac output include severe bradycardia, atrial fibrillation, complete heart block, supraventricular tachycardia, and frequent PVCs.
- Dysrhythmias are diagnosed using 12-lead ECG, continuous ECG monitoring, patient history, and electrophysiologic testing.
- Failure of the heart's natural pacemaker may require an artificial pacemaker.
- Artificial pacing can be temporary or permanent, external, transvenous, or internal.
- ICDs may be used in patients with an episode of ventricular tachycardia or ventricular fibrillation or those at risk for developing fatal arrhythmias.
- Inflammation of the heart may occur as endocarditis, myocarditis, or pericarditis.
- Medical treatment includes rest to reduce workload of the heart, anti-infective drugs to control infection, and surgery to replace or repair valves damaged by the inflammatory process.
- Severe cardiomyopathy is treated by heart transplant.
- Cardiac valve disorders are caused by congenital defect, rheumatic fever, endocarditis, or long-term hypertension.
- Valve disorders include stenosis and regurgitation (insufficiency).
- Valve disease, if left untreated, often progresses to HF.

Review Questions for the NCLEX® Examination

1. A nurse answers the call light of a patient admitted with HF. The patient states he is short of breath and appears to be in distress. Identify the actions of the nurse in priority order.

1. Apply supplemental oxygen.

2. Raise the head of the bed.
3. Notify the provider.
4. Check vital signs.
5. Listen to lung sounds.

NCLEX Client Need: Physiological Adaptation

2. A patient is admitted with a cardiac dysrhythmia. The morning laboratory values show potassium as 6.1 mg/dL. What action is most important to take?

1. Encourage intake of extra fluid.
2. Notify the provider immediately.
3. Check the breakfast tray for sodium-containing foods before serving.
4. Check the patient's vital signs.

NCLEX Client Need: Physiological Adaptation

3. _____ is the delivery of a mild electrical shock at a specific time of the cardiac cycle to interrupt an abnormal rhythm and to possibly initiate a normal rhythm.

1. Synchronized cardioversion
2. Unsynchronized defibrillation
3. Pacemaker initiation
4. Electrophysiology study

NCLEX Client Need: Reduction of Risk Potential

4. After pacemaker implantation, it is important to teach the patient to:

1. stay away from microwave ovens.
2. count her pulse regularly.
3. refrain from swimming.

4. use a safety razor to shave her legs.

NCLEX Client Need: Health Promotion and Maintenance

5. A 48-year-old patient is admitted for tachycardia, shortness of breath, and chest pain eased by sitting up and leaning forward. The nurse auscultates a high-pitched scratchy sound at the left sternal border of the chest. The patient most likely has:

1. heart failure.
2. pericarditis.
3. pneumonia.
4. aortic stenosis.

NCLEX Client Need: Physiological Adaptation

6. Which assigned patient would take priority for immediate attention?

1. A patient with infective endocarditis who has an antibiotic dose due
2. A patient awaiting aortic stenosis surgery who is complaining of pain
3. A patient with systolic HF whose weight is up 1.5 lb today
4. A patient with dysrhythmia whose heart rate has dropped to 42 bpm and is dizzy

NCLEX Client Need: Physiological Adaptation

7. A patient has HF and atherosclerosis. Which patient statement regarding healthy food choices demonstrates a need for further teaching?

1. "I can have an egg two to three times per week."
2. "I need to watch red meat intake, but can have all the cheese I want."
3. "I should read labels to see how much sodium a serving contains."
4. "Canned goods are often high in sodium."

NCLEX Client Need: Health Promotion and Maintenance

8. The nurse explains the importance of reducing salt in the diet to a Hispanic man who was recently diagnosed with HF. The nurse realizes that the relatives are at the bedside with the patient. An appropriate nursing action would be to:

1. involve the youngest male in the family to translate.
2. ensure patient privacy by directing the relatives out of the patient's room.
3. determine who does the cooking in the family.
4. include all the relatives in the diet teaching.

NCLEX Client Need: Health Promotion and Maintenance

9. While discussing HF with a student, a nurse explains that the underlying weakness of the left ventricle results in reduced cardiac output and backup of fluid in the pulmonary system. The student nurse anticipates which sign/symptom?

1. Edema in the sacrum, legs, feet, and ankles
2. Hepatomegaly
3. Crackles in the lungs
4. Ascites

NCLEX Client Need: Physiological Adaptation

10. The patient asks, "Why am I taking lisinopril (Zestril)?" An accurate statement by the nurse would be:

1. "The medication increases the force of contraction of the heart."
2. "The medication increases the heart rate."
3. "The medication helps prevent vasoconstriction."
4. "The medication causes excretion of extra fluid."

NCLEX Client Need: Pharmacological Therapies

Critical Thinking Questions

Scenario A

Mr. Jenkins, age 56 years, is admitted to the telemetry unit with a diagnosis of atrial fibrillation. Physical assessment reveals a restless, apprehensive man with an irregular heart rate of 155 and dyspnea.

1. Describe the rhythm you expect to note on the telemetry monitor.
2. What treatment do you expect the provider to prescribe for Mr. Jenkins?
3. List five priority teaching points you should establish for Mr. Jenkins if he continues in atrial fibrillation.

Scenario B

Mr. Zulic, age 76 years, received a permanent pacemaker to correct complete heart block. He is 1 day postoperative and preparing for discharge home.

1. What are the indications for a pacemaker?
2. Describe the types of pacemakers and indications for their use.
3. Describe preoperative and postoperative nursing interventions when caring for a patient receiving a pacemaker.

Scenario C

Mr. Postma, age 72 years, is diagnosed with systolic heart failure. He has been experiencing fatigue and shortness of breath when walking the dog for a mile and has gained 5 lb over the past 2 weeks.

1. What stage of heart failure is Mr. Postma in? What symptoms does he have, supporting this stage?
2. What would you expect to be prescribed for him?
3. What topics should your teaching plan cover?

CHAPTER 20

Care of Patients With Coronary Artery Disease and Cardiac Surgery

Objectives

Theory

1. Examine the risk factors for coronary artery disease.
2. Illustrate the pathophysiology of coronary artery disease.
3. Outline nursing interventions to care for a patient experiencing angina, including medication administration and patient teaching.
4. Explain the pathophysiology of myocardial infarction.
5. Compare and contrast the symptoms of and care for unstable angina with those of myocardial infarction.
6. Develop a nursing care plan for a patient experiencing a myocardial infarction.
7. Relate the nursing care of a patient undergoing cardiac surgery.
8. Discuss five complications of cardiac surgery.

Clinical Practice

9. Develop a teaching plan for a patient with coronary artery disease.
10. Identify signs and symptoms that indicate a patient may be experiencing a myocardial infarct.
11. Administer medications to patients experiencing cardiac disorders.
12. Collaborate with other health care providers to care for patients after cardiac surgery.
13. Contribute to discharge planning for a patient after cardiac surgery.

KEY TERMS

- angina pectoris** (än-JÍ-nä PĚK-tör-ís, p. 454)
- atherosclerosis** (äth-ěr-ō-sklē-RŌ-sís, p. 450)
- coronary artery bypass graft (CABG)** (p. 463)
- coronary insufficiency** (KÖR-ō-nér-ě īn-să-FISH-ăñ-sē, p. 451)
- drug-eluting stent** (drūg e-LÜ-tīng stěnt, p. 463)
- infarction** (īn-FÄRK-shún, p. 457)
- metabolic equivalent (MET) units** (p. 462)
- myocardial infarction (MI)** (mī-ō-KÄR-dē-ăl īn-FÄRK-shún, p. 450)
- necrosis** (nē-KRŌ-sís, p. 451)

Coronary Artery Disease

Coronary artery disease (CAD) is a progressive disease leading to narrowing or occlusion (blockage) of the coronary arteries. The coronary arteries are responsible for supplying oxygen and nutrition to the myocardium (see [Figure 17-2](#)). As the coronary vessel narrows, the patient may experience symptoms of ischemia, such as chest tightness and angina. When a sudden obstruction to blood flow through one or more major coronary arteries occurs and cuts off oxygen and nutrients to the cardiac cells, a **myocardial infarction (MI)** occurs. With rapid intervention, the amount of infarcted tissue can be limited.

Etiology

A major factor in the development of CAD is atherosclerosis, in which plaque containing cholesterol and lipids is laid down within the walls of the arteries as fatty streaks. Plaque can occur in the cerebral vessels, the aorta, and arteries other than the coronaries. Coronary arteries are smaller, and narrowing here produces symptoms sooner than in the larger vessels. **Atherosclerosis** is one form of arteriosclerosis. **Arteriosclerosis** is a general term for disorders that cause thickening and loss of elasticity of the arteries.

Factors such as age (older than 40 years), gender, and race contribute to the disease; however, these characteristics cannot be modified. Those who have had one or more immediate family members develop or die of coronary artery disease during middle age are considered to be at high risk for the disorder. Postmenopausal women and women who use oral contraceptives or hormone replacement therapy are at greater risk of coronary artery disease than are women outside these categories.

Cultural Considerations

Ethnicity and Coronary Artery Disease

The incidence of coronary artery disease is disproportionately higher in African Americans, especially African American males. Research continues to determine the etiology of this finding and the approaches to decrease the incidence. Ethnicity-based treatment of heart disease is also explored, because research has demonstrated that some classifications of medications are more effective for persons of diverse ethnicity.

Pathophysiology

The process of atherosclerosis begins during late childhood, when streaks or islands of fatty material are laid down on the inner walls of the arteries. Low-density lipoprotein (LDL) is the major contributing factor to the formation of this fatty material. Plaques accumulate, particularly where there has been irritation or inflammation of the blood vessel from smoking, hypertension, diabetes, or infection. Later, the plaques become fibrous as a result of inflammation and healing. The plaque area protrudes into the artery, decreasing the vessel's size ([Figure 20-1](#)). Over time, the plaque begins to calcify, causing rigidity of the vessel wall. The further narrowing of the coronary arteries causes **coronary insufficiency** (decreased or insufficient blood flow). Obstruction occurs from this process and from thrombosis. Arterial spasm may contribute to deficient blood flow and consequent heart muscle damage.

Older Adult Care Points

Compared with the coronary blood flow in a 25-year-old, coronary blood flow in a 60-year-old is decreased. Older adults have less cardiac reserve, meaning that any added oxygen demands may compromise the coronary circulation and the heart's ability to pump properly.

