Several environmental factors can have a direct effect on the health of the skin. These include prolonged exposure to chemicals, excessive drying from repeated immersions in water, very cold temperatures, and prolonged exposure to sunlight. Some of these are occupational hazards. A change of jobs may be necessary to eliminate contact with a factor that is causing a skin disorder. One of the *Healthy People 2020* objectives[®] is to reduce occupational skin diseases or disorders among full-time workers.

Overexposure to the UV rays of the sun can seriously and permanently damage the superficial and deeper layers of the skin. The damage results in severe wrinkling and furrowing, as well as loss of elasticity, and the skin assumes a tissue-paper transparency. In addition to the potential for premature aging and degenerative changes, solar damage also can result in malignant changes. Ultraviolet rays from the sun have long been known to be carcinogenic. This is especially true for fair-skinned people who have subjected their skin to prolonged exposure to sunshine. Although sunburns are particularly harmful, it is the normal daily exposure of unprotected fair skin to sun that causes long-term damage.

Health Promotion

Sun Exposure Precautions

Health teaching to inform the public about the dangers of solar UV radiation should include the following information:

- Although fair-skinned people who freckle easily are more likely to suffer sun-damaged skin, people of all complexions and races can and do burn if exposed to sufficient sunlight.
- Although a good tan might be considered by many to be desirable, dermatologists say that there is no such thing as a "healthy tan." Tanning causes damage to the skin. For those who insist on lying out in the sun, the initial exposure should be slow and gradual, and an adequate sunscreen with a sun protection factor (SPF) of at least 30, as well as ultraviolet A (UVA) and ultraviolet B (UVB) protection, should always be used. Too much sun too quickly only leads to blistering and peeling.
- Select a sunscreen preparation on the basis of skin type and ability to tan, as well as its active ingredients and the amount of time to be spent in the sun. Remember that the sunscreen can be

washed off by water or perspiration or rubbed off on sand and towels and must be periodically reapplied. Apply sunscreen liberally 15 to 30 minutes before sun exposure ([FDA, 2014](#)). Reapply every 2 hours. The ingredients in the sunscreen are actually used by the body and depleted within these 2 hours, so a higher SPF sunscreen will not last longer.

- Avoid exposure to the sun during the time its rays are most hazardous—that is, between 10 A.M. and 2 P.M. standard time or 11 A.M. and 3 P.M. during daylight saving time. Local radio and television stations often give information about current weather conditions and the chances for being burned by the sun at particular times during each day.
- You can be sunburned on a cloudy or overcast day.
- Light, loosely woven clothing will not give adequate protection from the sun's rays.
- Remember that snow, water, and sand can reflect the sun's rays and increase the intensity of exposure.
- Do not try to gauge how much you are being burned while in the sun. It may be 6 to 8 hours before a painful burn becomes obvious.
- Wear sunglasses and a hat when you go out in the sun, and, when possible, wear protective clothing.
- **Never use a tanning booth;** there is an eightfold increased risk to develop melanoma for persons under age 36 years ([CDC, 2014](#)).

Complementary and Alternative Therapies

Ultraviolet Radiation Protection

An oral form of fern plant extract may help protect the skin from UV radiation. The fern extract is from *Polypodium leucotomos* and is a natural antioxidant with tumor inhibition properties. Initial studies showed that volunteer subjects could tolerate threefold to sevenfold longer sun exposure time.

Clinical Cues

It is estimated that 90% of people between 50 and 71 years of age are not getting adequate vitamin D. Adults with limited sun exposure are at especially increased risk of vitamin D deficiency, if their skin is dark. During spring, summer, and autumn, 5 to 15 minutes of sun exposure without sunscreen twice per week to the face, arms, hands, and back is sufficient for adequate vitamin D production ([Drezner, 2014](#)).

Think Critically

You are talking to a young woman who works as a ski instructor. She is fair-skinned and says that “on really sunny days, my hat is in my pocket and I never use sunscreen.” Discuss some issues related to this woman’s integumentary health.

Integrity of Skin

Good nursing care includes protection of the skin and prevention of skin tears. A skin tear is a potentially preventable, traumatic wound that occurs primarily on the extremities of older adults because of age and debility. The wound occurs as a result of careless handling, friction alone, or shearing and friction forces that separate the epidermis from the dermis or separate both structures from the underlying tissue. More than 1.5 million skin tear injuries occur each year among institutionalized adults in health care facilities ([Stephen-Haynes and Carville, 2011](#)). The epidermis thins and becomes less elastic with age, making it susceptible to tearing with little trauma. Those

individuals who require total care are at the highest risk. Risk factors for skin tears, other than age older than 65 years, are presented in [Box 41-1](#).

Box 41-1

Risk Factors for Skin Tears in Older Adults

Assess the patient for the following factors:

- Dry skin with dehydration
- Areas of ecchymosis
- Presence of friction, shearing, or pressure from bed or chair
- Impaired sensory perception
- Impaired mobility
- Taking multiple medications
- Prolonged use of corticosteroids
- Presence of renal disease, congestive heart failure, or stroke impairment
- Incorrect removal of adhesive dressings
- Rough handling when being bathed, dressed, transferred, or repositioned

The Payne-Martin classification system ([Stephen-Haynes and Carville, 2011](#)) classifies skin tears as :

- *Category I:* A skin tear without tissue loss
- *Category II:* A skin tear with partial tissue loss
- *Category III:* A skin tear with complete tissue loss in which the epidermal flap is missing

Nursing Management

Rigorous nursing care ([Box 41-2](#)) to prevent skin tears is obviously preferable to treating skin tears that could have been prevented. However, when a skin tear is discovered, steps for its management are:

- Gently cleanse the skin tear with saline.
- Allow the area to air-dry, or pat dry gently and carefully.
- If the skin tear flap has dried, remove it using scissors and sterile technique.
- If the skin tear flap is viable, gently roll the flap back into place using a moistened cotton-tipped applicator.
- If bleeding has stopped, silicone-coated net dressings are preferred; Steri-Strips or petroleum-based protective ointments are also used. Cyanoacrylate skin protectants are in a liquid form that creates a barrier to protect damaged skin. The substance does not need to be removed because it will shed in approximately 1 week ([Knaff-Baker, 2013](#)).
- If bleeding continues, dress with alginate and a secondary dressing.
- Manage the same as a skin graft. The flap should not be disturbed for about 5 days to allow the skin flap to adhere.
- Assess and measure the size of the skin tear.
- Document assessment and treatment.

Box 41-2

Measures to Prevent Skin Tears and Protect Fragile Skin

- Have patients wear long sleeves and long pants to protect the extremities, or protect the fragile skin on extremities with stockinettes.
- Provide adequate lighting to reduce the risk of bumping into furniture or equipment.
- Maintain the patient's nutrition and hydration; offer fluids between meals.
- Lubricate the skin with cream or lotion twice a day, paying special attention to the arms and legs.
- Use an emollient soap for bathing, and do not use soap every day on extremities if no soiling has occurred.
- Use a lift sheet to move and turn patients.
- Avoid wearing rings or bracelets that could snag the skin.
- Use transfer techniques that prevent friction or shear.
- Pad bed rails, wheelchair arms, leg supports, or other equipment where the patient might bump an extremity.
- Support dangling arms and legs with pillows or blankets.
- Use nonadherent dressings on fragile skin. Use gauze wraps or stockinettes to secure dressing. If tape must be used, use a paper or nonallergenic tape and apply it without tension.
- Mark the dressing with an arrow showing the direction it should be removed.
- Remove tape and dressing with extreme caution:
 - Use a solvent or saline to loosen the adhesive bond.
 - Slowly peel tape away from anchored skin (stabilize skin).
- If a thin hydrocolloid or solid wafer skin barrier is used as a protective barrier between the skin and the dressing, allow it to fall off naturally.

Stephen-Haynes and Carville (2011) recommend that a skin tear comprehensive assessment is essential to ensure that adequate attention is given to the wound. The dressing should (1) continuously cleanse the wound, (2) conform to the wound, (3) absorb exudates, and (4) keep the wound bed moist and reduce pain and discomfort. The wound must be watched for signs of infection. Extra padding for the involved extremity will help to prevent additional injuries.

Clinical Cues

According to the Wound, Ostomy, and Continence Nurses Society, transparent adhesive dressings are no longer recommended for covering skin tears (Miner et al, 2009).

Diagnostic Tests and Procedures

Skin biopsy.

Removing a sample of tissue (**biopsy**) from a skin lesion usually is performed with a local anesthetic. It can be done by shaving a top layer off a lesion that rises above the skin line (**shave biopsy**), by removing a core from the center of the lesion (**punch biopsy**), or by excising the entire lesion (**excisional biopsy**).

Skin biopsy is used to differentiate benign from malignant lesions and to help identify the causative organism in bacterial and fungal infections. No special patient preparation is necessary beyond a simple explanation of the procedure and its purpose. If a local anesthetic is to be used, the patient is asked about any personal or family history of allergies. After the procedure, the patient is given instructions for the care of the biopsy site. Usually the bandage is changed daily. The site may or may not be treated with a topical antibiotic solution or ointment. Sutures from an excisional biopsy will need to be removed in 10 to 14 days.

Culture and sensitivity tests.

When a bacterial, viral, or fungal infection of the skin is suspected, culture and sensitivity tests can be used to identify the causative organism and the drug most appropriate for treating the specific infection. A sampling of **exudate** (drainage) is taken from the lesion and sent to the laboratory for culturing. Once the organism has been cultured, colonies can be tested for sensitivity to certain anti-infective agents. Care must be taken when handling the specimen and its container to avoid contaminating people who will later be handling the specimen.

Safety Alert

Skin Drainage or Weeping

Whenever there is a question of a pathogenic process, weeping or drainage from skin lesions, or the suspicion of scabies, Standard Precautions should be employed when touching the patient's skin to prevent self-contamination or transmission of an organism.

Microscopic tests.

Various stains and solutions are used to prepare skin, hair, scales, or nail material for study. These tests can identify fungal, bacterial, and viral organisms. To check for organism infestations, scrapings are suspended in mineral oil and examined under the microscope.

Special light inspection.

Inspection of the skin is one of the principal means by which skin lesions are diagnosed. To facilitate the diagnosis of certain kinds of skin disorders, special lights may be used by the examiner. A **cold light** is one in which the light is transmitted through a quartz or plastic structure to dissipate the heat. Because there is no danger of burning the skin, the cold light can be applied directly to the skin to illuminate its layers for visualization of malignant changes.

A **Wood's light** is a specially designed UV light. The nickel oxide filter holds back all but a few violet rays of the visible spectrum. This special light is especially useful to diagnose fungal infections of the scalp and chronic bacterial infection of the major folds of the skin (**erythrasma**). Under a Wood's light, fungal lesions and erythrasma are fluorescent. Erythrasma usually is seen on the inner thighs, scrotum, and axilla; under the breasts; and in the area between the toes.

Diascopy.

Diascopy uses a glass slide or lens pressed down over the area to be examined, blanching the skin and thereby reducing the erythema caused by increasing blood flow to the area. The shape of the underlying lesion is then revealed.

Skin patch testing.

When a rash is suspected to be of an allergic nature, patch testing is used to identify the responsible allergen. Test chemicals or substances are introduced to unaffected skin, usually on the forearm or back, by superficial scratches or pricks. If a localized reaction producing a **wheel** (smooth, slightly elevated area that is pale or reddened) occurs, the test is positive. Patch tests are sometimes evaluated at a later time.

Nursing care for diagnostic tests.

Check to see that the patient has signed an informed consent, if one is needed, for biopsies.

Reinforce what the provider has told the patient about the procedure and assess whether the patient understands or has additional questions. Check for allergies to the anesthetic or skin preparation solution. Properly label any specimens and send them to the laboratory. Apply a dressing and give both verbal and written postoperative instructions to the patient. Tell the patient approximately when the results will be back and that the patient will be notified. Advise whether a follow-up visit is necessary.

❖Nursing Management

■ Assessment (Data Collection)

History Taking

Diagnosing skin disorders requires a thorough history to identify factors that predispose a patient to skin disease or factors that cause some types of skin disease.

☒ Focused Assessment

Data Collection for Skin Disorders

The following questions should be asked when seeking data on a skin disorder:

- When did the rash or lesion first appear?
- Can you think of any event or different food you ate or substance you were using just before it appeared?
- What is your usual dietary pattern? What do you eat and drink?
- Have you noticed if anything makes it worse?
- What seems to make it better?
- Have you been using any chemicals lately for household cleaning or in pursuit of your hobbies?
- Have you been out in rural areas or the woods lately?
- Have you been traveling? Did you visit a tropical area?
- Have you had any recent exposure to animals?
- What drugs are you taking? Do you take any over-the-counter medications?
- Have you ever had a drug reaction?
- Have you ever had radiation therapy?
- Do you have a history of any skin disorders in your family?
- Does anyone in the family currently have similar symptoms, such as a rash?
- Do you have any allergies?
- Are you experiencing itching? Pain? Fever?
- Have you had any gastrointestinal problems that began about the same time that the rash or lesion appeared? What about a runny or stuffed-up nose? Cough?
- Has the skin condition affected your social life or work?

Scabies, lice, and other parasites can be transmitted through close personal contact with infected

persons at work, recreation, home, or school. It is important to know whether exposure has occurred, so that others can be notified and treated.

Many drugs can produce skin eruptions in certain individuals. Drug allergy or reaction can produce lesions and rashes that imitate those found in a long list of diseases, including measles, chickenpox, fungal infections, skin cancers, and psoriasis.

Itching and pain are the most common complaints. If the patient has recently been exposed to severe cold, her skin may be drier than usual and she may complain of severe itching (**winter itch**). If the disorder is caused by an allergy, the patient also may complain of shortness of breath, cough, or some gastrointestinal symptoms. The patient also may be able to relate what other factors, such as stress or excitement, could be related to the appearance of the skin lesions.

Physical Assessment

A thorough inspection of the skin under good lighting is essential. Provide privacy and have the room at a moderate temperature so that the patient does not become chilled. The patient should don a gown that allows access to all areas of the skin.

Cultural Considerations

Coin Rubbing

Coin rubbing is a Southeast Asian folk remedy that is intended to draw illness out of the body. An oiled coin is rubbed over the skin surface and creates bruise-like marks or patterns of red lines or welts on the skin. The redness is interpreted as a sign that the remedy is bringing the illness to the surface (D'Avanzo, 2008).

Seborrheic **keratoses** are common in older adults. They appear as wartlike, greasy lesions on the trunk, arms, scalp, and sometimes the face. They are not a cause for concern.

Darkly pigmented people will have areas that are darker than other parts of the skin. This is caused by hormonal influences. The darker areas are the nipples, areola, scrotum, and labia minora. This is true among both African Americans and Asians. When the skin of a darkly pigmented person is damaged, scar tissue may hypertrophy, forming a **keloid** (a thick ridge of scar tissue that stands up from the surrounding skin) (Figure 41-3).

FIGURE 41-3 A keloid scar. (From Lookingbill DP, Marks JG: *Principles of dermatology*, ed. 2, Philadelphia, 1993, Saunders.)

The hair of African Americans differs in texture. It varies from being long and straight to being short, thick, and tightly curled. It is very dry and fragile and requires daily grooming with oil. Asians tend to have straight hair. If an African American child has malnutrition, sometimes the hair will turn a coppery red.

Clinical Cues

When trying to differentiate between a **macule** and a **papule**, shine a flashlight at a right angle to the lesion. A papule will cast a shadow. If there is no shadow the lesion is a macule. To determine

whether there is fluid in a lesion, place the tip of a penlight against the side of the lesion. If the light illuminates it with a red glow, it is fluid filled. If there is no light illumination, the lesion is solid.

Clinical Cues

Pallor in a dark-skinned person presents as an ashen-gray tone to the skin. In a brown-skinned person, pallor gives the skin a yellow-brown color.

The skin should be lightly palpated to detect changes in texture and surface elevations. Palpation also is used to detect pain, areas of increased warmth, and tenderness. When checking the temperature of the skin, the back of the hand should be used. Skin turgor is assessed by lifting a fold of skin on the forearm, chest, or abdomen between two fingers and seeing how fast it falls back into place.

Focused Assessment

Physical Assessment of Skin

Perform a physical examination of the entire skin surface. Proceed from head to toe. Compare from one side of the body to the other. Use the metric system when measuring lesions; document all findings. Check the patient for:

- General appearance of skin surface: texture, elasticity, thickness
- Condition of areas between skinfolds
- Type of lesions and distribution, size, and appearance; photograph or measure and document measurements
- Appearance of skin adjacent to lesions; note whether reddened areas blanch when mild pressure is applied
- Localized or generalized skin edema
- Characteristics of secretions: color, viscosity, amount
- Odor: description of odor; strong or faint; source—local or generalized
- Temperature changes: location of hot spots or cold areas of the skin

In addition:

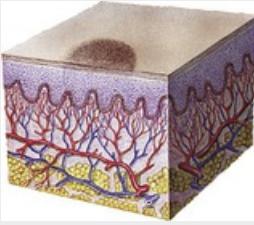

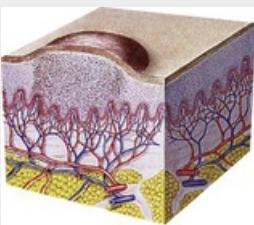

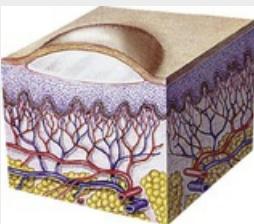

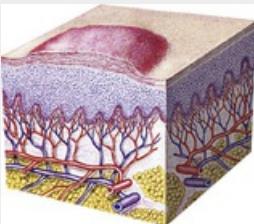

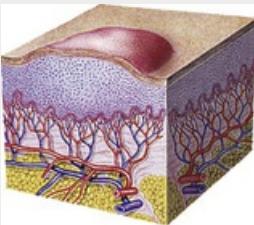

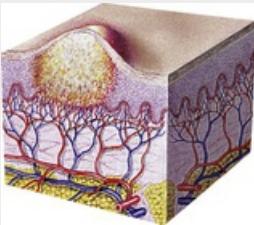

- Check the back and the soles of the feet, including between the toes
- Observe patient for scratching, rubbing, or picking at lesions
- Observe for scratching of the scalp or pubic areas
- Inspect the hair for texture, brittleness, thinning, and cleanliness
- Inspect the nails for chipping, splitting, discoloration, and ragged or inflamed cuticles

Table 41-1 shows characteristics of various types of skin lesions. As you are performing your assessment you can simultaneously teach the patient about self-examination of the skin.

Table 41-1

Types of Skin Lesions

LESION	DESCRIPTION
Macule	Circumscribed, flat area with a change in skin color; <1 cm in diameter

		<i>Examples:</i> Freckles, petechiae, measles, flat mole (nevus)
Papule		Elevated, solid lesion; <1 cm in diameter <i>Examples:</i> Wart (verruca), elevated moles
Vesicle		Circumscribed, superficial collection of serous fluid; <1 cm in diameter <i>Examples:</i> Varicella (chickenpox), herpes zoster (shingles), second-degree burn
Plaque		Circumscribed, elevated superficial, solid lesion; >1 cm in diameter <i>Examples:</i> Psoriasis, seborrheic and actinic keratoses
Wheal		Firm, edematous, irregularly shaped area; diameter variable <i>Examples:</i> Insect bite, urticaria
Pustule		Elevated, superficial lesion filled with purulent fluid <i>Examples:</i> Acne, impetigo

From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2014, Mosby. Figures from Patton KT, Thibodeau GA: *The human body in health and disease*, ed. 6, St. Louis, 2014, Mosby.

Patient Teaching

Self-Assessment of the Skin

Teach the patient that the skin should be examined every few months. For back or other areas, suggest that a family member or close friend examine that area of skin. If any changes have occurred, the patient should consult the provider right away. Advise that warts, moles, or discolorations of the skin should be checked each month for:

- Darkening or spreading of color or increasing unevenness of color
- Increase in size or diameter
- Change in shape; that is, has the lesion become elevated, or have its formerly regular edges become irregular?
- Redness or swelling of surrounding skin, or any other noticeable change around the lesion
- Itching, tenderness, or other change in sensation
- Crusting, scaling, oozing, ulceration, or other change in the surface of the lesion
- When assessing for melanoma, check for the ABCDs: A = asymmetric, B = irregular border, C = color change, D = diameter change greater than $\frac{1}{4}$ inch

Older Adult Care Points

When checking skin turgor on an older adult, test the upper chest, because the skin of the arms and hands of older adults may lose elasticity and is not a reliable index. Gently pinch a small amount of skin and lift up and let go. Note the time it takes for the skin to move back to its normal position. If the skin stays "tent" or takes more than 8 to 10 seconds to return to normal position, the patient is dehydrated. Older adults bruise more easily as the skin becomes thinner and collagen is lost. Patches of **senile purpura**, deep red areas, may occur even from minor injuries.

Assessing the Skin for Signs of Breakdown

Skin should be thoroughly assessed when the patient is admitted to your facility. Skin assessment is performed every shift on immobile patients, noting the condition of skin over bony prominences. Findings must be accurately documented.

Legal and Ethical Considerations

Skin Lesion Documentation

All data gathered when assessing the skin and any lesions should be accurately documented, including location, size, appearance, and characteristics. Measure lesions using a ruler device and note the measurements in the chart. For pressure ulcers, many facilities take photos and enter those in the chart so that healing progress can be demonstrated.

Once every 24 hours, usually during the bath, the skin is totally assessed. When a reddened area is found, it is checked for blanching by pressing gently in the center of the area to see if it turns from red to white, or to a paler color on darker skin. **Blanching usually indicates that the redness is temporary and will resolve when pressure on the area is relieved.** (See [Chapter 42](#) for additional information regarding pressure ulcers.)

Assignment Considerations

Observation While Bathing

Unlicensed assistive personnel are generally assisting with hygiene, and the nurse should give specific instructions to report reddening, bruising, breaks in the skin, or new lesions. **Remember that total skin assessment cannot be delegated; this is the nurse's responsibility.**

Nursing Diagnosis and Planning

Problem statements are based on the analysis of the data gathered from assessment. Problem statements commonly associated with skin disorders are presented in **Table 41-2**. Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

Table 41-2

Common Problem Statements, Expected Outcomes, and Nursing Interventions for Patients With Skin Disorders

PROBLEM STATEMENT	GOALS/EXPECTED OUTCOMES	NURSING INTERVENTIONS
Altered skin integrity due to injury and treatment; excoriation or scaling; infectious process	Patient's skin will be intact within 2 wk (4 mo for burns). Number of lesions will decrease within 2 mo. Patient will exhibit no signs of infection within 3 mo.	Cleanse skin and apply topical medications as prescribed. Monitor for signs of adverse reaction to topical medication. Preserve integrity of grafted areas with aseptic dressing technique and splinting. Apply light treatments as prescribed.
Pain due to itching, soreness, or tenderness of lesions, exposure of denuded skin to air, or involvement of nerve tissue	Patient's pain will be controlled by medication and relaxation or distraction techniques.	Apply topical medication as prescribed. Administer analgesia as prescribed and as required (PRN). Provide medicated baths as prescribed. Teach relaxation techniques. Provide distraction activities.
Decreased self-esteem due to disrupted skin surface and lesions	Patient will show increase in self-esteem by socializing with others within 3 wk.	Suggest ways to cover lesions. Help patient list positive aspects and achievements. Encourage socialization with others. Show acceptance and matter-of-fact attitude when dealing with patient's lesions.
Potential for infection due to loss of intact skin barrier	Patient will not experience skin infection before lesions are healed.	Cleanse skin carefully and gently. Use aseptic technique when attending to lesions. Apply prescribed topical medications. Encourage patient to keep hands off affected skin areas. Encourage hand hygiene for patient.
Anxiety due to chronic, recurring nature of skin disorder; reaction to diagnosis of cancer; slow healing	Patient will verbalize feelings within 3 wk. Patient will explore options for treatment of cancer. Patient will identify short-term and long-term goals that realistically match the slow healing process.	Provide atmosphere of acceptance. Allow patient time to verbalize feelings. Assist to recognize positive coping techniques by looking at ways patient has coped with anxiety in the past. Provide information on treatment and prognosis for skin malignancy.
Deficient knowledge regarding cause and treatment of skin disorder	Patient will verbalize knowledge of factors related to appearance of skin disorder. Patient will verbalize knowledge of treatment for disorder. Patient will demonstrate self-care techniques.	Explain the cause of the skin disorder and measures to prevent possible recurrence, if any. Instruct in various methods of treatment. Teach the side effects of medications. Instruct in self-care techniques for medication application, dressing changes, and so on. Obtain feedback of information and skills taught.
Disrupted sleep pattern due to itching or pain	Patient will obtain at least 7 hr of rest per day.	Administer medication to relieve itching. Keep environment cool to decrease itching sensation. Caution patient to take cool or tepid baths or showers to decrease itching. Caution not to scratch lesions; this often makes itching worse. Suggest ways to use distraction (e.g., card or game playing, intense concentration on learning something, or reading an absorbing book) to decrease focus on itching. Administer hypnotic as prescribed. Administer analgesics as prescribed. Encourage use of meditation, relaxation, or imagery techniques to decrease pain. Provide restful, quiet environment. Use massage as appropriate to promote relaxation and sleep. Allow usual bedtime rituals that help patient induce sleep.
Potential social isolation due to long treatment process; disfigurement	Patient will maintain social contact with family and friends. Patient will reintegrate into community within 3-24 mo.	Encourage family and friends to send cards, call, and visit. Encourage patient to continue dialogue with family and friends. Refer to psychologist or social worker for grief work and reintegration of new body image. Refer to support group for expression of feelings and realization patient is not alone with such problems. Encourage return to employment or job training. Encourage return to church or community activities.

Nursing goals for patients with skin disorders are to:

- Restore the skin to normal
- Decrease pain and itching
- Protect the skin from further damage
- Prevent infection
- Prevent scarring as much as possible

Planning of the daily work schedule should include consideration of time necessary for dressing changes, soaks, special baths, and other skin treatments.

Implementation

Some general rules when caring for patients with a skin disease may be helpful as a guide until

specific orders are obtained:

- Bathing with soap is usually contraindicated in all inflammatory conditions of the skin.
- Dressings covering the skin lesions that have been applied by a provider should not be removed when the patient is admitted unless there are specific orders to do so.
- Do not attempt to remove scales, crusts, or other exudates on the skin lesions until the provider has had an opportunity to examine the patient.
- Observe the skin very carefully at the time of the patient's admission, and record observations on the chart or report them to the nurse in charge.
- Avoid excessive handling or rubbing of the skin against the sheets and bedclothes when changing the bed.
- Lotions or other skin products should not be used on the skin unless the provider has approved their use.

Once the provider has determined the type of lesions present, specific treatments will be ordered to relieve the patient's symptoms and promote healing. The two most commonly used treatments are special dermatologic baths and wet compresses or dressings. In addition, lotions, salves, or ointments may be applied locally at frequent intervals.

Although most skin diseases are **not** contagious, nurses should be careful to observe rules of cleanliness and Standard Precautions when caring for any patient with a skin eruption. **Special care is needed to prevent spreading infection from the fluid in all pustules and in the vesicles of fever blisters and cold sores.**

Giving Medicated Baths

Among the agents that may be added to the bath water are sodium bicarbonate, sodium chloride, cornstarch, oatmeal, medicated tars, oils, potassium permanganate, and special bath preparations.

Safety Alert

Prevent Falls

A nonslip bath mat should be used in the tub when giving medicated baths. The substances used for the bath can make the tub very slippery. Showers should have nonslip mats in them as well, especially when showering an older adult.

Patient Teaching

Easy Cleanup After an Oatmeal Bath

Put dry, uncooked oatmeal into an old sock to make an oatmeal sachet. Place the sachet in the tub and squeeze it repeatedly. After the bath is finished, discard the sachet.

During the bath, the patient must be protected from chilling, because the bath usually lasts from 30 minutes to an hour, and most patients with skin diseases have a lowered resistance to cold.

When the patient is removed from the tub, the skin is dried by patting rather than by rubbing. If medication is to be applied locally, it should be put on as soon as the bath is completed to keep **pruritus** (itching) at a minimum. **Medication is applied in a thin layer unless otherwise ordered.**

The medicated bath has a very soothing and relaxing effect on the patient and also helps relieve the itching and burning commonly associated with skin diseases. Encourage the patient to rest in bed and perhaps to take a short nap after each bath.

Laundry Requirements

The bed linens and gowns used for patients with severe skin diseases may need special laundering to eliminate all traces of soap. If the patient is to be cared for at home, vinegar may be added to the rinse water to neutralize the soap. One tablespoon of vinegar is used for each quart of water. Only detergent without perfume or other additives should be used. Dryer sheets should not be used, because they contain chemicals that often cause skin problems. Residue from dryer sheets can

remain in the dryer and affect laundry that has been washed separately for the individual with a skin sensitivity. New clothes should be washed before wearing when skin sensitivity is a problem. Washing removes chemical fabric-finishing products.

Application of Wet Compresses or Dressings

Wet dressings may be applied to the skin in various ways. The two general types used are **open dressings** and **closed dressings**. Open compresses must be changed repeatedly and are never allowed to dry. They usually need to be remoistened every 20 to 30 minutes. The solution used should be at room temperature or warmer. This type of dressing is used when the dermatologist wishes to have air circulating to the skin lesions. Closed dressings are thoroughly soaked with the prescribed solution and wrapped with an airtight, waterproof material. Obtain specific instructions from the dermatologist before applying wet dressings to any skin lesions.

Clinical Cues

When changing wet dressings, inspect the skin adjacent to the wound for signs of maceration from the moisture; this condition could cause the wound to enlarge.

Application of Topical Therapy

Many skin lesions are treated by directly applying medications to the surface of the affected area. This method is called *topical therapy*. Lotion, cream, ointment, powder, or gel may be used. The provider prescribes the kind of medication to be used and the way in which the drug is to be applied. Patients with skin conditions do not always consult a provider and sometimes choose to treat themselves at home. All patients should be instructed in the proper application of topical medications (Box 41-3). Occlusive dressings must not be applied over the area after application of the medication unless ordered by the health care provider (see Table 41-2 and Chapter 42).

Think Critically

If a patient has an order for a topical cream to be applied to an area of rash on the right upper thigh, how would you apply this cream?

Box 41-3

Guidelines for Applying Topical Medications*

Powders

- Dry the area thoroughly before applying powder to prevent caking.
- Do not apply to raw and denuded areas.
- Some powders, such as cornstarch, can actually serve as culture media for the growth of bacteria.

Ointment

- Use only a small amount and gently massage into the skin until a thin film covers the area. An exception is when ointment is used as an occlusive dressing, as for a burn.
- Ointments tend to leave a greasy feeling to the skin. They are best for chronic lesions, because they help the skin retain moisture and natural oils.
- Avoid putting ointment on areas where the skin is creased and overlaps itself.

Gels

- A gel is a semisolid mixture that tends to liquefy when applied to the skin. It is absorbed into the skin and dries quickly, leaving a thin, nonocclusive film.

- If applied to abraded or sensitive areas, alcohol in the base can cause a burning or stinging sensation.

Lotions

- Lotions are actually powders suspended in water; they will leave a residue once the liquid evaporates from the skin. This residue should be washed off before a fresh dose is applied.
- Be sure powder is uniformly dispersed in solution before applying, then use a firm stroke to distribute the medication evenly. Do not “dab” on lotions, as this can be irritating to the skin.

All Types

- Always apply topical medications sparingly and in a thin film that extends beyond the affected area about $\frac{1}{4}$ inch. Thick layers of topical medications are wasteful, and some of these drugs, such as corticosteroids, are very expensive.
- Too much of some topical medications (e.g., antifungal agents) can chemically irritate the skin and delay healing. Thick layers also tend to soften the skin too much.
- If the skin condition appears to be getting worse after a topical agent is applied, or if the patient develops eczema, suspect an allergic contact dermatitis caused by the drug.

* Allergies must be assessed before applying a topical medication.

Evaluation

Evaluation of treatment and nursing interventions for skin disorders is based on improved appearance of the skin, absence of signs of infection, relief from itching and pain, and signs of healing. Many skin disorders are slow to respond to treatment, and patience is required on the part of the patient and the nurse. Even a minor fungal skin infection may take 7 to 14 days to clear with topical medication. A fungal infection of a nail may take up to a year to clear. A major part of evaluation is to determine that treatment is not aggravating the condition.

Get Ready for the NCLEX® Examination!

Key Points

- The skin is essential for the maintenance of life; it is the first line of defense against pathogenic organisms. Skin has two layers, the epidermis and the dermis. New cells to heal the skin are contained in the dermis.
- Factors in the prevention of skin disorders include cleanliness, appropriate diet, proper skin care, limiting exposure to the sun, and careful handling of fragile skin.
- With increased age the skin becomes thinner and more fragile, less elastic, and drier.
- Fragile skin requires special attention: protective clothing (such as long sleeves), lubrication with creams or lotions, bed transfer techniques that prevent shear, padded side rails and assistive devices, use of nonadherent tape, and use of solvent to loosen dressings and peeling them slowly.
- Several types of diagnostic measures are used: biopsy, culture, microscopic examination of scrapings or tissue, special light inspection, diascopy, and skin patch testing.
- A thorough health history is key in the diagnosis of skin disorders (see Focused Assessment on p. 961).
- Teach self-examination of the skin, including the ABCDs: A = asymmetric; B = irregular border; C = color change; D = diameter greater than $\frac{1}{4}$ inch (see Patient Teaching on p. 962).
- Standard precautions are used when touching patients with weeping lesions or when drainage is present.
- Treatments for skin disorders include medicated baths, special laundry precautions, application of compresses or dressings, and topical therapy.
- Systemic therapy may be used for some fungal infections and for serious bacterial infections.

Review Questions for the NCLEX® Examination

1. A nurse notes that a 55-year-old, light-skinned patient has dry, flaky skin. Which action by the patient should alert the nurse to a problem?

1. The patient always puts a moisturizing lotion on her hands after washing them.
2. The patient takes daily showers with soap and hot water.
3. The patient takes a daily multiple vitamin.
4. The patient spends some time outdoors, and uses sunscreen that she reapplies every $1\frac{1}{2}$ to 2 hours.

NCLEX Client Need: Health Promotion and Maintenance

2. A nurse is teaching teenagers regarding the importance of protecting the skin from UV rays. What information should the nurse include? (*Select all that apply.*)

1. Use a sunscreen with a sun protection factor (SPF) of at least 30.
2. Apply sunscreen thinly.
3. Wear light, loose clothing.
4. Gauge exposure while in the sun.
5. Wear sunglasses and a hat.

NCLEX Client Need: Health Promotion and Maintenance

3. A patient with a suspicious skin lesion is scheduled for a punch skin biopsy. What is the most accurate explanation that the nurse would give about the procedure?

1. "It is shaving a top layer off a lesion that rises above the skin line."
2. "It is removing a core from the center of the lesion."
3. "It is removing the entire lesion."
4. "It is aspirating a tissue sample."

NCLEX Client Need: Physiological Integrity: Basic Care and Comfort

4. A patient has a rash of unknown origin. Which assessment question(s) would help determine the underlying cause of the lesion? (*Select all that apply.*)

1. "When did the rash or lesion first appear?"
2. "Can you think of any event or different food you ate or substance you were using just before it appeared?"
3. "What drugs are you taking? Do you take any over-the-counter medications?"
4. "Have you ever had radiation therapy?"
5. "Do you have a history of any skin disorders in your family?"

NCLEX Client Need: Safe and Effective Care Environment

5. What physiologic changes in aging predispose older adults to skin breakdown? (*Select all that apply.*)

1. Thickening of skin
2. Loss of collagen
3. Increased elastic fibers
4. Decreased adipose tissues
5. Reduced sebaceous gland activity

NCLEX Client Need: Physiological Integrity: Physiological Adaptation

6. A nurse needs to apply a dressing to a patient who has fragile skin. Which intervention would the nurse use to protect the patient from skin tears?