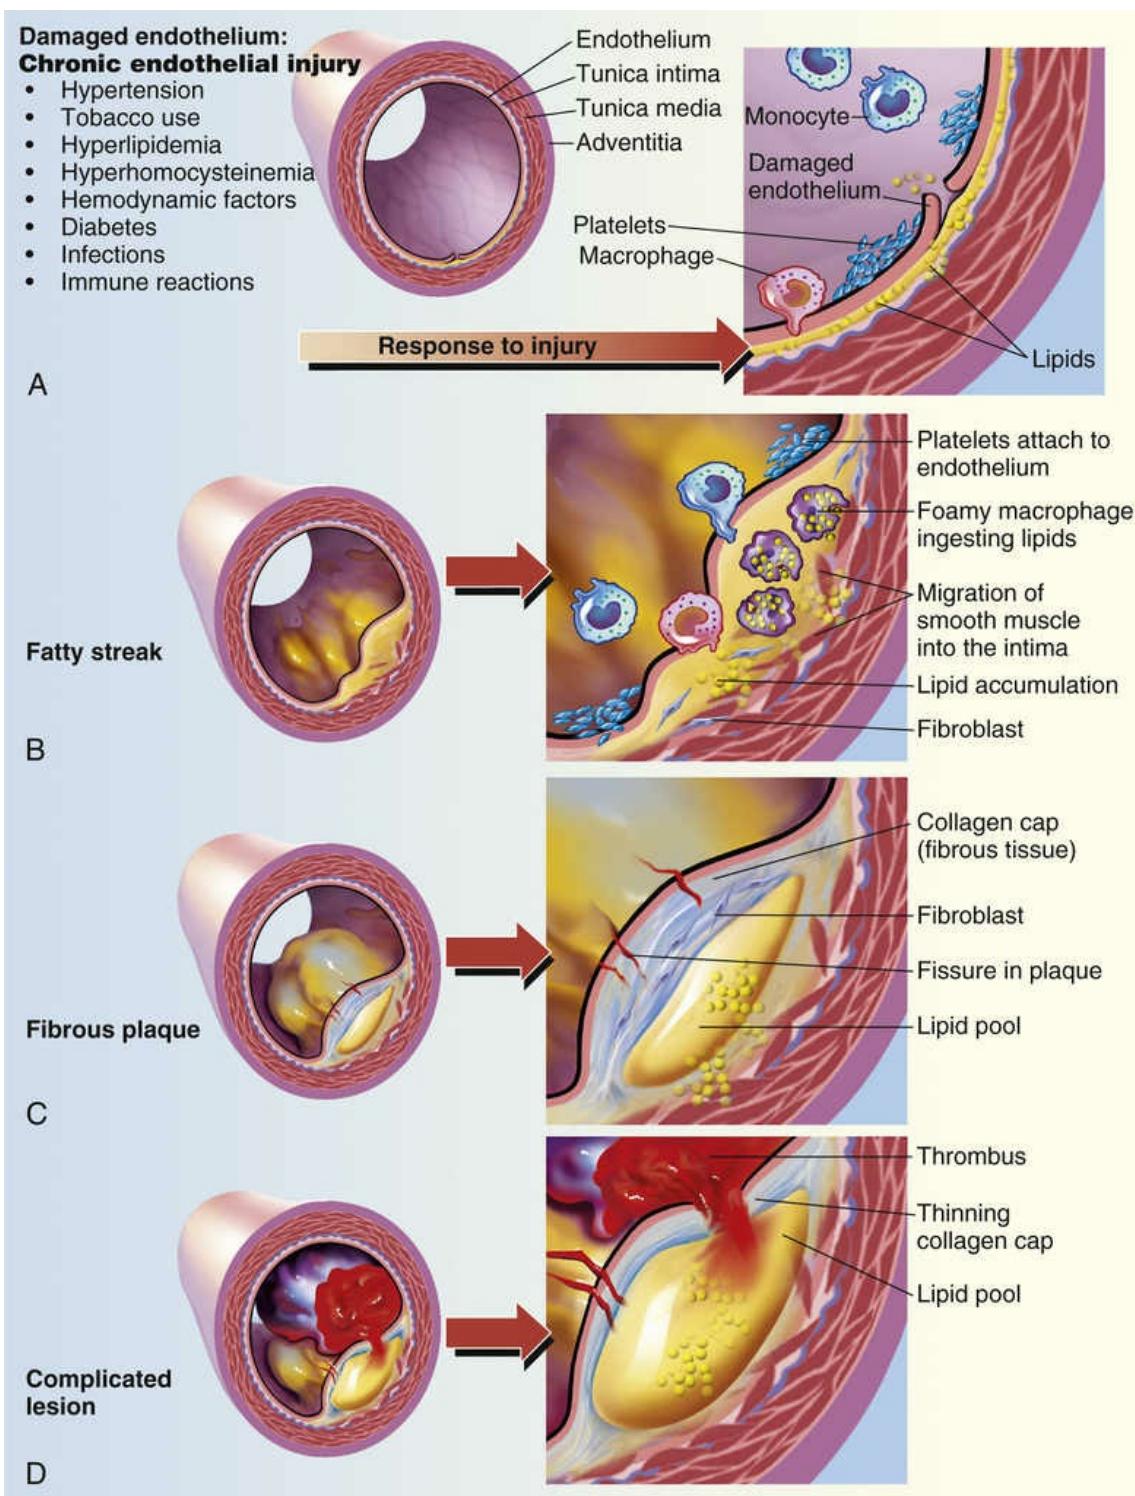

FIGURE 20-1 Progression of atherosclerosis. (From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 8, St. Louis, 2011, Mosby.)

There is a proven link between hyperlipidemia or high levels of LDL and triglycerides and atherosclerosis. High levels of homocysteine and episodes of inflammation causing an elevated level of C-reactive protein (CRP) are also factors in the development of atherosclerosis. Studies are currently investigating the use of anti-inflammatory and immunosuppressive agents as a treatment to inhibit plaque formation ([Moreira et al, 2015](#)).

As coronary artery disease progresses, the coronary vessels become narrower, decreasing blood supply to the myocardium. When plaque areas rupture, the rough edges cause platelet clumping and clotting (thrombosis). In women the blockages tend to occur in the very small arteries that

branch out from the coronary arteries. This is called *microvascular disease* (MVD; AHA, 2014). This lack of blood supply leads to ischemia and eventually **necrosis** (cell death) of the myocardium. If significant loss of muscle tissue occurs (MI), the heart muscle is unable to pump effectively, and cardiac output is reduced. Cardiac dysrhythmias and death may occur if medical intervention is not obtained.

Signs and Symptoms

Signs and symptoms of CAD are related to the lack of oxygen supply to the myocardium and inability of the heart to pump blood effectively to oxygenate tissues and cells (Box 20-1). Angina pectoris, acute coronary syndrome (ACS), or sudden cardiac death may occur.

Box 20-1

Signs and Symptoms of Coronary Artery Disease

- Chest discomfort, including feeling of tightness, aching, burning
- Chest pain (angina pectoris) radiating to the arm, jaw, or back
- Dyspnea (shortness of breath)
- Palpitations or tachycardia
- Nausea and vomiting
- Cold, clammy skin
- Undue fatigue (particularly in women)
- Weakness and inability to complete usual activities without chest pain or dyspnea

The condition is called *stable angina* when symptoms only appear with activity. *Unstable angina* occurs when symptoms occur even at rest. *Acute coronary syndrome* occurs when ischemic symptoms are prolonged and are not quickly relieved. It is an umbrella term for unstable angina and acute ischemic MI with or without ST-segment elevation on the electrocardiogram (ECG).

Diagnosis

Diagnosis of coronary artery disease is accomplished through tests such as ECG, echocardiogram, cardiac stress test, cardiac angiography (cardiac catheterization), cardiac computed tomography (CT) for calcium index, CT angiogram, or magnetic resonance angiogram.

Treatment

A low-fat diet, weight control, and exercise are prescribed to lower cholesterol and total lipids (Eckel et al, 2013). If elevated cholesterol and triglyceride levels cannot be lowered by a low-fat diet and exercise, lipid-lowering drugs are prescribed (Table 20-1). These medications are not effective alone and may not reduce cholesterol levels to a point of eliminating the risk for CAD. Several herbs and supplements have shown the ability to lower cholesterol. Advise patients to consult with their provider before taking over-the-counter medications or herbs.

 **Table 20-1**

Drugs Commonly Used to Treat Hypercholesterolemia

DRUG	ACTION	COMMON SIDE EFFECTS	USUAL ADULT DOSAGE	NURSING INTERVENTIONS
Bile Acid Sequestrants				
Cholestyramine (Questran, Locholest, Prevate) Colestipol (Colestid) Colesevelam (Welchol)	Bind bile acid in the GI tract, resulting in decreased absorption of cholesterol	Abdominal pain, constipation, nausea	4 g PO once or twice per day	Instruct patient to take before meals. Instruct to mix with 4–6 oz liquid. Advise drug may cause constipation and to increase fluid intake if not contraindicated. Counsel patient to continue low-fat diet and exercise.

Fibrin Acid Derivatives				
Gemfibrozil (Lopid) Clofibrate (Atromid) Fenofibrate (Tricor, Antara, Lipofen, Triglide, Trilipix) Lovaza	Reduce triglyceride production by the liver	Abdominal pain, diarrhea, epigastric pain	500 mg PO 4 times/day	Encourage to keep appointments for follow-up laboratory studies. Encourage to notify provider if symptoms of side effects occur.
HMG-CoA Reductase Inhibitors (Statins)				
Atorvastatin (Lipitor) Lovastatin (Mevacor) Fluvastatin (Lescol) Simvastatin (Zocor) Rosuvastatin (Crestor) Pitavastatin (Livalio) Pravastatin (Pravachol)	Inhibit the enzyme HMG-CoA reductase, which is responsible for synthesis of cholesterol	Abdominal pain, constipation, diarrhea, flatulence, heartburn, rash	Individual drug dependent	Teach to notify provider if severe muscle pain and weakness occur. Encourage to keep follow-up appointments and have periodic laboratory work performed. Pregnancy category X. Advise female patients to notify provider immediately if pregnancy is suspected. Notify provider of alcohol intake. May be at risk for liver disease.
Cholesterol Absorption Inhibitor				
Ezetimibe (Zetia)	Inhibit intestinal absorption of cholesterol	Possible headache and mild GI distress; infrequent	10 mg daily	Can be used along with other statins. Do not use for those with active liver disease. Take bile acid sequestrant 2 hr before or 4 hr after this drug. Obtain periodic lipid levels and liver function enzymes.
Niacin: Contains Nicotinic Acid				
Niacin (Nicobid, Nicotinex, Niacor, Slo-Niacin, Novo-Niacin)	Inhibit formation and secretion of VLDL and LDL	Flushing and itching of face and upper body, nausea and vomiting, indigestion, orthostatic hypotension	1-2 g/day in divided doses Start with 150 mg bid for 7 days and then gradually increase	Monitor liver function when patient is taking high doses. Instruct to take aspirin or NSAID 30-60 min before dose to decrease flushing. Take niacin with food. Increase folic acid intake if homocysteine levels rise.

GI, Gastrointestinal; HMG-CoA, 3-hydroxy-3-methylglutaryl coenzyme A; LDL, low-density lipoprotein; NSAID, nonsteroidal anti-inflammatory drug; VLDL, very low-density lipoprotein.

Complementary and Alternative Therapies

Herbs and Supplements That Naturally Lower Cholesterol

The following have been found to lower cholesterol in patients with hyperlipidemia:

- Garlic
- Omega-3 fatty acids
- Red rice yeast
- Milk thistle
- Fiber
- Phytosterols
- Soy
- Coenzyme Q₁₀

Patients who choose to use these substances should check for interactions with other medications they are taking. Some of the substances only lower cholesterol and LDL; others raise high-density lipoprotein (HDL).

Nursing Management

Patients should be encouraged to adopt a healthy lifestyle, including exercise and a diet low in saturated fat. Obtain a referral to a dietitian and assist the patient by reinforcing the need for changes in dietary habits. A cardiac rehabilitation program referral is very helpful. The program will help the patient choose an exercise regimen that he can manage on a long-term basis. Emphasize the importance of maintaining a normal body weight.

If the patient is on a statin drug to lower cholesterol, remind him that he needs to have blood drawn periodically to determine whether the drug is effective and to monitor for serious side effects.

Nutrition Considerations

Ways to Lower Fat and Cholesterol in the Diet

Teach the patient to:

- Avoid all fried foods; trim fat from meat and stick to 3-oz portions of meat per meal (a piece the size of a deck of cards). Remove skin from poultry.
- Eat fish with omega-3 fatty acids at least twice a week (salmon, mackerel, tuna).
- Use egg whites or Egg Beaters as cholesterol-free egg substitutes, both for breakfast and in recipes.
- Decrease or eliminate all commercial baked goods containing *trans* fat, saturated fat, or high levels of fat. Check the labels. Pies, doughnuts, croissants, and pastries are very high in fat.
- Use unsaturated fats for home baking and cooking. Avoid palm oil, coconut oil, lard, bacon fat, and hydrogenated vegetable shortening. Use olive oil whenever possible in salad dressings and for cooking. Do not use cube margarine that contains *trans* fats.
- Microwave bacon on paper towels to decrease the amount of fat; use turkey bacon rather than pork bacon.
- Check the amount of fat in cheeses and choose the lower-fat varieties. Eat only small amounts of cheese.
- Drink nonfat milk and use a nondairy, no-cholesterol creamer if you must have creamer in your coffee.
- Decrease the use of all dairy products and use only the low-fat or nonfat varieties.
- Eat more high-fiber whole grains, fruits, and vegetables.

Clinical Cues

- Because statins can injure muscle tissue and are toxic to the liver in some patients, blood should be drawn for levels of creatinine kinase (CK; an enzyme released from damaged muscle) and for liver enzymes. Elevated liver enzymes may indicate toxic damage to the liver.
- Patients should be told to report any unexplained muscle tenderness or pain persisting for more than a few days. When a statin drug is started, baseline blood values should be obtained before therapy. Laboratory tests for liver enzymes are recommended at the start of therapy and only when clinically indicated. Grapefruit juice should not be consumed when taking a statin drug. Grapefruit juice interferes with the metabolism of the drug, which can lead to increased serum levels and risk of toxicity ([FDA, 2012](#)).

Angina Pectoris

Angina pectoris (chest pain) occurs when blood supply to the heart is decreased or totally obstructed. The ischemia (inadequate blood and oxygen supply) of the heart tissue causes pain. Angina may be caused by vessel narrowing due to atherosclerosis or arterial spasm (sudden constriction). Any activity that increases the heart's workload increases its need for oxygen. When the narrowed coronary arteries cannot deliver adequate amounts of blood to meet normal needs, the patient experiences an angina attack.

Signs, Symptoms, and Diagnosis

Anginal pain or discomfort may vary in individuals, but in most cases it is described as a dull pressure or ache under the sternum or pain that radiates to the neck or jaw. The pain may also radiate down one or both arms. Angina sensation is seldom sharp or stabbing. The feeling may be described as suffocating. The pain can occur between the shoulder blades. In women, there may be no chest pain, but just a tenderness to touch or a burning or tingling sensation. Patients may think

they are experiencing indigestion or esophageal reflux. Shortness of breath without chest discomfort may also occur.

Stable coronary artery disease (SCAD) (formerly called stable angina) can be induced by stressors such as exercise or emotion. It can also occur spontaneously. Coronary artery disease is an ongoing process unless interrupted by change in lifestyle and medications. Although stages of the disease have had various labels, the symptoms exhibited are not a true reflection of the underlying pathology. Very low levels of troponin are found when high sensitivity tests are performed for patients with SCAD. Any patient exhibiting angina symptoms should be evaluated by a provider.

Medical diagnosis is established on the basis of history, clinical signs and symptoms, and diagnostic testing. Response of the heart muscle to increased oxygen demands can be determined by exercise stress testing in a stable patient. If noninvasive testing is positive, cardiac catheterization with coronary angiography may be performed (Figure 20-2). Echocardiography may be ordered to rule out a valve disorder or to evaluate left ventricular function. Laboratory levels of blood lipids will be tested, and cardiac enzymes may be ordered to rule out an MI. An electrocardiogram is a standard diagnostic procedure.

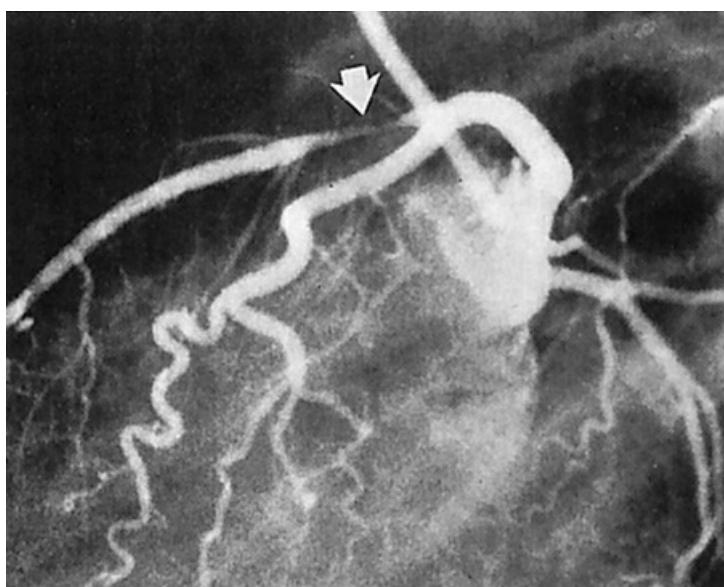

FIGURE 20-2 Stenosis (arrow) of the left anterior descending coronary artery. (From Chabner DA: *The language of medicine*, ed. 6, Philadelphia, 2001, Saunders.)

Treatment

The treatment of SCAD is mostly symptomatic, with emphasis on eliminating those factors that are known to precipitate an attack in the individual patient. With guidance and teaching, the patient may soon be able to correlate certain activities with an attack and thereby learn to avoid one whenever possible. Nitroglycerin, nitrates, calcium antagonists, and beta blockers are used in combination with drugs to lower cholesterol and prevent platelet aggregation. A low daily dose of aspirin (81 mg up to 325 mg) or other antiplatelet medication such as clopidogrel (Plavix) may be prescribed for the treatment of SCAD. Antiplatelet medications help prevent clotting and may prevent a thrombus that could cause an MI. Nitroglycerin administered sublingually is the most common drug for treatment of angina. An aerosol spray and a buccal form of the drug are also available.

Nursing Management

Collect data that assist in determining the type of angina the patient is experiencing. Patients with a history of angina may experience increased episodes when exposed to very cold environments. Externally cold temperatures result in vasoconstriction. The patient should be instructed to wear warm clothing when exposed to cold and may consider remaining indoors when the weather is extremely chilly. Nursing interventions for selected problems related to SCAD are summarized in

Nursing Care Plan 20-1.

Clinical Cues

Sublingual nitroglycerin tablets should be kept in a cool, dark place and should be carried by the patient at all times. Patients should frequently check the expiration date on the bottle and replace the nitroglycerin tablets accordingly. If the mouth is dry, a sip of water should be taken before placing the tablet under the tongue. If possible, the patient should lie down when using nitroglycerin. After taking the first dose, if the pain has not subsided, emergency services should be contacted. In the hospital, a baseline blood pressure should be measured, a tablet given, and then the pressure should be checked again in 5 minutes. If the pain has not eased or the pressure has risen, another tablet is placed under the tongue. Check the blood pressure again in 5 minutes. The blood pressure will likely decrease. If the blood pressure has not decreased significantly and if the pain is still present, administer a third sublingual tablet. Notify the provider immediately if the pain worsens or does not resolve after the three tablets. If oxygen is available, administer it according to hospital policy while waiting for communication from the provider. See the Evolve website for *Healthy People 2020* objectives to decrease the incidence of heart disease.

Nursing Care Plan 20-1

Care of the Patient With Angina

Scenario

Mrs. Ralston, age 63 years, is admitted to the telemetry unit. She has a history of chest pain and dyspnea precipitated by physical or emotional exertion. Her BMI is 30, and she has a history of smoking two packs of cigarettes per day for 40 years. She is admitted for unstable angina and evaluation of cardiac status. Cardiac enzymes are negative for MI.

Problem Statement/Nursing Diagnosis

Acute pain/Acute pain due to cardiac ischemia.

Supporting Assessment Data

Subjective: States she took five nitroglycerin tablets before admission with no relief of chest pain.

Objective: BP 100/70, HR 90, R 26. O₂ sat 92% on 5 L oxygen via nasal cannula.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Pain will be relieved within 15 min.	Assess level and duration of angina.	Determine severity of pain and need for additional intervention	Pain relieved after two nitroglycerin tablets 5 min apart.
	Teach to notify nurse and lie down and rest when pain occurs.	Early intervention for pain relief and assessment of change in condition	Nurse notified within 5 min of onset of pain.
	Assess vital signs during episodes of angina and medication administration.	Recognize side effects, such as hypotension and patient's response to treatment	Blood pressure maintained within 4 mm Hg of beginning of episode.
	Apply oxygen to maintain O ₂ saturation greater than 95%.	Increases available oxygen to cardiac muscle	Saturation 96% on 3 L nasal cannula oxygen.

Problem Statement/Nursing Diagnosis

Anxiety/Anxiety related to diagnostic tests and recurrent chest pain.

Supporting Assessment Data

Subjective: Asks, "Are you sure I didn't have a heart attack this time?"

Objective: Scheduled for cardiac catheterization in the A.M.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will verbalize that anxiety has decreased within 12 hr.	Assess level of anxiety. Administer medication if appropriate.	Increased anxiety can precipitate episodes of angina.	States is less anxious.
	Allow patient opportunity to express concerns.	Active listening will help reduce patient's anxiety.	Patient verbalized fear of dying from heart attack or complications of procedures.
Patient will verbalize understanding of cardiac catheterization.	Provide information related to cardiac catheterization.	Adults desire straightforward information concerning their medical status.	Verbalized understanding of procedure. Some anxiety.
	Answer questions or refer to appropriate health care provider as needed.	Provides level of control for decision making.	Reevaluate and continue plan.

Problem Statement/Nursing Diagnosis

Insufficient knowledge/Deficient knowledge due to lack of understanding regarding effect of diet on medical condition or methods to improve cardiac health.

Supporting Assessment Data

Subjective: "I just can't exercise, and I don't understand how to choose and cook foods without salt or frying."

Objective: Wt. 195 lb, elevated cholesterol, resting HR 98.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
By discharge, patient will be able to verbalize how to choose foods that are low in fat and sodium.	Assess current knowledge of food content and reading food labels. Refer for outpatient dietitian consult.	Provides starting point for teaching. Expert knowledge of dietitian needed to determine caloric needs and develop nutrition plan.	Patient able to choose low-fat and low-sodium foods from a menu list. States has dietitian consultation appointment.
Patient will establish regular exercise program. Patient will learn a new method of stress reduction.	Determine whether patient is candidate for cardiac rehabilitation program. Make referral after collaboration with provider. Reevaluate plan, refer to social services for assistance with financial concerns. Collaborate with patient and provider about evaluation of emotional status that may interfere with ability to remain compliant.	Provide structured, monitored exercise program that also includes dietary and emotional counseling. Social workers can assist with financial resources. Stress reduction will help her cardiac status as well as allow her to focus on maintaining her exercise program.	States she will consider participation in a cardiac rehabilitation program if funds are available. Contacted social services for consultation. Patient states that she will use meditation to help calm herself down so she can participate fully in her treatment plan.

Problem Statement/Nursing Diagnosis

Potential for injury/Risk for injury due to continued cigarette smoking.

Supporting Assessment Data

Subjective: "I have tried to quit smoking but it just doesn't work."

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will agree to enter a community smoking cessation program.	Assess willingness to reduce amount of or stop smoking. Teach complications related to heart disease and smoking.	Patient must be internally motivated for optimal success. Provide understanding of role of smoking and vasoconstriction that lead to episodes of angina.	Patient states she had tried many times to stop smoking with limited success. States she understands need to quit smoking and the effect smoking has on her health.
	Refer to social services for community programs available; give a smoking cessation packet of information.	Social services personnel are aware of community resources that can benefit patient care.	Identified smoking cessation program within patient's neighborhood in nearby church. Patient states she will contact program before discharge.

Critical Thinking Questions

1. What are five risk factors for coronary artery disease? What are complications?
2. Provide a teaching plan for a patient with angina. Include commonly used medications and side effects.
3. What is the most commonly used medication for angina/chest pain? How should it be administered?
4. What information would be helpful to know in regards to Mrs. Ralston's living situation?

BMI, Body mass index; *MI*, myocardial infarction; *PO*, orally.

Acute Coronary Syndrome and Myocardial Infarction

If ischemia is prolonged and not quickly reversed, acute coronary syndrome (ACS) occurs. ACS includes unstable angina, non-ST-segment elevation myocardial infarction (NSTEMI), and ST-segment elevation myocardial infarction (STEMI). All patients with heart disease should be taught the signs of MI and be advised that the best survival rate is directly related to obtaining medical attention as quickly as possible. About 620,000 Americans experience an MI annually. Although males outnumber females, females die more frequently after an MI. According to the American Heart Association, heart disease is the leading cause of death among American women, claiming about 379,559 lives each year. The incidence of heart disease, including MI, continues to rise among women. Women are more likely to experience heart attacks after reaching menopause; however,

poor dietary habits, sedentary lifestyle, and increased levels of stress contribute to the development of cardiovascular disease earlier in life for an increasing number of women.

Patient Teaching

Guidelines for Patients With Angina

Patients who experience anginal attacks are taught to:

- Avoid eating heavy meals.
- Avoid physical activity for an hour after meals to prevent excessive oxygen demands.
- Take nitroglycerin before heavy physical activity that is known to cause an attack, such as intercourse or sports activities.
- Avoid exposure to cold; do not walk into a cold wind.
- Decrease controllable risk factors, such as lifestyle stress, obesity, hypertension, and improper diet.
- Adopt a graduated exercise program.
- Stop smoking.
- Learn meditation or other deep relaxation techniques.
- Take a sublingual nitroglycerin tablet and lie down at the beginning of an anginal attack. Make certain that the tablet produces a tingling sensation where it contacts the mucous membrane. If the pain does not ease or go away after the first dose, call 911. Nitroglycerin may be repeated twice more at 5-minute intervals for a total of three tablets if the pain persists.
- Check the pulse rate once daily if taking a calcium channel blocker or a beta-adrenergic blocker. These drugs should never be stopped abruptly; call the provider if the heart rate drops below 60 beats per minute.
- Rise slowly from a supine or sitting position because of potential postural hypotension.
- Cleanse area of previous application of nitroglycerin patch when applying a new dose.
- Keep appointments for regular checkups.
- Obtain sufficient rest daily.
- Avoid high environmental temperatures and high humidity; stay in air-conditioned areas when such conditions occur, because they increase cardiac workload.
- Nitrates may initially cause a headache and hypotension.

Etiology and Pathophysiology

An MI is usually caused by thrombosis resulting from a ruptured atherosclerotic plaque. Sustained arterial spasm can produce angina pain or even MI. The pathophysiology is not understood completely, but there is thought to be more than one mechanism. Whatever the cause, blood flow is stopped to a portion of the myocardium. MI occurs most often in those older than 45 years.

An **infarction** is an area of necrosis in tissue caused by an obstruction to the flow of blood to that area for a prolonged period ([Figure 20-3](#)). In an MI, there is an area of necrosis (cell death) in the heart muscle. That portion of the heart muscle cannot contract normally to help pump blood out of the heart. Dead tissue does not return to normal, and scar tissue forms and interferes with the normal functions of pumping and electrical conduction. The prognosis for patients who experience

an acute MI depends on the location and the amount of heart tissue that is damaged. If a large area of the heart is affected, instant death may occur. Smaller ischemic areas may heal if treated promptly and effectively. As the coronary vessels narrow over time, small blood vessels are formed that supply oxygen to the myocardium. A patient with a well-established collateral circulation may experience a milder heart attack with fewer complications. Most MIs occur in the left ventricle, the main “pump.” Significant amounts of myocardial tissue injury cause a poorly functioning pump, leading to heart failure (HF).