1. Ask the provider to give specific orders for wound care.
2. Gently clean and apply a sterile transparent dressing.
3. Tape the dressing with paper tape and prevent tension.
4. Allow any tape and gauze dressing materials to fall off naturally.

NCLEX Client Need: Safe and Effective Care Environment

7. A nurse is observing a nursing assistant provide skin care to an older adult patient. Which action by the nursing assistant indicates a need for further training?

1. Using soap and hot water every day to clean the patient's body
2. Alerting the nurse about a wet dressing
3. Reporting redness and blanching over the sacral area
4. Applying lotion while the skin is still damp

NCLEX Client Need: Health Promotion and Maintenance

8. A nurse is supervising a new graduate nurse (GN) who is examining a new patient with skin lesions. The nurse would intervene if the GN:

1. gently handles the patient's extremities to prevent skin tears.
2. observes the condition of the skin and measures the size of the lesions.
3. removes the scales and crusts from the lesions to clean the skin.
4. assesses for and documents any home remedies that the patient has tried.

NCLEX Client Need: Safe and Effective Care Environment

9. A nurse is taking care of a 75-year-old man who spends most of his time in bed or sitting. What steps should be taken to prevent a skin tear? (*Select all that apply.*)

1. Have the patient wear long sleeves and long pants.
2. Lubricate the patient's skin with cream or lotion twice a day.
3. Massage the skin vigorously, especially over bony prominences.
4. Never use a lift sheet to move or turn the patient.
5. Pad bed rails, wheelchair arms, leg supports, or other equipment where the patient may bump an extremity.

NCLEX Client Need: Safe and Effective Care Environment

10. A nurse reads in a patient's record that the provider observed "circumscribed, superficial vesicles with a collection of serous fluid." The nurse anticipates that the provider will make which recommendation for the patient?

1. A prescription for a topical application for acne
2. Isolation precautions for herpes zoster
3. Over-the-counter antihistamine for an insect bite
4. Patient education to self-monitor the wart

NCLEX Client Need: Physiological Integrity: Basic Comfort and Care

Critical Thinking Questions

Scenario A

You have been asked to give a presentation to a ninth-grade class on skin care and prevention of skin cancer.

1. What specific information would you include on the subject of general skin care?
2. What would you say about lying out in the sun?
3. What information would you give regarding the use of tanning booths?
4. What would you say about protection when out in the sun?

Scenario B

Mrs. Hess, an 83-year-old resident of a long-term care facility, has very dry skin. She asks you to look at spots on her hand that are brown and "ugly."

1. What could this lesion on Mrs. Hess's hand be?
2. What would you tell her?
3. Mrs. Hess asks you why she bruises so easily. She says she hates these reddish purple areas she gets on her arms and legs. What would you answer?
4. What nursing measures should be instituted for skin care for Mrs. Hess's dry skin?

Scenario C

You and a home health aide have been assigned to care for an older adult woman in the patient's home for several days. The patient has a noncontagious itchy rash, and the provider has suggested using oatmeal as a soothing bath and topical application of lotion and has ordered daily assessments to monitor the patient's condition. In addition, the patient's daughter has asked that the linens be washed on a daily basis.

1. Discuss which tasks you (the nurse) should perform.
2. Which tasks can be delegated or assigned to the home health aide? What specific instructions should be given to the home health aide about assigned duties?
3. During one of the home visits the daughter asks the nurse to look at a mole on her own back. "I can't see it very well, and of course my mother is not able to help me either." What would you do and say in this situation?

CHAPTER 42

Care of Patients With Integumentary Disorders and Burns

Objectives

Theory

1. Describe the etiology of dermatitis.
2. Plan psychosocial interventions for a patient who has psoriasis.
3. Compare and contrast the treatment of fungal skin or nail disorders with the treatment of bacterial skin disorders.
4. Choose nursing interventions for a patient with herpes virus infection.
5. Examine the types of acne and their treatment.
6. Present the characteristics of the various types of skin cancer.
7. Analyze the important points of caring for an immobile patient to prevent pressure ulcers.
8. Construct a care plan for each stage of a pressure ulcer.
9. Summarize important assessment points for a patient who has sustained a burn.
10. Illustrate the nurse's role in emergency burn care.
11. Explain the psychosocial needs and interventions for burn patients.
12. Relate the process of rehabilitation for a patient with a major burn.

Clinical Practice

13. Teach a family about care for a patient at home when scabies is present.
14. Assess the skin of family members for signs of skin cancer.
15. Provide care for a patient with a stage III or stage IV pressure ulcer.
16. Apply Standard Precautions and sterile technique for the care of a burn.
17. Visit a burn intensive care unit and observe the wound care of a patient who is in the acute stage of a major burn.

Inflammatory Infections

Many skin diseases result from infection with bacteria, viruses, or fungi or from infestation with parasites. Diseases of this kind require special precautions to prevent spread of the infectious organism or the parasite. Hand hygiene is a first-line measure in the prevention of health care-associated infections and is mandated as one of The Joint Commission's National Patient Safety Goals. The Center for Infectious Diseases, a division of the Centers for Disease Control and Prevention, recommends that Contact Isolation, as well as Standard Precautions, be implemented for a number of these diseases (Box 42-1). Some skin infections are not necessarily contagious; however, it can be difficult to quickly determine whether a particular condition is a contagious type at the initial examination. Therefore isolate the patient, perform hand hygiene, and use Standard Precautions (see [Appendix B](#)) if there is any doubt.

Box 42-1

Review of Contact Isolation Requirements

Specifications for Contact Isolation are as follows:

- A private room is indicated. In general, patients infected with the same type of organism may share a room.
- Gloves are worn when entering the room. Change gloves after contact with infective material, such as wound drainage or feces, and before treating a different location on the body. Perform hand hygiene before donning clean gloves.
- Remove gloves when leaving the room, and perform hand hygiene using an antimicrobial agent.
- Gowns are indicated if soiling is likely, particularly if there is drainage from an uncovered wound or the patient is incontinent.
- Articles contaminated with infective material should be discarded in a biohazard waste receptacle or bagged and labeled before being sent for decontamination and reprocessing.
- Patient care equipment should be used only for the one patient and should be left in the room until no longer needed.
- Skin disorders that require Contact Isolation include:
 - Diphtheria, cutaneous
 - Furunculosis, group A *Streptococcus*
 - Herpes simplex, disseminated, severe primary, or neonatal
 - Herpes zoster (varicella zoster)
 - Varicella (chickenpox)
 - Impetigo
 - Infection or colonization by bacteria with multiple drug resistance (any site)

- Pediculosis
- Scabies
- Skin wound or burn infection, major (draining and not covered by dressing, or dressing does not adequately contain purulent material), including those infected with *Staphylococcus aureus*
- Vaccinia (generalized and progressive eczema vaccinatum)

Dermatitis

Dermatitis is not contagious unless a secondary infection has occurred in the lesions.

Etiology, Pathophysiology, Signs, and Symptoms

Contact dermatitis is a delayed allergic response involving cell-mediated immunity. On contact with the skin, the allergen is bound to a carrier protein and forms a sensitizing antigen. T cells become sensitized to the antigen. Local skin irritation is evident within a few hours or days after exposure to an antigen. Erythema and swelling, pruritus, and the appearance of vesicular lesions follow. Many chemicals; cosmetics; soaps; latex; and poison ivy, oak, and sumac are contact irritants and can cause such a reaction.

Atopic dermatitis affects about 10% of the population and is more common in infancy and childhood but does affect some adults. It results from a complex activation process that involves mast cells, T lymphocytes, Langerhans cells, monocytes, B cells that produce immunoglobulin E, and other inflammatory cells that release histamine, lymphokines, and other inflammatory mediators. Atopic dermatitis does seem to have a genetic, allergic association, because it is more prevalent in families.

Stasis dermatitis generally occurs on the legs as a result of venous stasis and edema and is seen in conjunction with varicosities, phlebitis, and vascular trauma. Erythema and pruritus occur first, after which scaling, development of petechiae, and **hyperpigmentation** (excessive pigmentation) occur. Lesions may become ulcerated, particularly around the ankles and tibia.

Seborrheic dermatitis is a common inflammation involving the scalp, eyebrows, eyelids, ear canals, nasolabial folds, axillae, chest, and back. It is most common on the scalp. The cause is unknown. Lesions appear as scaly white or yellowish plaques with mild pruritus.

Diagnosis and Treatment

Dermatitis is diagnosed by inspection and by compiling a complete history, looking for possible exposure to causative substances.

In general, treatment is aimed at avoidance of the contact irritant or allergen, good skin lubrication, preservation of skin moisture, and control of inflammation and itching. Topical agents are often used. Corticosteroids may be used topically, or sometimes orally or by injection to intervene in a severe episode of dermatitis.

Nursing Management

Teach patients to avoid contact irritants and to properly care for their skin. Instruct them in the proper way to apply topical agents. Caution any patient who is experiencing pruritus to avoid becoming hot, bathe in tepid water, and not puncture vesicles. The skin should be patted rather than rubbed dry.

Acne

Etiology, Pathophysiology, Signs, and Symptoms

Acne is a disorder of the skin characterized by papules and pustules over the face, back, and shoulders. Some types of acne are related to cosmetics or to chemicals in the environment. For

example, occupational acne is caused by prolonged contact with oils and tars.

There are many kinds of acne, but the two major types are **acne rosacea** and **acne vulgaris**. Acne rosacea usually begins between ages 30 and 50 years. It is characterized by erythema (redness), papules, pustules, and telangiectases. It occurs on the face over the cheeks and bridge of the nose. **Comedos** (dilated hair follicles filled with skin debris, bacteria, and sebum) do not occur. Factors that cause facial flushing precipitate worsening. Tea, coffee, alcohol (especially wine), caffeine-containing foods, spicy foods, sunlight, and emotional stress cause flare-ups.

Acne vulgaris is more common than acne rosacea. Factors that contribute to the development of acne include hereditary disposition, increased androgen levels, and premenstrual hormonal fluctuations. Use of heavy creams, use of certain drugs, and exposure to increased heat also contribute to the disorder. Acne vulgaris typically begins in early puberty, continues through the teens, and then begins to subside. Occasionally it persists, or it can recur several years later. The onset of acne vulgaris in adolescents is related to increased release of sex hormones, which stimulate activity of the sebaceous glands, causing increased production of sebum. Ducts leading from the sebaceous glands become plugged with sebum. It is not known why in some persons the ducts from these glands become plugged, but the increased production of sebum triggers the formation of blackheads and whiteheads. The color of blackheads is the result of particles of melanin, the skin's own pigment, combined with sebum and keratin. Accumulations of sebum, skin particles, and dead skin cells can cause an inflammatory reaction. Bacterial infection leads to the formation of pustules. An extensive inflammation can lead to the formation of cysts, with swelling above and below the surface of the skin.

There are many misconceptions about acne vulgaris and its treatment. It is not a contagious disease. It is not caused by uncleanliness or poor personal hygiene. Diet can contribute to the formation of lesions, but generally there is little or no relationship between the intake of certain foods and the appearance of the lesions of acne. Typically, chocolate, colas, and fried foods do not need to be eliminated from the diet in an effort to prevent or cure acne. A well-balanced diet is all that is recommended in the management of acne.

Diagnosis and Treatment

Diagnosis is by history and physical examination. Acne rosacea is treated by avoiding the triggers for flare-ups and with topical antibiotics, metronidazole (MetroGel), and retinoids. Sometimes oral antibiotics are prescribed.

Mild, noninflammatory cases of acne vulgaris respond well to efforts to remove blackheads and whiteheads by promoting dryness and peeling of the top layer of skin. The medication is applied directly on the skin. Nonprescription drugs, such as lotions, creams, and gels that contain sulfur, benzoyl peroxide, or sulfur combined with resorcinol usually are effective for noninflammatory acne.

Among the topical medications, retinoic acid (tretinoin [Retin-A]) is the best agent for **papular** and **pustular** acne problems. It should be used once or twice a day. Benzoyl peroxide is the most commonly used topical agent for acne and is available both by prescription and over the counter. Azelaic acid (Azelex) is applied topically twice a day. The U.S. Food and Drug Administration (FDA) has approved Veltin Gel, a water-based topical agent for the treatment of acne vulgaris in patients 12 years and older ([Drugs.com, 2015](#)). It is quite expensive, but financial assistance is available.

Antibiotics such as tetracycline and erythromycin also are sometimes prescribed topically and orally for cystic acne to inhibit the growth of bacteria in the plugged ducts.

Isotretinoin (13-cis-retinoic acid) has been especially effective in controlling cases of cystic acne that are resistant to other forms of treatment. The drug was initially marketed under the trade name Accutane, but after black box warnings and increasing numbers of reports of adverse events, including gastrointestinal concerns, birth defects, and increased rates of suicide, Roche discontinued making Accutane in 2009 ([Drugs.com, 2015](#)). It is still available in generic form. Accutane is taken by mouth daily for 2 to 4 months and inhibits activity of the sebaceous glands. Its effects are sustained for months to years after it has been discontinued. Almost all patients experience some adverse reaction to this drug. **Accutane is used only for severe cystic acne that is resistant to all other treatment. There are serious adverse side effects, including organ damage and mental problems.** Laboratory testing includes hemoglobin, hematocrit, glucose, triglycerides, uric acid, alkaline phosphatase, and liver enzymes.

For larger areas, lasers or a new light treatment called *photodynamic therapy* have been used with success.

If the patient has deep scarring and pitting as a result of cystic acne, appearance can be improved by **dermabrasion**. This dermatologic procedure involves mechanically scraping away the outer layers of skin and smoothing out its surface by applying motor-driven wire brushes or diamond wheels. Chemical dermabrasion is done by applying phenol or trichloroacetic acid to remove the scars.

Nursing Management

Teach the patient about the nature of the particular skin disease and give support while he is trying to cope with its physiologic and psychosocial effects. Acne can be particularly distressing to adolescents, who are often deeply concerned about their appearance and acceptance by their peers.

The face should be washed gently with a mild soap. Scrubbing the skin and using a harsh soap is damaging and contributes to inflammation. Special medicated soaps do not seem to be any better than a mild face soap. If the hair is oily, it should be shampooed frequently and kept off the face.

Squeezing pimples and pustules is not recommended. This can press the sebum and accumulated material more firmly in the clogged duct, increase the chance of inflammation, and spread an infection to other parts of the skin and body. Blackheads and whiteheads are best removed by applying a prescription medication that causes peeling of the skin. The hands should be kept off of the face.

Because the management of acne can go on for years and requires periodic evaluation by a dermatologist, patients and their families will need continued support and encouragement to follow the prescribed regimen. They will need to know the expected results of prescribed medications, any adverse reactions that might occur, and symptoms that should be reported immediately.

Think Critically

What skin care measures would you recommend to a young teenager who is just beginning to experience face blemishes such as blackheads or whiteheads? The kids at school are calling him "scab face."

Psoriasis

Etiology, Pathophysiology, Signs, and Symptoms

Psoriasis is a noncontagious, chronic, recurring skin disorder that typically appears as inflamed, edematous skin lesions covered with adherent silvery white scales (Figure 42-1). These scales are the result of an abnormally rapid rate of proliferation of skin cells. When the scales are removed, there is pinpoint bleeding. The plaques most often appear on the skin of the elbows, knees, and base of the spine. It also may affect the scalp, in which case it can be confused with **seborrheic dermatitis**. When the fingernails are involved, there can be pitting of the surface of the nails. The palms and soles also can be affected, making it difficult for the patient to carry out activities of daily living (ADLs).

FIGURE 42-1 Psoriasis lesion on the hand. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 6, Philadelphia, 2010, Saunders.)

In some cases the skin eruptions of psoriasis are accompanied by inflammation of the joints, especially those of the fingers and toes. This is called *psoriatic arthritis*. Psoriasis affects about 2% of the U.S. population. There is a genetic predisposition for the disease. It is likely that an immunologic event triggers the disorder, because the first lesion commonly appears after an upper respiratory infection. T cells are mistakenly activated and trigger immune responses that speed up the growth cycle of skin cells. [Maradit-Kremers and colleagues \(2013\)](#) found that patients with moderate to severe psoriasis had a higher incidence of cardiac disease and risk for stroke, but were not at an increased risk for cardiac death.

Diagnosis and Treatment

Diagnosis is by history, physical examination, and ruling out other skin disorders. Each case of psoriasis is treated individually. The disease is unpredictable, tends to go into remission spontaneously, and sometimes will clear up temporarily with or without treatment.

Mild cases usually respond to steroid creams (triamcinolone acetonide [Kenalog]), but there is a possibility that eventually the disease will become resistant to steroids. Sunlight in moderate doses can help, because the ultraviolet (UV) rays slow down the rate at which epithelial cells are produced. Extremes of UV radiation can have the opposite effect, resulting in an aggravation of the condition. Calcipotriene (Dovonex), a vitamin D analog cream, helps to regulate skin cell production, decreasing the incidence of psoriasis plaques.

Tar preparations also act to impede the proliferation of skin cells and have long been used to heal psoriasis lesions. They may be administered in the form of baths, topical applications, or shampoos. Combinations of artificial UV radiation and a coal tar product commonly are prescribed for severe cases. This usually requires hospitalization so that the dosage of each component of therapy can be measured precisely. A form of therapy called *PUVA* combines application of one of a class of drugs called psoralens, which penetrates the skin, with exposure to ultraviolet light type A (UVA).

Antimetabolites have been used to treat severe psoriasis, helping to control the disorder by their antiproliferative action. Methotrexate is the most commonly used antimetabolite for this purpose. Acitretin (Soriatane) or cyclosporine is sometimes used. In a phase II clinical trial, [Leavitt \(2013\)](#) found that brodalumab significantly improved psoriasis symptoms in patients who stayed on the drug for more than 6 months. Other biologic agents shown to be efficacious include infliximab (Remicade), etanercept (Embrel), efalizumab (Raptiva), and alefacept (Amevive).

Nursing Management

Patients with psoriasis will need instruction about the nature of their disease, teaching about the purpose of the prescribed treatment, and information about ways to avoid aggravating it. **The skin should be kept as moist and pliable as possible. Humidifiers to increase moisture in the environment are sometimes helpful.** Lubricating lotions and creams should be approved by the dermatologist before they are applied.

Minor scratches and abrasions and bacterial infections can trigger the formation of lesions at a new site. **Because any irritation or break in the skin seems to stimulate the growth of psoriatic plaques in a person susceptible to psoriasis, the patient should be cautioned to prevent injury of any kind.** This includes hangnails, damaged cuticles, blisters from poorly fitting shoes, scratches from pets, and potentially harmful agents in the environment such as radiation and chemicals.

Stevens-Johnson Syndrome

Stevens-Johnson syndrome (SJS) is an allergic reaction with skin manifestations. It is usually triggered by a medication. The signs and symptoms appear within 14 days of starting drug therapy. Offending drugs are the anticonvulsants carbamazepine (Tegretol) and phenytoin (Dilantin), the antimalarial sulfadoxine-pyrimethamine (Fansidar), and the antibiotic sulfamethoxazole-trimethoprim (Bactrim, Septra). However, over-the-counter medications can cause SJS. Lesions that may be mistaken for chickenpox develop on the face, trunk, palms, extensor surfaces of joints, soles of the feet, and dorsum of the hands. The lesions have irregular borders and may have blistered, necrotic centers.

Treatment of SJS is to discontinue the drug and provide supportive care with fluids and nutrition. Wound care is similar to that for a burn. The lesions are painful, and analgesia is provided. Sedatives may be necessary. If not treated early, SJS can cause death.

Clinical Cues

Assess the skin of every patient daily. Ask assistive personnel if they have observed any changes. If new skin lesions appear, seek an opinion from a provider. Check the medication profile and medication history to see what medications the patient has been receiving. Alert the provider if the patient has been taking a medication known to cause SJS.

Bacterial Infections

Etiology, Pathophysiology, Signs, and Symptoms

Cellulitis is an infection of the dermis and subcutaneous tissue and is generally caused by *Staphylococcus*. It may occur as an extension of a skin wound, as an ulcer, or from furuncles or carbuncles. The area will be erythematous, swollen, and painful. It is treated with systemic antibiotics, and Burow soaks may be used to relieve pain. Burow solution is an astringent and topical antiseptic also called *aluminum acetate solution*.

Furuncles (boils) are inflammations of hair follicles. The organism responsible is usually *Staphylococcus aureus*. Any skin area with hair can be affected. Initially there is a deep, firm, red, painful nodule 1 to 5 cm in diameter. The nodule changes to a large and tender cystic nodule accompanied by cellulitis. The lesion may drain large amounts of pus and necrotic tissue.

Carbuncles are a collection of infected hair follicles and most commonly occur on the back of the neck, the upper back, and the lateral thighs. It begins as a firm mass and evolves into an erythematous, painful, swollen mass. It may drain through many openings in the mass. Abscesses may develop with fever, chills, and malaise.

Diagnosis, Treatment, and Nursing Management

Diagnosis is by history and examination. Treatment of both furuncles and carbuncles is application of warm compresses to provide comfort, promote localization, and cause spontaneous drainage. Abscess formation requires incision and drainage. Recurrent episodes are treated with systemic antibiotics.

Nursing interventions are aimed at healing the infected areas and preventing recurrence. Rinsing very well after bathing to eliminate soap residue is recommended. The patient is taught to avoid using cosmetic products and over-the-counter topical remedies on the affected areas. A clean washcloth and towel should be used for bathing each day until the carbuncle or furuncle is healed. Linens should be washed in hot soapy water and thoroughly dried before reuse.

Viral Infections

Herpes Simplex

Herpes simplex virus type 2 (HSV-2) is most often associated with genital herpes, whereas herpes simplex virus type 1 (HSV-1) lesions are primarily nongenital (Figure 42-2). Either type can cause lesions in the genital area as well as other regions of the body. **Autoinoculation** of the virus is possible by direct contact, for example, lips to fingers to genitals or lips to fingers to eyes.

Health Promotion

Preventing Spread of Herpesvirus

Patients with genital herpes need to be aware that the disorder can be transmitted even when no lesions are present. When a person has a “cold sore,” the virus can be transferred to others. Contact with the lesion should be prevented. Care should be taken not to share drinking glasses and eating utensils, lipstick, or other items that touch the lesion.

Complementary and Alternative Therapies

Lemon Balm for Cold Sores

Lemon balm in a concentrated cream base has often been used to relieve the symptoms of **herpes labialis** (infection of the lips; commonly known as *cold sores* or *fever blisters*) (Sierralupe, 2015).

FIGURE 42-2 Herpes simplex virus lesions. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 5, Philadelphia, 2006, Saunders.)

Etiology and Pathophysiology

When initial infection occurs, the virus is imbedded in a nerve ganglion that innervates the site of the lesion. Reactivation of the virus causes new lesions to occur at the same site. The virus travels along the nerve to the site of the original infection. Reactivation is brought about by exposure to ultraviolet light, skin irritation, fever, fatigue, or stress.

Signs and Symptoms

An infection with HSV-1 appears as lesions on the lips and nares that are commonly called *cold sores* or *fever blisters*. As with other types of herpesvirus infections, no drug will completely cure the infection.

Diagnosis, Treatment, and Nursing Management

Diagnosis is by physical examination and history. Sometimes topical and oral acyclovir (Zovirax), famciclovir (Famvir), or valacyclovir (Valtrex), available by prescription, hastens healing. The

symptoms of itching and burning that accompany oral herpes infection sometimes can be minimized by applying warm compresses to the sores, followed by local application of tincture of benzoin or spirits of camphor to aid drying and facilitate healing. The disease usually is self-limiting, which means that it does not progress and will subside on its own, but it can recur. Contagion is possible up to 5 days after appearance of the lesion. Docosanol cream (Abreva) sold over the counter is a helpful treatment for this disorder.

Patients should be cautioned to use good personal hygiene to prevent spreading the virus to the eyes and genital area and other body parts. Hand hygiene is a very simple, but essential, part of preventing spread of the virus.

Herpes Zoster

Etiology and Pathophysiology

Herpes varicella-zoster causes chickenpox (varicella), mostly in young children, and shingles (herpes zoster) in all ages. In herpes zoster, the herpes viruses replicate in the peripheral nerve ganglia, where they lie dormant until reactivated by trauma, malignancy, possibly stress, or local radiation ([Figure 42-3](#)). Approximately 1 million cases per year occur in the United States, and about 1 in 3 people will be affected at some point in their lifetime ([CDC, 2014](#)). The risk is greater for immunocompromised individuals (those with cancer or HIV/AIDS). A vaccine is available for children to prevent chickenpox.

Older Adult Care Points

Approximately 50% of individuals who live past 80 years of age develop shingles. There is a vaccine available (Zostavax) that is about 50% effective in preventing shingles; it appears to be effective in attenuating the disorder if it occurs and is effective for about 6 years ([CDC, 2014](#)).

FIGURE 42-3 Herpes zoster (shingles). (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 7, Philadelphia, 2013, Saunders.)

Signs and Symptoms

Herpes zoster begins with vague symptoms of chills and low-grade fever and possibly some gastrointestinal disturbance. There may be only aching or discomfort along the nerve pathway with or without erythema. About 3 to 5 days after onset, small groups of vesicles appear on the skin. They usually are found on the trunk and spread halfway around the body, following the nerve pathways leading from the spinal nerve to the skin.

Safety Alert

Danger of Herpes Zoster Transmission

No health care worker, or visitor, should be in contact with a patient who has chickenpox or shingles if they have never had the disease. A pregnant woman should not care for a patient with chickenpox or herpes zoster. The virus is highly contagious and can harm a fetus.

The vesicles eventually change from small blisters to scaly lesions and are accompanied by pain and itching. The lesions usually affect only one side of the body or face. The pain of shingles often is quite severe. Pain can persist for several days or weeks after the skin lesions are completely healed. The pain of postherpetic syndrome is not easy to control.

Diagnosis and Treatment

Diagnosis is by history and physical examination. There is no cure for herpes zoster. The condition can persist for months, especially in older and debilitated patients. Herpes infections may be recurrent, because complete immunity does not occur. **The earlier the condition is diagnosed and treatment begins, the better are the chances to decrease the amount and duration of the associated pain (CDC, 2014).**

Symptomatic treatment typically involves administering an analgesic to relieve pain. Capsaicin, an over-the-counter analgesic that is applied topically five times a day, decreases pain for some patients. A paste made from aspirin and water placed on the lesions decreases pain for others. Antibiotics may be prescribed prophylactically against secondary bacterial infection of the lesions. Most providers prescribe oral acyclovir (Zovirax), famciclovir (Famvir), or valacyclovir (Valtrex) to diminish the extent or duration of the lesions. Valacyclovir is used only in otherwise healthy patients. Famciclovir, if given within the first 2 to 3 days of the outbreak, seems to shorten the duration of the chronic pain that typically follows shingles. Systemic corticosteroids may be used to decrease pain and in an attempt to prevent postherpetic pain syndrome. Their use is controversial. Tricyclic antidepressants and gabapentin (Neurontin), an anticonvulsant drug, have been used with variable success at controlling pain.

Narcotic analgesics are avoided if possible, because they can lead to addiction when used for an extended time. If the pain persists and is intractable, the provider prescribes a corticosteroid to reduce inflammation. Vidarabine, administered intravenously (IV), is sometimes given to patients who have an immune deficiency. It is usually effective in reducing, if not completely relieving, the pain.

Although shingles may be difficult to live with while the disease is running its course, the only lasting complication from the disease is postherpetic neuralgia (unless the virus attacks the eye, in which case it can cause blindness). However, the prognosis is less favorable in patients who have an underlying malignancy or who are immunocompromised.

Nursing Management

Care includes symptomatic relief from the pain and itching and prevention of a secondary bacterial infection.

Complementary and Alternative Therapies

Tai Chi Boosts Immunity to Shingles

Research has shown that practicing tai chi resulted in a level of immune response close to that of the varicella vaccine and that tai chi boosted the positive effects of the vaccine. The meta-analysis studied seven randomized, controlled trials, four controlled clinical trials, and five retrospective case-controlled studies (Ho et al, 2013).

Cold compresses, calamine lotion, and diversional activities are sometimes helpful. Rest and adequate nutrition can promote healing and shorten the acute phase of shingles. Teaching imagery, deep muscle relaxation, or use of distraction activities may help decrease pain. Evidence supports initiation of isolation procedures based on symptoms rather than waiting for a confirmed diagnosis. If lesions are **disseminated**, meaning widely dispersed, or if the patient is immunocompromised, airborne and Contact Isolation are necessary. If the lesions are localized and the patient is not immunocompromised, Standard Precautions are sufficient. Transmission precaution isolation is

needed until all the blisters are crusted ([CDC, 2011](#)).

Fungal Infections

Fungal infections are called **mycoses**; systemic fungal infections involving the lungs and other internal organs are called *systemic mycoses*. There are two groups of fungi that cause infections in humans: (1) fungi that are truly pathogenic to humans and (2) fungi that cause **opportunistic infections** (can cause an infection when the host has an altered immune system).

True pathogenic fungi can cause infection in an otherwise healthy person, but relatively few fungi are able to do this. Fungal infections are rarely fatal if they involve only the superficial tissues of the body. Nevertheless, mycotic skin infections can be exasperating because they are difficult to diagnose and are often resistant to treatment.

The most common types of fungal infections involving the skin are **tinea pedis** (athlete's foot or **dermatophytosis**), **tinea cruris** (jock itch), **tinea of the scalp** (commonly known as *ringworm*), and **tinea barbae** (barber's itch). **Moniliasis** (thrush) is a fungal infection that can attack the mucous membranes of the mouth, rectum, and vagina (**candidiasis**). (This condition is discussed more fully in [Chapter 11](#).)

The skin fungal infections produce itching, some swelling, and a breakdown of tissue. Because fungi thrive in warm, moist places, a tropical climate or other environmental factors that produce prolonged heat and moisture can encourage the development of fungal infections.

Older adults are prone to develop fungal infections of the fingernails or toenails (**onychomycosis**) ([Figure 42-4](#)). Hands and feet should be thoroughly dried after becoming wet, with special attention to drying between the toes after the bath or shower. Nails should be cut straight across without rounding the edges. Wearing clean socks daily helps prevent fungal growth. In the toenails, the condition may become quite painful. Treatment requires oral antifungal medication daily for several months or topical agents daily for a year or more.

Complementary and Alternative Therapies

Treatment of Nail Fungus

Tea tree oil used topically daily on the nail and cuticle has been successfully used for treatment of yeast and fungal infection ([Weil, 2015](#)). It must be used regularly to be effective and may take weeks or months to cure the infection. Another inexpensive treatment that may work with consistent daily use is the topical application of Vicks VapoRub twice a day. This salve contains camphor, menthol, and eucalyptus. It seems to arrest the development of further fungal growth, allowing a fungus-free nail to grow. It takes about 6 months of treatment and is not effective for everyone.

FIGURE 42-4 Onychomycosis (nail fungus).

There are many side effects of the oral antifungal medications. Liver function should be monitored during drug administration. Diagnosis of fungal infections is confirmed by microscopic examination of skin scrapings that have been treated with potassium hydroxide (KOH) solution. Fungal specimens generally show the typical filaments of fungal organisms. Patients should be taught how to prevent recurrence of fungal infections.

Patient Teaching

Preventing Recurrent Fungal Infection

Instruct the patient to do the following:

- Wear shoes that provide ventilation for the feet. Wear cotton socks when rubber-soled shoes or sneakers must be worn.
- Wash and dry the feet at least daily, being careful to completely dry the skin between the toes.
- Sprinkle an antifungal powder on the feet and between the toes if there is a tendency for athlete's foot. An antifungal spray may be used rather than powder.
- Change hose or socks daily; do not wear them more than 1 day without washing.
- Change underpants or shorts daily; do not wear them more than 1 day without washing.
- Use only clean towels, changing them at least every other day. Do not share towels or washcloths.
- Change bed linens at least once a week and wash in hot water.
- Do not use the combs, hairbrushes, hair clips or hair ties of others, and do not allow them to use yours.
- Inspect pets regularly for ringworm. Have a veterinarian check the animal if an infection is suspected.

Tinea Pedis

Tinea pedis (athlete's foot) affects the feet, particularly between the toes. The infection may spread

to the entire foot and cause blistering, peeling, cracking, and itching. If it continues unchecked, it can spread to other parts of the body. The condition can be complicated by a severe bacterial infection.

Etiology, Pathophysiology, Signs, and Symptoms

Most cases of tinea pedis are contracted and spread in swimming pools, spas, showers, and other public facilities of this type. *Trichophyton mentagrophytes* and *Trichophyton rubrum* are the usual infecting agents. These organisms may be normal flora that spread easily under conditions of excessive warmth and moisture. The skin between the toes becomes inflamed and develops cracks that become painful fissures. Intense itching is common.

Diagnosis and Treatment

Diagnosis is by physical examination. Treatment of tinea pedis consists of keeping the area dry, clean, and exposed to the air and sunlight as much as possible. Clean cotton socks should be worn every day, and the affected areas between the toes should be separated by gauze or cotton. Soaks of Burow solution help. Various topical antifungals can be prescribed, including ciclopirox (Loprox), miconazole, clotrimazole (Mycelex), econazole (Spectazole), ketoconazole (Nizoral), and naftifine (Naftin). Some medicated powders, such as undecylenic acid-zinc undecylenate, work to keep the feet dry and also help control fungal growth. Other treatments are available without prescription. Systemic treatment for stubborn infection includes oral itraconazole (Sporanox) and terbinafine (Lamisil).

Nursing Management

Encourage the patient to keep the feet clean and dry and to wear clean cotton socks every day. Daily application of the topical agent must be done diligently to eradicate the problem. The patient should only use his own towel, and the shower or tub should be thoroughly cleaned and disinfected after bathing to prevent transmission to other family members. Personal footwear should be used in public places, such as the swimming pool and in the showers at fitness centers, and feet should be washed and dried thoroughly after using public facilities.

Parasitic Infections

Pediculosis and Scabies

Etiology and Pathophysiology

The parasites that cause **pediculosis** and **scabies** are found throughout the world in all types of climates. They can infest anyone. The parasites are particularly troublesome, however, where people live under crowded conditions and are negligent in their personal hygiene. The occurrence of pediculosis and scabies in the United States has recently increased significantly because of the growth of the homeless population and communal living. These parasites are often found among schoolchildren. The parasites are also found in nursing homes, dormitories, and sometimes hospitals.

Three basic types of lice that infest human beings are (1) the head louse, *Pediculus humanis capitis*; (2) the body louse, *Pediculus humanis corporis* (Figure 42-5); and (3) the pubic or crab louse, *Phthirus pubis*. In addition, human beings also may be infested by *Sarcoptes scabiei*, the mange mite that produces scabies. The lice are oval and 2 to 4 mm long. All types are acquired by contact with infested people or their clothing, bed linen, and bedding. Pets have also been known to carry lice and the scabies mite.

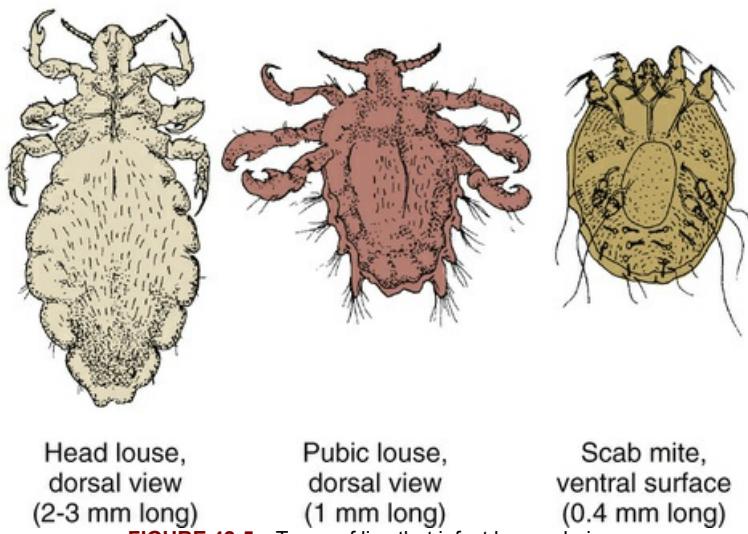

FIGURE 42-5 Types of lice that infest human beings.