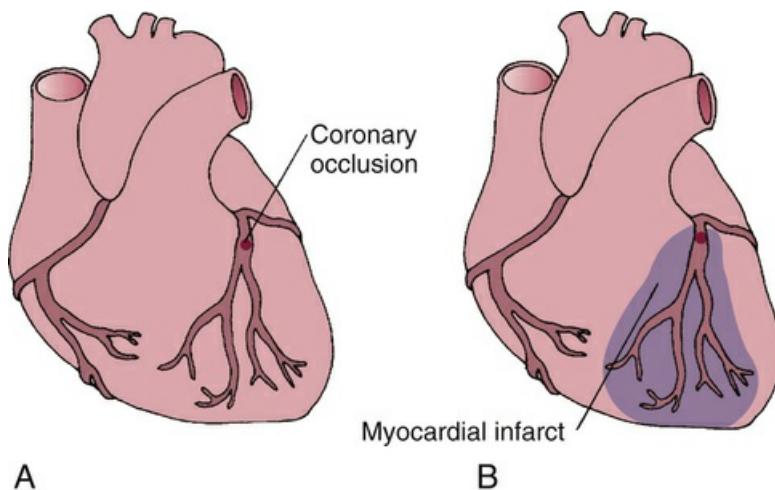

FIGURE 20-3 Occlusion of a major coronary artery (**A**) leads to area of infarct (**B**) resulting from ischemia.

Signs and Symptoms

Classically, during an MI there is a sudden, severe pain in the chest, usually described as tightness, pressure, squeezing, or crushing, that is not relieved by nitrates or rest. The patient also shows symptoms of dyspnea; nausea with or without vomiting; wheezing; and ashen, clammy, cool skin. Signs of shock with pallor, profuse sweating, and anxiety may occur. The heart rate may be very fast (tachycardia) or very slow (bradycardia), or the pulse may be irregular. In older adults, the attack may manifest as fatigue, syncope (temporary loss of consciousness), or weakness. Women often complain of recent episodes of extreme fatigue, with inability to complete daily activities without prolonged rest periods. These episodes may be accompanied by chest pressure, followed by eventual return to a full energy state. Feelings of “indigestion” are common. **Women tend to present with atypical symptoms such as sharp pain, fatigue, and weakness during an MI.** Denial is a significant factor in not seeking quick treatment and can lead to increased heart damage (Zafari, 2014).

Although these symptoms are usually present in an acute MI, they are not always severe, and in some cases patients have described their pain as mild. Sometimes the patient only experiences pain in the left arm, jaw, or back. Some people experience a “silent” MI, in which no symptoms are perceived. **It is paramount for the patient to seek quick medical attention when experiencing any new onset of chest pain.** The window of time to prevent significant myocardial damage is narrow (about 6 hours), and the sooner medical treatment is started for an MI, the greater the chance of saving myocardium and preserving life.

Older Adult Care Points

Older adult patients may never complain of chest pain when having an MI. Associated symptoms such as indigestion, nausea, dyspnea, and confusion are more common complaints.

Diagnosis

An ECG will be performed promptly when a patient is having symptoms that could be ACS. STEMI or NSTEMI will be ruled in or ruled out based on the ECG. Changes occur in the QRS complex, ST

segment, and T wave when ischemia or damaged tissue occurs. The severity of the symptoms will depend on the size of the area of ischemia or infarction. A chest x-ray will rule out other possible causes of the symptoms such as a thoracic aortic aneurysm. When there is necrotic tissue anywhere in the body, the white cell count increases and the sedimentation rate rises. Within 24 hours of an acute attack, the temperature of the patient with MI rises slightly, and mild leukocytosis appears.

In addition to the clinical manifestations, ECG changes, and other diagnostic tests, laboratory determinations of specific enzymes are used to establish a diagnosis of MI and evaluate the extent of damage done to the heart muscle (Table 20-2). Troponin levels are the preferred biomarker for diagnosis. Serum troponin T and troponin I are elevated within a few hours of MI. Troponin is found only in cardiac tissue. CK isoenzymes, lactic dehydrogenase (LDH), and LDH isoenzyme levels are observed over a 72-hour period. The CK is fractionalized into CK-MB, an enzyme that is only found in heart muscle. Other isoenzymes are CK-MM, found in skeletal muscle, and CK-BB, found in brain tissue. The level of CK-MB rises in 4 to 8 hours and begins to decline in 12 to 24 hours; LDH level increases 24 to 48 hours after an MI and stays high for up to 2 weeks. The most significant laboratory finding for diagnosis of MI is an elevated troponin level, especially if accompanied by an elevated CK-MB. Myoglobin levels rise with cardiac damage and do not diagnose MI but can rule out MI.

Table 20-2
Tests Performed to Determine Myocardial Infarction

	NORMAL VALUE	SIGNIFICANCE OF ABNORMAL VALUE
Troponin I (Tn I)	<0.3 mcg/L	Specific to heart muscle damage. Levels may elevate within 4-6 hr after MI, peak within 10-24 hr, and return to normal levels within 10 days.
Troponin T (Tn T)	<0.1 mcg/L	
CPK (creatinine phosphokinase)	Men: 55-170 international units/L Women: 30-135 international units/L	Elevated within 4-8 hr after heart attack (may also rise with injury to other muscles). Peaks within 12-24 hr, returns to normal levels within 3-4 days.
CK-MB	<3 ng/mL	Elevates within 2-6 hr after an MI, peaks within 12-24 hr, and returns to normal within 3 days. CK-MB is specific to myocardial injury.
Myoglobin	0-85 ng/mL	Detects muscle damage to myocardium. Presence of myoglobin is not diagnostic of MI, but absence of myoglobin rules out MI.

Other laboratory tests are listed in Table 17-2.

CK, Creatinine kinase.

Cardiac catheterization with angiography may be performed soon after the patient is admitted to the emergency department if MI is the probable diagnosis. This provides immediate, definitive diagnosis and treatment for occluded vessels. Thoroughly assess the status of the patient after cardiac catheterization. The patient may be up and about within 2 to 4 hours when an arterial closure device is used to seal the procedure site. Distal pulses on the affected leg must be assessed frequently, and the groin area must be assessed for the presence of hemorrhage or a hematoma. Renal function should be monitored because of potential adverse effects of contrast dyes used during the procedure.

Safety Alert

Intravenous Contrast (Dye)

If the patient is diabetic and takes metformin, hold the drug before the contrast-dye procedure. If the procedure is done as an emergency, metformin should be held for 3 days afterward. Metformin and contrast have an adverse effect on kidney function. When any patient has received contrast for a diagnostic test, promote good hydration either by oral or intravenous (IV) fluids. Keeping the patient hydrated will increase the rate of urine flow, dilute the urine, and help prevent kidney damage as the contrast is excreted.

Magnetic resonance imaging (MRI), echocardiography, and a technetium-99m sestamibi scan may be performed to determine whether there is myocardial dysfunction.

Think Critically

How would you prepare the patient who has experienced a probable MI for the diagnostic tests he will most likely undergo? What teaching is required?

Treatment

In many areas of the United States, there are specially designed and equipped mobile units staffed with trained personnel to give immediate care to the patient who has had a heart attack. Chewing and swallowing an aspirin when signs of an MI occur has been adopted as part of the emergency treatment protocol to decrease or prevent heart damage by decreasing platelet aggregation ([Amsterdam and Wenger, 2015](#)).

Outside the hospital, a trained emergency medical team should be called immediately. If the patient shows signs of cardiac or respiratory arrest, help should be called and cardiopulmonary resuscitation (CPR) with defibrillation, if indicated, should be started immediately. Many public areas, such as airports and shopping malls, have automated external defibrillators (AEDs) available which can be used by individuals trained in CPR. The AED will detect and treat possible shockable rhythms until emergency personnel are on the scene and take over care.

As soon as a patient with an acute MI is brought to the emergency department, measures are taken to relieve pain, decrease ischemia, and prevent further circulatory collapse and shock. The MONA (morphine, oxygen, nitrates, aspirin) regimen is initiated. Oxygen via nasal cannula or mask is started, IV access is obtained for administration of fluids and emergency drugs, and the patient is placed on a cardiac monitor. The Joint Commission has Core Measures in place for patients admitted with an MI ([Box 20-2](#)).

Think Critically

A patient has chest pain. The provider orders laboratory studies. Which results may indicate MI versus an episode of angina?

Box 20-2

The Joint Commission Core Measures for Myocardial Infarction

- Aspirin administered upon arrival at the hospital
- Beta blocker started within 24 hours of arrival
- Thrombolytic agent administered within 30 minutes of hospital arrival or percutaneous coronary intervention (PCI) within 90 minutes of arrival
- Aspirin or other antiplatelet therapy at discharge
- Beta-blocker therapy continued at discharge
- Angiotensin-converting enzyme (ACE) inhibitor or angiotensin-receptor blocker (ARB) therapy at discharge for left ventricular ejection fraction <40%

Sublingual nitroglycerin is given unless contraindicated. Drugs administered IV to control pain in a patient with acute MI are morphine sulfate or hydromorphone hydrochloride (Dilaudid). Morphine is the drug of choice because of its vasodilation property. **Pain medication given IV has a shorter duration, and doses must be repeated more frequently to keep the patient comfortable.** A bolus of heparin will be given and a heparin drip started to prevent the clot from enlarging. A nitrate infusion also may be started. Antidysrhythmia drugs are given as indicated by abnormal ECG rhythms. Oxygen is administered. Close assessment of respiration is essential, because the drugs for pain can depress respiration at a time when the heart's oxygen demand is increased. Pulse oximetry is instituted quickly to measure oxygen saturation.

If there is ST-segment elevation and the clinical picture indicates that there is complete occlusion of a coronary artery, the patient may immediately undergo cardiac catheterization and balloon angioplasty with placement of stents to restore blood flow. In many communities, facilities with cardiac catheterization capabilities may be designated as STEMI-receiving hospitals. Protocols are in place to fast track the diagnosis and mobilization of intervention teams to quickly treat a patient

experiencing an MI. If cardiac catheterization is not available, thrombolytic therapy may be considered to dissolve the clot occluding the coronary artery.

Thrombolytic therapy is started preferably within 6 hours but can be given up to 12 hours after the onset of symptoms to prevent necrosis of the myocardium and is indicated when the ECG shows ST-segment elevation (Rivera-Bou, 2014). To meet the Core Measure standard thrombolytics should be given within 30 minutes of arrival to the hospital. Agents used intravenously to dissolve the clot include alteplase (t-PA, Activase), tenecteplase (TNKase), and reteplase (Retavase). These drugs are contraindicated in patients who have severe, uncontrolled hypertension or a history of a hemorrhagic stroke, gastrointestinal (GI) bleed, intracranial or intraspinal surgery within the past 2 months, a brain tumor, arteriovenous malformation, or aneurysm. After one of these agents is infused, a heparin drip may be started to prevent reocclusion. When a patient is not a candidate for thrombolytic therapy, heparin and low-dose aspirin may be administered to prevent further thrombosis.

Think Critically

How would you explain the thrombolytic therapy used when a patient has acute coronary occlusion?

Nursing Management

In the acute phase of MI, nursing care is directed toward:

- Relieving pain.
- Administering ordered medical therapy and observing for side effects.
- Monitoring for signs of complications of MI, such as dysrhythmia, HF, pulmonary edema, pericarditis, cardiogenic shock, or cardiac arrest ([Table 20-3](#)).

Table 20-3
Signs and Symptoms of Complications After Myocardial Infarction

COMPLICATION	SIGNS AND SYMPTOMS
Dysrhythmia	Irregular pulse; abnormal ECG pattern. Ventricular fibrillation is the most common complication after MI. Report more than six PVCs per minute, heart rate of >120 or <40 bpm.
Heart failure (HF)	Dyspnea; pedal edema; sacral edema; crackles in lung bases; distended neck veins; enlarged, tender liver; weight gain of more than 2 lb in 24 hr; pulmonary edema.
Cardiogenic shock	Significant drop in systolic blood pressure (>20 points); diaphoresis; rapid pulse; cold, clammy skin; gray skin; restlessness.
Papillary muscle dysfunction	Mitral valve regurgitation with systolic murmur; dyspnea, pulmonary edema, and decreased cardiac output.
Ventricular aneurysm	Outpouching of ventricular wall may cause HF, dysrhythmias, and angina. May cause formation of thrombi that lead to a stroke.
Pericarditis	Pericardial friction rub on auscultation; chest pain aggravated by movement and lessened by sitting up and leaning forward.
Dressler syndrome	Occurs 4-6 weeks after MI. Chest pain, fever, friction rub, pleural effusion, and arthralgia.

bpm, Beats per minute; ECG, electrocardiogram; MI, myocardial infarction; PVCs, premature ventricular contractions.

- Maintaining a patent IV access at all times

In the recovery phase of MI, nursing care is directed toward:

- Decreasing anxiety and stress for the patient. Explain the function of all equipment and tests in simple terms. Explain the routine of frequent assessment and tests so the patient will know what to expect. Decreasing the family's anxiety by reinforcing what the provider has told them about the patient's condition and treatment.
- Monitoring physical status by performing a thorough cardiovascular assessment every 4 to 8 hours and monitoring vital signs every 2 to 4 hours.
- Recording daily weight and comparing with previous weight. Intake and output are accurately recorded and compared with previous amounts.
- Promoting rest.
- Monitoring tolerance of activities of daily living (ADLs) and ambulation.
- Assisting with rehabilitation activities.

Patients with damage to the myocardium are admitted to the critical care unit (CCU), or telemetry where they are initially kept on bed rest. Physical activity is gradually increased according to the patient's individual condition and response to activity. An IV line or a saline lock is maintained to provide a route for administration of emergency drugs to control blood pressure and

dysrhythmias.

Vital signs and SpO₂ are continuously monitored by electronic means and are assessed every 15 minutes to 2 hours. The temperature may be slightly elevated. Continuous ECG monitoring is essential to provide an accurate evaluation of the status of the heart. If death occurs it is most likely within the first 24 hours of an MI and is caused by ventricular fibrillation.

While in the CCU, if hemodynamic instability is present a pulmonary artery flow-directed catheter (Swan-Ganz type) may be inserted to monitor central venous pressure (CVP), pulmonary artery pressure (PAP), pulmonary capillary wedge pressure (PCWP), and cardiac output, which give a better picture of the injured heart's ability to pump. A heart-healthy diet is ordered when the patient's vital signs have stabilized. A stool softener is given to decrease the risk of bradycardia, which can be caused by straining to have a bowel movement. Potassium and magnesium are monitored closely, because imbalances can cause dysrhythmias. Medication to correct dysrhythmia is given as needed (see [Box 20-4](#)). A beta-adrenergic blocker, such as metoprolol (Toprol XL, Lopressor), may be ordered to decrease the heart's workload. An angiotensin-converting enzyme (ACE) inhibitor such as captopril (Capoten) may also be given. Oxygen via mask or nasal cannula is administered to maintain SpO₂ 95% or greater. Various IV drugs may be used to regulate blood pressure or to control dysrhythmias. A temporary pacemaker may be inserted if the patient develops a persistent bradycardia causing symptoms of inadequate cardiac output. External pacing patches can be used for emergency pacing. A transvenous temporary pacing wire will be placed as soon as possible. Rare but deadly complications of MI requiring surgical repair are ventral septal defect, a ventricular aneurysm, or papillary muscle rupture.

Cardiogenic Shock

If the left ventricle is badly damaged, cardiogenic shock may occur. Signs and symptoms are those that accompany decreased cardiac output, such as decreased BP, confusion, restlessness, diaphoresis, rapid and thready pulse, increased respiratory rate, cold and clammy skin, and diminishing urinary output to less than 20 mL/hr. The patient is cared for in the CCU, where a variety of drugs aimed at improving cardiac output may be administered.

An intraaortic balloon pump (IABP) may be used to ease the heart's workload while it begins to heal. ([Figure 19-3](#)) This device uses a balloon catheter positioned in the aorta that inflates during diastole and deflates during systole, effectively decreasing the workload of the heart and increasing blood flow through the coronary arteries. Only registered nurses who are certified in the care of patients on an IABP are assigned to care for these patients. See [Chapter 44](#) for further information on shock.

Intermediate Care

When very frequent assessment and monitoring are no longer essential and the patient is able to participate in his personal hygiene activities without detrimental effects on the healing heart tissues, he is transferred out of the CCU into a telemetry, or "step-down," medical unit. For some patients, this move is frightening because they know they will no longer have a nurse giving constant attention. Every effort is made to assure the patient that he is making progress toward recovery and no longer needs intensive care. While the patient is on the telemetry unit, physical activities are gradually increased according to ability to tolerate exercise, as evidenced by stable heart rate, blood pressure, and respiratory rate. There is close monitoring for symptoms of excessive strain on the heart, such as dysrhythmia or dyspnea, or for the development of complications. These measures may minimize damage from an MI, but the patient still has CAD, requires treatment, and must attend to lowering his risk factors.

If the patient received successful thrombolytic therapy or percutaneous cardiac intervention (PCI), he may have averted significant myocardial damage and not require CCU care after the MI. Patients with a STEMI who arrive for treatment before significant left ventricular damage has occurred may be sent to telemetry after PCI and are only hospitalized for 24 to 48 hours. Intensive teaching needs to occur to help the patient access resources to enable the lifestyle changes needed to prevent another MI.

Rehabilitation

A variety of emotional and behavioral responses may occur after an MI ([Box 20-3](#)). The patient and

his family may need help and support as they work to make the necessary adjustments. Many hospitals offer an outpatient cardiac rehabilitation program to help the patient make lifestyle changes to reduce future risk of cardiac problems. The program provides counseling on dietary changes for a heart-healthy diet; stress-reduction techniques; reduction of risk factors, such as avoiding tobacco use; controlling hypertension and diabetes; and a supervised exercise program with continuous ECG monitoring for 4 to 6 weeks. Such programs have been found to be effective in decreasing cardiac death and HF (Wenger, 2013). Progressive, supervised exercise is continued for an additional 6 to 8 weeks, and then a maintenance program is devised that the patient can do independently. A support group consisting of other individuals who have the same condition or have had similar surgery often is available. Most insurance coverage will pay for the exercise program because it has been highly successful in helping people to develop and maintain a healthier lifestyle and to reduce risk factors.

Box 20-3

Emotional and Behavioral Responses to Acute Myocardial Infarction

Denial

- May have history of ignoring symptoms related to heart disease
- Minimizes severity of medical condition
- Ignores activity restrictions
- Avoids discussing MI or its significance

Anger

- Is commonly expressed as, "Why did this happen to me?"
- May be directed at family, staff, or medical regimen

Anxiety and Fear

- Fears death and long-term disability
- Overtly manifests apprehension, restlessness, insomnia, tachycardia
- Less overtly manifests increased verbalization, projection of feelings to others, hypochondriasis
- Fears activity, recurrent heart attacks, and sudden death

Dependency

- Is totally reliant on staff
- Is unwilling to perform tasks or activities unless approved by health care provider
- Wants to be monitored by ECG at all times
- Is hesitant to leave CCU or hospital

Depression

- Experiences mourning period concerning loss of health, altered body function, and changes in lifestyle
- Realizes seriousness of situation

- Begins to worry about future implications of health problem
- Shows manifestations of withdrawal, crying, anorexia, apathy
- May have more evident depression after discharge

Realistic Acceptance

- Focuses on optimum rehabilitation
- Plans changes compatible with altered cardiac function

CCU, Critical care unit; *ECG*, electrocardiogram; *MI*, myocardial infarction.

From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 8, St Louis, 2011, Mosby.

One area of major concern is sexuality. The patient may be fearful of resuming intercourse, thinking that it may cause a heart attack. The partner often has these fears also. Both partners need reassurance that resumption of normal sexual activities will be possible. The patient may need to take a more passive role during intercourse, at least for a while, using alternate positions that cause less strain and less oxygen demand. The patient should be told that the workload of intercourse with a known partner is equal to climbing a flight of stairs. If a flight of stairs can be climbed without much change in heart rate, respirations, or blood pressure, intercourse should not cause harm. The provider should discuss this area with the patient and his partner, but if the provider does not, see that the proper information is given. Sexual dysfunction may be a side effect of some medications.

Patients should be taught to plan sexual activity for times when they are well rested and to avoid an environment that is too hot or too cold. It is best to space such activity at least 2 hours after eating a meal or drinking any alcohol. Nitroglycerin should be used prophylactically if intercourse causes angina symptoms. If angina does occur, the patient should cease activity, place a nitroglycerin tablet under his tongue, lie down, and rest.

Levels of physical activity are designated through **metabolic equivalent (MET) units**. One MET is the amount of oxygen needed by the body at rest. The patient's rehabilitation program slowly progresses stepwise to higher energy expenditures over a period of months (Box 20-4).

Box 20-4

Energy Expenditure in Metabolic Equivalents

Low-Energy Activities (<3 METs or <3 cal/min)

Activities in Hospital

Resting supine

Eating

Washing hands, face

Activities Outside Hospital

Sweeping floor

Painting, seated

Driving a car

Sewing by machine

Moderate-Energy Activities (3-6 METs or 3-5 cal/min)

Activities in Hospital

Sitting on bedside commode

Showering

Using bedpan

Walking at 3 to 4 mph

Activities Outside Hospital

Bricklaying

Ironing, standing

Cycling at 5.5 mph on level ground

Golfing

Dancing

High-Energy Activities (6-8 METs or 6-8 cal/min)

Walking 5 mph

Performing carpentry

Ascending a flight of stairs

Mowing lawn using walking mower

Very-High-Energy Activities (>9 METs or >9 cal/min)

Cross-country skiing

Running faster than 6 mph

Cycling faster than 13 mph

Shoveling heavy snow

cal, Calories; *METs*, metabolic equivalent units; *mph*, miles per hour.

From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St Louis, 2015, Mosby.

Rehabilitation involves three major aspects: (1) a program of increasing activity based on the patient's individual progress and needs; (2) instruction of the patient and family about the nature of the illness and the rationale for every aspect of its management; and (3) assistance to the patient and family as they work toward the goal of accepting the limitations imposed and the changes in lifestyle that may be required. The goal is to have the patient and family continue with heart-healthy living even after the formal program ends.

Patient Teaching

Guidelines for Recovery From an MI

Teach the patient to:

- Recognize the signs of recurrent MI and to seek immediate medical attention should they occur.

These are chest pain, diaphoresis, nausea, and anxiety.

- Adopt a lifetime regular, graduated exercise program.
- Alter controllable risk factors: reach and maintain a normal weight; cease smoking; keep alcohol consumption at a moderate level (no more than 1.5 oz per day); keep cholesterol within normal limits; control hypertension; continue on a low-fat, low-sodium diet individualized to taste.
- Reduce stress and learn relaxation techniques.
- Observe for complications, such as chest pain, irregular pulse rate, dyspnea, and fatigue.
- Take medications as ordered and monitor for side effects.

It is important to stress to the patient that he has control over his rehabilitation and prognosis. He alone has full control over his lifestyle changes and the treatment program. When the patient feels that he, rather than the provider, is in control, he is much more likely to remain on the treatment program.

Through its local chapters, the American Heart Association provides an abundance of written material designed for the person recovering from an MI (see Online Resources at the end of the chapter). Patients and their families should know about this valuable source of information and support as they work toward the goal of rehabilitation.

Surgical and Nonsurgical Treatment Options

Percutaneous Transluminal Coronary Angioplasty

If only a few areas of stenosis are identified, a PCI may be performed. The patient may have a percutaneous transluminal coronary angioplasty (PTCA) rather than **coronary artery bypass graft (CABG)** to improve blood flow. PTCA is a nonsurgical interventional technique to open blocked coronary arteries. It is performed in the cardiac catheterization laboratory using fluoroscopy. A catheter with a balloon tip is threaded into the blocked artery, and when the narrowed area is reached, the balloon is inflated, pushing aside the plaque and widening the interior of the artery. To maintain patency of the vessel, a coronary stent is usually placed. A stent is made of stainless steel and acts as a brace for the artery wall. A metal or **drug-eluting stent** may be placed in the artery to help maintain the opening (Figure 20-4). Several manufacturers provide drug-eluting stents. They all have a coating of a drug that is released slowly over several weeks after placement. The drug coatings are medications that are used in cancer treatment. The purpose is to either suppress cell growth so the body does not occlude the vessel with new cells or to decrease inflammation with immunosuppressants to reduce swelling and promote healing. Research has shown that the drug-eluting stents may reduce the need to restent the vessels over time because of cellular hyperplasia as the body adjusts to the foreign body. During the procedure a glycoprotein (GP) IIb/IIIa inhibitor such as abciximab (ReoPro), tirofiban (Aggrastat), eptifibatide (Integrilin), or direct thrombin inhibitor bivalirudin (Angiomax) maybe given as an IV infusion to reduce platelet aggregation. When a stent is placed, the patient must take antiplatelet agents, such as aspirin, and/or clopidogrel (Plavix) for up to 1 year after placement. A loading dose of antiplatelet medication is usually given before the patient leaves the cardiac catheterization laboratory; this reduces the need for infusions. CABG may be indicated if there is multivessel disease or a critical lesion that puts a large portion of myocardium at risk. Depending on the nature of the risk, patients may go emergently to the operating room (OR) from the cardiac catheterization laboratory or may be scheduled at a later time.

Safety Alert

Proton Pump Inhibitors

Proton pump inhibitors may interfere with the action of clopidogrel (Plavix); proton pump inhibitors should not be taken when clopidogrel is prescribed ([Juurlink, 2009](#)).

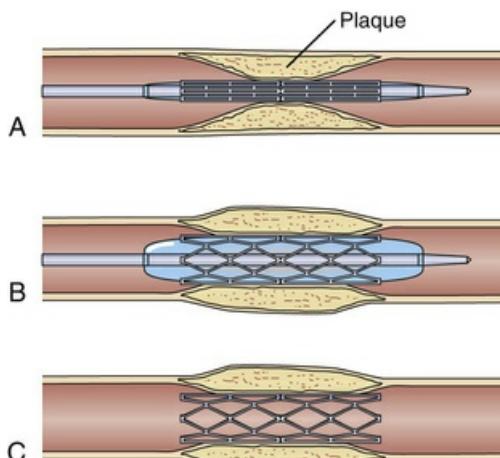

FIGURE 20-4 Placement of coronary artery stent. **A**, The stent is positioned at the site of stenotic lesion. **B**, The balloon is inflated, expanding the stent. The balloon is then deflated and removed. **C**, The implanted stent is left in place. (From Lewis SL, Dirksen SR, Heitkemper MM, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2014, Mosby.)