Signs and Symptoms

The most prevalent symptom of louse infestation is severe itching. The resultant scratching can lead to excoriation of the skin and secondary infection causing impetigo, furunculosis, and cellulitis. Systemic infections are not commonly associated with louse infestation, but they can and do occur in the forms of glomerulonephritis, septicemia, pneumonia, and cystic abscesses. If the lice infest the eyelids and eyelashes, the eyelids become red and swollen. Swelling may also occur in the lymph glands of the neck of a person heavily infested with head lice. The body louse can transmit typhus fever, trench fever, and some other diseases. Other types of lice are not known to be transmitters of disease.

The scabies mites burrow under the top layers of the skin and live their entire life there. They are more likely to be found in the skin between the fingers and toes, in the groin, and in other areas where there may be folds of skin. Excretions from the mites produce irritation with intense itching and blistering. Secondary infection is not uncommon with scabies, and some deaths have occurred when the scabies infestation has led to pneumonia or septicemia.

Diagnosis

Diagnosis is by body inspection and by examination of skin scraping of a lesion under the microscope. Lice eggs (known as nits) are deposited at the base of hair shafts and can be seen on close inspection. Scabies causes curved or linear white or erythematous ridges in the skin that are easily visible.

Treatment

The prescription drugs most commonly used and considered most effective against lice and scabies are permethrin (Nix, Elimite), pyrethrins (RID), and malathion (Ovide). These substances must be carefully used and the patient's liver functions monitored, because they can be very toxic. They are available as creams, lotions, and shampoos. Lindane has been found to be especially harmful and is no longer recommended. A fine-toothed (nit) comb is then used to remove the nits (eggs) that may have remained on the hair. Benzyl alcohol lotion 5% (Ulesfia) is effective for head lice. It works by suffocating the lice. The amount required is based on the length of the hair, and a second treatment is required in 7 days (Buck, 2012).

Nursing Management

Contact Isolation is recommended. In addition, clothing, bedding, hats, stuffed animals, and other infested articles must be decontaminated to prevent reinfection. Laundering in hot water and machine drying using the hottest cycle is effective. Dry cleaning of nonwashable bed coverings or clothing can be effective. Mattresses, upholstered furniture, carpets, and other articles should be sprayed with a specific disinfectant. All combs and brushes should be soaked in very hot water for more than 5 minutes. For items that cannot be cleaned, such as some stuffed animals, sealing them in plastic bags with the air expelled for 14 days can be effective. All family members must receive instruction about the infection and ways to prevent reinfestation.

Think Critically

How would you approach and instruct the parents of an 8-year-old who has scabies?

Noninfectious Disorders of Skin

Skin Cancer

Skin cancer is often neglected, because there is no pain associated with it and patients fear that treatment will involve extensive or disfiguring surgery. More than 2 million cases a year of basal cell and squamous cell cancers occur in the United States. These are highly curable cancers. It is expected that 73,870 persons will have been diagnosed with melanoma, the most serious type of skin cancer, in 2015 and that 9940 deaths from melanoma will occur ([American Cancer Society, 2015](#)). Most melanoma deaths could have been averted through early diagnosis and treatment. Kaposi sarcoma and T-cell lymphoma are discussed in [Chapter 11](#).

Etiology and Pathophysiology

Several factors predispose an individual to developing skin cancer. Among these are internal changes in the cells that may be caused by hereditary factors and external influences such as chronic exposure to ionizing radiation, petrochemicals, or vinyl chloride or to other irritants in the environment. Sunburn as a child is a particular risk factor. Because characteristics are inherited, susceptibility to skin cancer tends to run in families. Blue-eyed blondes and redheads seem to be most susceptible, probably because they lack sufficient pigment to protect the skin cells from outside irritants. Those with a light complexion have a 24-fold greater risk of developing melanoma than African Americans, and before age 45 years the risk is higher for women than men ([American Cancer Society, 2015](#)).

A major cause of skin cancer today is the alteration in the ozone layer of the earth's atmosphere that allows more UV radiation to reach the earth's surface. This type of radiation is inflicting much quicker damage to skin with much less sun exposure than in years past. Another problem is that the quickly proliferating skin cells of the younger generation are even more susceptible to this type of damage, and it is mostly the young who spend large amounts of time in the sun. Nurses should instruct all people about the dangers of sunning without an appropriate protective sunscreen.

Think Critically

You and a friend are going on a beach vacation. Your friend invites you to go to a tanning salon before the trip. "We want to look tan and sexy out there." How will you respond?

Signs, Symptoms, Diagnosis, and Treatment

Signs and symptoms vary according to the type of lesion. Diagnosis is by examination, biopsy, and pathology study. The three main types of skin malignancy are basal cell carcinoma, squamous cell carcinoma, and melanoma. **Basal cell carcinoma** usually appears first as a small, scaly area and tends to become larger as the disease progresses ([Figure 42-6](#)). It occurs most commonly on the face and trunk. As the scales shed, there is a small amount of bleeding and a scab will form. When the scab is shed, the affected area becomes wider, and it is bordered by a waxy, translucent, raised area. **If such a sore has not healed within a month, it may be a basal cell carcinoma.** This spreading may continue very gradually during several months or years. Even though these malignancies do not metastasize, they can invade underlying tissues, and death can result from complications such as infection or hemorrhage from encroaching into a blood vessel. Small lesions can be removed under local anesthesia in a doctor's office. Larger lesions respond well to radiation therapy.

FIGURE 42-6 Basal cell carcinoma. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 7, Philadelphia, 2013, Saunders.)

Squamous cell carcinoma is caused by sunlight, affects the epidermis, and can become invasive and metastasize to other areas of the body. It appears on the head and neck most frequently. The tumor begins as a small nodule that rapidly becomes ulcerated ([Figure 42-7](#)). Treatment must begin early if the condition is to be relieved before the skin cells sustain extensive damage. Surgical procedures involve total removal or destruction of the lesions and the surrounding tissues that have been invaded. Radiation therapy is advised for patients who are poor surgical risks or who are fearful of surgery.

Older Adult Care Points

Actinic keratoses are very common among older adults. They appear on fair-skinned people as a small, scaly, red or grayish papule particularly on areas of skin that are often exposed to the sun. These lesions should be removed, because they can evolve into a squamous cell carcinoma that can grow rapidly and metastasize.

FIGURE 42-7 Squamous cell carcinoma. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 7, Philadelphia, 2013, Saunders.)

Malignant melanoma is the least common form of skin cancer. It arises from pigment-producing cells and varies in its course and prognosis according to its type ([Figure 42-8](#)). Causative factors are genetic predisposition, solar radiation, and steroid hormone influence. There are several types of melanoma, but the three major kinds of malignant melanoma are superficial spreading, nodular, and lentigo maligna melanoma. In general, the superficial lesions can be cured, but the deeper lesions tend to metastasize more readily through the lymphatic and circulatory systems. Characteristics of the three main types of skin cancer are shown in [Table 42-1](#).

FIGURE 42-8 Melanoma. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 7, Philadelphia, 2013, Saunders.)

Table 42-1
Three Major Types of Skin Cancer

Type	Characteristics
Basal cell carcinoma	Slowly enlarging, firm, scaly papule. Crusted or ulcerated center that may be depressed; has pearly (semitranslucent) raised border. Dilated capillaries around lesion. Accounts for 70% of all skin cancers. Rarely spreads and is easily treated.
Squamous cell carcinoma	Appearance variable. Commonly seen as well-defined, irregularly shaped nodule or plaque. May be elevated, nodular mass, or fungated mass. Varying amounts of scale and crusting. May have ulcerated center. Predominantly on sun-exposed areas: head, neck, hands; 75% occur on the head. Spreads rapidly.
Malignant Melanomas	
Superficial spreading melanoma (SSM)	Appears in a variety of colors: white, red, gray, black, blue over a brown or black background. Has irregular surface and notched border. Small tumor nodules may ulcerate and bleed. Horizontal growth can continue for years. Vertical growth worsens prognosis.
Nodular malignant melanoma (NMM)	Nodules with uniformly grayish black color; resembles a blackberry. May be flesh-colored with specks of pigment around base of nodule. Itching, oozing, and bleeding may occur. Prognosis less favorable than superficial type.
Lentigo maligna melanoma (LMM)	Relatively rare. Arises from a lesion that resembles a large flat freckle that is of variable color from tan to black. Has irregularly spaced black nodules on the surface. Typically located on the back of the hand, on the face, and under fingernails. Develops very slowly; may ulcerate. Tends to metastasize; prognosis poor.

Malignant melanoma always requires surgical removal of the tumor and excision of adjacent tissues and possibly nearby lymphatic structures. Chemotherapy may be employed to destroy tumor cells believed to have migrated beyond the tumor site. Radiation therapy usually is not indicated unless there is extensive metastasis. The radiation does not eliminate the disease, but it can relieve symptoms by reducing tumor size. Interferon alfa-2b has been found to prolong life in patients who have undergone malignant melanoma surgery and are at high risk for systemic recurrence (American Cancer Society, 2015). In advanced cases, a newer immunotherapy drug, ipilimumab (Yervoy), has been shown to prolong life. An oral agent, vemurafenib (Zelboraf), is being used for late-stage melanoma and is the first drug approved that uses fragment-based drug discovery. In this method, small chemical fragments are grown or combined to produce a drug with a higher affinity for binding with the biologic target. In patients with malignant melanoma and a known *BRAF* mutation, treatment with vemurafenib has a response rate of 50%; when combined with other drugs, overall survival can reach 84% (Patrawala and Puzanov, 2012). In 2013, dabrafenib (Tafinlar)—another drug that targets the *BRAF* mutation—was approved and when used in combination with rametinib (Mekinist) has shown a 31% reduction in hazard for survival over treatment with vemurafenib alone (Robert, 2014).

The type of removal of cancerous skin tissue will depend on the type of malignant growth present. **In all but the most extensive growths, treatment is relatively simple and completely successful if started early.** Although benign precancerous lesions do not inevitably develop into malignant lesions, the most advisable course of action is to remove them when they are first diagnosed. Removal is performed by surgery, **electrodesiccation** (tissue destruction by heat), **cryosurgery** (tissue destruction by freezing with liquid nitrogen), topical application of 5-fluorouracil (5-FU), interferon therapy, laser therapy, and molecular therapy. Radiation therapy is sometimes used to destroy the cancer.

Nursing Management

While performing daily care of patients, you often are in a position to notice these lesions in their early stages and should do your best to persuade the person with such a lesion to seek prompt medical attention. It is also helpful to teach assistive personnel the cues and clues that help recognize these developments.

Assignment Considerations

Report Different Skin Lesions

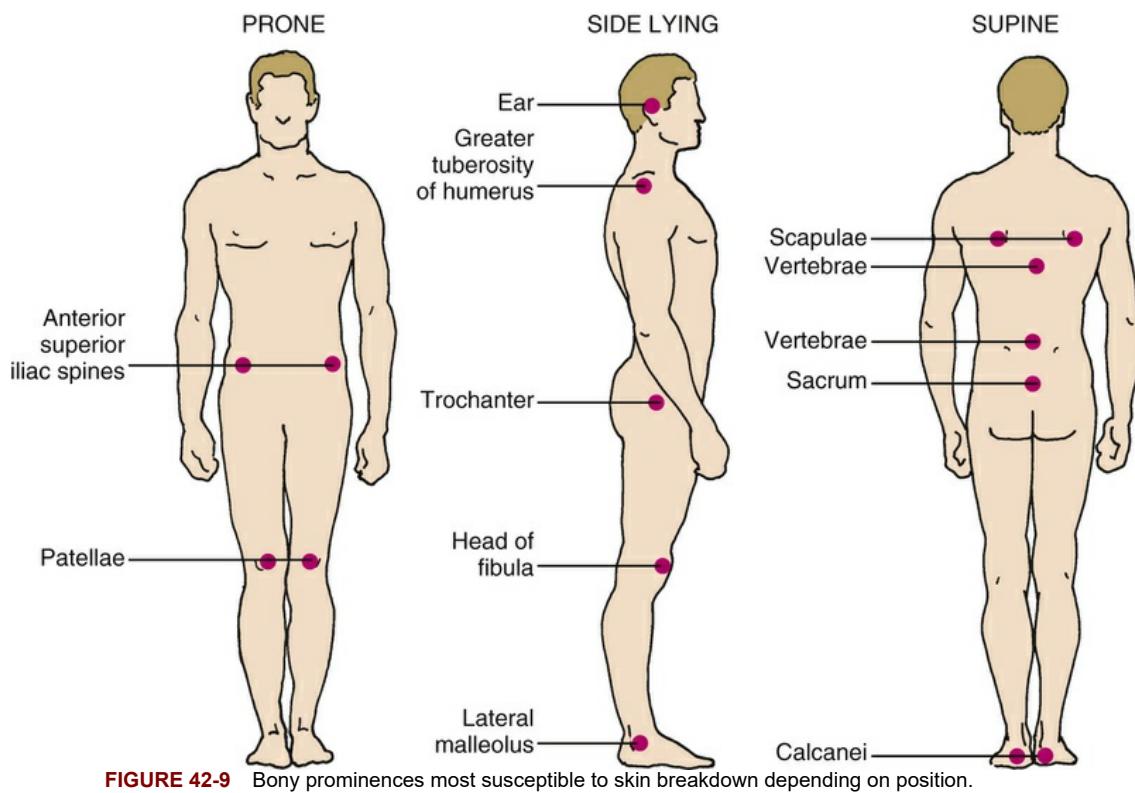

When assigning hygiene care to unlicensed assistive personnel, ask them to report any odd-looking lesions they find on the patient's skin. Skin cancers are often discovered on further assessment of suspicious lesions.

Because people who have skin cancer run a high risk of eventually developing another malignancy, either at the original site or elsewhere in the body, they should visit a provider at least once a year after the skin cancer has been cured. Although most skin cancers are easily curable, they should not be considered harmless and something to forget about after treatment (see [Chapter 8](#)).

Another nursing function is educating the patient about the type of cancer and helping to decrease fear. For many people, the diagnosis of “cancer”—even of an easily cured skin lesion—causes a change in body image and, possibly, in self-esteem. You can assist patients to talk about concerns and the future, point to community resources and support groups, and answer questions about treatment.

Pressure Ulcers

When a patient is on bed rest, or constantly sitting because of paralysis, pressure against the skin in various areas interferes with circulation. Because cells die very quickly without adequate blood supply, a pressure ulcer can develop. Depending on the patient's general condition, weight, and other factors, skin damage may occur within a few hours to a few days. Areas most prone to pressure ulcer formation are those over bony prominences. When the patient is placed in a position in which the bone is pressing on the skin where the skin is against the bed, the circulation to that area is compromised ([Figure 42-9](#)). **Shearing action** (in which superficial layers of tissue are pulled and stretched across deeper layers of tissue) can cause damage to the skin if the patient is slid along the sheets for positioning, rather than lifted. The National Pressure Ulcer Advisory Panel (NPUAP) defines pressure ulcers as injury to the skin caused by pressure alone, or in combination with shear ([NPUAP, 2012](#)).

Risk Factors and Prevention

Every patient needs and deserves good skin assessment, but there are risk factors that make some patients more susceptible to problems, such as confinement, immobility, incontinence, malnutrition, decreased level of consciousness or confusion, obesity, diabetes mellitus, dehydration, edema, excessive sweating, and extreme age. Preventing pressure ulcers is far more desirable, more cost-effective, and less time-consuming than treating them. In fact, the importance of excellent nursing care is now a financial issue, because Medicare and Medicaid no longer reimburse for hospital-acquired pressure ulcers (Coomer and McCall, 2013). Pressure relief, positioning, padding, use of pressure-relief devices, adequate nutrition, and excellent skin care are the hallmarks of pressure ulcer prevention. Box 42-2 presents interventions for preventing pressure ulcers based on the Institute for Clinical Systems Improvement health care protocol. Pressure ulcers can be very costly to the health care system, and an average stage IV ulcer has a treatment cost of \$129,248 per admission (Tzeng et al, 2013). One study showed that numbers of hospital-acquired pressure ulcers are directly related to call bell response time (Tzeng et al, 2013).

■ Nutrition Considerations

Nutrition and Wound Healing

Ongoing research is being conducted about the optimal amounts; however, increased energy (calories); protein; zinc; and vitamins A, C, and E have been shown to reduce pressure ulcers in high-risk patients by 25% (Sernekos, 2013).

Box 42-2

Best Practice for the Prevention of Pressure Ulcers

- Assess the skin of all patients every 8 to 24 hours (interval depends on condition), paying particular attention to the bony prominences (see Figure 42-9).

- Reposition patients on bed rest at least every 2 hours; use a written schedule for systematically turning and repositioning each patient.
- Use positioning devices, such as pillows, foam wedges, and padding, for patients on bed rest to keep body prominences from being in direct contact with one another.
- For patients on bed rest who are completely immobile, use devices that totally relieve pressure on the heels by raising the heels off the bed. Do not use donut-type devices.
- When the side-lying position in bed is used, avoid positioning directly on the trochanter.
- For patients on bed rest, maintain the head of the bed at the lowest degree permitted by the medical condition. Limit the time the head of the bed is elevated.
- Use lifting devices, such as a trapeze or bed linen, to move patients rather than dragging those who cannot assist during transfers and position changes.
- For patients with limited mobility, use a pressure-reducing device on the bed, such as a foam, static air, alternating air, gel, or water mattress.
- Minimize skin injury caused by friction and shear forces by proper positioning and correct transferring and turning techniques. Reduce friction injuries by using lubricants, protective films, protective dressings, and protective padding.
- Skin cleansing should occur at the time of soiling and at routine intervals based on patient need and preference. Do not use hot water, and use a mild cleansing agent that minimizes irritation and dryness of the skin. Cleanse gently, minimizing the force and friction applied to the skin.
- Keep the environmental humidity above 40% and prevent exposure to cold. Treat dry skin with moisturizers.
- Do not massage bony prominences.
- Minimize skin exposure to moisture from incontinence, perspiration, or wound drainage. When sources of moisture cannot be controlled, underpads or briefs that absorb moisture and present a quick-drying surface to the skin should be used. Use an incontinence management program for incontinent patients. Check for incontinence at least every 2 hours.
- Correct inadequate dietary intake of protein and calories with nutritional intervention either by oral supplementation or enteral or parenteral feedings.
- For wheelchair-bound patients, use a pressure-reducing device such as those made of foam, gel, air, or a combination of items. Do not use donut-type devices.
- Positioning of wheelchair-bound patients should include consideration of postural alignment, distribution of weight, balance and stability, and pressure relief by device or repositioning.
- Any person at risk for developing a pressure ulcer when sitting in a chair or wheelchair should be repositioned, shifting the points under pressure at least every hour (every 15 minutes is preferable); patients who are able should be taught to shift weight every 15 minutes.
- If a potential for improvement of mobility and activity status exists, institute a rehabilitation program. Maintain current activity and mobility status with a range-of-motion exercise program.

Signs and Symptoms

Once a patient has developed a pressure ulcer, treatment depends on the stage of the ulcer. Several kinds of preprinted forms can be used to assess the risk of developing pressure ulcers. These assessment tools take into account the general condition of the skin, control of urination and defecation, mobility, mental status, cleanliness, and nutritional status. They provide a more

systematic approach to evaluate a patient's potential for pressure ulcer development. Many agencies use either the Braden scale system (Figure 42-10) or the Norton system for systematic assessment of the skin.

Patient's Name _____	Evaluator's Name _____	Date of Assessment			
SENSORY PERCEPTION Ability to respond meaningfully to pressure-related discomfort	<p>1. Completely limited: Unresponsive (does not move, flinch, or sleep) to painful stimuli, due to diminished level of consciousness or sedation. OR Limited ability to feel pain over most of body surface.</p> <p>2. Very Limited: Responds only to painful stimuli. Cannot communicate discomfort except by moaning or restlessness. OR Has a sensory impairment that limits the ability to feel pain or discomfort over half of body.</p>	<p>3. Slightly Limited: Responds to verbal commands, but cannot always communicate discomfort or need to be turned. OR Has some sensory impairment that limits ability to feel pain or discomfort in one or two extremities.</p>	<p>4. No Impairment: Responds to verbal commands. Has no sensory deficit which would limit ability to feel or voice pain or discomfort.</p>		
MOISTURE Degree to which skin is exposed to moisture	<p>1. Constantly Moist: Skin is kept moist almost constantly by perspiration, urine, etc. Dampness is detected every time patient is moved or turned.</p>	<p>2. Very Moist: Skin is often, but now always moist. Linen must be changed at least once a shift.</p>	<p>3. Occasionally Moist: Skin is occasionally moist, requiring an extra linen change approximately once a day.</p>	<p>4. Rarely Moist: Skin is usually dry, linen only requires changing at routine intervals.</p>	
ACTIVITY Degree of physical activity	<p>1. Bedfast: Confined to bed</p>	<p>2. Chairfast: Ability to walk severely limited or non-existent. Cannot bear own weight and/or must be assisted into chair or wheelchair.</p>	<p>3. Walks Occasionally: Walks occasionally during day, but for very short distances, with or without assistance. Spends majority of each shift in bed or chair.</p>	<p>4. Walks Frequently: Walks outside the room at least twice a day and inside room at least once every 2 hours during waking hours.</p>	
MOBILITY Ability to change and control body position	<p>1. Completely Immobile: Does not make even slight changes in body or extremity position without assistance.</p>	<p>2. Very Limited: Makes occasional slight changes in body or extremity position but unable to make frequent or significant changes independently.</p>	<p>3. Slightly Limited: Makes frequent though slight changes in body or extremity position independently.</p>	<p>4. No Limitations: Makes major and frequent changes in position without assistance.</p>	
NUTRITION Usual food intake pattern	<p>1. Very Poor: Never eats a complete meal. Rarely eats more than a third of any food offered. Eats two servings or less of protein (meat or dairy products) per day. Takes fluids poorly. Does not take a liquid dietary supplement. OR Is NPO and/or maintained on clear liquids or IVs for more than 5 days.</p>	<p>2. Probably Inadequate: Rarely eats a complete meal and generally eats only about half of any food offered. Protein intake includes only three servings of meat or dairy products per day. Occasionally will take a dietary supplement. OR Receives less than optimum amount of liquid diet or tube feeding.</p>	<p>3. Adequate: Eats over half of most meals. Eats a total of four servings of protein (meat, dairy products) each day. Occasionally will refuse a meal, but will usually take a supplement if offered. OR Is on a tube feeding or TPN regimen that probably meets most of nutritional needs.</p>	<p>4. Excellent: Eats most of every meal. Never refuses a meal. Usually eats a total of four or more servings of meat and dairy products. Occasionally eats between meals. Does not require supplementation.</p>	
FRICITION AND SHEAR	<p>1. Problem: Requires moderate to maximum assistance in moving. Complete lifting without sliding against sheets is impossible. Frequently slides down in bed or chair, even from high position, with maximum assistance. Spasticity, contractures, or agitation leads to almost constant friction.</p>	<p>2. Potential Problem: Moves feebly or requires minimum assistance. During a move, skin probably slides to some extent against sheets, chair, restraints, or other devices. Maintains relatively good position in chair or bed most of the time but occasionally slides down.</p>	<p>3. No Apparent Problem: Moves in bed and in chair independently and has sufficient muscle strength to lift up completely during move. Maintains good position in bed or chair at all times.</p>		
				Total Score	

At risk = 15-18; Moderate risk = 13-14; High risk = 10-12; Severe Risk = 9.

Key: IV, intravenously; NPO, nothing by mouth; TPN, total parenteral nutrition.

FIGURE 42-10 Braden scale for predicting pressure sore risk. (Copyright Barbara Braden and Nancy Bergstrom, 1988. Reprinted with permission. All Rights Reserved.)

The presence and stage of an ulcer must be documented on admission to any health care facility or service. Classifying an ulceration can also be helpful in evaluating the effectiveness of treatment and progress toward healing and repair. The NPUAP has updated pressure ulcer definitions for the prediction and prevention of pressure ulcers and a staging system for classification⁹:

- **Suspected deep tissue injury:** Intact skin with a purple or maroon discolored tissue may be firm, boggy, painful, cool, or warm.
- **Stage I:** An area of intact skin that is reddened, deep pink, or mottled that does not blanch (Figure 42-11).

FIGURE 42-11 Stage I pressure ulcer. (From the National Pressure Ulcer Advisory Panel and European Pressure Ulcer Advisory Panel: *Pressure ulcer prevention and treatment: Clinical practice guideline*. Washington, DC: National Pressure Ulcer Advisory Panel, 2009.)

- *Stage II:* Partial-thickness skin loss involving the epidermis and/or dermis. The skin appears blistered or abraded, or has a shallow crater. The area surrounding the damaged skin is reddened and probably will feel hot or warmer than normal ([Figure 42-12](#)).

NPUAP.org | Copyright © 2011 Gordian Medical, Inc. dba American Medical Technologies

FIGURE 42-12 Stage II pressure ulcer. (From the National Pressure Ulcer Advisory Panel and European Pressure Ulcer Advisory Panel: *Pressure ulcer prevention and treatment: Clinical practice guideline*. Washington, DC: National Pressure Ulcer Advisory Panel, 2009.)

- *Stage III:* The skin is ulcerated. There is a crater-like ulcer, and the underlying subcutaneous tissue is involved in the destructive process. The ulcer may or may not be infected. Bacterial infection is almost always present at this stage, however, and accounts for continued erosion of the ulcer and the production of drainage ([Figure 42-13](#)).

FIGURE 42-13 Stage III pressure ulcer. (From the National Pressure Ulcer Advisory Panel and European Pressure Ulcer Advisory Panel: *Pressure ulcer prevention and treatment: Clinical practice guideline*. Washington, DC: National Pressure Ulcer Advisory Panel, 2009.)

- *Stage IV:* There is deep ulceration and necrosis involving deeper underlying muscle and possibly bone tissue. The ulcer can be dry, black, and covered with a tough accumulation of necrotic tissue, or it can be made up of wet and oozing dead cells and purulent exudates. Depth can be determined ([Figure 42-14](#)).

FIGURE 42-14 Stage IV pressure ulcer. (From the National Pressure Ulcer Advisory Panel and European Pressure Ulcer Advisory Panel: *Pressure ulcer prevention and treatment: Clinical practice guideline*. Washington, DC: National Pressure Ulcer Advisory Panel, 2009.)

- *Unstageable:* Full-thickness wounds with eschar and/or tissue that obscures depth determination.

■ Assignment Considerations

“On-Time”

The On-Time Quality Improvement for Long-Term Care was developed by the Agency for Healthcare Research and Quality (AHRQ). Part of the program includes assessment tools that can be completed by certified nursing assistants. The tool provides information about nutritional status, behavior, incontinence, and contributing factors. Data are then made available to providers, nurses, dieticians, and other care providers. The program fosters teamwork and communication

and helps to identify patients who are at risk for pressure ulcers ([AHRQ, 2012](#)).

A new technology called *pressure mapping* may help to identify areas of high pressure. The patient lies (or sits) on a sensor-filled mat, and the mat sends data to a computer, which creates a display of color-coded images. Red areas indicate higher pressures, and blue or green images suggest lesser pressures. The patient can then be repositioned accordingly. The technology is an adjunct to, not a replacement for, good nursing assessment ([Behrendt et al, 2014](#)).

Treatment and Nursing Interventions

Débridement.

Removal of any **eschar** (dead, necrotic tissue) has to occur for a pressure ulcer to heal. The exception is a heel ulcer with dry eschar that has no edema, erythema, drainage, or boggy tissue.

Débridement can be done surgically with forceps and scissors or mechanically. Mechanical débridement is accomplished by whirlpool baths, wet-to-dry saline dressings, dextranomer beads sprinkled over the wound, or other proteolytic enzymes or chemical products that break down the dead tissue and absorb the exudate. When wet-to-dry dressings are used, the patient should be medicated for pain before the dressing is pulled from the wound, because pulling necrotic tissue pulls some viable tissue with it. **This method is not recommended because of the damage that occurs to new granulation tissue.** Carefully read the instructions for whatever product is being used. Surgical débridement may be done in the patient's room, the provider's office, or the surgical suite depending on the depth and extent of the wound. Surgical débridement may require a skin graft to cover the area exposed. Whenever surgical débridement, forceful irrigation, or whirlpool débridement is to occur, provide sufficient analgesia for the patient, because the procedure is painful.

Cleansing and dressing.

Many hospitals and larger long-term care facilities have a wound care nurse specialist who oversees wound treatment; nurses should consult these specialists for valuable advice about wound cleansing and dressing materials. After sharp débridement with bleeding, clean and dry dressings are used for 8 to 24 hours, then moisture-retaining dressings are applied. Ulcers are cleaned whenever the dressing is changed. Normal saline or other nontoxic solutions, such as Shur-Clens, and light mechanical action with sponges or irrigation equipment is a way of cleansing that prevents disruption of granulation tissue. At least 250 mL of solution and a 30-mL syringe with a small catheter or 18-gauge needle attached is used to irrigate and to reach undermined areas and tunnels. A reddened wound bed requires gentle irrigation with a 30- to 50-mL needleless syringe to prevent damage to newly developing tissue.

Wound dressings are selected according to the characteristics of the wound. Common dressing materials include moisture retentive dressings, hydrogel dressings, hydrocolloid wafers, alginates, biologic dressings, and absorptive dressings. Use hypoallergenic tape when tape is necessary. Choose a dressing that keeps the ulcer moist and the surrounding skin dry. Prevent abscess formation by loosely filling all cavities with dressing material. Pressure must be kept off the wound for it to heal.

Other treatment methods.

[Franek and colleagues \(2012\)](#) found that application of electrical stimulation increased the rate of healing of pressure ulcers for patients with spinal cord injuries. In this study, high-voltage electrical stimulation (HVES) was applied to the wound area (stage II or greater). At 6 weeks, the size of the wounds was reduced and appearance was improved.

In some facilities, vacuum-assisted wound closure is being used. A suction tube covered by a special sponge is sealed into place for 48 hours. Low negative suction pressure is applied through the tube. This seems to stimulate the formation of granulation tissue. This treatment is used for chronic ulcers ([Gestring, 2011](#)).

For an ulcer that will not heal with other methods, hyperbaric oxygen therapy may be prescribed if the equipment is available in the community. The patient is placed in the hyperbaric oxygen chamber for the treatments. Tissue becomes flooded with more oxygen than is normally available

when breathing atmospheric-pressure air. This is an effective treatment for other difficult-to-heal wounds as well ([Bhutani and Vishwanath, 2012](#)).

Documentation.

Pressure ulcers should be measured and documented when they are discovered and at least once a week thereafter. Document the characteristics of the wound and any exudate present. Exudate is usually **purulent** (containing pus) or **serosanguineous** (containing serum and blood). Serosanguineous exudate is amber colored and blood tinged. Purulent drainage may be one of several colors ([Table 42-2](#)).

Table 42-2
Color of Purulent Exudate and Probable Pathogen

Color Exudate	May Indicate
Beige with a fishy odor	Proteus
Brown with a fecal odor	Bacteroides
Creamy yellow	Staphylococcus
Green-blue with a fruity odor	Pseudomonas

All aspects of risk assessment, preventive measures instituted, objective description and measurement of pressure ulcers, treatment, and progress toward healing are documented regularly in the patient's chart. The Pressure Ulcer Scale for Healing® (PUSH) tool is a good way to objectively document your findings. Photographs are usually taken of the ulcer on discovery and during treatment to document progress.

Burns

Etiology and Pathophysiology

Burns are injuries to the skin caused by exposure to extreme heat, hot liquids, electrical agents, strong chemicals, or radiation. Inhaling smoke or fumes also causes injury. About 450,000 Americans seek care for burns each year. Most burns are relatively minor, but approximately 40,000 patients are hospitalized for burns each year. Fire and burns kill approximately 4000 people each year in the United States ([American Burn Association, 2013](#)). Thirty years ago most patients with burns over 50% of the body did not survive. Today, because of fluid resuscitation, burn wound excision and grafting techniques, new skin coverings, and nutritional supplementation, a patient may survive a 99% burn.

Electrical burns damage tissue deep within the body. The extent of damage is not always visible, and the entrance site and exit site may appear small. Cardiac monitoring should be initiated even if the patient does not complain of chest pain.

Chemical burns result from accidents in homes or industry. The severity of the injury depends on the duration of contact and the concentration of the chemical. The amount of tissue exposed to the chemical and the action of the chemical affect severity. Alkalies (e.g., industrial cleaners and fertilizers) cause greater injury and burn by liquefying tissue. Acids damage the tissue by coagulating cells and proteins. Chemicals for swimming pools, rust removers, and bathroom cleaners are acids. Organic compounds damage tissue by their fat solvent action.

Radiation skin injury is typically from therapeutic radiation treatment. In industries in which radioactive isotopes are used, the degree of injury depends on the amount and type of energy deposited over time. See [Chapter 8](#) for care of skin damaged by radiation treatments.

Burns cause an acute inflammatory response (see [Chapter 6](#)). Serious burns have local and systemic effects. **All burns should be considered potentially life threatening until they are thoroughly assessed.** When a burn area is large, the inflammatory response can result in a massive shift of water, electrolytes, and protein into the tissues. This causes severe edema. Evaporation from denuded areas is four times that from intact skin. Hyperkalemia occurs when potassium is released from the damaged cells. Hyponatremia is caused by the stress response and potassium shifts. Metabolic acidosis develops. The loss of fluids from the vascular space leads to hypovolemia with low blood pressure and possible hypovolemic shock. Hematocrit will be increased because of concentration of the blood, which is missing the components that have shifted into the tissues. The increased viscosity of the blood causes slowing of blood flow in the small vessels, which in turn causes tissue hypoxia. There is danger of kidney failure from both the hypovolemia and the cellular

debris that the kidneys must clear from the body. If the burn was caused by a fire, lung tissue injury from inhalation of heat and smoke may cause alveolar edema.

The decreased perfusion to other organs causes changes in the gastric mucosa that impair its integrity. A type of ulcer called a **Curling ulcer** can occur within 24 hours.

The stress response to the trauma releases catecholamines, aldosterone, cortisol, and antidiuretic hormone. A hypermetabolic state results, and unless nutrition needs can be met, the body falls into negative nitrogen balance. A low-grade fever may develop as core temperature rises.

Signs, Symptoms, and Diagnosis

Burn severity depends on the cause, the temperature and duration of contact, the extent of burned area, and the anatomical site of the burn. Signs and symptoms vary from slight reddening of the skin to full loss of tissue down to bone with black, charred areas. Blisters may form. A dry, scablike crust forms over a superficial burn. Eschar is a hard, leathery layer of dead tissue that results when there has been a full-thickness injury. It is dark brown to black.

Diagnosis of the depth of burn is made based on a classification system.

Classification of Burns

The classification of burns is based on the amount of the body surface that has been burned and the depth of the burn. The extent of a burn is roughly calculated outside of the hospital according to the “rule of nines” and is expressed as a percentage of total body surface (Figure 42-15). The figures used in this method are fairly accurate for gross assessment in adults. The Lund-Browder classification or the Berkow chart can be used to compute the depth of the burn and the extent of the injury according to relative age, and the total burn estimate is used as the basis for treatment. Burns are a prevalent pediatric injury as well, and children cannot be assessed using the standard rule of nines. Special pediatric charts are available and should be used (Toon et al, 2011).