Other procedures to remedy clots and plaque are laser angioplasty, thrombectomy, and atherectomy. Laser angioplasty breaks up the clot. Rheolytic thrombectomy uses low-pressure, high-speed saline jets to break up the clot. Atherectomy devices either excise and retrieve plaque or destroy it. These procedures are sometimes used when a patient has reocclusion after CABG and PTCA. CABG surgery is covered in the section on cardiac surgery.

Studies are ongoing to determine whether a regimen consisting of a very-low-fat diet, regular exercise, reduction of stress, and practice of relaxation techniques can reverse CAD without surgery. These methods have been effective in people who can maintain the discipline to stick to the program.

Clinical Cues

Patients may have a genetic resistance to clopidogrel (Plavix). For clopidogrel to inhibit platelets it must be activated by a sequence mediated by the liver. P2Y12 platelet function testing can identify resistance.

Transmyocardial Laser Revascularization

For patients who are critically ill and are not candidates for PTCA or CABG, transmyocardial laser revascularization (TMR) is an option. This procedure may be available to patients with severe chest pain that limits their ability to perform ADLs, who have a history of CABG, and who have no other treatment options. The procedure is done with general anesthesia without use of cardiopulmonary bypass (heart-lung machine), and the heart is approached through a small thoracotomy incision. A carbon dioxide or holmium:YAG laser is used to drill multiple tiny holes in the heart's left ventricle. These channels heal on the outside of the heart, and over time heal on the inside. The mechanism that causes improvement in patient symptoms is not well understood. Postoperatively the patient will have a chest tube and be monitored in the CCU.

Cardiac Surgery

Open heart surgery is made possible by the heart-lung machine. The machine functions as an artificial heart (pump) and lung (oxygenator). Because all this is done outside the patient's body, the procedure is called *extracorporeal circulation*. The surgeon inserts large tubes in the vena cava and reroutes the unoxygenated venous blood through the heart-lung machine. There, the blood is exposed to an atmosphere of oxygen in which an exchange of gases takes place (carbon dioxide is released and oxygen is taken up), and the oxygenated blood is returned to the patient via the aorta. The blood may be cooled so that the patient's body temperature is lowered (hypothermia), thereby reducing the body's metabolic needs during surgery.

Open heart surgery technically means that the chest is opened, the heart is stopped, and blood is routed through a heart-lung machine. The term is used for any procedure where these conditions take place. Some procedures are done with minimally invasive techniques not requiring a sternotomy. In others, the heart is not stopped, and "off-pump" (beating heart) surgery is performed. Congenital heart defects, valve replacements, bypass of clogged coronary arteries, and heart transplant are conditions requiring surgical repair.

Coronary Artery Bypass Graft Surgery

CABG is performed (1) when ischemia cannot be controlled medically or (2) to prevent greater occlusion and consequent MI. The CABG surgery bypasses the artery that is blocked, replacing it with sections of a vein or artery taken from another part of the patient's body. Usually the mammary artery or sections of saphenous vein or radial artery are grafted. The mammary artery is left attached to the subclavian artery, and the other end is sewn distal to the blockage in a coronary artery. Saphenous vein grafts are sewn to the aorta and then distal to the blockage in a coronary artery. These new vessels supply blood to the myocardium. The patient will have a midsternal incision if an open approach was used and, if saphenous veins were used for the grafts, will have leg incisions. A small dressing as shown in [Figure 20-5, B](#) will be seen if an endoscopic approach was used. [Figure 20-6](#) shows CABG procedures using vein grafts or the internal mammary artery.

Older Adult Care Points

Older adult patients tolerate CABG surgery well, but the recovery period is longer because of the slower healing rate and decreased ability of the body to handle this degree of physical stress.

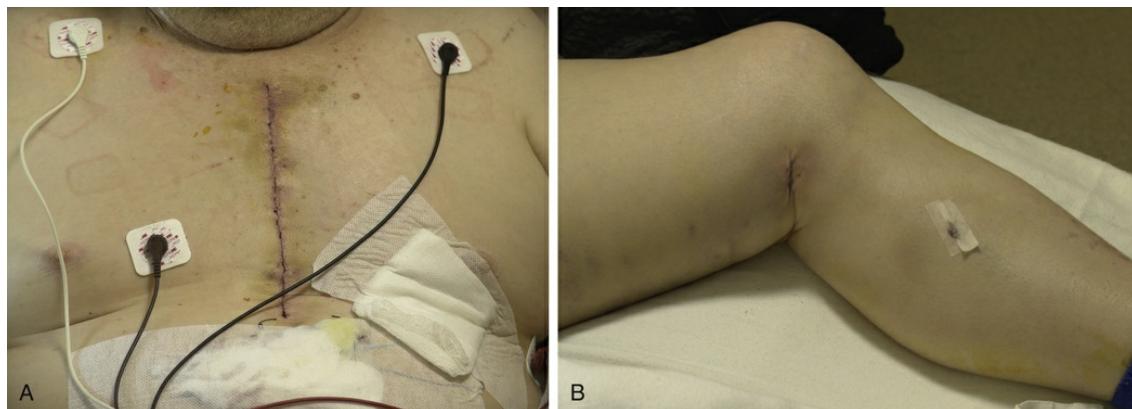

FIGURE 20-5 **A**, Sternal incision for coronary artery bypass graft (CABG). **B**, Endoscopic leg incision for removal of saphenous vein for grafting to coronary arteries.

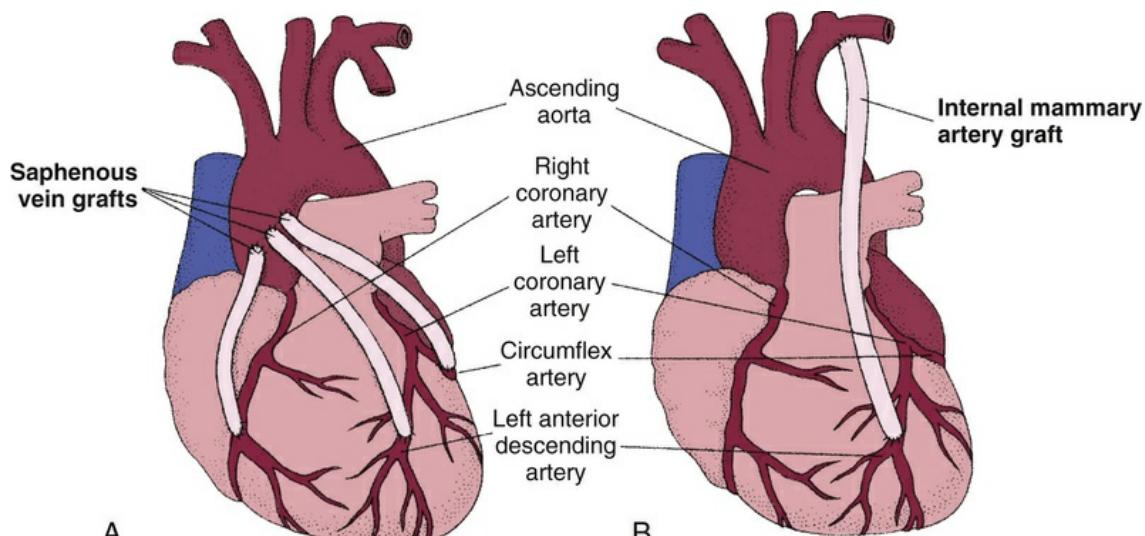

FIGURE 20-6 Two methods of coronary artery bypass grafting. **A**, Saphenous vein grafts. **B**, Internal mammary artery graft.

An off-pump coronary artery bypass technique for CABG procedures—minimally invasive direct coronary artery bypass (MIDCAB)—does not require stopping the heart's activity and therefore does not require using the heart-lung machine. MIDCAB procedures are performed on only the vessels in the front of the heart because the access only allows contact with those arteries. There are other techniques for myocardial revascularization being studied with the goal of reducing recovery time and potential complications. Coronary bypass surgery does not cure the disease; it only relieves the symptoms and may prevent myocardial damage from total occlusion of a coronary artery. After the surgery, anginal chest pain disappears in about 65% of patients, and another 25% show improvement. Many of those patients who had a coronary artery bypass in the past 10 years are returning for a second operation because the grafted arteries or venous bypass grafts have become occluded. A greater emphasis is being placed on the need for adherence to lifestyle changes to prevent a second operation. [Nursing Care Plan 20-2](#) summarizes care of a patient after cardiac surgery.

Nursing Care Plan 20-2

Care of a Patient After Cardiac Surgery

Scenario

Mr. Jacobi, age 57 years, was transferred to the telemetry unit after a coronary artery bypass graft (CABG) and is 2 days postoperative. Mr. Jacobi is married and has three teenage children. He plans to return to his job as a truck driver after surgical recovery.

Problem Statement/Nursing Diagnosis

Altered activity tolerance/Activity intolerance due to postsurgical hemodynamic changes.

Supporting Assessment Data

Subjective: States, "I'm feeling faint and short of breath" after ambulating 30 feet.

Objective: RR 32, SpO₂ 90% after ambulating short distance, PO₂ increases to 95% to 100% when returned to chair, RR decreased to 24.

Goals/Expected Outcomes	Nursing Intervention	Selected Rationale	Evaluation
Patient will be able to ambulate 50 feet in halfway without complaints of dizziness and dyspnea.	Assess SpO ₂ and vital signs before and after ambulation.	Provides baseline values for evaluation.	SpO ₂ 96%, no complaints of dizziness by third postoperative day.
	Provide safety during ambulation (e.g., follow with wheelchair, use gait belt, instruct to use handrails).	Prevent falls if hemodynamic changes occur.	Patient did not sustain fall.
	Provide rest periods every 15 feet.	Improves success of ambulation.	Patient able to ambulate 100 feet without rest period by third postoperative day.
	Gradually increase distance of ambulation as condition stabilizes.	Physical conditioning decreases the workload on heart and facilitates patient recovery.	Patient ambulated 100 feet three times per day without complaints of dizziness and dyspnea by third postoperative day. Continue plan.

Problem Statement/Nursing Diagnosis

Altered skin integrity/Impaired skin integrity due to thoracotomy and saphenous vein graft.

Supporting Assessment Data

Subjective: Patient asks about care of wounds to chest and left lower leg.

Objective: Incisions to midsternum and left lower leg. Both incisions intact, no areas of redness noted. Skin staples intact.

Goals/Expected Outcomes	Nursing Intervention	Selected Rationale	Evaluation
Surgical incisions will remain intact and free of signs of infection.	Assess and document status of incision at the beginning of each shift.	Determines changes in status of wound, such as development of redness, edema, opening of suture lines.	Midsternal incision intact, no signs of infection. Incision to left lower leg slightly edematous, $\frac{1}{2}$ -inch opening of wound on fourth postoperative day. Continue to monitor.
	Assess vital signs.	Elevated temperature and heart rate may indicate beginning of wound infection.	HR 72, T 100° F (37.8° C).
	Provide wound care as ordered.	Keeps incisions free of drainage, irritants, and pathogens.	Wounds are clean and dry with skin staples intact.
	Include wound management in discharge teaching plan.	Provides knowledge to prevent and recognize complications associated with wound healing.	Demonstrated appropriate wound care. Verbalized signs and symptoms of infection.

Problem Statement/Nursing Diagnosis

Acute pain/Acute pain due to midsternal surgical incision.

Supporting Assessment Data

Subjective: States, "It hurts too much to do these breathing exercises."

Objective: Unable to reach incentive spirometer goals; SpO₂ 94%.

Goals/Expected Outcomes	Nursing Intervention	Selected Rationale	Evaluation
Patient will verbalize decreased pain during deep-breathing exercises.	Assess pain level before deep-breathing exercises and use of incentive spirometer. Provide pain medication as needed. Teach to splint incision during respiratory exercises.	Patient will be more likely to complete exercises if he is more comfortable.	Completes breathing exercises without pain medication by third postoperative day.
Patient will reach incentive spirometer goals within 24 hr.	Encourage patient to use incentive spirometer at least q2h. Gradually increase goal.	Prevents postoperative respiratory complications.	Reaches 90% of incentive spirometry goal by third postoperative day.
SpO ₂ will remain at or above	Monitor O ₂ saturation before and after use of incentive spirometer.	Baseline values to determine	PO ₂ 98% before and after use of

98% on room air.		effectiveness of treatment.	incentive spirometer. Continue plan.
------------------	--	-----------------------------	---

Problem Statement/Nursing Diagnosis

Insufficient knowledge/*Deficient knowledge related to postoperative care after discharge from hospital.*

Supporting Assessment Data

Subjective: States, "I don't know how I can manage all this at home. When can I return to work?"

Objective: Patient anxious, irritable during discussion of discharge planning.