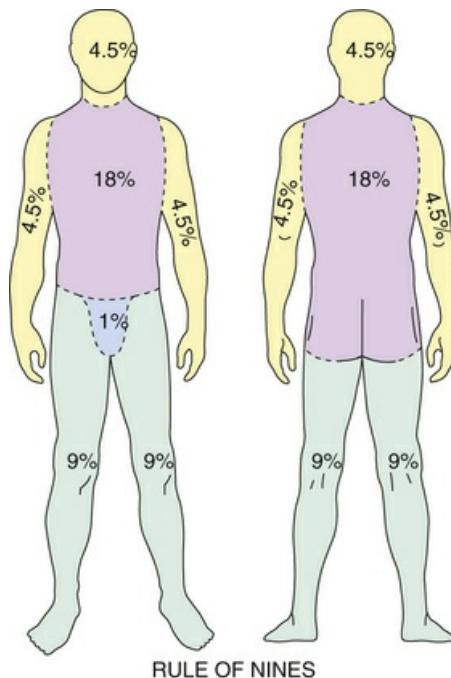

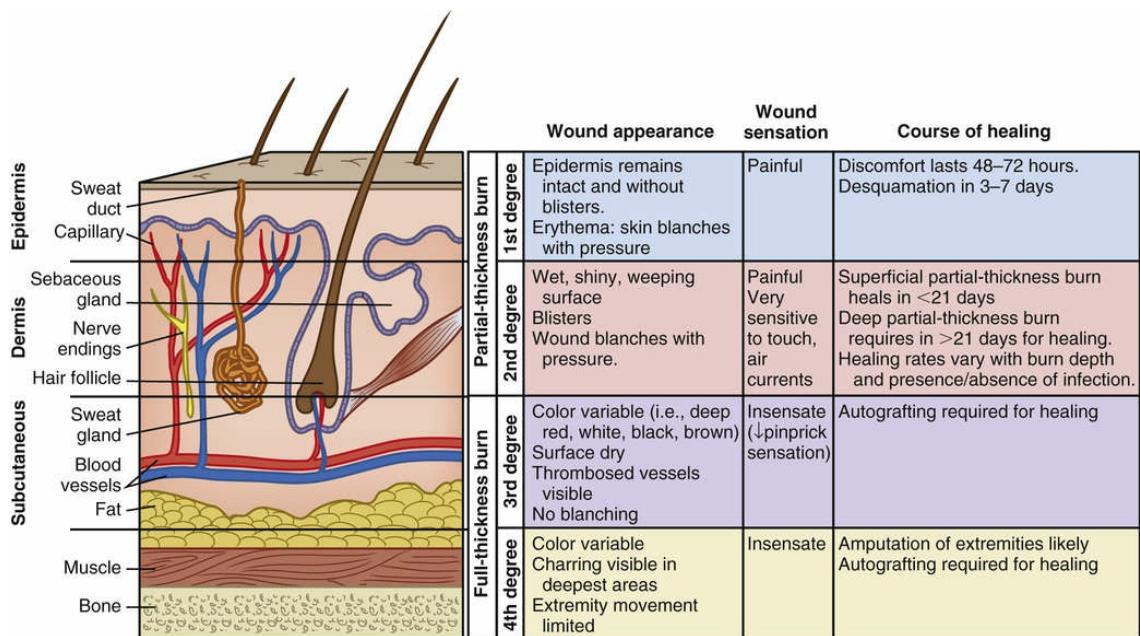

FIGURE 42-15 Chart used for burn area estimate (“rule of nines”).

The depth of a burn is more difficult to determine, because various gradations of injury are sustained in a major burn. Some small patches may be more deeply burned than the areas adjacent to them. Burn depth originally was classified according to degrees, a first-degree burn being the most superficial and a fourth-degree burn being the deepest.

A more current method to evaluate the depth of burns is based on the layers of skin that have been damaged (Figure 42-16). **Partial-thickness wounds** (Figure 42-17) are those in which the epidermal appendages (sweat and oil glands and hair follicles) are not destroyed and the wound

will heal by itself if no further injury occurs from either infection or inappropriate treatment (see [Table 5-1](#) for the phases of wound healing). Grafting may or may not be necessary. **Full-thickness wounds** ([Figure 42-18](#)) involve all layers of skin and the destruction of the epidermal appendages. Wounds of this type will require grafting for the wound to heal and for optimal function to be restored. [Table 42-3](#) provides a guide for estimating the depth of a burn.

The diagram illustrates the cross-section of skin layers: Epidermis (Sweat duct, Capillary), Dermis (Sebaceous gland, Nerve endings, Hair follicle), and Subcutaneous (Sweat gland, Blood vessels, Fat, Muscle, Bone). To the right is a table comparing burn severity across four degrees:

		Wound appearance	Wound sensation	Course of healing
Epidermis	Partial-thickness burn 1st degree	Epidermis remains intact and without blisters. Erythema: skin blanches with pressure	Painful	Discomfort lasts 48–72 hours. Desquamation in 3–7 days
	Partial-thickness burn 2nd degree	Wet, shiny, weeping surface Blisters Wound blanches with pressure.	Painful Very sensitive to touch, air currents	Superficial partial-thickness burn heals in <21 days Deep partial-thickness burn requires >21 days for healing. Healing rates vary with burn depth and presence/absence of infection.
Dermis	Full-thickness burn 3rd degree	Color variable (i.e., deep red, white, black, brown) Surface dry Thrombosed vessels visible No blanching	Insensate (↓pinprick sensation)	Autografting required for healing
	Full-thickness burn 4th degree	Color variable Charring visible in deepest areas Extremity movement limited	Insensate	Amputation of extremities likely Autografting required for healing

FIGURE 42-16 The tissues involved in burns of various depths. (From Black JM, Hawks JH: *Medical-surgical nursing: Clinical management for positive outcomes*, ed. 8, Philadelphia, 2009, Saunders.)

FIGURE 42-17 Partial-thickness burn injury. (From Black JM, Hawks JH: *Medical-surgical nursing: Clinical management for positive outcomes*, ed. 8, Philadelphia, 2009, Saunders.)

FIGURE 42-18 Full-thickness burn injury. (From Black JM, Hawks JH: *Medical-surgical nursing: Clinical management for positive outcomes*, ed. 8, Philadelphia, 2009, Saunders.)

Table 42-3
Classification of Burn Depth

Characteristic	Superficial Burn	Superficial Partial-Thickness Burn	Deep Partial-Thickness Burn	Full-Thickness Burn	Deep Full-Thickness Burn
Color	Pink to red	Pink to red	Red to white	Black, brown, yellow, white, red	Black
Edema	Mild	Mild to moderate	Moderate	Severe	Absent
Pain	Yes	Yes	Yes	Yes and no	Absent
Blisters	No	Yes	Rare	No	No
Eschar	No	No	Yes, soft and dry	Yes, hard and inelastic	Yes, hard and inelastic
Healing time	3-5 days	Approximately 2 wk	2-6 wk	Weeks to months	Weeks to months
Grafts required	No	No	Can be used if healing is prolonged	Yes	Yes
Example	Sunburn, flash burns	Scalds, flames, brief contact with hot objects	Scalds; flames; prolonged contact with hot objects, tar, grease, chemicals	Scalds; flames; prolonged contact with hot objects, tar, grease, chemicals, electricity	Flames, electricity, grease, tar, chemicals

From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 7, Philadelphia, 2012, Saunders.

Emergency Treatment

First, all burn patients are treated as trauma patients. Establishment and maintenance of an airway is the first priority. The patient may have other life-threatening injuries besides their burns. Hemorrhage does not usually occur with burns. If a burned patient shows signs of bleeding, he must be checked for some other type of injury, such as a penetrating wound, fracture, or laceration that occurred at the same time that he was burned.

Generally, patients are undressed and covered with a sterile or freshly laundered sheet; however, clothing that is stuck to the burn area is not removed before the patient is in the hospital. Rings, bracelets, and watches should be removed from injured extremities to prevent a tourniquet effect when swelling occurs. Salves, ointments, or any greasy substance should not be applied to a burned area, because the removal of greasy substances is very painful and increases the possibility of infection. Blisters should not be disturbed initially, because they serve as a protective covering over the wound. **Box 42-3** outlines first aid for minor burns.

Box 42-3

First Aid for Minor Burns

- Run cool water over the burn continuously for 10 to 15 minutes.
- Apply cool compresses if continuous water flow is not available.
- Do not apply ice, ice water, butter, or ointments.

- Do not pop blisters.
- Cover loosely with a sterile gauze bandage.
- Take ibuprofen or acetaminophen for pain.

Patients with serious burns are generally given nothing by mouth. Oxygen is administered if pulse oximetry indicates a problem with respiratory function or if inhalation injury is suspected. Assessment for carbon monoxide inhalation includes checking the mucous membranes for a cherry-red color. Intravenous fluid therapy and more extensive medical treatment are started as soon as possible. The American Burn Association has identified criteria for minor and major burn injuries. It recommends that all major burn injury patients be treated in a burn center. Every emergency department has guidelines that indicate whether a burn victim needs to be transferred to a burn center.

Emergent Phase of Burns

The emergent phase averages 24 to 48 hours but may last as long as 3 days. It begins with fluid loss and edema formation and lasts until edema fluid is mobilized and diuresis begins.

The first hour of treatment after burning can be crucial to the eventual outcome of a serious burn. Other life-threatening injuries must be treated first.

If possible, details of the nature of the accident should be obtained so that a more thorough assessment can be made. Knowing the causes of the burn and whether there is any possibility of thermal damage to the respiratory tract can alert the team to the specific needs of the patient. The depth and extent of the burn area are estimated, and multiple IV lines are established. A tetanus toxoid injection is given in the emergency department; it is the only intramuscular injection given initially.

Respiratory support.

There is a potential for respiratory obstruction if upper airway passages have been burned. Swelling will occur, and it will become increasingly difficult for the patient to breathe. Signs of respiratory distress such as increased respiratory rate, use of accessory muscles, nasal flaring, retractions, restlessness, and confusion may occur. Early intubation is recommended for an extensive upper airway injury.

Lower airway injury (damage to lung parenchyma) is caused by breathing in smoke and soot from the fire. This type of injury may also require intubation and ventilation and may be life threatening.

Patients who should be watched closely for signs of developing respiratory problems include those who have:

- Burns of the face and neck
- Singed nasal hair or darkened membranes in the nose and mouth
- Smoky-smelling breath
- Dark or black sputum
- Burning sensation in the throat or chest
- A history of having been burned in an enclosed space

Watch for increasing restlessness, coughing, hoarseness, rapid shallow respirations, stridor (high-pitched musical sound on inspiration), and falling oxygen saturation (below 95%).

Humidified oxygen is given if the patient is experiencing respiratory distress; intubation and mechanical ventilation may be required. Keep necessary equipment at hand and constantly assess the patient's respiratory effort. Employ the use of an incentive spirometer, coughing, turning, and early ambulation to maintain good respiratory function. Respiratory therapy treatments may be ordered.

Fluid resuscitation and prevention of shock.

A major concern in the care of a burn victim is to prevent shock from circulatory collapse. The two most important measures used to relieve profound shock in a burn patient are:

- Replacement of lost fluids and electrolytes (fluid resuscitation)
- Enhancement of tissue perfusion

The loss of fluids and electrolytes results from the sudden capillary leak and shifting of the blood plasma and tissue fluids from their normal site to the area of the burn. This shift occurs in the first 24 to 48 hours after the burn. The fluids are then lost by movement from the vascular space to the interstitial spaces. Fluid resuscitation needs are based on one of several burn formulas. The Parkland formula for fluid resuscitation is:

$$4 \text{ mL Ringer's lactate (RL)} \times \% \text{ burn} \times \text{weight in kg}$$

One half of the required fluid should be given within 8 hours of the time of the burn. The second half is given over the next 16 hours. After that, fluids are based on specific volume and electrolyte imbalances and response to treatment. **Fluid replacement is calculated from the time of injury, not from the time of arrival at the medical facility.** Important nursing functions are to keep IV access sites patent and secured in place and to ensure that the fluids are administered at the ordered rates.

Clinical Cues

In trauma patients, a Foley catheter is inserted to monitor hourly urine output and provide data to determine whether fluid resuscitation is adequate. The minimum acceptable urine flow for an adult is 30 mL/hr. To obtain accurate hourly measurements, the standard drainage bag should be changed to a drainage bag that has a urometer.

Unless fluids are replaced immediately, the cardiac output will drop, and the resultant profound shock may be fatal to the patient. The patient's vital signs must be checked hourly and recorded accurately. A blood pressure reading taken by cuff from an extremity may not be reliable. An arterial line may be inserted for more accurate monitoring of blood pressure changes. The state of sensorium or level of consciousness is another key observation in the assessment of tissue perfusion. Constantly assess the patient's level of alertness and clarity of thinking, asking the patient who he is, where he is, his age, what happened, and so on. There are significant dangers to fluid resuscitation; for example, excessive fluid potentiates adult respiratory distress syndrome, and extreme fluid deficit will cause acute renal failure. It is very important to monitor the signs of adequate fluid resuscitation and know when to increase or decrease the fluids based on clinical findings.

After the first 24 hours, 5% dextrose in water (D_5W) is given to maintain a serum sodium level of 135 to 145 mEq/L. Fluid intake and output and daily weights are measured as long as the patient has open wounds. Laboratory data are checked frequently for evidence of either a deficit or surplus of specific electrolytes.

Pain management.

As soon as IV lines are established and fluid resuscitation is begun, pain control can begin. Measures to relieve pain include the administration of IV morphine or hydromorphone hydrochloride (Dilaudid). Doses of IV morphine may be higher than you are accustomed to seeing: 2 to 4 mg every 5 to 10 minutes is the standard starting dose, and the patient may require a much larger total dose because of the severe pain (Conolly, 2011). Fentanyl is another powerful opioid medication that can be combined with a benzodiazepine, such as midazolam, before painful wound care procedures. Ketamine and propofol are anesthetic agents that are used for control of pain during procedures. The massive fluid shifts that occur after a burn injury make absorption from an intramuscular site unpredictable in the first 24 hours after the burn.

For chronic pain, gabapentin and methadone can be prescribed. Nonsteroidal anti-inflammatory drugs (NSAIDs) work to control pain but may not be used if ongoing grafting is necessary or because of stress ulcers.

Acute Phase of Burns

The acute phase extends from the time of fluid mobilization and diuresis to when the burned area is

completely covered by skin grafts or when burns are healed. Goals during this phase include management of pain and anxiety, prevention of wound infection, promotion of nutritional intake, and rehabilitation therapy.

Prevention of infection.

Although wound infection is no longer the major cause of death in burn victims (the main cause of death is pneumonia), its prevention is important to recovery. Today patients are taken to the operating room very early after the burn. Burn eschar is excised away from the wound and the area is covered with a biologic or biosynthetic skin. During the granulation stage of repair, the wound should look slightly pink and somewhat shiny. Healthy granulation tissue does not emit exudates. **A very wet wound that has a foul odor indicates infection.** A greenish blue wound exudate is a sign of *Pseudomonas* infection. Signs of inflammation, such as redness and swelling of the tissues adjacent to the wound, may indicate **cellulitis** (acute inflammation of the subcutaneous tissues). Signs of infection should be reported to the provider. If wound sepsis occurs, IV antibiotics specific to bacteria in the wound are given and topical antibacterial soaks are applied to the wound.

Critically burned patients have a high risk for ventilator-acquired pneumonia. [Quinn and colleagues \(2013\)](#) reported that strict adherence to ventilator-acquired pneumonia (VAP) surveillance protocols decreased the complications and the mortality rate associated with VAP, although there was no decrease in ventilator use, intensive care unit (ICU), or hospital days. Examples of Core Measures for ICU patients include protocols to prevent deep vein thrombosis, tighter glucose control, elevation of bed to 30 degrees, and reinforcement of mandatory weaning and spontaneous breathing trials.

Wound treatment.

There are six general principles for the daily care of burn wounds ([Nurselabs, 2014](#)):

1. Cardiopulmonary status should be monitored during the procedure.
2. Tubes and catheters are a source of infection and must not become wet.
3. Patient must be kept warm; heat lamps or radiant heat shields can be used.
4. Infection must be prevented via use of gowns, gloves, masks, and so on, and cleansing should progress from “cleaner to dirtier” wounds.
5. Analgesia and sedation should be preadministered. Provide adequate stress management.
6. Motion must not be impaired (except for new grafts).

Burn wounds are cleansed using sterile technique at least once daily with diluted chlorhexidine. The goal is to remove excess exudate and drainage and to minimize the danger of infection. Wounds of the face or ears are left undressed. After the wounds are cleaned, a topical ointment such as bacitracin is usually applied every 8 hours to prevent infection and promote healing. Burns on the hands, extremities, or trunk may be cleansed at the bedside, on a shower table in the burn unit treatment room, or in a whirlpool bath. Cleansing is done at least once a day, and these wounds are dressed. Dressings are composed of layers of sterile gauze saturated with topical medications, biologic dressings, synthetic dressings, or artificial skin. The wound is then wrapped with stretch gauze, such as Kling, or with elastic mesh webbing. Silver sulfadiazine has long been used for burn care and is still frequently used; however, it is poorly absorbed through eschar and it releases silver for only a few hours. Other preparations include hydrogels, ionic silver powder, alginate combinations, and silver site dressings. [Table 42-4](#) lists the most common topical medications and their nursing implications.

 **Table 42-4**

Topical Medications Commonly Used to Treat Burns

Medication	Action	Nursing Implications
Silver sulfadiazine (Silvadene, Flamazine)	Interferes with DNA synthesis by binding to bacterial cell	Assess for allergy to sulfonamides. Observe for rash, itching, or burning, which may indicate allergic reaction. Observe for leukopenia. Not effective against <i>Pseudomonas</i> infections. Cream must be removed and reapplied once or twice per day.

	membrane.	
Mafenide acetate (Sulfamylon)	Bacteriostatic agent; effective against both gram-positive and gram-negative organisms.	Assess for allergy to sulfonamides. Observe for signs of allergic reaction. May cause metabolic acidosis; monitor blood gases and electrolyte levels. Application may cause pain for 30-40 min; medicate before applying. Penetrates eschar and is effective against Pseudomonas. Very effective for electrical burns.
Silver nitrate	Antimicrobial action.	Dressings must be kept continually wet with 0.5% solution. Stings on application; stains fabric. Monitor electrolyte levels; may cause imbalances. Penetrates wound only 1-2 mm.
Sodium hypochlorite solution (Dakin solution)	Bactericidal action; inhibits blood clotting and may dissolve clots.	Observe for signs of irritation. Keep dressings moist with the solution at all times. Helps dry wounds and assists débridement.
Collagenase (Santyl) with polymyxin B (Polysporin) powder	Digests collagen in necrotic tissue; powder prevents infection.	Monitor for wound infection.
Gentamicin sulfate (Garamycin)	Interferes with protein synthesis in bacterial cell.	Monitor for ototoxicity and nephrotoxicity. Use with caution if decreased renal function is present. Monitor creatinine clearance during treatment. Used when there is resistance to other drugs.
Polymyxin B-bacitracin	Wide-spectrum antibiotic action.	May cause itching, burning, and inflammation. Will not penetrate eschar. Must be applied q2-8h.
Nystatin	Interferes with fungal DNA replication.	May cause itching or allergic reaction. Requires long-term use to clear fungal infection.

Escharotomy.

Eschar is a source of infection, and it impairs healing. Removal of eschar and skin grafting are usually done within 1 week after the burn (Figure 42-19). When tissue perfusion or quality of respiration is compromised because of eschar constriction, an **escharotomy** is performed. **An incision into the burn eschar with a scalpel or electrocautery relieves pressure caused by circumferential burns that encircle an extremity or that constrict movement of the chest.** The incisions extend into the subcutaneous tissue. If the pressure is not relieved, arterial blood flow in the extremity will be compromised, possibly causing necrosis; nerve damage from the pressure also may occur. An escharotomy on the chest improves lung expansion and oxygenation. The procedure does not cause discomfort, because the nerve endings have been destroyed by the burn. No anesthesia is required.

FIGURE 42-19 Escharotomy of the lower extremity. (From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2011, Mosby.)

Be alert for compartment syndrome, which occurs when increased pressure within a compartment (e.g., arm, leg) causes compromise of circulation to the area. Fluid accumulation from edema can cause compartment syndrome in burn patients. Monitor for increasing pain, paleness and tenseness of the tissue, numbness or tingling, discoloration in the distal portion of the extremity, and decreased sensation (**paresthesia**).

Débridement.

Débridement involves removing the eschar and necrotic material from underlying tissues. It is

usually done in the operating room. Whirlpool tubs are used 3 to 4 days after grafting procedures. Pain medication is given before the bath. Enzyme compounds, such as collagenase (Santyl), containing proteolytic agents may be applied topically to digest necrotic tissue. They are used in conjunction with a polymyxin B (Polysporin) powder to prevent bacteria from the wound from entering the bloodstream. Surgical débridement and grafting may require IV anesthetic agents, sedation, nitrous oxide, or narcotic analgesia.

Grafting.

Surgical removal of eschar and applications of biologic dressings are done within the first week after the burn injury. **Biologic dressings** are materials obtained from cadavers or from animals. It is most desirable to graft the patient's own skin (**autograft**), but when this is not possible, a **homograft** (the skin of another person [**allograft**], obtained from a cadaver), a heterograft (**xenograft**, usually obtained from a pig), or artificial (**biosynthetic**) skin, such as Biobrane, can be used as a temporary measure. Biobrane is a nylon fabric with a silicone film that allows exudate to pass through. The many synthetic dressings available consist of silicone, plastics, or alginate (brown seaweed combined with other substances) and remain in place for 1 to 14 days. **The patient's own skin is the only permanent graft material.** Some success has been achieved in growing skin cells harvested from the patient in cultures, but this is a slow, expensive process. The epithelial sheets grown are then used for grafting.

When autografting is performed, there is a donor site from which a split-thickness piece of skin has been removed. That piece of skin may be used intact, or it may be cut into a mesh pattern (Figure 42-20). It takes longer for a mesh graft area to heal, because the skin cells need to grow into the holes between the links of skin. Artiss is a fibrin sealant used for adhering skin grafts for burn patients. Recovery time from a split-thickness skin graft is rapid, commonly less than 3 weeks (Jaliman, 2014).

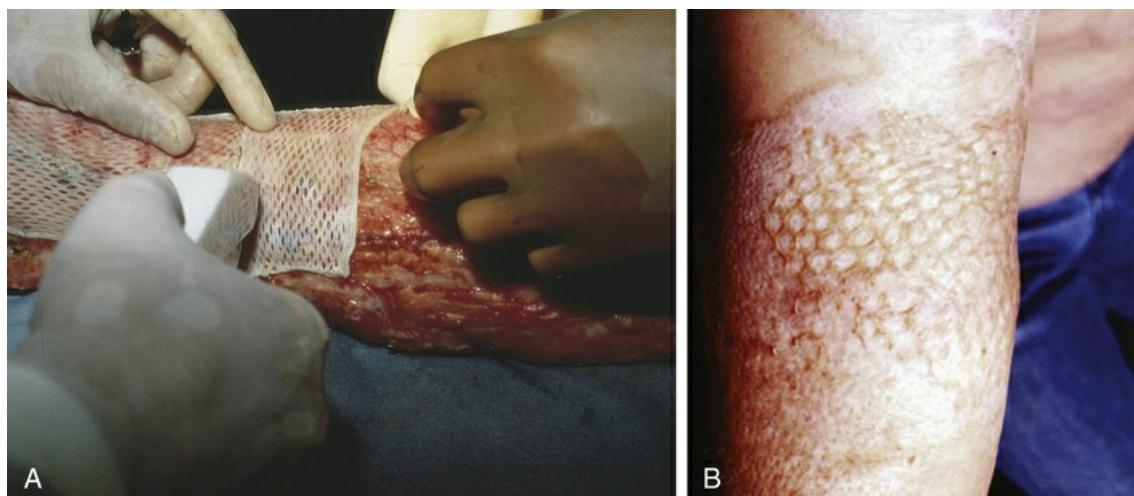

FIGURE 42-20 Typical appearance of meshed autografts. **A**, Appearance during application of meshed autograft. **B**, Appearance of meshed autograft after healing. (From Ignatavicius DD, Workman ML: *Medical-surgical nursing: Patient-centered collaborative care*, ed. 7, Philadelphia, 2013, Saunders.)

Donor sites may be covered by a film dressing to hasten healing and decrease pain. The donor site is often more painful than the graft site. Once the donor site has healed completely, skin may be harvested from that site again.

Pressure dressings are worn as soon as grafts heal to decrease scarring that can inhibit mobility. The pressure dressing may be an elastic wrap or a custom-fitted, elasticized piece of clothing that provides uniform pressure over the burned area. These pressure dressings must be worn 23 hours a day, every day, until the scar tissue is mature. Scar maturity takes 12 to 24 months. Daily exercise and splint applications are used to prevent contracture formation. After burns are fully healed and the scar tissue has matured, plastic surgery may be performed to try to rebuild lost structures, such as the nose or an ear, or to enhance appearance.

Complications

When a sizable burn occurs, blood flow is shifted to the brain, heart, and liver because of the fluid changes that occur. The gastrointestinal tract receives decreased blood, and gastric motility is impaired. Monitor peristalsis and be alert to signs of paralytic ileus. Severe abdominal distention may occur. A Curling ulcer may develop, inducing gastrointestinal bleeding. Stools are monitored for signs of occult blood. A histamine (H_2)-receptor antagonist, such as cimetidine (Tagamet), ranitidine (Zantac), famotidine (Pepcid), or nizatidine (Axid), may be administered IV to prevent this complication.

Contractures always are a threat with major burns and sometimes with minor burns. Proper positioning and regular exercise are essential to prevent musculoskeletal deformities after a burn. Although the motion of physical therapy exercises may be painful, the muscles and skin must be exercised and stretched every day for normal motion to be maintained. Sometimes it is necessary for the patient to continue visiting the physical therapist for several months after discharge from the hospital. Ambulation two or three times a day is begun as soon as the fluid shift has stabilized for patients who have no fractures or serious injuries to the feet or legs.

Rehabilitation Phase of Burns

A patient who has experienced a major burn is transferred to a rehabilitation facility. The rehabilitation phase begins with wound closure and ends when the patient reaches the highest level of function possible. This phase may last for years. The phases of burn rehabilitation have been referred to as the first 2 minutes; the first 2 hours; the first 2 days; the first 2 weeks; the first 2 months; and the first 2 years (Price and Milner, 2012). Continued physical therapy and psychological care are essential to help the patient achieve his optimal level of function. Some patients must learn to use adaptive devices or alter the way they formerly accomplished tasks.

When the patient is ready to accept some responsibility for self-care, preparation for release from the hospital begins. Teach the patient how to apply topical agents without contaminating the wound and how to change dressings if these are used. A family member, if available, is included in burn care education.

Maturing scars usually appear red, hard, and raised before they eventually begin to fade and soften. Pressure garments and masks help prevent thick and disfiguring scars but are uncomfortable (Figure 42-21). The patient may resist wearing them unless he understands their intended purpose. Your encouragement and reinforcement of the purpose can help.

FIGURE 42-21 Pressure garments are individually fitted. (Courtesy Medical Z.)

Reintegration into roles, community activities, and employment takes time. Participation in a support group of burn victims is sometimes helpful. In this way the patient and family realize that they are not alone in their struggles with the many problems that the injury has brought. Assessment of the home environment and family interaction is essential before discharge. Knowing how the patient formerly coped with stressful situations helps professional personnel involved support him. Having friends visit and making short trips out in public is helpful in dealing with the reactions of others to burn scars and disfigurement. Referral for job retraining may be required if the patient will be unable to return to a former occupation because of residual physical deficits. See [Chapter 9](#) for rehabilitation goals and principles.

❖Nursing Management

Care of a burn patient is interdisciplinary and includes the services of the provider, surgeon, nurses, dietitian, respiratory therapist, physical therapist, occupational therapist, psychologist or psychiatrist, and social worker. Other health professionals are added to the team as needed. Collaborative planning meetings are scheduled at least once a week initially. Input for the plan of care is contributed by all members of the team.

■ Assessment (Data Collection)

A thorough assessment of all body systems and psychological response is performed on admission and continues throughout because of the potential for complications. The patient's vital signs and pain level must be checked and recorded at regular intervals. The condition of the wounds also should be assessed systematically to determine whether healing is taking place as it should and infection is being prevented. Wounds are carefully assessed at each dressing change. Signs that indicate infection include:

- Strong odor
- Color change to dark red or brown
- Redness around edges extending to unburned skin
- Texture change

- Exudate and purulent drainage
- Sloughing of graft
Such signs should be reported, because a culture or biopsy should be performed.

Think Critically

What would you do if, when taking vital signs, you find that the pulse on the burned arm is weaker than that on the other, unburned extremity?

Nursing Diagnosis

Care of a burn patient is extremely complex. The plan of care must be frequently revised and updated. Problem statements/nursing diagnoses commonly used for burn patients are included in [Nursing Care Plan 42-1](#). Additional problem statements include:

- Altered nutrition due to increased caloric demands and inability to orally ingest sufficient calories
- Anxiety due to pain, guilt associated with injury, financial concerns, appearance, treatment, and prognosis
- Altered body image due to disfigurement secondary to burn injury
- Altered family coping due to alteration in roles
- Insufficient knowledge due to home care

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

Nursing Care Plan 42-1

Care of a Patient With a Burn

Scenario

Mr. Young, age 33 years, sustained partial- and full-thickness burns over both arms when a container of gasoline he was carrying ignited. He also suffered superficial partial-thickness burns on his hands and face. In the emergency department, his wounds were cleaned and a topical agent was applied; no dressings were applied. Intravenous lines were established, and fluids were administered to prevent potential fluid and electrolyte imbalance. He received morphine for pain and on admission to the unit was fairly comfortable, conscious, and oriented. He is in the emergent phase.

Problem Statement/Nursing Diagnosis

Fluid volume deficit/*Deficient fluid volume related to fluid shift and loss of fluids via open burn wounds.*

Supporting Assessment Data

Objective: Partial-thickness burns over hands and face with full-thickness burns on arms; burn areas becoming edematous.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will have adequate circulating blood volume as evidenced by blood pressure (BP), pulse, and urine output.	Monitor vital signs q2h.	Falling BP and rising pulse can indicate hypovolemia.	BP 120/80. Pulse 78/min. Respirations 24/min. Temperature 98.6°F (37°C).
	Monitor urine output, report drop below 0.5 mL/kg/hr.	Urine output may also indicate hypovolemia, because kidneys will be less perfused.	Urine output at 45 mL/hr.
	Monitor laboratory values for electrolyte imbalances.	Changes in fluid volume may alter electrolyte balance.	Potassium is 4.5 mEq/L. Sodium is 140 mEq/L.
	Maintain IV fluids on schedule.	Adequate fluid resuscitation prevents hypovolemia.	IV fluids on schedule. Continue plan.

Problem Statement/Nursing Diagnosis

Potential for infection/*Risk for infection related to burn damage to skin.*

Supporting Assessment Data

Objective: Skin on face, hands, and arms damaged by burns.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will not experience infection of burn wounds as evidenced by normal vital signs and normalization of WBC count.	Assess for medication allergy. Use strict aseptic technique for wound care.	Medication prescribed may be contraindicated. Infection is the greatest cause of burn wound depth.	No allergies to medication. Strict aseptic technique provided to wounds.
	Do not submerge catheters or insertion sites during cleansing.	Invasive catheters are potential portals of infection.	Peripheral IV catheter and site covered with plastic for cleaning process.
	Assign private room and use Contact Isolation Precautions. Use Standard Precautions, including hand hygiene.	Major burns generally require Contact Isolation Precautions (follow facility procedures). Hand hygiene is a first line measure to prevent infection.	Contact Isolation Precautions initiated. Isolation supplies gathered and placed outside the door. Sign posted for isolation procedures and instructing visitors to see the nurse before entering.
	Apply topical silver sulfadiazine as ordered to wounds tid.	Suppresses bacterial growth and promotes healing.	Wounds cleansed, silver sulfadiazine applied, and wounds redressed.
	Monitor WBC count for signs of infection; assess and cleanse wounds tid.	Cleansing wounds helps prevent infection and promotes healing.	Results for WBC count pending. No signs of wound infection. Not taking food as yet. Continue plan.
	Encourage adequate nutrition.	High caloric intake with sufficient vitamins and minerals is needed for healing.	

Problem Statement/Nursing Diagnosis

Pain/Acute pain related to burn wounds and cleansing procedures.

Supporting Assessment Data

Subjective: States is in constant pain at an 8-10 level.

Objective: Grimacing and holding body rigid.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient's pain will be controlled to tolerable levels with analgesia.	Assess for quality, location, and intensity of pain. Assess patient's "acceptable" level.	Pain is subjective, and patient must report own experience. "Acceptable" level reflects the patient's expectations and tolerance.	Reports pain at 4/10 currently; medicated 3 hours ago. Acceptable level is 4/10, but requests additional medication before dressing change.
	Assess for and control noxious social or environmental stimuli.	Perception of pain is affected by various noxious stimuli, such as loud noise, visitors, dirty sheets, bad odors.	Reports that visitors are laughing loudly in the stairwell; would like to have door closed.
	Administer IV analgesia as ordered, giving boluses as appropriate before procedures and at bedtime.	IV narcotic analgesia is best for burn pain control initially.	Bolus given for pain of 4/10 before dressing change.
Patient's pain will be controlled with oral medication before discharge.	Teach relaxation and imagery techniques to assist with pain control.	Relaxation and imagery techniques have proven helpful in pain control.	Began instruction on relaxation technique.
	Supply diversionary activities to diminish pain awareness.	TV, card games, visitors, computer games, and reading help divert attention from pain.	Is watching TV; not ready for greater activity yet. Continue plan.

Problem Statement/Nursing Diagnosis

Altered self-care ability/Self-care deficit: hygiene, feeding, toileting, and grooming related to inability to use hands and arms.

Supporting Assessment Data

Objective: Burns on hands and arms being treated and grafted; unable to use hands and arms for self-care activities.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will assist with self-care activities within 3 mo.	Assist with hygiene, toileting, grooming, and feeding as needed.	Assistance as needed must be provided to prevent infection and increase well-being.	Requires full assistance with ADLs today.
	Allow him to make decisions as much as possible to lessen feelings of helplessness.	Participation in care decreases feelings of dependency and increases feelings of control.	Choosing time for bath. Unable to use hands and arms at this time.
	Allow him to do as much as he is able to do.	Gradual resumption of activities can occur with encouragement and time.	"At least I can walk to the bathroom by myself." Continue plan.

Problem Statement/Nursing Diagnosis

Decreased self-esteem/Situational low self-esteem related to burned hands and worries about role in family as "bread winner."

Supporting Assessment Data

Subjective: "With my hands and arms burned, I won't be able to work anymore. I'm not much of a man anymore if I can't take care of my family."

Objective: Unable to use hands and arms because of burns.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will verbalize frustrations and concerns before discharge.	Establish trusting relationship, actively listen to concerns and frustrations.	A trusting relationship helps him to freely verbalize concerns and facilitates acceptance of treatment plan.	Expressed concerns about helplessness.
	Help him establish his active role in recovery of use of hands and arms.	Collaboration helps improve his self-esteem.	States wants to recover self-sufficiency.
	Allow him to do whatever ADLs are possible for him.	Performing self-care helps increase self-esteem.	Unable to perform any arm or hand movements yet.
	Praise him for his efforts with PT exercises and use of splints.	Praise encourages his actions.	Passive PT thus far.
	Help him establish small, accomplishable goals on a weekly basis.	Accomplishing small goals increases self-esteem.	Is thinking about goals for next week.
	Review past successes in overcoming obstacles.	Reflecting on past strengths helps patient to envision transferring success to current challenges.	Recalls having a broken arm as a child and remembers learning to adapt and function with a cast in place.
Patient will discuss possible job retraining if needed.	Refer for job retraining if needed.	Extensive burns may affect ability to perform in current employment role.	Need for job retraining unknown at this time. Continue plan.

Critical Thinking Questions

- With partial-thickness burns on his hands, do you think Mr. Young will be able to use his hands as a mechanic again?
- Because he had burns on his face, what specific assessments should be made to determine whether there has been an inhalation injury?
- Will he probably need skin grafting? If so, where? Is it likely that autografts could be used?