Goals/Expected Outcomes	Nursing Intervention	Selected Rationale	Evaluation
Patient and wife will demonstrate knowledge of home care instructions, including wound management, medications, exercise, diet, ADLs, and when to return to work.	Assess level of understanding of discharge instructions.	Baseline for developing discharge plan.	Verbalized understanding of discharge instructions.
	Provide opportunity to verbalize concerns.	Reduces patient anxiety.	Verbalized concerns openly, stated some anxiety relieved.
	Provide instructions concerning medications, wound care, ADLs.	Knowledge of expectations increases confidence and reduces anxiety.	Demonstrated understanding of instructions.
	Refer to dietitian/nutritionist for dietary requirements.	The dietitian can help the family understand the dietary requirements and how to adapt their traditional diet to comply.	States understands diet instructions and will attempt to follow them. Wife also states understanding.
	Collaborate with provider concerning additional instructions, such as return to work and cardiac rehabilitation recommendations.	Expert knowledge may be needed to provide appropriate information.	Patients states understanding of how to make an appointment with cardiac rehabilitation and when he may expect to return to work.
	Reinforce information as provided by provider.	Patients may not question a provider even if they do not understand all they were told. The nurse is in the best position to reinforce the information given by the provider.	Verbalized disappointment that he will be unable to return to work for at least 8 wk. May require part-time basis for longer period. Continue plan.

ADLs, Activities of daily living; *RR*, Respiratory rate.

Critical Thinking Questions

1. List five additional nursing problem statements that are appropriate for a patient after cardiac surgery.
2. List five additional priority assessments you should complete for this patient.

The vein grafts have an average life of 10 years before occlusion begins, unless the patient truly makes the commitment to a heart-healthy diet, lowers stress, and exercises regularly. Multiple studies have shown that patients with CAD symptoms and disease well controlled by medical therapy do not show an improvement in mortality rates by having surgery or PCI. Those without adequate medical control showed no difference in mortality rates whether they received surgery or PCI ([Kalyanasyndaram, 2012](#)).

Heart Transplant

Heart transplants are performed for selected patients who have a history of hospitalizations for HF, need a left ventricular assist device (LVAD), increasing types and doses of medications or documentation of decreased oxygen supplied to the body as measured by VO₂ (VO₂ is the amount of oxygen consumption by the tissues of the body), have good renal function, and are psychologically stable. There is some flexibility with the age requirements.

Candidates for heart transplant undergo psychological evaluation and a thorough physical assessment. Patients must also be evaluated for the ability to remain in compliance with health care instructions and for the ability to obtain and administer antirejection medications. Transplant patients must take immunosuppressants and other medications for the remainder of their lives. Very few donor hearts are available, and the waiting lists are long. Allocation of available organs is determined by evidence-based criteria with oversight of the United Network for Organ Sharing (UNOS). In addition to meeting transplant criteria, patients are limited by geography. A heart can only be out of the donor body for 4 to 6 hours if it is to be successfully transplanted into the recipient. Patients who receive a heart transplant face considerable financial cost, a life of taking immunosuppressive drugs that have many serious side effects (including risk for infection), and the constant threat of organ rejection. However, the benefits are considerable, with an average 1-year survival rate of about 85% to 90%, a 3-year survival rate of about 75%, and a 5-year survival rate of 79% ([Eisen, 2014](#)). A significant number of heart transplant patients survive beyond 10 years.

Transplant patients must adhere to strict dietary and exercise regimens to prevent the new heart from becoming affected with problems that led to the original HF. Heart transplants are performed in highly specialized medical centers. Patients who are too unstable for care in the home may remain in the hospital for an extended period until a heart is available. Other patients may be given a special pager for notification of an available heart. These patients must be available for immediate admission to the hospital. Patients awaiting a heart transplant are placed on a national waiting list. A heart may be available within 24 hours, or one may be months away. Unfortunately, some patients die before a suitable heart is available. There has been increasing success with use of LVADs and mechanical artificial hearts in providing needed perfusion for patients awaiting transplant surgery. For some patients who are not a candidate for transplant, smaller, fully-implanted LVADs have been used as the intervention to support and improve perfusion (see [Figure 19-2](#)).

Nursing Care of Patients Having Cardiac Surgery

Preoperative care.

Before cardiac surgery, the patient undergoes diagnostic tests and examinations, mostly on an outpatient basis. The teaching plan should include expectations during the preoperative and postoperative periods. There is considerable apprehension on the part of both the patient and the patient's family when faced with open heart surgery. If the surgery was emergent, teaching must be done postprocedure.

The patient is given information about the procedure, explaining what to expect and what kind of equipment will be used. Admission occurs early the morning of surgery. Specific information regarding what medications to take and which ones to stop is included in the preoperative instructions. See [Nursing Care Plan 20-2](#) for care of the patient after cardiac surgery.

Postoperative care.

During the early postoperative period, the patient remains in a CCU, where specialized cardiac monitoring equipment is used and highly skilled personnel are in constant attendance. Cardiac rate and rhythm are monitored closely. For patients who had an open heart procedure, chest tubes for drainage and proper re-expansion of the lungs are in place for 24 hours. The patient often continues to receive mechanical ventilation for a few hours after surgery. Once consciousness has fully returned, weaning from the ventilator is begun if oxygenation is adequate. Autologous blood transfusion is performed with blood drained from the chest cavity. Chest tubes are usually removed before the patient is moved out of the CCU. Temporary epicardial pacemaker leads may be in place and may or may not be connected to a pacemaker pulse generator. Usually, a multilumen central line is in place for medication delivery and fluid maintenance, as well as an arterial line and PA line for hemodynamic monitoring. If saphenous vein grafts were used, there will be leg incisions to care for along with the chest incision. Urine output is initially monitored hourly for 8 hours and thereafter every 2 hours to detect signs of decreased perfusion to the kidneys.

After the first 12 to 24 hours, the surgeon will assess the patient's condition and decide whether transfer to a step-down unit is appropriate. The patient will continue to need special nursing care and continuous ECG monitoring. Vital signs must be taken and recorded at frequent intervals; urinary output is monitored closely. Lung sounds and oxygenation are priority assessments. Daily weight is monitored to assess fluid balance.

Clinical Cues

Priorities for care of the postsurgical patient must be established. Plan on frequent assessment of respiratory and cardiac status, care of invasive lines and chest tubes, wound assessment and care, fluid and electrolyte balance, pain management, and assessment of emotional status.

Coronary artery bypass surgery can produce many special problems related to rehabilitation of the patient. Among the physiologic symptoms that can persist into the home recovery period are fatigue and weakness, incisional discomfort, edema in the donor leg, dysrhythmias, loss of appetite, and unusual physical sensations. Depression for weeks to months is not uncommon after heart surgery. Patients should be alerted to this possibility and referred for assistance if this occurs.

Women are more likely than men to experience depression after heart surgery, and their cases are more severe.

Most patients do not experience all these problems during the home recovery period after coronary artery bypass surgery, and some have relatively trouble-free recovery periods. It is important that bypass surgery patients and their families realize that bypass surgery is not a cure for CAD. Bypass surgery is simply one form of therapy for a chronic condition that will require continued management to slow the disease process and reduce the incidence of life-threatening events in the person's life. Other specific postoperative care is directed at preventing infection to the surgical sites, managing wounds, monitoring for complications, and promoting rehabilitation.

With an uncomplicated recovery, the patient is usually discharged home within 3 to 7 days and referred to a cardiac rehabilitation outpatient program.

Cardiac transplant patients are at risk for organ rejection, infection, and development of CAD in the new heart. Heart biopsies are performed regularly. Post-transplant malignancy is a known risk factor and is believed to result from the prolonged immunosuppression. Skin cancer is the most common malignancy after organ transplant.

Community Care

With early discharge from the hospital after surgery, many patients have continuing care from home health nurses. Patients recovering from cardiac surgery, MI, atherosclerotic heart disease, angina, or valvular heart disease all may be referred to a cardiac rehabilitation program. The goal of such programs is to reduce risk of further heart problems or death.

Home care nurses have many patients diagnosed with heart disease. The goal of home care is to monitor the patient's condition and to prevent complications, such as life-threatening dysrhythmias, MI, and CHF. Nurses supervise the medication regimen, monitor weight gain, draw blood for laboratory tests to determine drug levels and electrolyte status, and assess for beginning signs of complications. By detecting complications early, patients can be treated at home rather than at the hospital, thereby decreasing costs of care.

Many residents in long-term care facilities have cardiac disorders. Assessing changes in condition is a high priority. If changes can be identified quickly, the severity of a complication can be reduced in this population. It is important to know each resident's history.

Get Ready for the NCLEX® Examination!

Key Points

- High levels of cholesterol (LDL) contribute to development of atherosclerosis, a major factor in occlusion of coronary vessels.
- Ischemia occurs as blood supply is decreased to the myocardium.
- A cardinal sign of myocardial ischemia is angina pectoris (chest pain).
- SCAD may be treated medically or by PCI.
- *Acute coronary syndrome* is an umbrella term for a group of symptoms indicating severe myocardial ischemia.
- Nitrates (nitroglycerin) are the most commonly used drugs to treat angina.
- Patients should be monitored for hypotension and development of a throbbing headache while taking nitroglycerin.
- When a coronary artery becomes completely obstructed, necrosis of myocardial tissue occurs (MI).
- Necrotic myocardial tissue cannot perform its function of pumping.
- Diagnosis of MI is made by patient history, ECG, and serum cardiac enzyme levels.
- A patient may be given an aspirin tablet if an MI is suspected. Aspirin helps prevent further clot formation.
- Emergency care for a patient suspected of experiencing an MI includes oxygen; IV access; cardiac monitoring; pain management, usually IV morphine sulfate; ECG; and management of dysrhythmias. These activities are done promptly if STEMI is suspected.
- Medications prescribed after MI may include nitrates, antihypertensive drugs, anticoagulants, beta blockers, ACE inhibitors, and antidysrhythmic drugs.
- Cardiac catheterization is likely to be performed on a patient experiencing an MI.
- Nursing care after cardiac catheterization includes cardiac monitoring, maintaining the patient in a supine position with the legs straight for at least 2 hours, monitoring the femoral area for hematoma formation, assessing peripheral pulses frequently, and monitoring urinary output.
- Stents may be placed to maintain patency of coronary vessels in an attempt to prevent the need for CABG. Stents may be placed during PTCA.
- CABG may be needed when a patient's angina cannot be controlled by medical means or when there is myocardial damage caused by occlusion of one or more coronary vessels.
- An alternative to CABG is MIDCAB performed off-pump.
- A heart transplant may be needed for a patient with end-stage left ventricular heart failure.
- Patients receive physical and psychological assessment before acceptance into a cardiac transplant program. Family counseling is also advisable.
- Donor hearts are not readily available; therefore patients must be carefully screened to determine the most appropriate recipient.
- Patients who are candidates for cardiac transplant must be advised of potential complications, the need to follow through on dietary and exercise recommendations, and the need to continue medications, such as immunosuppressants, for the remainder of their lives.
- Nursing care of patients after heart transplant includes intense monitoring in the CCU; assessing for signs of complications; wound management; administration of emergency, antirejection, and appropriate cardiac drugs; pain management; assessment of respiratory function; and initial return to physical activity such as out of bed to chair.
- Discharge planning should prepare the patient for return home and the beginning of care in the community.
- Monitoring the patient's understanding of and compliance with prescribed medications is an important responsibility of the home health nurse.

Review Questions for the NCLEX® Examination

1. After reviewing risk factors for cardiac disease, a patient is prescribed atorvastatin (Lipitor) to reduce cholesterol levels. The nurse must include which instruction(s)? (*Select all that apply.*)

1. Report any muscle weakness.
2. Avoid exposure to sunlight.
3. Keep appointments for laboratory work.
4. Drink grapefruit juice.
5. Maintain a low-protein diet.

NCLEX Client Need: Pharmacological Therapy

2. A patient asks, "What causes angina pectoris?" An accurate response by the nurse would be:

1. "It is caused by the decreased blood flow to the coronary arteries resulting from shunting of the blood."
2. "It is caused by a decreased blood flow to the myocardium resulting from partial obstruction of the coronary arteries."
3. "It is caused by poor oxygenation of the coronary arteries resulting from poor gas exchange across the alveolar basement membrane."
4. "It is caused by the inflammation of the sternal cartilage."

NCLEX Client Need: Physiological Adaptation

3. A patient is diagnosed as having attacks of angina pectoris. As part of the discharge instructions, the patient is instructed on the appropriate storage and use of sublingual nitroglycerin. Which of the following patient statements indicates a need for further instructions?

1. "The tablets should be kept in a cool, dark place."

2. "I need to lie down after I take the medication."
3. "I can take the tablet every 15 minutes for angina pains."
4. "The expiration date on the bottle is important."

NCLEX Client Need: Pharmacological Therapy

4. A 44-year-old patient is admitted with a sudden, severe chest tightness unrelieved by rest or nitroglycerin and profuse sweating. Which test would exhibit an elevated level only if the patient has had an MI?

1. Serum troponin
2. Blood urea nitrogen
3. Myoglobin level
4. Prothrombin time

NCLEX Client Need: Reduction of Risk Potential

5. Immediate therapeutic measures provided for a patient entering the hospital with an acute myocardial infarction include which measure(s)? (*Select all that apply.*)

1. Morphine sulfate
2. Oxygen therapy
3. Furosemide
4. Nitroglycerin
5. Aspirin

NCLEX Client Need: Physiological Adaptation

6. Which food has been found to reduce cholesterol levels?

1. Garlic
2. Onion
3. Ginger

4. Nutmeg

NCLEX Client Need: Reduction of Risk Potential

7. The provider explains the treatment options to a Hispanic woman diagnosed with occlusion of multiple coronary vessels. Before signing an informed consent, the patient is most likely to defer her health care decisions to her:

1. oldest adult son.
2. oldest adult daughter.
3. brother-in-law.
4. husband.