ADLs, Activities of daily living; *IV*, intravenous; *PT*, physical therapy; *WBC*, white blood cell count.

■ Planning

Examples of appropriate expected outcomes are written for the individual patient, such as:

- Patient will regain nutritional balance.
- Patient will decrease anxiety.
- Patient will integrate the altered body image.
- Patient will develop new coping mechanisms.
- Family will develop ways to cope with caring for patient at home.
- Patient and family will learn to provide good care at home.

■ Implementation

Managing Pain

Use gentleness and care in handling the patient as he is turned or treatment is administered. This reduces the amount of pain, and the less the patient is handled, the less danger there is of contaminating the wounds. **Despite advances in burn care, research studies show that pain continues to be undertreated, and even experienced clinicians tend to overestimate the efficacy of opioids.** Morphine or hydromorphone hydrochloride should be administered with a patient-controlled analgesia pump when possible. Boluses are necessary before treatments or surgical procedures and at bedtime. Sedatives such as lorazepam (Ativan), midazolam (Versed), and haloperidol (Haldol) should be used along with analgesia. Burn pain can be distressful for years after the burn occurs (Wiechman and Sharar, 2014).

Pain continues even after the wound appears to have healed completely. Exercises to prevent contractures can cause pain because they stretch the skin while it is very tender. Splints to prevent musculoskeletal complications can also cause discomfort. Analgesics will allow the patient to get sufficient rest, but they should be given judiciously as the pain becomes less acute. If a patient begins to depend too much on one kind of analgesic, alternative drugs can be given.

■ Complementary and Alternative Therapies

Helping Patients to Cope with Pain

Proper body positioning, distraction therapy, music, television, games, and virtual reality technologies may help burn patients to cope with pain. These adjunctive interventions do not

replace medication or attentive nursing care ([Melville, 2013](#)).

Preventing Infection

An aseptic environment is needed for burn care. Standard Precautions are used for all burn care, and protective isolation techniques are used. Those in attendance usually wear sterile caps, gowns, shoe covers, and gloves while caring for the patient. Contact Isolation measures are used for infected wounds. Gloves are worn for all contact with open wounds and are changed when handling wounds on different areas of the patient's body and between handling soiled and sterile dressings. **Patient care items are not shared, and great attention is paid to maintaining asepsis for all patient care.** Bed linen is changed daily and whenever soiled, and a bed cradle or some other device is used to support the weight of the top covers to keep them off the burned areas.

Managing Itch

Administer antihistamines proactively before itching becomes intense ([Richardson et al, 2014](#)). Nonpharmacologic measures to reduce  itching, such as massage, transcutaneous electrical nerve stimulation (TENS), music therapy, and botulinum toxin are used along with medication. Therapeutic touch may prove helpful. Acupressure and acupuncture may assist with pain and itch relief.

Nutritional Support

Enteral feedings are started shortly after the fluid resuscitation is completed for a patient with a severe burn. Patients with large burns often develop paralytic ileus as a response to the trauma. The stomach stops working when this occurs, and a nasogastric tube must be inserted and attached to intermittent suction. Bowel sounds should return 48 to 72 hours later, and then intake may begin with high-protein, high-calorie drinks if tolerated.

A diet high in protein and calories is necessary for healing. The patient has increased metabolic needs directly proportional to the size of the burn area. Nutritional needs may be increased 50% to 150% above normal, and increased requirements can continue for 9 to 12 months. Caloric needs are calculated to include the patient's weight, age, and percentage of burn over total body surface ([Prins, 2013](#)). Only high-calorie liquids are given to drink. Free water intake is restricted. Dietary supplements include vitamins, especially vitamins A, C, and D. Minerals such as zinc and copper are supplied, because deficiencies are seen in burn patients. Consultation with a nutritionist is essential because of the dietary issues that can occur for burn patients. There appears to be a maximum glucose load, and high carbohydrate intake can lead to hyperglycemia, dehydration, and respiratory problems. Excessive lipid intake has been associated with impaired wound healing, and ability to tolerate protein is related to renal function and fluid balance ([Prins, 2013](#)).

Complementary and Alternative Therapies

Helping Burn Patients to Relax

In a small study, it was found that jaw relaxation techniques lowered anticipatory anxiety states for burn patients ([Rafii, Mohammadi-Fakhar, and Orak \(2014\)](#)).

Psychosocial Support

Burn patients may face loss of mobility and independence or disfigurement involving the face or other parts of the body usually visible to others. Many experience post-traumatic stress syndrome, and others may feel guilt, anger, or depression. Strive to develop an attitude of acceptance of the patient, a calm approach to dressing changes and discussions of scar formation, and an optimistic emphasis on what the patient can do and will be able to do in the future. When a patient has difficulty coping with the physical and psychosocial effects of a severe burn, effective nursing intervention can help the patient deal with his fears, anxieties, and sense of loss. Assist the patient through the grief process and encourage the patient to relate what is experienced and his feelings about what has happened or is happening. Encourage him to ask questions and to verbalize his concerns about the care and the treatment plan. You can reinforce the patient's self-esteem by emphasizing the strengths you have noticed when the patient was coping with pain, inconvenience,

or some other unpleasant situation. Involving the patient in performing self-care as much as possible and giving some sense of control over the situation are helpful.

The patient's body image may have been severely disrupted. Assist the patient to grieve over the loss and integrate the present body image. If the burns were caused by a suicide attempt or a risky behavior, psychiatric therapy will probably be necessary to deal with feelings of guilt. Although males and children younger than 4 years are more likely to experience burns, female patients tend to have greater adjustment difficulty with altered body image (Rowley-Conwy, 2014). A psychiatric clinical nurse specialist should be consulted to help the staff and the patient work through the complex psychological issues. Referrals to a psychologist, psychiatrist, social worker, or religious leader may also be necessary.

Clinical Cues

Noise, lights, or certain people—visitors or staff—may be very irritating to the patient; these factors usually can be adjusted. If the patient is unhappy about being isolated, bringing in a television, radio, computer games, mobile phone, and books may help.

Patient and Family Education

The patient and family are taught about daily skin and wound care before discharge. They must be familiar with dressing instructions, lubrication of grafts, and donor site care. Moisturizing with an alcohol-free skin moisturizer is necessary at least three times a day. Pressure dressings or garments must be worn for 23 hours daily. Direct sunlight should be completely avoided for 1 year after injury because of increased sensitivity to ultraviolet rays.

Information regarding medication dosages, precautions, and potential side effects are sent home with the patient. Nutritional needs and particular diet recommendations are discussed. Adequate protein and calories are very important to full recovery. Referral is made to support groups or peers and counseling as needed for readjustment to life after the burn incident. The need for follow-up care is stressed, and appointment dates and times are established. See [Nursing Care Plan 42-1](#) for interventions for selected problems in a burn patient.

Evaluation

Although the provider chooses the type of medication to be applied topically or administered systemically for pain, infection, and wound healing, the nurses are responsible for continued assessment of the burn wounds to evaluate the effectiveness of the prescribed treatments. A systematic and ongoing assessment of scar tissue formation should be performed and evaluated to determine whether the patient is making an adjustment to the fact that burn scars may take as long as 12 to 24 months to mature completely. If outcomes are not being met, interventions are changed.

Community Care

Nurses in the community can do much to educate the public about the dangers of unprotected sun exposure and the signs of skin cancer. Nurses vigilantly assess changes in skin lesions that may indicate cancer. Skin self-screening is taught at every opportunity.

School nurses perform assessments for signs of lice and scabies. They teach families how to deal with these problems and how to prevent their spread.

One of the objectives for *Healthy People 2020* is to reduce the number of hospitalizations for older adults that result because of pressure ulcers; therefore nurses employed outside the hospital setting are tasked with the challenge of prevention. Long-term care nurses must promote good skin integrity in all residents, handling older adults with special care to prevent tearing of the skin. Patients who are immobile are turned diligently to prevent pressure ulcers, and skin is inspected regularly. Home care nurses can encourage older adult patients to use skin emollients to moisten and protect the skin.

Teaching fire safety to children and parents and to workers in various occupational settings helps to decrease fire injury. Home care nurses must continually assess patient homes for fire dangers and reinforce teaching to prevent home fires.

Get Ready for the NCLEX® Examination!

Key Points

- Dermatitis causes erythema and itching; a thorough history is necessary to locate the offending agent. Teach patients to avoid causative factors and how to apply topical medications.
- Acne often occurs at puberty; there is an accumulation of sebum and dead skin cells, which causes an inflammatory reaction. Drying agents that cause peeling work best to rid the skin of blackheads and whiteheads.
- There is a genetic predisposition to psoriasis, which appears as inflamed, edematous skin lesions with adherent silvery white scales. It can be controlled, but not cured.
- SJS is a potentially life-threatening allergic reaction usually triggered by medication.
- Hospitalized patients with bacterial skin infections require Contact Isolation.
- Viral skin disorders are caused by herpesviruses.
- Herpes zoster lesions follow nerve pathways; it is a very painful condition, and postherpetic neuralgia can occur. Anyone who has not previously had chickenpox or the immunization should not care for a patient with herpes zoster.
- Fungi prefer warm, moist places; for example, tinea pedis is one of the most common fungal infections and occurs on the feet.
- Treatment of pediculosis and scabies requires treating both the patient and objects that may harbor the parasites.
- Exposure to ultraviolet radiation (sunlight) is a major cause of skin cancer. Encourage use of a hat and sunglasses and sunscreen with UVB protection and a sun protection factor (SPF) of 30.
- Skin cancer has increased in incidence but is highly curable if treated in the early stages. All patients should be screened for skin cancer lesions and taught prevention measures and self-screening.
- Basal cell, squamous cell, and melanoma are the usual carcinomas arising from the epidermis.
- Actinic keratoses are a premalignant lesion common on the skin of older adults.
- If squamous cell carcinoma is not treated early, it can become invasive and metastasize.
- Melanoma is the most aggressive of the skin cancers and needs to be treated early to prevent metastasis.
- Pressure ulcers are a potential problem for all immobile patients. Assessment includes risk factors and staging. Pressure ulcers should be measured and documented on discovery and then measured and documented regularly to show progress in healing. Treatment depends on the stage and location.
- Burns are caused by extreme heat, hot liquids, electrical agents, strong chemicals, or radiation. Treatment is based on classification.
- Burn care is divided into phases: emergency care, emergent care, acute care, and rehabilitation. Pain control is a major concern in every phase.
- Burn patients must be assessed for signs of respiratory problems. Suspect an inhalation injury if there are burns on the face or neck, singed nasal hair, darkened membranes in nose or mouth, or a history of burn in a small space.
- With a major burn, fluid shifts can cause hypovolemic shock. Early fluid resuscitation is essential to prevent death.
- Burn care is aseptic. Eschar must be removed and wounds must be débrided. Débridement can be very painful but is essential for healing and prevention of infection. Contracture prevention begins at the time of admission; special splints and positioning are used to preserve anatomical alignment.
- Early grafting with biologic or synthetic substances helps burn wounds heal more quickly. When skin grafts are healed, pressure dressings or garments are used to prevent excessive scarring.
- Burn patients can have problems with body image and also experience grief, loss, anger, or depression.

Review Questions for the NCLEX® Examination

1. In managing dermatitis, the nurse should provide which instruction(s)? (*Select all that apply.*)

1. “Avoid the irritant or allergen.”
2. “Provide adequate skin lubrication.”
3. “Wash skin frequently with germicidal soaps.”
4. “Maintain skin moisture.”
5. “Apply steroid-based preparations.”

NCLEX Client Need: Physiological Integrity: Physiological Adaptation

2. A major type of skin disorder is acne rosacea. What information may be valuable for the patient education plan? (*Select all that apply.*)

1. Acne rosacea usually occurs in adolescence and then begins to subside during adulthood.
2. Diet is important, and flare-ups may be caused by caffeine-containing foods, spicy foods, sunlight, and alcohol.
3. Comedos may occur on the face, upper shoulders, and back.
4. The primary location for occurrence is on the face over the cheeks and bridge of the nose.

5. Treatments may include metronidazole, retinoids, and occasionally antibiotics.

NCLEX Client Need: Physiological Integrity: Physiological Adaptation

3. A male patient has inflamed, edematous skin of the elbows and knees accompanied by swelling of the joints of the fingers and toes. On examination, the skin is found to be covered with adherent silvery white scales. Which question would provide more information regarding the patient's condition?

1. "What do you do for a living?"
2. "How much do you smoke?"
3. "Have you had an upper respiratory tract infection recently?"
4. "Have you recently changed your laundry detergent?"

NCLEX Client Need: Health Promotion and Maintenance: Data Collection

4. A patient has skin lesions on the face, trunk, palms, extensor surfaces of joints, soles of the feet, and dorsum of the hands. On inspection, the lesions are found to have irregular borders and blistered, necrotic centers. The provider makes the medical diagnosis of SJS. What is the priority problem for this patient?

1. Altered body image.
2. Altered self-care ability.
3. Potential for infection.
4. Acute pain.

NCLEX Client Need: Health Promotion and Maintenance

5. A school-age girl with evidence of severe itching in the scalp is checked for pediculosis. The problem of insufficient knowledge regarding management of the disease is identified for the child and the parent. What instructions would the nurse include? (*Select all that apply.*)

1. "Machine wash clothes and bedding using the cold cycle."
2. "Share combs and hairbrushes with family members, but not with friends."
3. "Soak all combs and brushes in very hot water for more than 5 minutes."

4. "Seal items that cannot be washed in air-expelled plastic bags for 14 days."
5. "Reinfestation is unlikely if all family members are treated."

NCLEX Client Need: Health Promotion and Maintenance: Self-Care

6. The nurse is developing a plan of care for a wheelchair-bound patient. To prevent development of pressure ulcers, which nursing interventions must be implemented? (*Select all that apply.*)

1. Maintain postural alignment.
2. Use pressure-relieving devices.
3. Teach to shift weight every 15 minutes.
4. Use donut-type devices.
5. Reposition in the chair every hour.

NCLEX Client Need: Safe and Effective Care Environment: Safety and Infection Control

7. Place these patients in order from 1 to 4 (1 being the highest risk, 4 having the lowest risk) for their risk for developing a pressure ulcer based on the Braden scale.

1. _____ Older adult who is NPO for procedure; able to independently ambulate and accomplish ADLs
2. _____ Patient who is paraplegic, well nourished, with strong upper body strength to self-transfer to wheelchair
3. _____ Thin older adult patient who walks occasionally, but has limited mobility and cognitive impairments; reluctant to eat
4. _____ Patient who is comatose and unresponsive after a near-drowning accident; receives enteral feedings and is incontinent.

NCLEX Client Need: Health Promotion and Maintenance: Disease Prevention

8. The nurse notes a reddened area on a patient's sacral area and checks for blanching. What is the best rationale that supports this nursing action?

1. Blanching suggests that the redness is probably temporary and will resolve when the pressure to the area is relieved.

2. Checking for blanching is part of the daily routine for assessing any patient who is at risk for pressure ulcers.
3. Evidence of blanching indicates that the patient is at high risk for a pressure ulcer according to the Braden scale.
4. Occurrence of blanching indicates that the redness is associated with a localized skin infection.

NCLEX Client Need: Physiological Integrity: Basic Care and Comfort

9. The nurse makes a home health visit 1 year after a patient was burned over 30% of his body. What problem may the patient be experiencing at this stage? (*Select all that apply.*)

1. Concern with body image due to extensive scarring.
2. Chronic pain due to contractures and nerve compartmentalization.
3. Continued risk for infection due to reconstruction wounds.
4. Increased risk for falls due to joint contractures.

NCLEX Client Need: Physiological Integrity: Physiological Adaptation

10. While the nurse is performing an initial assessment, a patient with extensive burn injuries suddenly develops increasing hoarseness and stridor. Pulse oximetry is 86%. What is the priority nursing action?

1. Encourage the patient to take deep breaths.
2. Provide humidified oxygen.
3. Administer respiratory treatments.
4. Suction respiratory secretions.

NCLEX Client Need: Adaptation: Medical Emergencies

Critical Thinking Questions

Scenario A

Mrs. Nash, age 32 years, has been assigned as your patient on the evening shift. She has severe dermatitis, which is probably allergic in origin. Her provider has ordered a topical lotion, dermatologic baths twice a day, and an antihistamine to relieve itching.

1. What kinds of data would you include in your ongoing assessment of Mrs. Nash's skin disorder?
2. What nursing care problems is Mrs. Nash likely to present?
3. What objectives and nursing measures to meet them would you include in Mrs. Nash's nursing care plan?
4. What would you teach Mrs. Nash about the application of topical agents when she returns home?

Scenario B

Ms. Moore, age 22 years, was badly burned when her clothing caught fire while she was grilling hamburgers on her patio. She has partial-thickness and full-thickness burns over her abdomen and down the front of both upper legs.

1. What is the priority of care after assessment when Ms. Moore reaches the emergency department?
2. What nursing measures should be taken to prevent infection of her burns?
3. What nursing measures would be included in the patient's nursing care plan to ensure that she did not suffer from an undetected fluid and electrolyte imbalance?
4. How is Ms. Moore's pain treated? Why?
5. List some specific things you and the other nurses could do to help her handle her sense of loss and altered self-image as a result of the appearance of the burns and scars.

Scenario C

Mrs. Chaco is an older adult who was admitted to your unit for dehydration and malnutrition. She responds to verbal commands, but seems somewhat confused by your questions. She will quietly sit in a chair, with some movement of her arms, but makes no attempts to walk or stand. She can feed herself, but her appetite and food and fluid intake are very poor. She has had one episode of incontinence with a scant amount of dark yellow urine.

1. Rate this patient's risk for pressure ulcers using the Braden scale.
2. Discuss interventions that you will use to address her positioning and apparent lack of spontaneous mobility.
3. Discuss interventions that you could use to address her nutritional issues.
4. What instructions will you give to the nursing assistant about cleaning the skin?

UNIT XV

Emergency and Disaster Management

OUTLINE

Chapter 43 Care of Patients During Disasters, Bioterrorism Attacks, and Pandemic Infections

Chapter 44 Care of Patients With Emergencies, Trauma, and Shock

CHAPTER 43

Care of Patients During Disasters, Bioterrorism Attacks, and Pandemic Infections

Objectives

Theory

1. Analyze differences between an emergency situation and a disaster.
2. Discuss an emergency preparedness plan for a health care facility.
3. Compare the stages of psychological response that occur with a disaster.
4. Compare and contrast the parameters used in the triage system for victims after a disaster versus the routine triage that occurs in hospital emergency departments.
5. Identify responsibilities and duties of nurses in the care of disaster victims.
6. Explain safety measures to be employed for a chemical emergency.
7. Demonstrate knowledge of measures to be taken in the event of a nuclear disaster.
8. Explain warning signs that suggest a bioterrorism attack has occurred.
9. Differentiate the signs and symptoms of the various agents that could be used for a terrorist attack.
10. Recognize the importance of debriefing of health care personnel after a disaster.

Clinical Practice

11. Participate in a disaster drill.
12. Gather supplies for a “bug out” bag and other disaster preparedness items.
13. Teach a group of adults how to prepare safe water after a disaster has disrupted the water supply.
14. Identify the measures you would take for your own safety when assisting others after a disaster has occurred.

KEY TERMS

- bioterrorism (p. 1015)**
debriefing (p. 1022)
decontamination (dē-kōn-tām-ē-NĀ-shūn, p. 1015)
disaster (p. 1002)
mass casualty (p. 1010)
pandemic (p. 1020)

surge capacity (p. 1003)
triage (TRĒ-ăhzh, p. 1004)

Disaster Preparedness and Response

An extraordinary event, such as a multi-victim incident involving an explosion or a train crash, requires a rapid and skilled response to manage the wounded. There may be walking wounded, critically wounded, and fatally wounded victims. This type of event usually can be handled by the community's emergency medical services and the hospital emergency departments.

A **disaster** exists when the number of casualties exceeds the resource capabilities of the area; thus the community's existing emergency resources may be overwhelmed. Natural disasters include epidemics, earthquakes, explosions, hurricanes, tornadoes, fires, and floods. Intentional terrorist attacks or accidental man-made disasters may result from transportation incidents or events involving chemical, biologic, or nuclear materials. A disaster causes mass casualties, psychological as well as physical trauma, and permanent changes within the community.

The governmental agencies for disaster planning are the Department of Homeland Security, the Office of Domestic Preparedness, Federal Emergency Management Agency (FEMA), and the U.S. Public Health Service. The American Red Cross is a voluntary organization that traditionally provides the basic essentials of shelter, food, and first aid during a natural disaster (Figure 43-1). In most communities, the local Office of Emergency Services (OES), the Red Cross, and the Salvation Army work together to formulate disaster plans. They coordinate their services with each other and with other agencies in planning for essential services, such as shelter, transportation, communication, and welfare. The Centers for Disease Control and Prevention (CDC) has a website with information on all types of disasters, weather events, and mass casualty events (<http://emergency.cdc.gov/disasters/alldisasters.asp>).

FIGURE 43-1 A Red Cross volunteer checks on a resident affected by the extreme heat in Algiers, Louisiana, after Hurricane Katrina. (Courtesy the American Red Cross, printed with permission. Copyright The American Red Cross.)

Special courses in civil defense and disaster nursing are offered by the OES, the Red Cross, and professional organizations. These courses help nurses and volunteer workers to understand the function and coordination of agencies involved in a particular type of disaster. To increase availability of volunteer health care professionals, registries such as the Emergency Systems for Advance Registration of Volunteer Health Professionals (ESAR-VHP) have been designed to proactively verify credentials, provide disaster response training, and coordinate deployment of professionals in conjunction with local, state, and national response plans. Other legislation identifies responsibility, accountability, and liability for health care professionals working outside of their licensure state (Buck, 2013).

Hospital Preparedness

The Joint Commission requires that hospitals have an emergency preparedness plan in place. There are guidelines for emergency preparedness by type of facility. Emergency department providers undergo formal training for disaster events. Emergency department nurses are encouraged to obtain certification in emergency preparedness. You should **proactively** (take action in preparation) seek out disaster training at your work setting and advocate for sufficient emergency supplies and support. Health care systems must self-evaluate **surge capacity**, which is defined as the maximum services that a facility can offer when every resource is mobilized (Bayram et al, 2013). This is also termed *crisis capacity* by the **Institute of Medicine (IOM)** in a 2012 report. The emergency plan should be tested with drills at least twice a year.

Hospitals must plan for many possible scenarios from trauma to chemical contamination. Plans also must be in place for whether or not the incident affects the physical functioning of the facility. If a storm or earthquake damages the hospital building or eliminates power or water sources, decisions on evacuation of patients will have to be made. If the hospital is intact and functional, then focus moves to management of a large volume of patients. Hospital disaster plans outline the command and decision-making structure in addition to details of communication and triage.

The emergency preparedness plan will identify who will be in charge and the chain of command for the facility. The designated communications officer is responsible for internal communication, such as keeping the staff informed, and for external communication, such as contacting other agencies for help or reporting data about infection or chemical contamination that could have widespread effects. There^{will} be a hospital incident commander (provider or administrator) who assumes responsibility for launching the emergency preparedness plan. This person's role as commander is to view the entire situation, bring in needed human and supply resources, and facilitate the flow of patients through the system. Usual hospital routine will be altered to accommodate care for high numbers of patients. Departmental roles will be changed. Physical therapy and other departments may close down usual operations and become the minor treatment area for the nonurgent patients. The concept of "reverse triage," or sending relatively stable patients home, can be used to free up beds. Reports from actual disaster events have shown that inpatients discharged a day earlier than planned showed no adverse outcomes.

A medical command provider will focus on determining the number, acuity, and medical needs of the casualties arriving from the scene of the disaster. This person will organize the emergency health care team response to the injured or ill patients. Specialists trained for the particular type of disaster will be called in to help as the need is foreseen. Decisions will be made about who is to be evacuated to a facility with specialty care not available at the sending facility.

A triage officer, usually a provider, with the assistance of triage nurses, will rapidly evaluate each patient at the hospital and send the patient to the appropriate area for immediate or eventual treatment. The emergency department supervisor or charge nurse collaborates with the medical command provider and triage officer to organize nursing and ancillary personnel to meet patient needs. The disaster call list will be activated to call in off-duty staff as needed. In addition to these personnel, there will be a supply officer, communications officer, infection control officer, and public information officer. The public information officer will manage the media. Hospital staff, at all levels, will be called on to assist with whatever care is needed. Long-term care facilities may need to evacuate residents, or they may need to take in people from other facilities or the community.

Crisis standards of care (CSC) were developed by the IOM at the request of the U.S. Department of Health and Human Services. The publication outlines preparation for a crisis surge response and decision-making guidelines for delivering the best possible medical care to patients when there are not enough resources to provide the level of care normally given (IOM, 2012).

Triage

After a disaster, prehospital care of victims is prioritized according to a **triage** system that is different from regular emergency department triage (Table 43-1). Those with life-threatening conditions and a good chance of survival are cared for first. When there are more victims of a disaster than medical personnel to treat them, those who are likely to survive are treated first; these patients are given red, yellow, or green tags (some classification systems may also include a white tag). The mortally wounded and those who are not expected to survive are attended later,

and these patients are issued a black tag (Figure 43-2). The choice of issuing tags is difficult for most nurses, but in a disaster, the good of many must prevail over benefit to the few.

Table 43-1
Disaster Triage System

Classification	Triage Tag	Typical Conditions	Treatment
Class I: Emergent	Red tag	Immediate threat to life, such as airway compromise or hemorrhagic shock	Immediate
Class II: Urgent	Yellow tag	Major injuries, open fractures, large wounds	Within 30 min to 2 hr
Class III: Nonurgent	Green tag	"Walking wounded" (closed fractures, sprains, strains, contusions)	Wait for more than 2 hr
Class IV: Minor	White tag	Minor injuries not requiring provider care (abrasion, bruises)	Dismiss
Class V: Dead or expected to die	Black tag	Dead, or imminently dying with little chance of survival	None

FIGURE 43-2 Example of triage tags. (Courtesy Disaster Management Systems, Inc., Pomona, Calif.)

Even though triage may have been done in the field, triage is performed again at the emergency care facility. Green-tagged patients usually comprise the greatest number in large-scale disasters. Patients need to be managed until they are able to be treated. If not managed, patients can become a health hazard by walking around with infection, radioactivity, or chemical contamination. A special bracelet with a disaster number may be applied to tagged patients.

Nursing Roles and Responsibilities During Disaster

Your nursing skills will be called into play under disaster conditions; for example, you could be asked to:

- Perform emergency nursing measures

- Evaluate the environmental and physical risks and shortages (e.g., no electrical power)
- Know measures for prevention and control of environmental health hazards (e.g., hand hygiene and food and water safety)

There are many variables to be managed in a disaster setting. Preparation and training are key to effective treatment of large volumes of patients. You are held accountable to practice within the scope of practice of your licensure and training when in your work setting. You may be called on to provide care that you have not performed since your initial training but is within your scope of practice. Nurses should ask for help when needed and focus on delivering the best possible care. The Uniform Emergency Volunteer Health Practitioner Act (UEVHPA) provides immunity from lawsuits when nurse volunteers are providing care within the scope of practice of the state of licensure.

During emergency care, you will perform needed procedures such as inserting catheters, nasogastric tubes, and possibly intravenous (IV) lines and drawing blood. Basic principles of nursing apply in a disaster, but adaptation to “crisis standards” is necessary if there is a disparity between need and availability of equipment, supplies, or personnel. Performing nursing procedures in a disaster situation demands skill and judgment to provide for the good of the greatest number of people. You may be asked to help cook, serve food, pass out water, or do whatever else is a priority need at the time. Observing, recording, and reporting information about patients to appropriate authorities must be done in an organized manner. General physical and mental conditions of patients and signs and symptoms that may indicate change in condition must be quickly identified. During a disaster, preventing the spread of infection is a primary nursing concern. **Table 43-2** identifies the communicable diseases that can become epidemic after a disaster. Infection control is a top priority when large groups of people are together in a shelter, because the incidence of communicable disease is much greater. Although the National Patient Safety Goal is intended for the prevention of health care–related infections under normal circumstances, hand hygiene has an even greater potential as a basic infection control measure to protect large groups of people who may gather together after a disaster.

Table 43-2
Communicable Diseases With Epidemic Potential (All Except Tetanus) in Natural Disasters

Disease	Transmission	Agent	Clinical Features	Incubation Period	Diagnosis	Treatment	Prevention/Control
Waterborne							
Cholera	Fecal/oral, contaminated water or food	<i>Vibrio cholerae</i> serogroups O1 or O139	Profuse watery diarrhea, vomiting	2 hr-5 days	Direct microscopic observation of <i>V. cholerae</i> in stool	Intensive rehydration therapy; antimicrobials based on sensitivity testing	Hand hygiene, proper handling of water/food and sewage disposal
Leptospirosis	Fecal/oral, contaminated water	Leptospira species	Sudden-onset fever, headache, chills, vomiting, severe myalgia	2-28 days	<i>Leptospira</i> -specific IgM serologic assay	Penicillin, amoxicillin, doxycycline, erythromycin, cephalosporins	Avoid entering contaminated water; safe water source
Hepatitis	Fecal/oral, contaminated water or food	Hepatitis A and E viruses	Jaundice, abdominal pain, nausea, diarrhea, fever, fatigue, and loss of appetite	15-50 days	Serologic assay detecting anti-HAV or anti-HEV IgM antibodies	Supportive care; hospitalization and barrier nursing for severe cases; close monitoring of pregnant women	Hand hygiene, proper handling of water/food and sewage disposal; hepatitis A vaccine
Bacillary dysentery	Fecal/oral, contaminated water or food	<i>Shigella dysenteriae</i> type 1	Malaise, fever, vomiting, blood and mucus in stool	12-96 hr	Suspect if bloody diarrhea; confirmation requires isolation of organism from stool	Antibiotic treatment is usually not necessary. If treated, fluoroquinolones, ceftriaxone; hospitalization of seriously ill or malnourished; rehydration	Hand hygiene, proper handling of water/food and sewage disposal
Typhoid fever	Fecal/oral, contaminated water or food	<i>Salmonella typhi</i>	Sustained fever, headache, constipation	1-3 days	Culture from blood, bone marrow, bowel fluids; rapid antibody tests	Fluoroquinolones, ceftriaxone, ciprofloxacin	Hand hygiene, proper handling of water/food and sewage disposal; mass vaccination in some settings
Acute Respiratory							
Pneumonia	Person to person by airborne respiratory droplets	<i>Streptococcus pneumoniae</i> , <i>Haemophilus influenzae</i> , or viral	Cough, difficulty breathing, rapid breathing	1-3 days	Clinical presentation; culture respiratory secretions	Treatment is pathogen driven. Macrolides for outpatient. Beta-lactam for inpatients. Combination therapy is most common	Isolation; proper nutrition; if cause is <i>Streptococcus</i> , polyvalent vaccine to high-risk populations
Direct Contact							
Measles	Person to person by airborne respiratory droplets	Measles virus (Morbillivirus)	Rash, high fever, cough, runny nose, red and watery eyes; serious post-measles complications (5%-10% of cases)—diarrhea, pneumonia, croup	7-21 days	Throat or nasopharyngeal swab. Tested for measles-specific IgM antibody and measles RNA	Supportive care; proper nutrition and hydration; vitamin A; control fever; antimicrobials in complicated cases with pneumonia, dysentery; treat conjunctivitis, keratitis	Rapid mass vaccination within 72 hr of initial case report (priority to high-risk groups if limited supply); vitamin A in children 6 mo-5 yr of age to prevent complications and reduce mortality risk)
Bacterial meningitis (meningococcal meningitis)	Person to person by airborne respiratory droplets	<i>Neisseria meningitidis</i> serogroups A, C, W135	Sudden-onset fever, rash, neck stiffness; altered consciousness; bulging fontanel in patients younger than 1 year	10-12 days	Examination of CSF—elevated WBC count, protein; gram-negative diplococci	Penicillin, chloramphenicol, ampicillin, ceftriaxone, cefotaxime, co-trimoxazole; supportive therapy; diazepam for seizures	Rapid mass vaccination
Wound-Related							
Tetanus	Soil	<i>Clostridium tetani</i>	Difficulty swallowing, lockjaw, muscle rigidity, spasms	2-10 days	Entirely clinical	Tetanus immune globulin	Thorough wound cleansing, tetanus vaccine
Vector-Borne							
Malaria	Mosquito	<i>Plasmodium</i>	Fever, chills, sweats, head and	7-30 days	Parasites on	Chloroquine phosphate,	Mosquito control; insecticide-treated

	(Anopheles species)	<i>falciparum</i> , <i>P. vivax</i>	body aches, nausea and vomiting		blood smear observed using a microscope; rapid diagnostic assays if available	hydroxychlorquine,	nets, bedding, clothing
Dengue fever	Mosquito (<i>Aedes aegypti</i>)	Dengue virus-1, -2, -3, -4 (Flavivirus)	Sudden-onset severe flulike illness, high fever, severe headache, pain behind the eyes, and rash. Severe cases can become hemorrhagic.	4-7 days	Serum antibody testing with ELISA or rapid dot-blot technique	Intensive supportive therapy	Mosquito control; insecticide-treated nets, bedding, clothing
Japanese encephalitis	Mosquito (<i>Culex</i> species)	Japanese encephalitis virus (Flavivirus)	Quick-onset, headache, high fever, neck stiffness, stupor, disorientation, tremors	5-15 days	Serologic assay for JE virus IgM-specific antibodies in CSF or blood (acute phase)	Intensive supportive therapy	Mosquito control, isolation of cases, mass vaccination
Yellow fever	Mosquito (<i>Aedes</i> , <i>Haemagogus</i>)	Yellow fever virus (Flavivirus)	Fever, backache, headache, nausea, vomiting; toxic phase – jaundice, abdominal pain, kidney failure	3-6 days	Serologic assay for yellow fever virus antibodies	Intensive supportive therapy	Mosquito control, isolation of cases, mass vaccination

CSF, Cerebrospinal fluid; ELISA, enzyme-linked immunosorbent assay; HAV, hepatitis A virus; HEV, hepatoencephalomyelitis virus; IgM, immunoglobulin M; JE, Japanese encephalitis; WBC, white blood cell.

From Waring SC, Brown BJ: The threat of communicable diseases following natural disaster: A public health response. *Disaster Management and Response* 3(2), 44-45, 2005 with permission from the Emergency Nurses Association. All information verified to be current via CDC website 2015.

The emotional and physical comfort and safety of large numbers of disaster victims must be attended to with limited supplies, equipment, utilities, and personnel. You must understand the emotional stress caused by fear, problems of displacement and separation of families, personal and material losses, crowded living conditions, increasing anxiety, and continuing danger. Nurses will need to help people of different cultural backgrounds and religious beliefs accept and adapt to temporary living conditions in crowded and often adverse situations (Danna and Bennett, 2013). People should be encouraged to verbalize their concerns and fears. **In a disaster situation, the nurse should provide basic instructions about appropriate self-care within the current environment and encourage people to provide for their own needs. The prepared nurse will:**

- Be prepared for self-survival (i.e., stock your own household with emergency supplies)
- Know the disaster plan for your workplace and identify your duties accordingly
- Know the meaning of warning signals of disaster and the action to be taken
- Know measures for protection against radioactive, chemical, or biologic contamination
- Know the community disaster plans and community health resources
- Know and interpret community resources for citizen preparedness, such as first aid and medical self-help courses

?

Think Critically

You have just started your new nursing job. During your orientation and preceptorship you do not receive any training about the hospital's disaster plan or what your role would be as a staff nurse. What should you do?

Community Preparedness

Whether the disaster is natural or man-made, it will involve physical injuries, loss of property, and interruption of the normal activities of daily living. People often will need food, water, clothing, shelter, medical and nursing or hospital care, and other basic necessities of life.

Preparedness by health care professionals involves both personal and employment-related responsibilities. Disaster supplies, with all the recommended items, should be prepared by every household.

Every family should have a contact person out of the geographic area where extended family members can call to receive information about the welfare of their relatives. Communication into and out of the disaster region is often cut off. Each member of a family living together should know whom they are to call if separated from one another. Even if telephone communication is functional, the service is usually overwhelmed with activity. Texting or social media uses a different bandwidth and may be a more successful mode of communication.

?

Think Critically

If a disaster occurred in your community and you were not injured, where would you call, or go, to see how you could help?

Health Promotion

Community members should be encouraged to prepare for a disaster. Preparations should include a minimum of 3 days' supplies. At a minimum, have the basic supplies listed here. Keep supplies in a kit that you can use at home or take with you in case you must evacuate.

- Water in plastic containers (1 gallon per person per day). Change the supply every 6 months.
- Nonperishable food that requires no refrigeration, preparation, or cooking and little water. Disposable dishes and eating utensils, or camping or military "mess kit" and manual can opener, are ideal.
- Flashlight
- Battery-operated or hand-crank radio (National Oceanic and Atmospheric Administration [NOAA] Weather Radio, if possible)
- Extra batteries
- First aid kit containing an assortment of bandages, scissors, tweezers, gloves, antiseptic, antibiotic ointment, thermometer, and moistened towelettes
- Supply of essential prescription medications and nonprescription drugs: pain relievers, antacids, vitamins, laxatives, anti-inflammatory agents
- Sanitation and personal hygiene items (e.g., hand sanitizer, soap, disinfectant wipes)
- Extra set of clothing
- Copies of personal documents (medication list and pertinent medical information, proof of address, deed/lease to home, passport(s), birth certificate(s), insurance policies, copies of insurance cards and official identification)
- Cell phone with chargers
- Family and emergency contact information
- Extra cash or traveler's checks
- Emergency blanket
- Map(s) of the area

Add to the kit any items specific to the types of disaster common to your geographic area. Also include any items specific to individual family members such as infants or people with special needs.

A 3- to 6-week supply of food and water is recommended. In a disaster situation, it may take several days for rescuers to arrive. Food items should be used and replaced every 6 months to maintain freshness.

Data from American Red Cross. *Be Red Cross Ready*. Retrieved from <http://www.redcross.org/prepare/location/home-family/get-kit>.

Most people know about these recommendations, but few are truly prepared. According to an annual report by the Federal Emergency Management Agency (FEMA), preparedness has improved in the time since the September 11, 2001, terrorist attacks. There is still much more to be put in place on federal and state levels. Natural disasters including tornados, flooding, wildfires, hurricanes, and earthquakes are frequent and seasonal in some areas. Knowing that such events are likely means preparation is prudent and responsible. In addition to the standard disaster supplies, items specific to the event may be needed. The CDC website at www.emergency.cdc.gov gives instructions on how to prepare, what to do if the event occurs, and what resources are available. All nurses must encourage people in the community to prepare.

The local law enforcement agency, the city or county emergency management department, and the state public health department are responsible for coordinating efforts to assist people when a disaster happens. The American Red Cross may disperse personnel and supplies to assist with essential needs and medical care. If the state requests assistance, Homeland Security determines whether FEMA is to be called. If so, FEMA brings personnel and aid to the area. If a disaster is of major proportions, a Disaster Medical Assistance Team (DMAT) may be activated at the state or federal level. These units bring medical, paraprofessional, and support personnel along with medical equipment and supplies to sustain an operation for a minimum of 72 hours. The team provides **triage** (sorting out of casualties by priority of need for treatment), evacuation, primary health care, and assistance to local health care facilities that are overwhelmed. The emergency management team sets up a communications system, and the emergency medical services (EMS) personnel at the scene notify the emergency departments at the hospitals of the situation. Essential personnel are notified of a disaster or **mass casualty** (many-victims incident). If electronic communication systems are functional, alert messages are sent via telephone, computer, pagers, and other devices. In the event of communication failure amateur radio operators can provide essential communication services.

Community residents are instructed about what to do in the event that an earthquake, wildfire, hurricane, tornado, or flood occurs in their area.

Safety Alert

Fire

In the event of a fire, if told to evacuate, leave quickly. If at home and the smoke detector goes off, do not wait to dress or gather belongings—get out of the dwelling. If fire or smoke is evident, drop to the floor and crawl to the exit. Cover your mouth and nose with a moistened cloth if smoke is present. Feel any door before opening it. If it is hot, find another way out. If clothes catch on fire, drop to the ground and roll to suffocate the fire. Keep rolling until flames are out.

Safety Alert

Tornado, Hurricane, and Flood

Choose ahead of time where you could go if evacuation is necessary. Evacuate when you are told to do so. Listen to a NOAA Weather Radio or local radio or television stations for evacuation instructions. Keep road maps handy, because you may have to take unfamiliar routes and your electronic devices may not be functional. Bring the following with you:

- Prescription medications and medical supplies, glasses, hearing aid, and other assistive devices
- Bedding and clothing, including sleeping bags and pillows
- Bottled water, battery-operated radio and extra batteries, first aid kit, and flashlight
- Documents, such as driver's license, Social Security card, proof of residence, insurance policies, wills, deeds, birth and marriage certificates, and tax records, if they are readily available within the home

If advised to evacuate the area, residents should gather essential belongings, medications, pets, and keepsakes and leave immediately. If tornado sirens are sounded, people should take refuge in a basement or in an inner room without windows, such as a closet or a bathroom, to avoid flying debris. Getting into the bathtub and covering oneself with cushions or a mattress can also protect a person from flying debris. If outside, it is best to lie in a culvert or ditch below ground level.

Think Critically

Consider your current level of nursing knowledge and your personal circumstance at home to

include your family, pets, and any preparations that you have (or have not!) made for a disaster event. What would be your reaction if your instructor called you and asked you to help because of a local environmental disaster?

Psychological Responses to Disaster

Any intense event results in an emotional response. Natural disasters or massive injuries from a man-made event have both physical and emotional effects. The phrase “they are in shock” is used to explain the emotional state of the victims after one of these events. Although emotions can trigger physical signs and symptoms, the condition is usually not life threatening unless the individual affected has a preexisting condition that puts her at risk.

Signs and symptoms of emotional shock include headaches, nausea, and chest pain. Preexisting medical conditions may worsen because of the stress. Remaining calm and seeing to immediate physical needs can reassure the patient that someone is in charge that has control over the situation. Severe emotional trauma, such as post-traumatic stress disorder, may take years of therapy to process.

After a major disaster, psychological events occur in stages. The stages are not always linear, and people progress through them at different rates ([CDC, 2012](#)):

- *Impact stage.* Survivors are stunned, apathetic, and disorganized. For several hours after the initial event, they may have difficulty following directions and will need strong support and firm guidance.
- *Heroic stage.* Individuals want to be helpful, and may minimize or ignore their own injuries and demonstrate rescue behavior that is risky to self.
- *Honeymoon stage.* Survivors are grateful that they are still alive. There is a strong sense of brotherhood and community spirit.
- *Disillusionment stage.* Reality of loss occurs. Ongoing physical and emotional fatigue can result in substance abuse and discouragement. Survivors feel abandoned and ignored by the larger community because of the gap between resources and need.
- *Reconstruction stage.* This stage may continue for years as people rebuild lives and even begin to see the crisis, in retrospect, as a growth and opportunity period.

Individuals in communities that are affected by a disaster will need time to cope with events. Ineffective coping requires follow up. Signs and symptoms that should prompt a mental health referral are severe anxiety, suicidal thoughts, inability to care for self, abuse of alcohol or drugs, depression, or domestic violence.

Think Critically

Are you and your family prepared for a disaster? Do you have a disaster kit on hand? If you have children, do you have measures in place for their care by others if you are unable to reach them? Is there an out-of-state contact person for family to call and inform of their status?

Care of Special Populations

Ideally, there should be a community database that includes the needs of vulnerable groups (older adults, disabled, and immunocompromised persons) that require special assistance, because a delay can result in death. Loss of electrical power is a serious issue for those who require oxygen or other life-sustaining mechanical equipment. Patients requiring hemodialysis may need to be temporarily relocated to areas with intact power and water resources. Older adults may be without their prescriptions for chronic or other serious health conditions. Eyeglasses or hearing aids may be lost, and many older adults cannot see or hear well without these aids. Developmental concerns should be considered; for example, infants need diapers, bottles, formula or powdered milk. Infants are especially vulnerable to diarrhea and dehydration related to contaminated water sources.

Individuals with disabilities may need a means of mobility if they are separated from their belongings. They may need assistance with bathing, eating, and general activities of daily living. Immunocompromised people need special attention and care to prevent infection when in large crowds.

Water and Food Safety

Disruption or contamination of the water supply is probable when a disaster occurs. Floodwater or storm water should not be used to wash dishes, brush teeth, wash and prepare food, wash hands, make ice, or make baby formula. People will need to be taught how to purify water.

Health Promotion

Preparing Safe Water

When the normal water supply is disrupted, water may be purified by:

- Bringing it to a rolling boil for 3 to 5 minutes. Let the water cool before drinking.
- Adding household liquid bleach containing 5.25% sodium hypochlorite. Add 16 drops of bleach to a gallon of water and let stand for 30 minutes.
- Distilling the water. To distill, fill a large pot halfway with water. Tie a cup securely to the handle on the pot's lid so that the cup will hang right side up when the lid is upside down. Set the lid upside down on the top of the pot so that the cup hangs down into the pot below the lid (the cup should not dangle in the water). Boil the water for 20 minutes. The water that drips from the lid into the cup is distilled. This method frees water of microbes that may remain after bleach treatment.

Data from United States Environmental Protection Agency (EPA): Ground water and drinking water. Retrieved from <http://safewater.supportportal.com/ics/support/default.asp?deptID=23015>; American Red Cross: Be Red Cross ready—Get a kit. Make a plan. Be informed (Brochure), Washington, DC, 2009; Federal Emergency Management Agency (FEMA) and American Red Cross: Food and water in an emergency (Brochure), Jessup, MD, 2006.

Healthy People 2020 objectives include improved food and water safety; during a disaster, special attention is required to safeguard food and water supplies. If there is a power outage, and people can stay in their homes, they will need to know how to keep their food supply safe to eat ([CDC, 2014](#)) ([Box 43-1](#)).

Box 43-1

Keeping Food Safe to Eat

Perishable foods should not be kept warmer than 40° F (4.4° C) for more than 2 hours. A closed refrigerator will ordinarily keep food chilled to below 40° F for 2 to 4 hours during a power outage. It is wise to have a quick-response digital thermometer on hand. If a power outage occurs, do the following:

- Keep the refrigerator and freezer doors closed. A freezer that is half full will keep food safe for up to 24 hours; a full freezer will keep food safe for 48 hours.
- If it appears that the outage will be for more than 2 to 4 hours, pack refrigerated milk, dairy products, mayonnaise, meats, fish, poultry, eggs, gravy, stuffing, and leftovers into coolers and surround them with ice.
- When uncertain as to how long the power has been out, check the internal temperature of foods in your refrigerator with the quick-response thermometer. If the internal temperature is higher than 40° F, throw the food away.
- Throw away food that may have come into contact with flood or storm water.
- Throw away food that has an unusual odor, color, or texture.
- Food containers with screw-on caps, snap-on lids, crimped caps (beer bottles), twist-off caps, and snap-open caps, as well as home-canned foods, should be discarded if they have come into contact with floodwater, because they cannot be disinfected.

- If cans have come into contact with floodwater or storm water, remove the labels and wash them with hot soapy water or dip them in a solution of 1 cup of bleach in 5 gallons of clean water. Relabel the cans with a marker.

Data from American Red Cross: Food safety guidelines. Retrieved from <http://www.redcross.org/prepare/disaster/food-safety>; and CDC: Keep food and water safe after a disaster or emergency. Retrieved from <http://emergency.cdc.gov/disasters/foodwater/facts.asp>.

Nursing Management in the Reconstruction Stage

Working toward restoring community and family life after the disaster—according to available resources—involves the nurse and other members of the health care team. Individual self-help and work therapy are encouraged, as are activities of daily living, with adaptations designed to attain and maintain a clean and healthy environment. Existing community facilities and resources must be used as much as possible for continued patient care.

You can promote the effectiveness of the health service agency in disaster preparedness by knowing and helping implement the agency's disaster plan. You should understand the relationship among the plans of health agencies, local government, and community agencies. Trying to maintain and restore community health by controlling environmental health hazards is an important responsibility for every nurse.

Preparing for Chemical, Nuclear, or Biologic Disasters

Chemical Disaster

A chemical emergency can occur from a transportation accident or an explosion at a chemical plant. Chemical agents such as the Sarin gas used in the Tokyo subway attack and more recently in Syria can also be used by terrorists. Awareness of a chemical attack or accident is difficult because most chemical agents vaporize quickly from their liquid form. A lesson learned during the Sarin attack is that chemical agents are difficult to identify, and front-line staff are not always informed.

Many chemical agents give off no odor or have a familiar odor such as that of newly mown grass, peach kernels, or almonds. Indications that a chemical attack has occurred might include ([National Terror Alert, 2014](#)):

- Foglike or low-lying cloud suddenly appearing in the atmosphere
- Many dead birds, domestic animals, or insects within a particular area
- Many dead, dying, or sick people in an area or downwind from a suspicious cloud or fog
- An atypical, unexplained odor for the location

Chemical agents ([Table 43-3](#)) that might be used in a terrorist attack include pulmonary/choking agents, blood agents, vesicant (blistering) agents, and nerve agents ([Jagminas, 2015](#)). These agents may be delivered through aerosol sprays, in explosive devices, or through food or water, depending on the action of the substance. Chemical agents may be dispersed as a terror action rather than with the intent of mass destruction ([Shea, 2013](#)).

Table 43-3
Chemical Agent Symptoms and Care

Clinical Presentation	Decontamination Procedures	Treatment
Vesicant Agents (e.g., Phosgene, Mustard, Lewisite)		
<i>Ocular:</i> Eyelid swelling and inflammation, severe pain, conjunctivitis, and keratitis. <i>Dermal:</i> Pain, erythema, blisters, and burning followed by necrosis. <i>Respiratory:</i> Immediate upper airway irritation; burning of mucous membranes, laryngitis, shortness of breath, productive cough; inhalation and systemic absorption may cause pulmonary edema and death. <i>Gastrointestinal:</i> Nausea and vomiting, diarrhea, and abdominal pain. <i>Cardiovascular:</i> High-dose of lewisite exposure may cause capillary permeability and subsequent intravascular fluid loss, hypovolemia, and organ congestion. <i>Renal:</i> High levels of lewisite may cause renal failure caused by hypotension. <i>Hepatic:</i> High levels of lewisite may cause hepatic necrosis and hypoperfusion.	Decontamination for eyes must begin immediately by flushing eyes with water 5-10 min and washing skin to minimize tissue damage. Decontaminate before bringing into health care facility. Negative-pressure room if available. All clothing is removed and skin washed with soap and water. If showers are available, showering with water alone is adequate. Place contaminated clothing and personal belongings in biohazard bag. Contain decontamination runoff. Patients whose clothing or skin is contaminated can contaminate health care providers by direct contact or through off-gassing vapor.	<i>For phosgene:</i> Restrict fluids. Obtain chest radiographs and blood gases. Oxygen/PEEP. <i>For mustard:</i> Possible tracheostomy. Establish IV: Do not push fluids as with thermal burns. Drain vesicles and large blisters and irrigate with topical antibiotics. Antibiotic eye ointment. Morphine as needed (PRN). <i>For lewisite:</i> Treat affected skin with British anti-lewisite (BAL) ointment, if available. Treat affected eyes with BAL ointment, if available. Treat pulmonary symptoms. BAL deep IM; repeat q4h × 3. Morphine PRN. Severe poisoning: shorten interval for BAL injections to q2h.
Nerve Agents (e.g., Sarin)		
<i>Respiratory:</i> Bronchial constriction and spasm; severe respiratory distress or apnea; miosis; rhinorrhea. <i>Gastrointestinal:</i> Do not induce emesis.	Decontaminate before bringing into health care facility. Negative-pressure room. Contain decontamination runoff. Patients whose clothing or skin is contaminated with liquid or solid nerve agents can contaminate health care providers by direct contact or through off-gassing vapor. If exposed to liquid nerve agent, irrigate eyes 5-10 min with water or saline within minutes of exposure to limit injury. If exposed to liquid nerve agent, cut and remove all clothing and wash skin immediately with soap and water. If shower is not available, wash with 0.5% bleach solution. If exposed to vapor only, remove outer clothing and wash exposed skin with soap and water or 0.5% bleach solution. Place contaminated clothing and personal belongings in biohazard bags.	<i>Nerve agent protocol:</i> Intubate and ventilate as needed. Atropine. Pralidoxime chloride (2-PAM C1). Diazepam for seizures. Reevaluate q3-5m for worsening.
Blood Agents (e.g., Cyanide)		
<i>Dermal:</i> Possible cherry red color to skin. <i>Respiratory:</i> Respiratory distress from cellular hypoxia, tachypnea, dyspnea, bradypnea, apnea.	Decontaminate before bringing into health care facility. Negative-pressure room. Contain decontamination runoff.	<i>For cyanide:</i> Administer antidotes: cyanide poisoning antidote kits containing amyl nitrite perles and infusion, sodium thiosulfate, and hydroxocobalamin are available.
<i>Cardiovascular:</i> Dysrhythmias caused by acidosis. <i>Neurologic:</i> Syncope, seizures, lethargy, confusion, coma.	Patients whose clothing or skin is contaminated with cyanide can contaminate health care providers by direct contact or through off-gassing vapor. Patients exposed only to vapor require no decontamination. Prevent dermal contact with gastric contents that may contain ingested cyanide-containing materials. Remove contaminated clothing and wash with soap and water.	Amyl nitrite, sodium nitrite, sodium thiosulfate. Hydroxocobalamin. Sodium bicarbonate for acidosis.
Pulmonary/Choking Agents (e.g., Chlorine)		
Acute exposure to gas can cause immediate coughing, eye and nose irritation, tearing.	Health care providers are at minimal risk of secondary contamination from patients who have been exposed to	<i>For chlorine:</i> Dyspnea.

<i>Dermal:</i> Skin irritation, burning pain, inflammation, and blisters. Treat as thermal burns. Liquefied, compressed chlorine can cause frostbite. Treat by rewarming affected areas in a water bath of 102°–108° F (38.8°–42.2° C) for 20–30 min. Continue until flushing has returned to affected area. <i>Ocular:</i> Do not irrigate frostbitten eyes; if exposed to vapor, irrigate for at least 15 min; check for corneal damage. <i>Respiratory:</i> Airway constriction, pulmonary edema, and hemoptysis may occur.	chlorine gas. Remove contaminated clothing and wash with soap and water. Flush exposed skin and hair with plain water for 2-3 min; then wash twice with soap and water. Clothing or skin soaked with industrial-strength bleach or similar solutions may be corrosive to personnel and may release chlorine gas.	Oxygen by mask. Chest radiograph. Bronchodilators. Give supportive therapy and treat other problems.
---	---	---

IM, Intramuscular; *IV*, intravenous; *PEEP*, positive end-expiratory pressure.

The public should be informed of what to do in the event of a chemical disaster.

Safety Alert

Chemical Disaster

When a chemical disaster has occurred in your neighborhood, you should do the following (unless you are told to evacuate immediately):

- Close all windows and doors to the dwelling.
- Turn off all fans, heaters, and air conditioning systems.
- Close the fireplace damper.
- Wet some towels and jam them in the cracks under the doors. Use plastic garbage bags or plastic sheeting and duct tape to cover doors, windows and skylights, electrical outlets, exhaust fans or vents, window air conditioners, and heat registers.
- Go to an above-ground room with the fewest windows and doors.
- Take your emergency kit and a portable radio with you.
- Stay inside until you are told all is safe or you are asked to evacuate.

Chemicals are dispersed as a gas or liquid or are aerosolized and may contaminate skin, clothing, and any object they touch. The vapor from a liquid or solid toxic chemical also is harmful. Those exposed to toxic chemicals should be decontaminated in the field before transport to a medical facility. Decontamination is usually done with running water and scrubbing. Most emergency departments have an isolated decontamination area in which the water from the shower area goes into a special holding tank. If multiple victims need decontamination, a portable tent may be placed outside of the facility ([Figure 43-3](#)).

FIGURE 43-3 Inflatable decontamination shower for ambulatory victims. (Courtesy PeaceHealth Southwest Medical Center.)

The Tokyo Sarin attack highlights the importance of decontamination to protect staff and preserve the hospital environment: 110 staff members developed signs and symptoms of Sarin exposure as well as 10% of the ambulance staff (Byers, 2014). Chemical warfare agents can produce immediate respiratory distress if inhaled; therefore respirator masks are essential. First responders must use personal protective gear and have training to respond to chemical emergencies. Recognition that a chemical attack has occurred is the first step in adequate protection for the patient, the first responders, and the emergency department personnel.

Patient Teaching

Removal and Disposal of Contaminated Clothing

If you are in an area where a chemical spill has occurred and the liquid or solid comes into contact with your clothing, you will need to (1) remove and bag contaminated clothing and (2) decontaminate your skin. Chemicals will penetrate the clothing and contaminate the skin. If the exposure to a chemical was by vapor (gas), you will only need to remove your clothing and the source of the toxic vapor. Up to 90% of the contaminant can be eliminated by removal of clothing (Emergency Medical Services Agency, 2012). Perform the following steps:

- Quickly take off clothing that has a chemical on it. Any clothing that has to be pulled over the head should be cut off instead of pulling it over the head.
- When helping others remove clothing, be careful not to touch any contaminated areas. Remove clothing as quickly as possible.
- As quickly as possible, wash any chemicals from your skin with large amounts of soap and water. If the eyes are burning, rinse with plain water for 10 to 15 minutes.
- If contact lenses are worn, remove them and place with the contaminated clothing.
- After washing yourself, carefully place all contaminated clothing and contact lenses into a plastic bag. Avoid touching contaminated areas; use tongs, a stick, or a tool to place the clothing in the bag. Place the implement within the bag as well when finished using it.
- Thoroughly wash eyeglasses worn at time of chemical contamination before wearing again. Wash hands thoroughly again after cleaning glasses.

- Carefully seal the bag and place it within another plastic bag and seal the outer one.
- Dress in clothing that has not been contaminated (i.e., clothes that have been in the closet or dresser drawers).
- When health department or emergency personnel arrive, have them handle the bags and arrange for disposal.

Adapted from CDC: Chemical Agents: Facts about personal cleaning and disposal of contaminated clothing. Retrieved from <http://www.bt.cdc.gov/planning/personalcleaningfacts.asp>.

Depending on the chemical agent, there may be an antidote that can be used (see [Table 43-3](#)). Each hospital should have a set of protocols in place. Symptomatic supportive care is supplied with oxygen, IV fluids, and comfort measures.

Nuclear Disaster

A nuclear disaster may be the result of an accident at a nuclear power plant, a disruption of a nuclear power plant by terrorists, or a nuclear or “dirty bomb” (one containing radioactive substances). The amount of damage to each person depends on the type of radiation, the dose received, the length of time of exposure, and the route of the exposure. **Time, distance, and shielding are key to the quantity of radiation an individual will receive.** The shorter the time of exposure, the farther away from the radiation source, and whether or not the person was shielded by materials that are impermeable to radiation are details pertinent to radiation risk ([World Nuclear Association, 2015](#)) (see [Chapter 8](#)). Some types of radiation produce particles, and other types produce rays. Particles will adhere to airborne dust particles; may be inhaled; and will settle on clothes, crops, water supplies, and other surfaces.

Decontamination is done with showering and scrubbing the skin to remove particles. Radiation exposure to rays does not require decontamination, although rays can cause serious health effects or death, because they do internal damage to tissues. However, if the exposure is from a terrorist attack, it would not be immediately known if the exposure to radiation was in the form of particles or rays. Therefore everyone exposed, or suspected of being exposed, will need to be decontaminated. Personnel performing triage and decontamination must be protected from radioactive particulates and contaminated dust.

Usually, specially trained units supply personnel to handle decontamination. Minimal protective equipment includes protective gear for clothes and shoes (Tyvek suit), double gloves (one under clothing and taped to the skin, and one over the clothing cuffs), and a high-efficiency particulate air (HEPA) respirator mask with a full facepiece. If no such mask is available, a fit-tested N-95 respirator mask such as used for tuberculosis precautions is better than no mask. Radiation detection badges are worn underneath the protective clothing. After disposing of the protective gear in specially marked biohazard containers, each person will be assessed to make certain radiation contamination has been eliminated ([Radiation Emergency Medical Management, 2014](#)).

Exposure to high doses of radiation rays that penetrate the body even for a few minutes may result in acute radiation sickness syndrome. Three subsyndromes may occur, depending on the dose of radiation received: bone marrow syndrome, gastrointestinal syndrome, and cardiovascular/central nervous system syndrome. Bone marrow tissue is affected first; then with increased dosage, the gastrointestinal lining is affected. A person who receives a high enough dose of radiation to cause cardiovascular/central nervous system syndrome will experience effects on the bone marrow and gastrointestinal system as well. The effects of radiation are progressive as the dosage increases. Signs and symptoms may include nausea, vomiting, diarrhea, leukopenia, signs of bleeding or hemorrhage, lethargy, confusion, ataxia, convulsions, hair loss, and respiratory complications with fever and pneumonia ([Table 43-4](#)). Treatment of life-threatening injuries takes precedence over the radiologic damage ([Pae, 2015](#)).

Table 43-4
Acute Radiation Syndrome

Signs and Symptoms*	Time of Onset*	Duration	Treatment
Initial or Prodromal (Dose Dependent)			

Nausea, vomiting, diarrhea Progressive cognitive impairment at high doses	Minutes to days after exposure	May last for several days	Serial CBC (for lymphocyte count) obtained every 2-3 hr for 8-12 hr; then every 4-6 hr for 2-3 days. Record all symptoms and time of onset (vomiting is correlated with prognosis). Fluids and antiemetics. Chelating, blocking, excretion, or diluting agents.
Latent			
Feels and appears relatively healthy	Hours to weeks after prodromal phase	May last several weeks	Patient education about significance of latent stage, need for infection control, and possible progression to phase of manifest illness. Continue to monitor for symptoms and CBC.
"Manifest Illness" (Obvious Illness)			
Signs and symptoms of leukopenia purpura, hemorrhage Pneumonia Hair loss Diarrhea, fever, electrolyte disturbance Convulsions, ataxia, tremor, lethargy	Hours-weeks	Hours to months	Supportive and symptomatic treatment. Isolation for leukopenia as needed. Possible stem cell replacement.
Recovery or Death			
Death	Days to years Death may occur within 1-2 days at >3000 rads; death occurs 3 wk-6 mo at >200-600 rads	Recovery lasts from several weeks up to 2 years.	Educate those who recover about increased future risk for cancers and advise to have frequent health checkups.

*Progression through phases and symptoms depends on the dose and type of radiation received.

CBC, Complete blood count; rads, unit of absorbed radiation dose.

From Radiation Emergency Medical Management: <http://www.remm.nlm.gov/index.html>.

Once injuries are managed and decontamination is complete, nursing care is supportive, with strict infection control procedures in place. Maintaining an accurate record of the onset and duration of the clinical symptoms is essential for the provider to decide on treatment strategies. Record hair loss, inflamed mucosa, and locations of erythema hourly and, if possible, record skin symptoms with a camera. Serial blood counts will be performed. Nausea is treated with antiemetics. Blood problems may be treated with blood component transfusions.

When the radiation exposure is in the form of particulates that have entered the body, treatment depends on the type of radiologic substance. The four types of agents used to reduce the radiation damage by reducing exposure to the radiologic substance are chelating agents, isotope-specific blocking agents, excretion agents, and diluting agents.

Chelating agents bind with the radioactive material and allow it to be excreted without being absorbed into the tissues. Radioactive iodine exposure is treated with potassium iodide, an isotope-specific blocking agent, to prevent the thyroid cancer this type of radiation causes. Excretion agents are used when radioactive material has been ingested; these reduce the time the radiologic material is in the gastrointestinal tract. Diluting agents reduce the concentration of the radioactive material. Water is the best example of a diluting agent. Special precautions need to be used when administering a mobilizing or diluting agent, because the fluids produced could be radiologically contaminated ([Radiation Emergency Medical Management, 2013](#)).

Biologic Disaster

Bioterrorism involves the deliberate release of microorganisms or toxins derived from living organisms that cause disease or death to humans or to the animals or plants on which we depend for food. The CDC lists more than 40 pathogens that have potential as biologic weapons; however, anthrax, plague, smallpox, botulism, viral hemorrhagic fevers, and tularemia are category A because they pose a threat to national security ([CDC, n.d., Bioterrorism agents](#)). These organisms cause a high death rate and are easily transmitted. Public panic and fear is likely to accompany any breakout. The organisms are invisible to the naked eye and are easily transported without detection.

Recognizing a Bioterrorism Event

Many of the likely bioterrorism agents do not produce symptoms right away. Certain signs or events may present a warning that a bioterrorism attack has occurred. Some of the signs include ([Jagminas, 2015](#)):

- Large numbers of patients with similar symptoms of disease
- Higher than expected illness and death incidence with common disease
- Unusual disease presentation
- Large numbers of patients with unexplained symptoms, diseases, or deaths
- Disease typical to the area with a sudden unexplained increase in incidence
- Atypical incidence of disease in patients not usually affected
- Sudden death of many animals in the community

Biologic Agents

Biologic agents ([Table 43-5](#)) are divided into three groups ([CDC, 2013](#)):

- **Category A agents:** Easily disseminated, and some may be transmitted from person to person as well. These could cause mass casualties and require a well-organized and extensive health care system response for management.
- **Category B agents:** Delivered through water and food sources. These produce moderate amounts of illness and low death rates. Public health department action is needed for management. Examples are Q fever, brucellosis, glanders, ricin toxin, epsilon toxin of *Clostridium perfringens*, and *Staphylococcus aureus* enterotoxin B.
- **Category C:** Agents that have yet to be weaponized, but have the potential for high morbidity and mortality. These agents are plentiful and easy to produce and disseminate. Examples include *Hantavirus*, tick-borne encephalitis, yellow fever, and multidrug-resistant tuberculosis.

Table 43-5
Category A Agents of Bioterrorism

Pathogen and Description	Clinical Manifestations	Transmissibility	Treatment
Anthrax (<i>Bacillus anthracis</i>)			
Inhalational			
Bacterial spores multiply in the alveoli Toxins cause hemorrhage and destruction of lung tissue High mortality rate	Incubation period: 1-2 days to 6 wk Abrupt onset Dyspnea, diaphoresis, fever, cough, chest pain, septicemia, shock, meningitis, respiratory failure, widened mediastinum (seen on chest radiograph)	No person-to-person spread Found in nature and most commonly infects wild and domestic hoofed animals Spread through direct contact with bacteria and its spores Spores are dormant, encapsulated bacteria that become active when they enter a living host	Antibiotics prevent systemic manifestations Effective only if treated early Ciprofloxacin (Cipro) is the treatment of choice Penicillin Doxycycline Postexposure prophylaxis for 30 days (if vaccine not available) Vaccine has limited availability
Cutaneous			
95% of anthrax infections Least lethal form Toxins destroy surrounding tissue	Incubation period: up to 12 days Small papule resembles an insect bite Advances to a depressed, black ulcer Swollen lymph nodes in adjacent areas Edema	Spores enter skin through cuts or abrasions Handling of contaminated animal skin products	Oral doxycycline or quinolones are the antibiotics of choice
Gastrointestinal			
Intestinal lesions in ileum or cecum Acute inflammation of intestines	Nausea, vomiting, anorexia, hematemesis, diarrhea, abdominal pain, ascites, sepsis	Ingestion of contaminated, undercooked meat	Penicillin, doxycycline, or ciprofloxacin may be prescribed
Botulism (<i>Clostridium botulinum</i>)			
Spore-forming anaerobe Found in soil Seven different toxins Lethal bacterial neurotoxin	Incubation period: 12-72 hr Abdominal cramps, diarrhea, nausea, vomiting, cranial nerve palsies (diplopia, dysarthria, dysphonia, dysphagia), skeletal muscle paralysis, respiratory failure	Spread through air or food No person-to-person spread Improperly canned foods Contaminated water Contaminated wound	Antitoxin given immediately Mechanical ventilation Penicillin No vaccine available Toxin can be inactivated by heating food or drink to 185° F (85° C) for at least 5 min
Plague (<i>Yersinia pestis</i>)			
Bacteria found in rodents and fleas Forms: Bubonic (most common) Pneumonic Septicemic (most deadly)	Incubation period: 2-4 days Hemoptysis, cough, high fever, chills, myalgia, headache, respiratory failure, lymph node swelling	Direct person-to-person spread Transmitted through flea bites Ingestion of contaminated meat	Antibiotics only effective if administered immediately Drug of choice: streptomycin or gentamicin Vaccine under development Hospitalization Isolation for containment
Smallpox			
Variola Major and Minor Viruses			
United States ended routine vaccination in 1971 Global eradication declared in 1980	Incubation period: 7-17 days Sudden onset of symptoms Fever, headache, myalgia, malaise, back pain Lesions progress from macules to papules to pustular vesicles	Highly contagious Direct person-to-person spread Transmitted in airborne droplets Transmitted by handling contaminated materials (i.e., linens)	No known cure. Vaccinia immune globulin (VIG) is first line therapy Cidofovir (Vistide) may be used under an investigational drug protocol Isolation for containment Vaccine available for those exposed
Tularemia (<i>Francisella tularensis</i>)			
Bacterial infectious disease of animals Mortality rate about 35% without treatment	Incubation period: 3-10 days Sudden onset Fever, swollen lymph nodes, fatigue, sore throat, weight loss, pneumonia, pleural effusion, ulcerated sore from tick bite	No person-to-person spread Aerosol or intradermal route Spread by rabbits and ticks Contaminated food, air, water	Gentamicin treatment of choice Streptomycin, doxycycline, and ciprofloxacin are alternatives Vaccine in developmental stage
Hemorrhagic Fever			
Caused by several viruses, including Marburg, Lassa, Junin, and Ebola Ebola virus is life threatening	Fever, conjunctivitis, headache, malaise, prostration, hemorrhage of tissues and organs, nausea, vomiting, hypotension, organ failure	Carried by rodents and mosquitoes Direct person-to-person spread by body fluids Virus can be aerosolized	No intramuscular injections No antiplatelet drugs Isolation for containment Ribavirin (Virazole) effective in some cases No FDA approved treatment available

Adapted From Lewis SL, Heitkemper MM, Dirksen SR, et al: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2014, Mosby.

Symptoms from exposure to a biologic agent are not immediate. There are various incubation periods. So, unless someone knows that she has been exposed to a strange powder or substance, decontamination does not take place. Nurses particularly need basic knowledge about the category A agents because they are easily disseminated and spread from person to person.

Anthrax.

Anthrax is a category A agent caused by the gram-positive bacteria *Bacillus anthracis*, which forms spores. It is primarily a disease of sheep and cows. Animal vaccination programs have controlled naturally occurring anthrax in the United States. There are three forms of the disease: cutaneous (95%), gastrointestinal (less than 1%), and inhalational (5%). Aerosolized inhalable anthrax is most likely to be used for a terrorist attack. The greatest chance of inhaling the spores after aerosolization is during the first day after the event, before the particles hit the ground. Symptoms in those who have inhaled the spores will resemble a nonspecific influenza at first. A rapid downhill progression is then seen with respiratory failure, shock, and possibly death over a 2- to 5-day period. Features that differentiate anthrax illness from flu are shortness of breath, a nonproductive cough, chest discomfort, myalgia, and fatigue. The lack of a sore throat and rhinorrhea and the appearance of nausea and vomiting are also flu symptoms. Treatment is with ciprofloxacin (Cipro) or doxycycline (Vibramycin) for 14 days. Antibiotics are adjusted after culture and sensitivity results are known. Treatment continues for 60 days if infection is confirmed, because the disease can continue to develop from germinating spores up to that time. Otherwise prophylaxis lasts for 10 to 14 days when cultures are completed and results obtained. Other care is supportive for respiration, fluid and electrolyte balance, and comfort. Extended precautions are not necessary, because anthrax is not transmissible from person to person. There is a vaccine, but no controlled trials have been completed, so its effectiveness is unknown ([Cunha, 2014](#)) (see Online Resources). From plasma of individuals that were immunized with the vaccine, a new immunoglobulin treatment has been FDA approved for inhaled anthrax. The medication is given intravenously. The antibodies present in the medication neutralize the toxins produced by the anthrax bacteria. This does not replace antibiotic therapy which should be continued ([FDA, 2015](#)).