NCLEX Client Need: Psychosocial Integrity

8. A patient has experienced an MI and has ST-segment elevation on the ECG. The priority problem would be:

1. Altered gas exchange.
2. Limited coping ability.
3. Altered tissue perfusion.
4. Altered activity tolerance.

NCLEX Client Need: Reduction of Risk Potential

9. Postoperative nursing care of a patient who has undergone CABG includes which priority intervention(s)? (*Select all that apply.*)

1. Assessing cardiac rate and rhythm
2. Encouraging use of incentive spirometer
3. Monitoring liver enzymes
4. Assessing bowel sounds
5. Managing pain

NCLEX Client Need: Physiological Adaptation

10. After the change-of-shift report, which of the following assigned patients should the nurse attend to first? The patient with:

1. stable vital signs who returned 40 minutes ago after a PCTA.
2. an MI complaining of a headache who was transferred from the CCU earlier.
3. stable angina whose chest pain was relieved by two nitroglycerin tablets 2 hours ago.
4. unstable angina who is having chest pain, shortness of breath, nausea, and anxiety.

NCLEX Client Need: Physiological Adaptation

Critical Thinking Questions

Scenario A

Ms. Trotter, a 62-year-old woman, comes to the clinic for her annual examination results. Her cholesterol level is 260 mg/dL, with HDL 30 mg/dL and LDL 220. She has a family history of atherosclerosis and heart disease. She asks about the danger of her high cholesterol level.

1. Describe to her how atherosclerosis can lead to heart problems.
2. Help her identify ways to decrease her cholesterol level and raise her HDL level.
3. Describe to her the symptoms of heart problems she should report to her doctor.
4. Have her identify the symptoms that might indicate a heart attack and what she should do if they occur.

Scenario B

Mrs. Yee, a 50-year-old woman, comes to the emergency department complaining of a burning, squeezing sensation in her chest and a feeling of nausea. She is diaphoretic and apprehensive.

1. Compare and contrast the symptoms of heart attack between men and women.
2. Describe the probable emergency treatment of Mrs. Yee in the emergency department.
3. What laboratory tests may be ordered to evaluate for possible MI? What is a significant ECG finding indicating MI?

Scenario C

Ms. O'Hare, a 45-year-old woman, is on the list for a heart transplant. She has a LVAD and is waiting at home.

1. What signs and symptoms would be displayed indicating that Ms. O'Hare was no longer stable enough to wait at home?
2. Describe the purpose of the LVAD.
3. Develop a discharge teaching plan for Ms. O'Hare after transplant.

UNIT VII

Neurologic System

OUTLINE

Chapter 21 The Neurologic System

Chapter 22 Care of Patients With Head and Spinal Cord Injuries

Chapter 23 Care of Patients With Brain Disorders

Chapter 24 Care of Patients With Peripheral Nerve and Degenerative Neurologic Disorders

CHAPTER 21

The Neurologic System*

Objectives

Theory

1. Define the vocabulary particular to problems of the nervous system.
2. Examine the differences in the action of the sympathetic and parasympathetic nervous systems.
3. Devise four specific ways in which a nurse can contribute to preventing neurologic disorders.
4. Provide rationale for the appropriate preparation and postprocedure care for patients undergoing lumbar puncture (spinal tap), electroencephalogram (EEG), and radiologic studies of the brain and cerebral vessels.
5. Demonstrate techniques used for assessment of the nervous system.
6. Compare and contrast the various signs and symptoms of the common problems experienced by patients with nervous system disorders.

Clinical Practice

7. Gather a pertinent history for a patient with a nervous system problem.
8. Demonstrate a “neuro” check.
9. Score the neurologic status of a patient with a nervous system disorder according to the Glasgow Coma Scale.

KEY TERMS

- accommodation (äk-köm-ě-DÄ-shūn, p. 487)
aphasia (ä-FÄ-zhā, p. 496)
Babinski reflex (Bab-INS-key, RĒ-flēks, p. 484)
calculi (KÄL-kū-lī, p. 494)
caloric testing (käl-Ö-rik, p. 484)
clonus (KLÖ-nūs, p. 484)
decerebrate posturing (dē-SĒR-ě-brāt PÖS-chür-ěng, p. 487)
decorticate posturing (dē-KÖR-tī-kāt, p. 487)
delirium (dē-LĒR-ě-ūm, p. 495)
dysphagia (dīs-FÄ-jē-ă, p. 493)
hemiparesis (hēm-ě-pă-RĒ-sīs, p. 492)
hemiplegia (hēm-ě-PLĒ-jă, p. 492)
nystagmus (nis-TÄG-mūs, p. 486)
quadriplegia (kwöd-rī-PLĒ-jă, p. 493)
tetraplegia (TĒT-ră-PLĒ-jă, p. 492)

Anatomy and Physiology of the Neurologic System

Organization of the Nervous System

- The functional unit of the nervous system is the neuron, which consists of a cell body, dendrites, and an axon (Figure 21-1). Neurons react to stimuli, conduct impulses, and influence other neurons. There are afferent and efferent neurons.

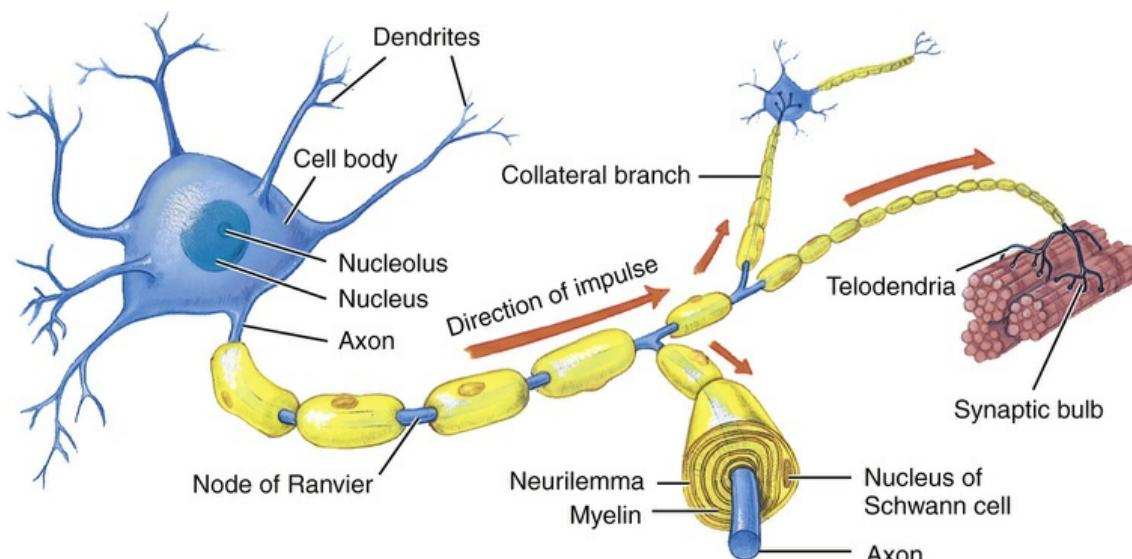

FIGURE 21-1 Structure of a neuron. (From Applegate E: *The anatomy and physiology learning system*, ed. 4, Philadelphia, 2011, Saunders.)

- The nervous system consists of the central nervous system (CNS) and the peripheral nervous system (PNS).
- The CNS is made up of the brain and spinal cord (Figure 21-2).

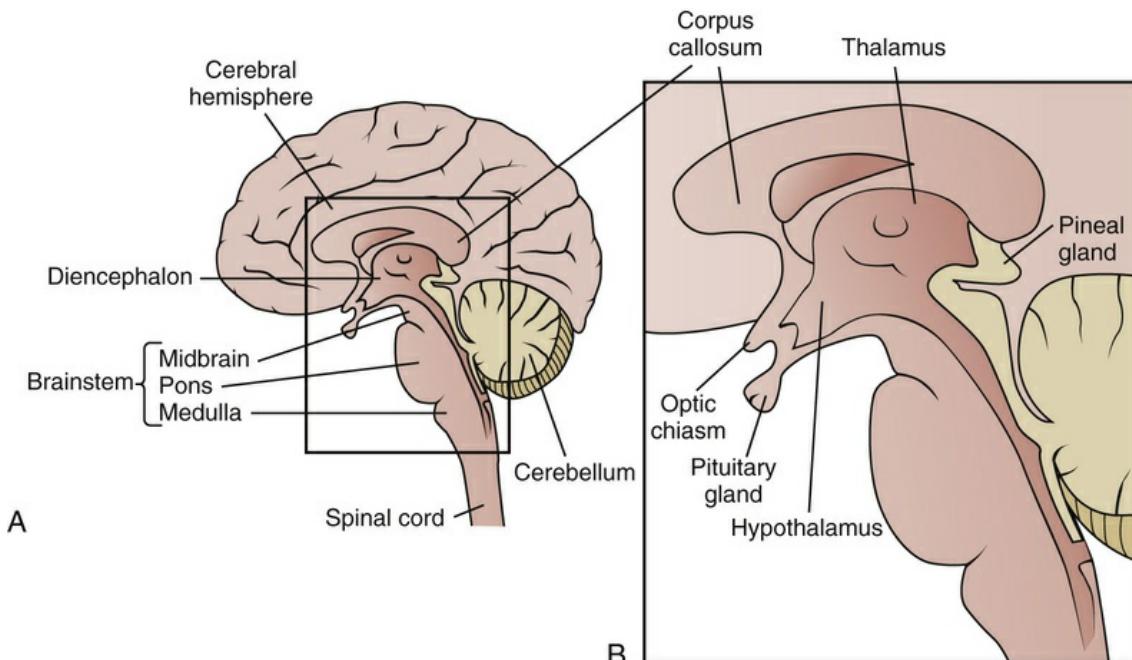

FIGURE 21-2 A, Main divisions of the central nervous system. B, Diencephalon (thalamus and hypothalamus).

- The brain is divided into the cerebrum, diencephalon, cerebellum, and brainstem, which each perform various functions. [Table 21-1](#) lists the functions of the various divisions of the brain.

Table 21-1
Functions of the Divisions of the Brain

DIVISION	FUNCTION
Cerebrum	Center of intellect and consciousness. Receives and interprets sensory information; controls voluntary movements and certain types of involuntary movements; responsible for thinking, learning, language capability, judgment, and personality; stores memories.
Cerebellum	Responsible for coordination of movement, posture, and muscle tone that are the mechanisms of balance.
Diencephalon	Consists of two parts.
Thalamus	Relay center between spinal cord and cerebrum.
Hypothalamus	Controls body temperature, appetite, and water balance; links nervous and endocrine systems.
Brainstem (consists of three parts):	
Midbrain	Mediates visual and auditory reflexes; controls cranial nerves III and IV and certain eye movements.
Pons	Links connecting various parts of the brain; helps regulate respiration.
Medulla oblongata	Contains reticular formation that regulates heartbeat, respiration, and blood pressure; controls center for swallowing, coughing, sneezing, and vomiting; relays messages to other parts of the brain.

- The brainstem consists of the midbrain, pons, and medulla.
- The different parts of the brain control various functions ([Figure 21-3](#)).

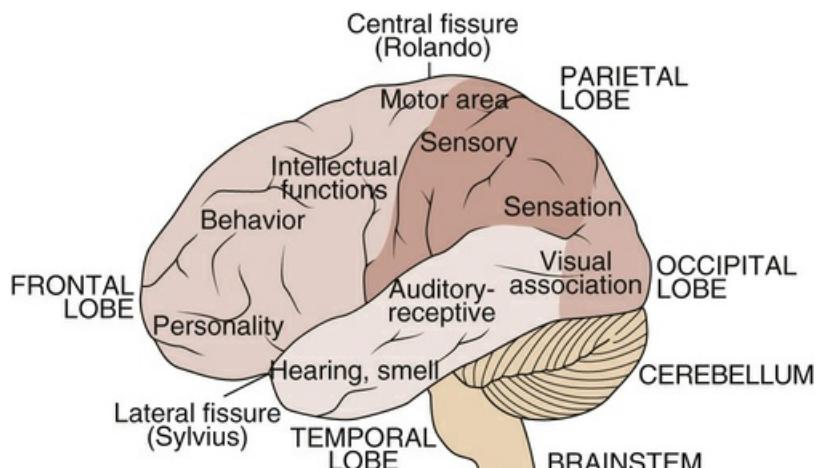

FIGURE 21-3 Specialized functions of the lobes of the cerebrum.

- The PNS is composed of the sensory organs—eyes, ears, taste buds, olfactory receptors, and touch receptors—12 pairs of cranial nerves, and 31 pairs of spinal nerves and ganglia that link the sensory organs, muscles, and other parts of the body to the brain and spinal cord. The distribution pathways of the spinal nerves are called *dermatomes* ([Figure 21-4](#)).