Botulism.

Botulism is a category A agent caused by the botulinum toxins produced by *Clostridium botulinum*. There are six forms of botulism described by how they are obtained: food-borne, wound, injection-related, inhalational; and adult intestinal and infant botulism, which are acquired in a similar manner. Foods can become contaminated with botulism spores when canned or processed under conditions favorable for toxin production (e.g., insufficient heat). Botulism is not contagious, and the organism is destroyed by the addition of chlorine to water supplies or by boiling foods for 10 minutes ([CDC, 2014a](#)). Organisms are naturally present in the soil and can cause wound infection. Inhalational botulism does not occur naturally and would most likely indicate a terrorist attack.

Double vision, drooping eyelids, and difficulty swallowing and speaking may be the early symptoms of botulism. A triad of symptoms is classic for the disorder:

- Symmetrical descending flaccid paralysis progressing to respiratory weakness
- Absence of fever
- Alertness and orientation without sensory deficits

Respiratory support may require intubation and mechanical ventilation. If a large number of persons are infected, the community health care resources would be taxed to provide adequate care for all. Treatment is with botulinum antitoxin if the toxin type is A or B. The CDC and public health departments stock these antitoxins. Early treatment is required, because the antitoxin does not reverse the muscular paralysis that has already occurred. Supportive therapy may be needed for several weeks until new synapses can grow to replace those damaged by the toxins (see Online Resources).

Plague.

Plague is a category A agent caused by a gram-negative bacillus, *Yersinia pestis*. The bubonic form starts as a skin infection and spreads to the lymph nodes; it is naturally transmitted by infected fleas that bite rodents or people. Pneumonic plague is the most likely type to be spread by a terrorist attack with aerosolized plague organisms. Fortunately, plague bacilli are killed by sunlight and remain viable in aerosolized form for only about an hour after release. Clinical signs are an abrupt onset of pneumonia with bloody sputum (**hemoptysis**) that follows a rapidly progressive course. Disseminated intravascular coagulation (DIC) can develop and lead to multiorgan system failure. Death is likely within 24 hours of infection if treatment is not started.

Gentamicin (Garamycin) is the intravenous drug of choice for this organism. Streptomycin given intramuscularly is the first-line treatment. Ciprofloxacin and doxycycline are used to treat

pneumonic plague and are given for 7 to 10 days. If treated early, the infection is usually not fatal. Plague can be transmitted from person to person, and respiratory droplet precautions along with Standard Precautions are necessary until 48 hours after treatment has been initiated. Researchers are currently working on a vaccine ([Dufel, 2013](#)).

Smallpox.

Smallpox is caused by variola virus. It is communicable, has no known effective treatment, and has a high mortality rate. The disease was declared eradicated worldwide in 1980, but laboratory strains of the virus still exist. Because it is so lethal and highly contagious, it is listed as a category A agent.

Smallpox has an average incubation period of 12 to 14 days. Symptoms begin with fever for 1 to 4 days and then a rash occurs. High fever may be accompanied by headache, backache, malaise, vomiting, and delirium. The rash contains firm, deep-seated vesicles or pustules all in the same stage of development on any one area of the body ([Figure 43-4](#)). The rash starts on the buccal and pharyngeal mucosa; spreads to the face, hands, and forearms; and then spreads to the rest of the body over several days. A cough may develop. Lesions progress from macules to papules to vesicles to pustules to scabs, with each stage lasting 1 or 2 days. It must be differentiated from chickenpox. With chickenpox, the lesions appear before illness symptoms and are usually concentrated on the trunk. Chickenpox lesions are usually more superficial and are "flimsy," rather than firm, as in smallpox. Chickenpox lesions do not usually occur on the palms and the soles of the feet; smallpox lesions do occur in those areas ([Figure 43-5](#)). Chickenpox lesions are often in various stages within the same area of the body, whereas smallpox lesions are all in the same stage within a body area.

FIGURE 43-4 Face lesions on a boy with smallpox. (Courtesy CDC, Public Health Images Library.)

FIGURE 43-5 Comparison of smallpox and chickenpox lesions. **A**, Smallpox. **B**, Chickenpox. (Courtesy CDC, Public Health Images Library.)

Smallpox is communicable from the onset of rash until all scabs have separated from the skin. Patients should be treated with strict Airborne Infection Isolation and Contact Precautions and be placed in a negative-pressure room with a HEPA-filtered exhaust system. All linens should be placed in biohazard bags and autoclaved before being laundered or incinerated.

Although there is no treatment for smallpox, receiving the smallpox vaccine within 4 days of exposure can reduce the severity of the disease. The vaccine is not available in large amounts, and for that reason isolation and quarantine of infected patients will be the most likely course of action. Smallpox vaccine has significant possible side effects. If health care workers are to be vaccinated, they will receive all the necessary information about the vaccine and how to take care of the vaccination site. Medical management is supportive, with antimicrobial drug treatment for secondary infection of lesion sites, fluid and electrolyte replacement, and nutritional therapy. The first dose of smallpox vaccine lasts 3 to 5 years with decreasing immunity. Those who had multiple vaccinations may have longer-lasting immunity.

Think Critically

Can you explain to someone how to distinguish smallpox lesions from those of chickenpox?

Tularemia.

Tularemia is a category A agent caused by a gram-negative coccobacillus, *Francisella tularensis*. It is a

vector-borne illness that is transmitted by an infected tick, mosquito, or deer fly bite, by direct exposure to contaminated animal tissues and fluids, or by ingestion of contaminated food or water. A variety of small mammals are natural reservoirs of the organism. It is seen throughout the United States except in Hawaii. If aerosolized, it could be inhaled, and this is the most likely form for a terrorist attack. The disease is not spread by person-to-person contact.

Tularemia occurs in three different forms: cutaneous, pneumonic, and typhoidal. The pneumonic form is the one most likely to occur in a terrorist attack. The pneumonia caused by the inhaled form is difficult to differentiate from other pneumonias. Symptoms include abrupt onset of fever, chills, headache, muscle aches, nonproductive cough, and sore throat. Laboratory testing can establish the correct diagnosis.

Treatment or prophylaxis is with streptomycin and gentamicin, the drugs of first choice. Doxycycline and ciprofloxacin may also be used. The course of treatment should extend through 10 to 14 days depending on the drug used. Tularemia is fatal if not treated with the proper antibiotics. Standard Precautions are used, but the inhalational form is not transmitted by person-to-person contact, and no other extended precautions are necessary. A vaccine for protection from tularemia is under review by the U.S. Food and Drug Administration.

Viral hemorrhagic fevers.

The hemorrhagic fevers are a group of illnesses caused by four families of viruses: arenaviruses, filoviruses, flaviviruses, and bunyaviruses. The viruses, which are within the category A agents, cause Ebola, Marburg, and Lassa hemorrhagic fevers. Junin, Machupo, Guanarito, and Sabia hemorrhagic fevers are more common in the Southern Hemisphere. There are no vaccines available for these diseases. These occur in different geographic parts of the world. Reservoirs for the viruses are rodents and arthropods. Human infection usually occurs by being bitten by an infected arthropod, by contact with infected animal carcasses, or by inhaling aerosolized rodent excreta. Once contracted, the virus can be transmitted from person to person by blood and body fluids. Contact and Airborne Infection Isolation Precautions are necessary. The CDC has guidelines on personal protective equipment (PPE) for caregivers ([CDC, 2014b](#)). Only special biosafety laboratories can test for the viral hemorrhagic fevers. Such tests are performed at the CDC. It is thought that an aerosolized form of Ebola or Marburg virus might be used for a terrorist attack. Travelers from a region experiencing an outbreak could also carry the virus into other countries ([CDC, 2013](#)).

The incubation period is between 2 and 42 days, depending on the virus, and there is a prodromal syndrome that lasts less than a week. Signs and symptoms are marked fever, fatigue, dizziness, muscle aches, and loss of strength. Symptoms may progress to abdominal pain, nonbloody diarrhea, weakness, and exhaustion. Later, bleeding begins, starting with bleeding under the skin causing petechiae and progressing to spontaneous bleeding and DIC. Many body systems are affected. Hypotension, conjunctivitis, pharyngitis, and skin rash may reflect increasing capillary permeability. Shock, nervous system malfunction, seizures, delirium, and coma may occur. Mortality rates can be very high with Ebola but are not always so with the other viruses.

There is no specific treatment for these hemorrhagic fevers; treatment is supportive. Early identification is essential for supportive treatment to be effective. A point-of-care fingerstick test for Ebola is being evaluated ([Broadhurst, Kelly et al, 2015](#)). The antiviral ribavirin may be useful in treating Lassa fever. Contact and Airborne Expanded Precautions are essential. Double gloves, impermeable gowns, leg and shoe coverings, face shields, eye protection, and an N-95 mask are required for patient contact. A negative-pressure room is desirable.

Prevention measures include use of insect repellent, bed nets, window screens, and proper clothing and the eradication of rodents from living spaces. Mosquito abatement is performed in areas of outbreak, when possible. Vaccines are available for yellow fever and Argentine hemorrhagic fever but not for the others. All linens should be treated as infectious and either carefully disinfected or incinerated.

Pandemic influenza infection.

Pandemic infection is an international outbreak of disease. Most people have had firsthand experience with the flu, but the H1N1 (swine) flu episode in 2009 heightened awareness of how readily a disease moves back and forth across international borders. The severe acute respiratory syndrome (SARS) outbreak in China made health care professionals feel particularly vulnerable to

airborne respiratory infections (see [Chapter 14](#)). Flu is seasonal, and there are always fatalities associated with influenza. Unless the death rate is significantly elevated with international epidemiology, it is not labeled a pandemic.

Preparations for pandemic flu include teaching people to be prepared to stay at home for at least 2 weeks. Nurses also need to reassure people that basic measures for prevention of respiratory infection can be effective. These include healthy lifestyle to support the immune system, hand hygiene, covering the mouth during coughing or sneezing, disposing of tissues, and staying away from public places if at all possible.

Nurse's Role in Preparedness and Response

In addition to learning about hospital protocols, community resources, and specific knowledge related to disaster care, you should explore your feelings about professional participation in a disaster event. Under normal circumstances, such as caring for infectious patients, a nurse's duty to care is high, because the risk of harm to self is low; however, when the danger to the nurse is unclear or apparent—such as in the SARS outbreak—the nurse could decide that preservation of self is reasonable ([Blum, 2014](#)). Studies have shown that nurses do not feel prepared to function in a disaster situation. Education and hands-on training are recommended to increase nurse preparedness ([Baack and Alfred, 2013](#)). Ethical questions regarding the obligation of health care providers to render care to Ebola-infected patients are discussed in a bioethics forum on the Hastings Center website ([Frader and Ross, 2014](#)), which is an example of the bioethical discussions taking place nationally. Arming yourself with knowledge, preparing your own household, and having ethical discussions with colleagues will help you in your decision-making process.

The nurse's role during a bioterrorism event includes:

- Recognizing clusters of cases or unusual cases suggestive of a biologic event
- Promptly evaluating and assisting with medical management
- Promptly communicating with the local public health department and infection control department
- Working closely with law enforcement, emergency management, public health, and other government agencies

Nursing management.

When such patterns are discovered, nurses should implement the hospital and community response plan. **All staff must strictly adhere to infection control procedures and policies.**

If your assessment has aroused suspicion of a biological event, ask these questions:

- Was there a sudden onset of severe respiratory or gastrointestinal problems?
 - Has the illness progressed rapidly?
 - Has the patient been healthy otherwise?
 - Are the patient's family, friends, or colleagues ill?
- If the answers indicate that an infectious agent is present, immediately take the following steps:
- Notify your supervisor and the infection control department regarding the situation.
 - Put a surgical mask on any patient who is coughing.
 - Pay strict attention to Standard Precautions and hand hygiene, and encourage the patient and family to do the same.
 - Wear an N-95 or P-100 respirator mask (one certified by the Occupational Safety and Health Administration [OSHA]).
 - If indicated, isolate the patient in a negative-pressure room; obtain specimens for laboratory testing.
 - Use all recommended personal protective equipment whenever caring for the patient, and pay strict attention to Standard and Expanded Precautions.

When a known terrorist airborne event has occurred and victims are triaged to the hospitals and to emergency field medical units, victims will need to be decontaminated before being brought into the medical facility. Outside shower areas will be set up to accomplish the decontamination.

Whether the agent used in the attack is biologic or nuclear, the outside of the body must be thoroughly scrubbed. Personnel in biohazard suits handle this task ([Figure 43-6](#)). Clothing must be

removed and sealed in plastic biohazard bags to prevent contamination of others. The skin should be scrubbed in every area with warm soapy water for at least 30 seconds. The hair should be soaped and shampooed several times.

FIGURE 43-6 Personnel wearing biohazard suits perform a decontamination scrub during a hospital bioterrorism drill. (Courtesy AP/Wide World Photos.)

In a crisis situation, firm directions should be given with a kindly tone. People need to know what will happen next. Active listening and assisting with problem solving provides needed psychosocial support. If a family has been separated, health care workers can help locate children and other family members. Nurses should direct people to available support services to meet physical and psychological needs.

Active Shooter

Other critical incidents may occur in a public or health care setting that require a trained response from the health care team. One that is rare but can be deadly is an active shooter. First responders are trained and law enforcement officers are armed to manage a shooting situation. When it happens in a health care setting, there is much less preparation. The Joint Commission and OSHA require hospitals to address an active shooter scenario in their workplace violence plan. Some facilities have an overhead page to notify staff of the situation. Many hospitals are using the designation "Code Silver."

The general guidelines include first of all to be aware of potential violence based on behaviors, actions, and speech. Security or community law enforcement should be called as appropriate. Potential violence may come from patients, staff, or visitors. If a firearm is seen, health care workers should evacuate if possible, hide in a location not visible to the shooter, lock the doors, and silence pagers and cell phones. A call to 911 should be made when it is safe to do so. As a last resort and if life is in imminent danger, incapacitating or acting with physical aggression and throwing items at the shooter may be attempted. Even more important is what to do when law enforcement arrives. They know someone is using deadly force and they do not know who is the perpetrator. Bystanders should immediately raise their hands and spread their fingers to show they are not holding a weapon, remain calm, and follow instructions. They should avoid making quick movements, pointing, or yelling. If there are shooting victims, law enforcement will determine when it is safe to render aid, while maintaining the integrity of the crime scene; if there are fatalities, the area becomes off limits to health care personnel and regular hospital activities may need to be relocated.

Debriefing.

Critical incident stress **debriefing** (CISD) teams provide sessions for small groups of personnel to help with effective coping strategies. After the turmoil and the emotional impact of the disaster or critical incident, including its aftermath, personnel may find it difficult to return to their normal routine. Without intervention, some may develop post-traumatic stress disorder (see [Chapter 45](#)). There is strict confidentiality and unconditional acceptance of any information shared during the sessions. Participants are encouraged to bond by talking about where they were and what they were doing when they first heard about the disaster, and to describe what they saw, heard, or smelled during the event. They are asked to share how they felt during the event, discuss how they feel now, and describe physical symptoms that have occurred since the incident. Facilitators reassure that strong reactions are normal, and they offer coping strategies. These coping strategies may include avoiding the use of alcohol or drugs, making sure to eat a well-balanced diet, watching for obsessing or fixation, taking time off from work, socializing with friends and coworkers, and getting professional help if necessary.

Get Ready for the NCLEX® Examination!

Key Points

- A disaster exists when the number of casualties exceeds the resource capabilities of the area.
- Nurses should be proactive in being familiar with the facility's disaster plan, encouraging people to stock a disaster kit at home, and teaching the public about what to do when a disaster occurs (see Health Promotion on p. 1009).
- A chain of command is set in place when a disaster occurs, and it must be followed to ensure that appropriate notification and information is provided to the Office of Emergency Services.
- The stages of psychological response include impact, heroic, honeymoon, disillusionment, and reconstruction.
- Triage for a disaster is based on treating those with life-threatening conditions who have a likelihood of survival and identifying those whose treatment can be delayed.
- Reverse triage can be used to increase surge capacity.
- First aid, safety measures, and prevention and control of health hazards are priorities.
- Special populations such as older adults, infants, people who have disabilities, and immunocompromised individuals need help to stay safe and meet basic life requirements.
- People must be taught how to purify water (see Health Promotion on p. 1011).
- Knowledge of food safety when there has been a power outage or a flood is essential (see Box 43-1).
- Warning signs that a bioterrorism event has occurred include large numbers of patients with similar symptoms, illness and death rates higher than expected for common diseases, unusual disease presentation, increase in unexplained symptoms, diseases or deaths and sudden death of animals.
- Decontamination of individuals affected by a chemical, radiologic, or bioterrorism event is performed before they are allowed into the health facility.
- Debriefing by a trained team after a disaster helps prevent long-term psychological problems among the personnel involved in caring for people affected by the event.

Review Questions for the NCLEX® Examination

1. A large number of patients are arriving at the hospital from the scene of a chemical disaster. What is the nurse's priority action?

1. Take vital signs to determine which patients are in distress.
2. Call poison control for assistance in determining antidotes.
3. Decontaminate all patients outside the hospital by showering.

4. Instruct all caregivers to don personal protective equipment.

NCLEX Client Need: Safety and Infection Control

2. At a disaster scene, a nurse notices that a person has been triaged with a black tag who has respiratory distress and severe total body burns. What should the nurse do?

1. Immediately obtain a portable oxygen tank and apply an oxygen mask.
2. Seek out emergency services personnel to transport the patient to the hospital.
3. Try to locate family members so that they can be present when the person dies.
4. Stay with the person for as long possible to give support and comfort.

NCLEX Client Need: Coordinated Care

3. A nurse is participating in a disaster drill. A mock victim with a green tag asks, "What does this tag mean?" What is the nurse's best response?

1. "You can go home because you no longer need health management."
2. "You potentially pose a health hazard so you must sit in the green area."
3. "You will have to wait for care because your injuries are not life threatening."
4. "You will be seen and treated immediately by a provider."

NCLEX Client Need: Health Promotion and Maintenance

4. While admitting a young, previously healthy patient with a severe respiratory illness, a nurse becomes suspicious of a bioterrorism event. Which question would the nurse ask to confirm the suspicion?

1. "Have you been washing your hands frequently?"
2. "Has the illness progressed rapidly?"

3. "Do you have a fever?"
4. "Are you a local resident?"

NCLEX Client Need: Safety and Infection Control

5. A patient is tentatively diagnosed with chickenpox. During skin assessment, what is the nurse likely to find that confirms the diagnosis?

1. Skin lesions are firm.
2. Skin lesions are found on palms and soles.
3. Skin lesions occur in various stages.
4. Skin lesions occur with other signs and symptoms.

NCLEX Client Need: Physiological Adaptation

6. A nurse is teaching a group of people about water and food safety after a disaster. Which comments by the learners indicate successful teaching? (*Select all that apply.*)

1. "Contaminated water should be boiled for at least 20 minutes."
2. "Sixteen drops of bleach to a gallon of water will purify the water."
3. "A full freezer will keep food safe for 48 hours."
4. "Any food that has an unusual odor, color, or texture should be thrown away."
5. "Tightly sealed containers of food are safe to use even if in contact with flood waters."

NCLEX Client Need: Health Promotion and Maintenance

7. Which patient needs to be put immediately into isolation?

1. Diagnosed case of botulism poisoning
2. Probable case of inhalational anthrax
3. Known exposure to a high dose of radiation rays

4. Suspected smallpox, but probable chickenpox

NCLEX Client Need: Safety and Infection Control

8. Which behavior by the nurse indicates that there is a need for additional counseling beyond the counseling offered through a critical incident stress debriefing?

1. Talks openly about the incident, but is not ruminating
2. Avoids coworkers and friends for a prolonged period
3. Takes extra vacation time away from the city
4. Attempts to resume a healthy lifestyle, but is not sleeping well

NCLEX Client Need: Psychosocial Integrity

9. In the event of a disaster requiring evacuation of homes, what items should be in a "go bag"? (*Select all that apply.*)

1. All personal valuables.
2. Water and medications.
3. Flashlight and batteries.
4. Camp stove and eating utensils.
5. Clothing and important documents.

NCLEX Client Need: Health Promotion and Maintenance

10. There is a power outage, and the IV pumps are no longer functional. The nurse must deliver a fluid bolus of 500 mL over 20 minutes. The drip factor for available IV tubing is 10 gtt/mL. What is the drip rate in drops/minute? _____

NCLEX Client Need: Pharmacological Therapies

Critical Thinking Questions

Scenario A

A hurricane has hit the town in which you live. There is widespread wind damage in much of the town, many streets are flooded, and a lot of people are injured. The power is out and the phones are dead. Your neighbor has a gash in his lower leg and is bleeding.

1. Describe how you would stop the bleeding.
2. How would you transport him to a health care facility? What precautions would you take on the journey?

3. If teenagers want to go out and wade in the floodwater and see if they can rescue stranded people or animals, what would you tell them?

Scenario B

You and several other health professionals have been asked to come and teach a community group about what to do in the event of a disaster or bioterrorism attack.

1. Outline what should be included in the teaching plan.
2. If questions arise about a nuclear disaster, what would you say about measures they could take?

Scenario C

You are working in a busy walk-in clinic. You recognize that emergency departments and clinics are likely to be the first places where infected people will begin to show up if there is a biologic event. You must be vigilant for clusters of cases or unusual cases that may suggest that a bioterrorism event has occurred among the population that serves the clinic.

1. What signs or events would suggest that a bioterrorism event has occurred?
2. What assessment questions would you ask if you suspect a patient has been exposed to a bioterrorism agent?
3. If you determine that an infectious agent is likely, what should you do?

CHAPTER 44

Care of Patients With Emergencies, Trauma, and Shock

Objectives

Theory

1. Evaluate how your personal attitudes, experiences, beliefs, and values affect your ability to care for victims of abuse.
2. Explain the basic principles of first aid.
3. Summarize the importance of mechanism of injury and index of suspicion in caring for patients with traumatic injury.
4. State the key components of assessing a trauma patient.
5. Discuss prevention of injuries from extremes of heat and cold.
6. Determine specific interventions appropriate in the emergency care of accidental poisoning by ingestion and inhalation.
7. Describe emergency care of victims of insect stings, tick bites, and snakebites.
8. Review the appropriate nursing actions and care needed for a patient who has experienced a respiratory or cardiac arrest.
9. Identify signs and symptoms of shock.
10. Compare and contrast the treatment of cardiogenic, hypovolemic, and distributive shock.

Clinical Practice

11. Role play with fellow students, practicing techniques to calm a combative patient.
12. Observe how the triage nurse in the emergency department sets priorities for patient care.
13. Observe how the emergency team works together on a major accident victim.

Prevention of Accidents

Home Safety

Accidents in the home and community rank fifth as a leading cause of death for all age groups ([Medical News Today, 2015](#)). People younger than 5 years and older than 65 years are the principal victims of fatal mishaps occurring in the home. Attention to home safety for the very young and the elderly could potentially prevent many of these fatalities and injuries ([Box 44-1](#)).

Box 44-1

Home Safety

Kitchen

- For a gas, coal, or wood-burning stove, use the vents or flues; keep windows open a crack. Never light the stove with kerosene or gasoline. Turn off all flames after cooking. Repair any gas leakage.
- Use pot holders. Keep handles of pots and pans turned away from edge of stove.
- Keep matches; sharp instruments; and poisons, such as bleach and household cleaners, out of children's reach. Place child safety locks on storage cabinets.
- Wipe up spills on floor.
- Keep electrical appliances in good working order.
- Place broken glass in a heavy paper sack to prevent cuts through plastic bags.

Storage Areas

- Always keep cellars, attics, and garages neat.
- Clean and disinfect the area where garbage is kept, and dispose of garbage frequently.
- Never place poisonous substances in drinking glasses, cold drink bottles, or other containers that have been used for food or drink.
- Always label poisonous compounds; read labels of poisons and store the containers out of reach.

Living Room

- Be sure floors are not slippery. Use rubber mats under rugs to prevent slipping.
- Replace frayed or torn carpets.
- Cover electrical sockets.
- Replace frayed electrical cords. Keep electrical cords off floor where people walk.
- Place heaters a safe distance from walls. Use screens around fireplace.
- Pad sharp edges on furniture as necessary.
- Check ashtrays for lit matches or cigarettes when going to bed or leaving the house.

Furnace

- Have a professional check and maintain the furnace every year, especially for leaks.
- Change filters monthly.

Bathroom

- Use a rubber mat in the tub.
- Store medicines out of children's reach. Keep all medicines capped and labeled. Throw out old medicines. Keep phone number of poison center close to telephone.
- Be cautious in using appliances plugged into a wall plug near water.
- Keep hot water heater set at 120° F (48.8° C) or lower.

Bedroom

- Do not smoke in bed.
- Use rubber mats under scatter rugs.

Stairways

- Cover with carpeting or rubber safety treads.
- Replace torn or frayed carpeting. Keep stairs clear of toys and cleaning equipment.
- Install handrails and proper lighting.
- Use gates at top and bottom for young children and confused older adults.

General Areas

- Install smoke and carbon monoxide alarms throughout the house.
- Make sure candles are away from flammable materials. Never leave a lit candle unattended.

Highway Safety

Motor vehicle accidents are the leading cause of accidental death in the United States. Improper driving, which is responsible for almost 90% of all accidents, can be caused by the influence of alcohol and/or drugs, distractions, fatigue, excessive speed, or emotional instability. Emphasis on using seat belts, better enforcement of laws against driving drunk, and discouraging use of cell phones have helped to decrease accidents and injury. According to the Centers for Disease Control and Prevention (CDC), every 16 minutes someone dies in a motor vehicle crash in the United States. Motor vehicle crashes are the leading cause of death for Americans in the first three decades of life ([CDC, 2013](#)).

Water Safety

Water safety rules include selecting safe swimming areas, ensuring supervision of children and adults who are not strong swimmers, diving where the water is sufficiently deep and is free of rocks or obstacles, never swimming alone, and never swimming distances beyond one's ability. Every day about 10 people die of unintentional drowning ([CDC, 2014](#)). **The victim of a diving injury preferably should not be removed from the water until emergency medical services (EMS) arrives because of possible neck and spinal cord injury. Bystanders should immobilize the head and neck, keeping the victim's face out of the water** ([American Red Cross, 2012](#)). Bystander intervention makes a critical difference in the survival of drowning victims. First, the rescuer should call for help. If possible, try to reach the victim without going into the water. After the rescued person is brought out of the water, he must be given cardiopulmonary resuscitation (CPR) and

rescue breathing if he is not breathing and is pulseless. If he is breathing, he should be placed on his side ([Figure 44-1](#)) and his head should be turned to one side to prevent aspiration. Near-drowning victims should be transported to a medical facility. Although they may appear to be uninjured, they may have aspirated water, and pulmonary edema may occur. Bacterial or fungal pneumonia may follow aspiration of fresh water. There is danger of delayed cardiac irregularities for any victim who struggled in the water. Hypothermia has a protective effect, especially in young children, and can increase survivability; however, prolonged immersion negates this effect.

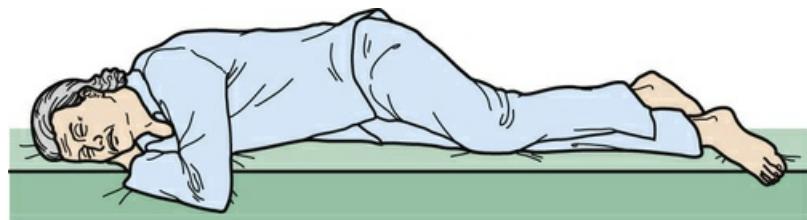

FIGURE 44-1 Recovery position. (From Elkin M, Perry AM, Potter PA: *Nursing interventions and clinical skills*, ed. 5, St. Louis, 2012, Mosby.)

First Aid and Good Samaritan Laws

Most states have adopted “Good Samaritan” laws that protect medical personnel and nonmedical civilians from liability when rendering emergency medical care for victims of accidental injury. These laws guard against liability for care, as long as medically trained individuals act in good faith and to the best of their ability. Individuals who offer care are held to the standard of care consistent with their level of training. If a nursing assistant stops to provide emergency care, she will be held to a different standard than a physician who stops at the same accident scene. Both are expected to do the best they can in the circumstances. A bad outcome is not proof of improper care. Even in states in which there are no such protective laws, malpractice suits of this kind very rarely occur. **Table 44-1** shows guidelines for first aid. Some states require medical personnel to render aid if they witness or come upon an accident scene. You should know the laws in your state.

Table 44-1
General Principles of First Aid

ACTION	REASONING
Before attending to the victim or victims of an accident, quickly survey the accident scene to determine whether there are further hazards to yourself and the victims.	Spillage of gasoline after a motor vehicle accident can cause a fire or explosion, or there may be danger to the victim, yourself, and onlookers from oncoming traffic and secondary collisions. In both highway and home accidents, live electrical wires may be in the vicinity. Whenever there is a high risk of death from hazardous conditions in the immediate environment, the victims should be moved at once, regardless of the nature of their injuries. Victims may receive severe burns from lying on a sun-baked street or sidewalk while waiting for the ambulance. Although it may not be safe to move the victim to a shaded area, it is advisable to place clothing, newspaper, or some other protective covering between skin and the hot pavement.
If there are several victims of the accident, make a quick check on each one before beginning treatment.	The most serious and life-threatening injuries must be treated first; those victims who do not seem to be in immediate danger can be attended to by someone else who is capable of watching them and reporting any change in their condition.
Use a calm tone and short sentences to explain what you are doing. You must sound as if you are in control of yourself and the situation.	Giving reassurance to the victim will decrease anxiety and promote cooperation. Using short, simple explanations facilitates understanding during duress. Forcing yourself to remain calm can increase your own ability to function in an emergency situation.
Do not move the victim unless he is in immediate danger or until you have immobilized injured parts.	This is particularly true if spinal injury is suspected. Moving the victim can cause further injury if precautions are not taken.
Do not remove an object that has penetrated a part of the body and is still in place.	A knife, piece of metal, or sliver of wood that is protruding from the chest or abdomen should be left as is until it can be removed in a controlled situation by trained professionals. Removal of the object can cause further damage and make bleeding worse. Bandages are applied around the object to stabilize it and control bleeding as necessary.
Look for a Medic-Alert bracelet or necklace.	If the victim is wearing one or has some other identification showing specific medical needs, bring this to the attention of the ambulance or hospital personnel.
Try to determine the mechanism of injury.	This will give clues about the type of injury sustained and the treatment required. When evaluating the victim, begin at the head and work downward to the toes (see <i>Focused Assessment</i> on p. 1030).
Do not try to give anything by mouth to a person who is unconscious or has a decreased level of consciousness or has injuries that might require surgery.	Aspiration of the material into the air passage may occur, causing breathing difficulty or complete airway obstruction.
Give an organized and chronologic report to the EMS or provider, including details of incident (if you were a witness), assessment of injuries, and care rendered.	Any details of events leading to the incident, mechanism of injury, baseline assessment data, and care rendered will be useful in the emergency care at the hospital. Being brief and organized is important, because the EMS personnel must simultaneously intervene and take a history if the victim is in critical condition.

The Cardiac Arrest Survival Act is a Good Samaritan law covering the use of automated external defibrillators (AEDS) in the event of a cardiac arrest. Each state has specific guidelines for implementation.

Think Critically

You come upon an automobile accident in which several people were involved and stop to render aid. How would you assess the situation for safety for yourself and the victims? How would you act to ensure safety at the scene?

Psychological and Social Emergencies

The Combative Patient

Half of all health professionals have been verbally assaulted, and one quarter have been physically assaulted. Patient factors associated with an increased incidence of attacks on health care personnel include paranoid schizophrenia, personality disorders, dementia, substance abuse, and a history of abuse or violence (LaGrossa, 2013). Patients who are not diagnosed as mentally ill can also become violent when nurses and other health care personnel fail to respect their rights and needs or when they feel threatened. Pain, cognitive impairment, and being under the influence of mind-altering substances can contribute to a patient's lashing out. Signs and symptoms that usually precede an attack include increasing agitation or resistance, aggressive behavior, pacing, frowning, hyperalertness, increasing demands, and glaring. Health care workers should approach such patients in a nonthreatening manner, use a calm tone of voice, and remain calm (Box 44-2).

Language barriers and hearing difficulties need to be considered as possible contributors to an escalating situation. It may be necessary to help the patient by exerting control. Physical force should be used only when there is threat of physical danger and verbal intervention is ineffective. One may simply tell the patient to stop screaming, to sit down, or to put down a weapon-like object. If physical restraint becomes necessary, enough people must be available to control the patient (see Chapter 47).

Safety Alert

The Occupational Safety and Health Administration (OSHA) requires employers to provide a workplace "free from recognized hazards that are causing or are likely to cause death or serious physical harm." Patient violence toward health care workers falls in this category. Workplaces are required to have a violence prevention program. The CDC offers an online Workplace Violence Prevention for Nurses program that can be accessed at http://www.cdc.gov/wpvhc/Course.aspx/Slide/Intro_1.

Box 44-2

Strategies for Approaching a Combative Patient

- Offer help on a one-to-one basis. Several people trying to simultaneously talk to or subdue the patient may add to fear and disorientation.
- Establish eye contact.
- Use the person's name frequently.
- Explain who you are and what you are trying to do.
- Express genuine concern about the situation.
- Use a soft voice.
- Make sure the patient can hear and understand what is being said.
- Observe for signs of drug or alcohol use.

Domestic and Intimate Partner Violence

According to a report released in 2013 by the U.S. Department of Justice analyzing intimate partner violence from 1993 to 2011, violence declined 72% for females and 64% for males (Catalano, 2013). Although this is an encouraging report, the problem is still significant and has a profound impact on society and health care.

Nurses are mandated reporters in most states and need to recognize signs of physical and

psychological abuse. Physical signs include bruises, swellings, lacerations, fractures, hematomas, blackened eyes, abdominal injuries (especially during pregnancy), burns, and open wounds that do not match the description of how they occurred. Bruises or fractures in various stages of healing and signs of old lacerations and wounds in the presence of new ones indicate a need for a thorough assessment for abuse. Often the victim may explain all of the injuries as the result of logical accidents rather than disclose that battering by an intimate partner has occurred.

Psychologically the person may display signs of depression, low self-esteem, anxiety, and stress. **Box 44-3** presents the types of questions that might be asked to elicit more information. Asking these questions after establishing rapport with the patient may encourage honest sharing of thoughts and feelings. Research shows that women actually welcome the opportunity to talk about domestic violence, but health care personnel do not routinely ask unless there is a high index of suspicion. If battering is revealed, the person is referred to an appropriate shelter and community resources, and the incident is reported to the appropriate agency. **Most states have laws requiring health care providers to report domestic violence.**

Clinical Cues

Financial concerns, fear of reprisal against children or pets, lack of social support, and limited work experience may all prevent a woman from permanently leaving her abuser. As a nurse, you may feel frustrated, astonished, or helpless as you meet women who repeatedly return to their abusers. Understanding that leaving the abusive relationship does not guarantee safety can help you provide the needed resource referrals so the victim can escape safely. Although statistically women are more likely to be abuse victims, annually 1 in 10 men are victimized and need referrals and support ([CDC, 2014a](#)).

Box 44-3

Questions to Detect Abuse

- Have you been hit or hurt in any way in the past year?
- Who injured you? Has it occurred before?
- Are you afraid of anyone?
- Do you feel safe at home?
- Does your partner use drugs or alcohol? How does his or her behavior change after using them?

Child Abuse

If a child and caregiver make frequent trips to a clinic or emergency department (ED) for unexplained or questionable injuries, abuse could be occurring. Suspicion increases when the mechanism of injury reported by the caregiver (or child) does not match the injury pattern. **The law requires that child abuse or suspicion of child abuse must be reported.**

Think Critically

A caregiver reports that a child reached for a hot surface; there is a perfectly round burn in the middle of the palmar surface. What might you conclude about the caregiver's explanation?

Elder Abuse

The population of people older than 65 years is the fastest growing demographic. Just by sheer numbers alone, elder abuse will increase. Underreporting of events makes it difficult to get a true picture of the extent of the problem. It is estimated that 3% to 10% of older adults are affected ([Sellas, 2013](#)). Neglect is the most common form, but also assess for physical, emotional, psychological, or financial abuse. Older adults should be assessed for signs of fear, withdrawal, anxiety, or evasiveness. The caregiver should be assessed for a hostile, critical, or unsympathetic

attitude. The same signs of physical abuse listed for domestic abuse should be assessed for, as should signs of malnutrition, uncleanliness, or severe depression. **The law requires that signs of elder abuse must be reported.** Immediate safety must be established, but referrals to support groups, counseling, respite care, Meals on Wheels, and transportation services can alleviate stress for caregivers. Elders with dementia are at higher risk for abuse.

Emergency Care

A nurse may need to give emergency care in a variety of community, clinic, or hospital settings, but emergency nursing is generally associated with care of patients in the ED of a hospital. In a survey of hospital ED directors, 90% said that overcrowding and long wait times are an issue. One of the *Healthy People 2020* objectives is to reduce the proportion of patients who wait beyond the recommended time frame to see an emergency provider. A new Joint Commission Core Measure holds hospital facilities accountable for the time patients wait in the ED for transport to an inpatient bed, the time from assessment to treatment, and the efficiency of the throughput process. A variety of conditions contribute to overcrowding, which leads to decreased patient satisfaction, frustration for health care personnel, and increased risk for poor outcomes. Lack of beds for admitted patients, nursing staff shortages, increased patient volume, and increasing complexity and acuity of patients requiring more time and resources are some of the factors that contribute to overcrowding. This causes delays in treatment of time-sensitive conditions such as acute coronary syndromes, antibiotic administration, and pain management (Carter, Pouch, and Larson, 2014).

Emergency nurses need excellent assessment and clinical decision-making skills and the ability to prioritize care under stressful conditions. Emergency nurses routinely follow protocols to initiate diagnostic testing or to start therapy, such as oxygen administration or peripheral intravenous (IV) access. Clinical decisions, prioritization, and use of protocols are based on (1) events or incidents that preceded the emergency visit, (2) mechanism of injury, and (3) index of suspicion. For example, two patients arrive at the hospital in an unresponsive state. For the first patient, friends report, "She was drinking and taking a lot of drugs for fun, and then we found her passed out with vomit on her mouth." For the second patient, bystanders report hearing him complain of chest pain and needing his heart medication, and finding him unresponsive in the parking lot. Both patients are unresponsive, but preceding events suggest that the first patient is an overdose with possible aspiration, whereas the second is more likely to have an acute cardiac problem.

Mechanism of injury refers to how the injury occurred; an experienced clinician may use this information to predict damage and complications. For example, toddlers commonly sustain dramatic-looking "goose eggs" on the forehead by falling against a coffee table, but these incidents are usually more traumatic for the parents than the child. A high **index of suspicion** is required to detect problems that are not initially obvious. For example, a patient reports being kicked and punched several times in the abdomen. At first the patient appears to be stable with minor abrasions; however, this patient will require a series of abdominal assessments to detect slow hemorrhage or internal tissue damage. Maintaining a high index of suspicion is important in a busy emergency setting, because everyone (including the patient) is anxious for discharge or transfer to make room for others in the waiting room.

Triage: Initial (or Primary) Survey

The process of setting priorities for treatment is known as **triage**. One of the most common methods for triage of patients uses "ABCDE" as a memory trigger for the sequence of assessment. *A* is airway, *B* is breathing, and *C* is circulation. *D* is assessment of neurologic disability. *E* is exposure: all areas of the body should be exposed so that injuries are not missed underneath clothing. The *E* can also mean environmental controls, such as decontamination and warming. This is a good systematic method for assessing inpatients who have had a change in condition so that critical assessments are not overlooked. Abnormalities identified that are life threatening should be addressed before moving on to the next assessment.

Airway

A patent airway and adequate oxygenation are priorities. A simple way to assess airway is to ask the person to tell you his name and to ask how he is feeling. If the airway is partially obstructed, the voice quality may sound muffled or coarse. With severe shortness of breath, a person cannot complete full sentences. A confused answer suggests possible decreased cerebral perfusion and oxygenation. If the patient is unconscious, look for the rise and fall of the chest.

The most common cause of airway obstruction in an unconscious person is the tongue. The

head tilt–chin lift maneuver repositions the trachea and tongue and opens the airway. The jaw thrust method should be used if a spinal injury is suspected. For this, the provider positions himself at the head of the victim, placing his hands on either side of the patient's head and his thumbs on the patient's lower jaw near the corners of the mouth and pointing toward his feet; the fingertips are positioned around the bone of the lower jaw, which is then lifted ([Figure 44-2](#)). (Note: Jaw thrust is not taught to lay rescuers; however, health care professionals must learn this maneuver.)

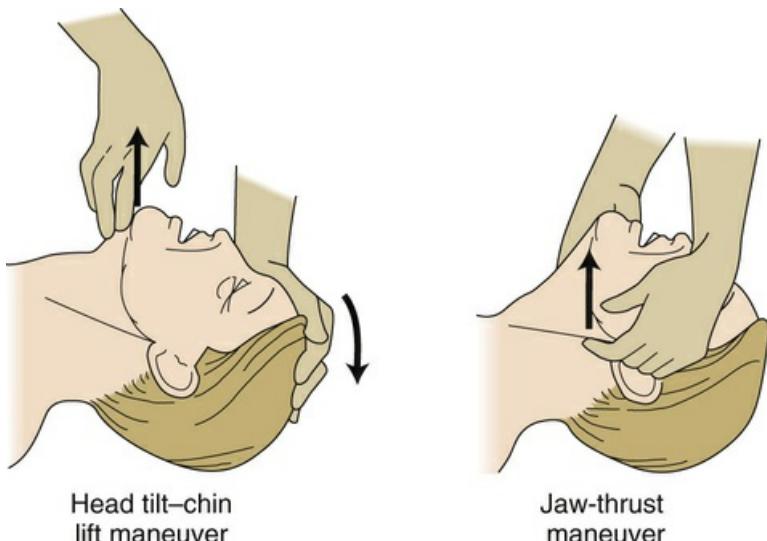

FIGURE 44-2 Opening the airway. (From Elkin M, Perry AM, Potter PA: *Nursing interventions and clinical skills*, ed. 2, St. Louis, 2000, Mosby.)

Breathing

After ensuring that the airway is patent, assess chest rise and effort of breathing, noting rate and any respiratory distress. A pulse oximetry reading is taken and oxygen provided as needed; respiratory rate and effort are monitored. Emergency equipment for resuscitation and intubation should be checked every day, and use of the equipment should be reviewed periodically. If the patient is not breathing, the bag-valve-mask resuscitation bag should be used to ventilate the patient.

Clinical Cues

During emergency situations, “verbal orders” may appear to be the norm to inexperienced bystanders; however, the health care team members are working off well-established algorithms, such as Advanced Cardiac Life Support (ACLS). Nurses are responsible to seek clarification of orders; even under extreme circumstances, the excuse of misunderstanding a verbal order is not acceptable. The provider is responsible for writing or entering orders as soon as the crisis has passed.

Focused Assessment

Evaluation of Accident and Emergency Patients

AREA OF ASSESSMENT	MODE OF ASSESSMENT	RATIONALE
PRIMARY SURVEY	ABCDE	A systematic approach is needed for assessment.
A: Airway	Assess for signs of breathing and respiratory distress, gasping, wheezing, stridor (high-pitched sound made by partial airway obstruction), choking. Check mouth for easily removable foreign body. Do not tilt head and hyperextend neck; immobilize cervical spine (C-spine) as needed for suspected injury.	Adequate air exchange is necessary for the body's oxygen needs. The tongue may block the airway in an unconscious patient. Any patient with an unknown degree of trauma is at risk for cervical spine injury. Movement may worsen the injury.
B: Breathing	Quickly assess breathing. Watch chest and abdomen for rhythmic rise and fall. Note rate and quality of respirations.	Normal breathing requires no intervention. Abnormal breathing should be further evaluated and assisted as needed.
C:	Feel for pulse in carotid or femoral artery; note rate and quality. Check blood	Absence of a pulse indicates cardiac arrest or obstructive shock. A rapid

Circulation/hemorrhage	pressure Check for bleeding.	bounding pulse may indicate fright or hypovolemia. A rapid thready pulse may indicate further blood loss, leading to shock.
D: Disability (neurologic status)	Note if alert, oriented to time, place, person. Note response to verbal stimuli. Check for Medic-Alert identification. Assess ability to move all extremities.	Additional assessment of trauma patients helps identify injuries.
E: Exposure/environmental controls	Remove clothing to look for injuries that may be covered, especially if the patient is not alert or cannot communicate. Look for life-threatening injuries. Provide decontamination as needed. Keep patient warm.	The only way to verify whether there are other injuries is to look. Protect patient privacy.
SECONDARY SURVEY	Head to toe	Initiated after life-threatening injuries are addressed.
Head, face, neck, neurologic status	Look for bleeding, bruising, abrasions. Inspect pupils, assess level of consciousness. Note and record Glasgow Coma Scale score for baseline. Maintain cervical spine precautions, assess for neck injury.	Alterations in level of consciousness can be caused by a variety of conditions such as head trauma, stroke, hypoglycemia, or drug overdose. Neck injuries may be hidden by the cervical collar.
Chest	Listen to breath sounds. Look for equal chest expansion.	Tension pneumothorax can develop after a chest injury.
Abdomen/genitourinary system	Auscultate for bowel sounds. Palpate for tenderness, guarding, and fullness. Look for bloody urine. Note bruising or abrasions, such as Grey Turner or Cullen sign.	Abdominal trauma can result in ruptured spleen or bladder, or liver damage. External trauma may indicate internal damage.
Limbs	Assess adequacy of circulation in all extremities.	Dislocations or fractures can compress nerves and blood vessels.
Log roll	Using at least four people, stabilize the neck and head and gently log roll the victim to assess the back of the head, neck, back, and buttocks.	Bleeding and fractures may obscure additional injuries that are located on the back. In penetrating injuries observe for entrance and exit wounds.

Control of Bleeding

Severe bleeding can rapidly lead to irreversible hypovolemic shock. Arterial blood is bright red and gushes in spurts at regular intervals. Blood from a severed or punctured vein leaks slowly and steadily and is dark red. Even major bleeding can usually be stopped by **applying pressure directly** over the wound. When in a health care work setting, CDC and OSHA requirements mandate use of personal protective equipment that includes barrier devices such as gloves when in contact with body fluids. In a community setting, adapt available material.

Safety Alert

Protective Gear

In a community setting, personal protective equipment may not be present where needed. If gloves are not available, create a barrier with plastic or multiple layers of cloth. Hands and any other skin in contact with blood should be washed as soon as possible.

A guideline published by the American College of Surgeons Committee on Trauma in 2014 recommends for prehospital control of bleeding that direct pressure be held on the area of bleeding. If this is ineffective or impractical, then a tourniquet may be implemented. If available, a topical hemostatic agent may also be used. Elevation of an injured extremity is no longer recommended (Bulger et al, 2014).

Clinical Cues

Many patients are on antiplatelet drugs such as aspirin, clopidogrel (Plavix), prasugrel (Effient), or ticagrelor (Brilinta) or anticoagulants such as warfarin (Coumadin), dabigatran (Pradaxa), rivaroxaban (Xarelto), or apixaban (Eliquis) to treat heart and vascular conditions. If there is injury, bleeding will be significant and may be difficult to stop.

If bleeding is copious and cannot be stopped with pressure and a tourniquet, occlusion of the arterial input may help stop or slow the bleeding. It is not always possible to compress the artery at the needed location, so this is not a first-line intervention. Pressure points for control of arterial bleeding are shown in [Figure 15-3](#). If compression of the pressure point is successful, the distal pulse will be absent and the patient will notice a tingling and numbness in the area. Compression of pressure points on the neck and head should not be used unless there is no other choice, because this will interfere with the blood supply to the brain.

Neck and Spine Injuries

Neck or spinal injury should be suspected in any situation in which the individual has sustained multiple injuries, has fallen, or is unconscious. Examples of accidents that would increase index of suspicion for spinal injury include motor vehicle collisions, diving, biking, or any situation in which the neck receives significant force. In emergency or accident situations, the rescuer may be distracted by severe bleeding or other life-threatening conditions and thus overlook the possibility

of a spinal cord injury.

Safety Alert

Cervical Spine Immobilization

In any traumatic injury, spinal injury must be considered. Cervical spine immobilization is implemented as indicated. Regardless of mechanism of injury, if the patient is awake, alert, conversant, and without significant distracting injury or intoxication, spinal immobilization is not necessary. New evidence-based guidelines have reduced the number of patients who require prehospital spinal immobilization ([Morrissey, 2013](#)). Once in place, spinal immobilization is maintained in the health care facility until spinal injury is ruled out.

If a victim must be moved to safety before EMS arrives, the neck may be immobilized with a coat or towel rolled in the shape of a collar. The goal is to keep the neck as straight as possible, preventing it from flexing or hyperextending. Applying a cervical collar or other commercial device and maintaining traction on the head requires advanced training ([Figure 44-3](#)). A cervical collar is not particularly comfortable for the patient, and it partially obscures assessment of the neck, jaw, and upper midchest, but removal of the collar is strictly at the discretion of the provider (see [Chapter 22](#)).

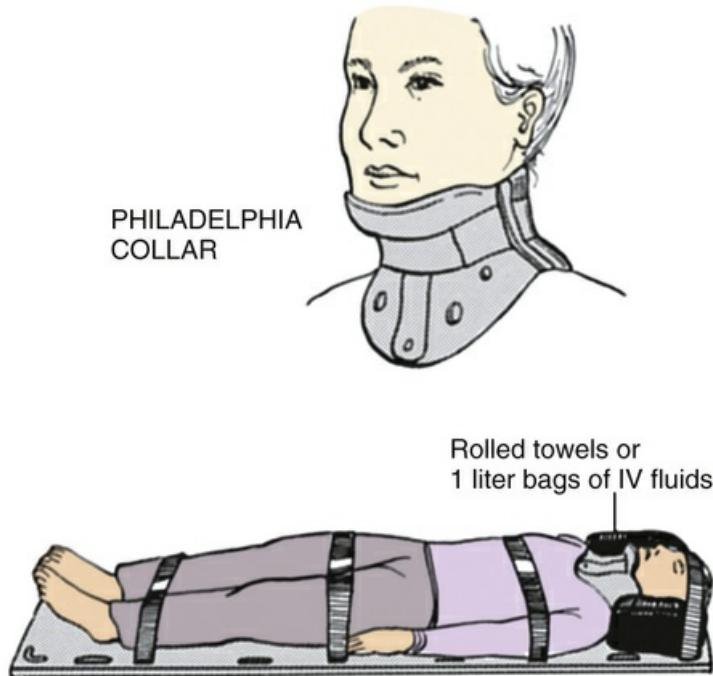

FIGURE 44-3 Spinal immobilization. (From Black JM, Hawks JH: *Medical-surgical nursing: Clinical management for positive outcomes*, ed. 7, Philadelphia, 2005, Saunders.)

Chest Trauma

Penetrating thoracic trauma is less common but is more likely to be fatal than blunt chest trauma. Any of the structures located in the chest may be involved in the injury. There can be contusion of the myocardium, puncture of lungs, rupture of the aorta, diaphragm rupture, and tracheobronchial injuries in addition to bone fractures. Communities with access to a trauma center and shorter transport times have increased survival rates for penetrating chest trauma. ([Swaroop et al, 2013](#)).

Fractured ribs are very painful, because breathing causes movement at the site of injury. The treatment goal is to decrease pain so that the patient can breathe adequately. NSAIDs and ice to the

injury are first-line pain interventions. Intercostal nerve block with local anesthesia may be used to control pain. Narcotic drug therapy is used cautiously, because it can depress respirations. **Binding the ribs is not used as treatment, because it impairs the ability to take deep breaths, causing atelectasis and possibly pneumonia.**

When three or more ribs are broken in two or more places, the chest wall becomes unstable. This condition is called **flail chest**, which produces **paradoxical chest movement**. When the patient breathes in, the fractured portion of the chest is drawn inward instead of expanding outward as the rest of the chest does; with exhalation, the flail portion expands outward as the rest of the chest collapses normally. This process interferes with oxygenation, because the lungs cannot expand normally. Emergency treatment consists of turning the patient onto the affected side so that the ground or bed will act as a splint and reduce the pain of breathing. The patient is observed for signs of external and internal bleeding, pneumothorax, and shock; the force needed to break multiple ribs in multiple locations will also injure the underlying structures which may result in bleeding.

Once the patient is in an emergency facility, flail chest is treated by intubation and mechanical ventilation while the ribs heal. The patient is usually given sedatives and pain medications to prevent fighting the action of the ventilator. Intermittent dosing or continuous infusion may be used depending on the needs of the patient. A study by the American College of Surgeons published in 2013 found that surgical fixation of the flail segment reduced length of stay in the intensive care unit and ventilatory requirements ([Marasco et al, 2013](#)).

Pneumothorax, Hemothorax, and Tension Pneumothorax

An open, or “sucking,” chest wound is one in which pneumothorax (accumulation of air) or hemothorax (accumulation of blood) results from external penetration of the pleural cavity. Symptoms of pneumothorax or hemothorax include labored, shallow respirations that cause bubbling of blood at the site of the wound, lack of movement on one side of the chest when the person inhales and exhales, and chest pain. The patient should be placed in a semi-Fowler position if possible. Once the patient is in an emergency facility, treatment includes chest tube insertion with closed-system drainage (see [Chapter 14](#)).

Tension pneumothorax develops when air enters the pleural space on inspiration but remains trapped there rather than being expelled on expiration. It can occur from trauma, mechanical ventilation, or rib fracture during cardiopulmonary resuscitation. The air in the pleural space increases with each breath, and the pressure within the chest builds, which gradually collapses the lung. If unrelieved, this increasing pressure will cause a **mediastinal shift**: The structures in the mediastinum—the heart, great vessels, trachea, and esophagus—are all shifted to the unaffected side of the chest. This shift puts pressure on the heart so it cannot fill with blood. Decreased cardiac output results, causing a decrease in blood pressure. Emergent treatment is a needle thoracostomy. A chest tube with a drainage device or Heimlich valve may be placed to remove the air from the pleural cavity.

Cardiac Trauma

Blunt chest trauma often causes myocardial contusion, but it also can cause tears in the great vessels and massive bleeding. Blunt force trauma directly on the sternum can cause cardiac arrest. Contusion may result in cardiac dysrhythmia. Symptoms may mimic those of a myocardial infarction (MI), because cardiac tissue has been damaged. Treatment is much the same as for an MI. The patient's cardiac rhythm is monitored closely when such trauma has occurred.

Penetrating trauma usually causes a hemothorax. Cardiac tamponade can occur from blunt force or penetration if bleeding into the pericardial sac occurs. Blood collects in the pericardial sac, which will not stretch, compressing the myocardium; the heart cannot fill or pump effectively. Heart sounds become muffled and distant, and hypotension occurs along with increased central venous pressure evidenced by neck vein distention. Shock and death will result if the bleeding is not stopped and the fluid removed. Surgical repair may be necessary.

Abdominal Trauma

Penetrating abdominal trauma is usually the result of a knife or gunshot wound. Particularly with gunshot injuries, exit and entrance wounds are anticipated; thus all clothing must be removed by

the EMS or ED staff, and the anterior and posterior body surfaces must be examined. Patient management depends on the means of injury, location, associated injuries, and hemodynamic and neurologic status of the patient. (Offner, 2014).

Blunt trauma is less dramatic but can result from improperly worn seat belts or physical assault. Rapid changes in speed, crushing, or shearing actions result in hemorrhage and damage to internal organs. The overall prognosis for blunt abdominal trauma is good, but the patient must be observed closely for symptoms of shock, and serial abdominal assessments must be performed. A bluish tinge around the umbilicus may indicate abdominal hemorrhage (Cullen sign). Ecchymosis or bruising along the flank can be a sign of retroperitoneal or intraperitoneal bleeding (Grey Turner sign).

Focused abdominal sonography for trauma (FAST), peritoneal lavage, or computed tomography may be performed to diagnose intra-abdominal bleeding. Additional diagnostic tests include serial hemoglobin and hematocrit, blood chemistries, and urinalysis. Treatment includes two large-bore IV lines, nasogastric tube, Foley catheter, and type and crossmatch for blood. Hemodynamically stable patients may not need immediate surgical intervention even if the FAST scan is positive (Legome, 2014).

Multiple Trauma

The most common cause of multiple trauma is motor vehicle accidents. Among older adults, falls are the most common cause. Head injury, fractures, and chest and abdominal injuries are anticipated. Airway management is always the first priority (see [Focused Assessment on p. 1030](#)). In head trauma, ventilation and oxygenation may be compromised because of decreased level of consciousness, and C-spine precautions must be observed when performing airway interventions. Threats to breathing may include injuries such as pneumothorax, rib fractures, or open chest wounds. A multiple-trauma patient has a high risk for hypovolemic shock. Tension pneumothorax and cardiac **tamponade** (compression) can also compromise circulation and lead to shock. To manage these critically ill patients, evidence-based practice protocols are implemented based on Advanced Trauma Life Support, developed by the American College of Surgeons. More information can be found at <http://www.facs.org/trauma/atls/>.

Think Critically

What do you have available at home or in your car that could be used to hold pressure on a bleeding wound? Are you prepared to respond to an emergency?

Metabolic Emergencies

Insulin Reaction or Severe Hypoglycemia

Brain cells need a constant supply of glucose. If glucose levels drop, level of consciousness is altered and blood vessels dilate from lack of function of the vasomotor center in the brain. The classic clinical picture of a patient who has received too much insulin includes altered level of consciousness; cold, clammy skin; and hypotension, dizziness, and tachycardia. Most, but not all, patients experiencing hypoglycemia have diabetes.

Treatment

A glucose reading should be obtained first if possible; if glucose monitoring equipment is not available, but hypoglycemia is suspected, treatment should be initiated without delay. If the patient is awake, he should be given a glass of juice or milk. Glucose tablets or hard candy may also be used. Alteration in level of consciousness often results in impaired swallowing. Attempts to give glucose by mouth could result in aspiration. If a patient has a decreased level of consciousness, IV glucose may need to be given. If an IV line is not in place, intramuscular glucagon can be given by medical personnel or trained family members. Mental status should improve within minutes of receiving glucose. The patient should be given a protein meal, such as a meat sandwich, as soon as he is alert enough to eat. Follow-up care includes teaching about prevention of hypoglycemic episodes, recognition of the signs and symptoms of hypoglycemia, and emergency treatment.

Clinical Cues

Many patients with chronic renal failure are diabetic. If they become hypoglycemic, do not give orange juice—it is high in potassium. Use apple, cranberry, or grape juice.

Other Metabolic Emergencies

Other metabolic emergencies include thyroid storm, Addisonian crisis, and diabetic ketoacidosis (see [Chapters 36](#) and [37](#)).

Injuries Caused by Extreme Heat and Cold

Heat Illness

The body responds to heat exposure in various ways. Initially rash and edema may occur, progressing to cramps and syncope with nausea and vomiting. These symptoms are diagnosed as heat exhaustion. This may progress to heatstroke, which is the most severe heat illness and is identified by a body temperature higher than 106° F (41.1° C) with neurologic dysfunction.

Heatstroke is the result of a serious disturbance of the heat-regulating center in the brain and can be exertional or nonexertional. Exertional heatstroke tends to occur in young, healthy individuals who engage in prolonged physical activity in a hot environment. The very young, very old, those with chronic disabilities, those on medications such as anticholinergics, or those with weight or alcohol abuse problems are at risk for nonexertional heatstroke ([Helman, 2014](#)). Normally, the body is able to regulate body temperature even with increased activity or changes in environmental temperatures by increasing perspiration and by using other internal mechanisms. In heatstroke, these mechanisms fail to function properly and the patient's temperature rises, the skin becomes dry and hot, and there may be convulsions and collapse. Alteration in neurologic function is common with both types of heatstroke. Other symptoms include visual disturbances; dizziness; nausea; and a weak, rapid, irregular pulse.

Prevention

Precautions are necessary in hot weather or when active in warm weather. Drinking plenty of fluids that are nonalcoholic, noncaffeinated, and low in sugar content (the wrong fluids can increase fluid loss) is important, as is not waiting until thirsty to drink fluids. Staying indoors during extremely hot weather, or, if air conditioning or adequate cooling is not available in the home, going to a public place with air conditioning should be encouraged ([CDC, 2011](#)).

Lightweight, light-colored, loose-fitting clothing should be worn in the heat. Limiting outdoor activities to morning and evening hours and using sun protection such as wide-brimmed hats, sunglasses, and sunscreen will help prevent heat-related illness. Those out in the heat should rest often in shaded areas and limit exertion if possible.

Treatment

A person suffering from heatstroke should be placed in the shade and cooled immediately by sprinkling with water and fanning until EMS arrives. Active cooling measures at the hospital include removal of extra clothing or coverings, wiping the skin with cool wet towels or application of ice packs to the groin and axillae, use of a cooling blanket, and infusion of cold fluids. Active cooling measures are discontinued when the rectal temperature reaches 102.2° F (39° C); this prevents rebound hypothermia ([Helman, 2014](#)).

Hypothermia

People most at risk for hypothermia are older adults, very young and thin children, the mentally ill, the homeless, and others unable to alter their ambient environment. Hypothermia is a serious lowering of the total body temperature caused by prolonged exposure to cold. The extremities can withstand lower temperatures (20° to 30° F). When the core (central) temperature drops even 2° or 3° F, fatal cardiac dysrhythmias or respiratory failure can occur.

Symptoms of hypothermia range from mild shivering, complaints of feeling cold, and loss of coordination to eventual loss of consciousness and a deathlike appearance. Mild or moderate hypothermia may be hard to identify in some patient populations. The symptoms of confusion, dizziness, chills, or shortness of breath may be misdiagnosed. In severe hypothermia, the body's protective mechanisms drastically slow the metabolic processes and require less than half the normal oxygen. Pulse and respiration are barely detected, reflexes are absent, and the person is unconscious.

Prevention

Prevention of hypothermia includes eating high-energy foods, exercising, wearing layers of

clothing, and covering the head. Between one half and two thirds of the body's heat is lost through the head. Hypothermia in older adults can easily be misdiagnosed, because the symptoms resemble those of many diseases to which older adults are most susceptible. Mild hypothermia (90° to 95° F [32° to 35° C] body temperature) is usually tolerated fairly well. Moderate hypothermia (84° to 90° F [29° to 32° C] body temperature) results in a mortality rate of about 21%. Severe hypothermia (core temperature below 82° F [28° C]) has an even higher mortality rate.

Most oral clinical thermometers used in hospitals and clinics do not register temperatures below 94° F (34.5° C). In the ED, rectal, bladder, or esophageal probes will be used to monitor true core temperature throughout the warming process.

Older Adult Care Points

With aging, the body's ability to withstand the cold decreases. Older people may also be less active, thus generating less body heat. Older adults are at risk for accidental hypothermia after exposure even to mild cold weather or a small drop in temperature (Box 44-4).

Box 44-4

Prevention of Hypothermia in Older Adults

- Room temperature should not be lower than 65° F (18° C). An indoor thermometer should be kept in the house and checked daily during the cool seasons.
- An energy audit with suggestions from the utility company can prevent heat loss from the home.
- Suggest heating one or two rooms and closing off the other rooms of the house.
- Suggest aids such as a throw or quilt, extra socks, and warm hats to be worn indoors.
- Recommend wearing several loose layers of clothing to retain body heat.
- A head covering should be worn even while sleeping to prevent heat loss.
- Advise against using fireplaces in extremely cold weather, because a substantial amount of heat is lost through the flue.
- Arrange for someone to check in daily with older adults who live alone.
- Suggest an early alert system be installed, allowing the individual to call for help by pressing a button if unable to get to the phone.

Treatment

Once hypothermia is diagnosed, the core must be rewarmed first and continuous monitoring implemented. The goal is to prevent lactic acid or cold blood that has pooled in the extremities from being rapidly shunted to the heart, which can cause ventricular fibrillation. **The heart is extremely sensitive when cold, and the patient must be handled carefully to prevent dysrhythmias.** Rewarming outside a health care facility should be more gradual by wrapping the patient in a blanket and moving him to a warm location.

Frostbite

Frostbite is a localized injury to tissue caused by freezing. Exposure of the tissues to extreme cold constricts the blood vessels, damages vessel walls and tissue cells, and leads to the formation of blood clots. Frostbite is most common in the fingers, toes, cheeks, and nose, where exposure usually is greatest and blood supply is most easily hampered. Frostbite can be categorized by four degrees of severity; however a simplified classification divides injury into superficial or deep (Loar et al, 2015). The full extent of injury cannot be detected upon first examination. The appearance of a first-degree injury (superficial) includes reddened skin, swelling, waxy appearance, hard white plaques,

and sensory deficit. Second-degree injury (superficial) also has redness and swelling and formation of blisters filled with clear or milky fluid that form within 24 hours of injury. In third-degree injury (deep), the blisters are blood filled, and black eschar forms over several weeks. Fourth-degree injury (deep) involves full-thickness damage affecting muscles, tendons, and bone, resulting in tissue loss.

Prevention

Like hypothermia, frostbite can be prevented by wearing protective clothing and avoiding exposure to extreme cold. Those who are intoxicated or under the influence of drugs may not realize they are suffering from frostbite; likewise, when a person is significantly hypothermic, cognition and judgment are impaired. Friends, family members, or bystanders must take the initiative to direct impaired individuals toward shelter and warmth.

Treatment

Once the patient is removed from the cold, the affected area should be warmed in the field by forced warmed air; however, the **rewarming process should not be started if there is a chance of refreezing. Refreezing of thawed tissue is more damaging than prolonged freezing (Mechem, 2013)**. After the patient arrives at the health care facility, rewarming is accomplished in a whirlpool bath with water at 40° to 42° C for 15 to 30 minutes for superficial injuries and up to an hour for deep injuries. Health care workers must handle the frostbitten part gently. Skin that has been frozen should **never** be rubbed or massaged. Rubbing snow or ice on the part is dangerous and can cause further damage to the fragile tissues. The affected area should be wrapped in bulky clean or sterile bandages, separating skin areas, such as between the fingers, and elevated. The patient should not be given alcohol or sedatives, which tend to further depress function. A tetanus immunization is given if not up to date. Débridement of dead tissue and skin grafting or amputation will be necessary if the deeper tissues have been destroyed. Extent of tissue injury may be unknown for several months.

Safety Alert

Frostbite

Do not try to hasten the warming process by using water that is hotter than recommended, because this can add to the damage.

Poisoning

Accidental Poisoning

According to the CDC, the incidence of prescription drug overdose has steadily increased and has now become the leading cause of injury and death in the United States, the rate exceeding that of motor vehicle accidental injury and death. Nine out of 10 poisoning deaths are caused by prescription medications. The drugs most commonly related to pharmaceutical overdose are opioids and benzodiazepines (CDC, 2014b). Cardiovascular drugs and antihistamines are also increasing in number of exposures (Mowry et al, 2013). Many states have passed laws or are in the process of doing so to further control prescription and dispensing of schedule II medications.

Children younger than 5 years are at risk of accidental poisoning. Children 12 years and older more commonly have an intentional ingestion. Prescription medications of family members are the most common poisoning emergency in the 5 years and younger age group. Substances ingested by children may include cosmetics, personal care products, cleaning substances, insecticides, and plants. Children explore their environment by sight, touch, smell, and taste; thus children are at risk for ingestion of a variety of substances including poisonous mushrooms, plants, or toxic berries. Older adults are also at risk for accidentally taking too much prescribed medication because of forgetfulness, confusion about dosage or frequency, or inability to read small print on a medication bottle. The Joint Commission requires medication reconciliation for patients in an effort to prevent duplication of medications from different providers that could contribute to overdose.

Older Adult Care Points

If medications have not been adjusted as a patient has aged, dosages that were appropriate when prescribed may later lead to overdosage. Metabolic changes with aging include decreased liver and kidney function, both of which are responsible for drug metabolism.

Prevention

Prevention of accidental poisoning begins with a realization that there are literally thousands of poisonous substances in an individual's environment. Every home has a variety of poisons in the medicine cabinet; under the kitchen sink; or in the laundry room, utility room, and garage. Encourage families to look at their environment through the eyes of their children and older adults to discover potential poison sources. Make sure adequate teaching has been done for use of prescription medications and their potential complications, including proper disposal of transcutaneous drug patches.

Symptoms

The symptoms of poisoning vary according to the substance ingested and the time that has elapsed since it first entered the body. Poisoning should be suspected if the victim becomes ill very suddenly and there is an open poison or drug container nearby. A peculiar odor to the breath may be present; for example, a garlic smell is associated with organophosphate poisoning. Other symptoms of poisoning include pain or burning sensation in the mouth and throat, an increase or decrease in pulse or respiratory rate, nausea, vomiting, disorientation, visual disturbances, loss of consciousness, or a deep unnatural sleep.

Treatment

The health care team must first ensure circulation, airway, and breathing. Nurses should listen carefully to the patient, family, or EMS personnel, because they provide invaluable information as to **what** was taken (or inhaled) and **when** the event occurred. Availability of the container and any of the contents may help in identifying the poison. The **poison control center** (at 1-800-222-1222) should be immediately consulted, and the caller should be prepared to give the patient's age; weight; medical and medication history; allergies; what, when, and why the substance was taken; current signs and symptoms with vital signs and laboratory results; and any treatment rendered. Poison control gives advice about the severity of toxicity and treatment options.

Health Promotion

Poison Prevention

- Dispose of all medicines that are no longer being used by delivering them to an approved collection location. Many pharmacies and health care facilities will accept medications for disposal. Some drugs undergo chemical changes with age and become toxic compounds.
- Store poisons and inedible products separately from edible foods.
- Do not transfer poisonous substances from their original container to an unmarked one. **Never** place a poison in a container that is normally used for edible solids or liquids (such as a soft drink bottle).
- Never tell children that medicine is candy. Explain that medicine will make the child feel better and that it must be taken only as the doctor has directed.
- Always read the labels of chemical products before using them.

Safety Alert

Never dispose of unused or outdated medications in the sewage or water system. Measurable amounts of prescription medications have been found in drinking water. The Food and Drug Administration (FDA) has issued guidelines on drug disposal (see www.fda.gov/ForConsumers/ConsumerUpdates/ucm101653.htm).

Treatment of ingested poisons.

Remember to ask about first-aid measures that were initiated before arrival at the hospital. Syrup of ipecac is not recommended as a home remedy. However, if ipecac was given at home, initiate aspiration precautions, because vomiting is likely to occur. A sample of vomitus should be saved for analysis and identification.

Treatment in the ED is targeted to the specific substance. Treatment for drug ingestion may include activated charcoal to decrease absorption of poison, gastric tube insertion (a sample of stomach contents should be saved for analysis), irrigation to remove stomach contents, sorbitol to enhance bowel excretion, and antidotes that are specific to the poisons. If a caustic substance was ingested, evacuation of stomach contents by a nasogastric tube may be helpful if done quickly. Lavage, activated charcoal, and other standard interventions are contraindicated (Kardon, 2012). If the nonmedication substance can be identified, the Safety Data Sheet (SDS) will provide treatment recommendations.

Inhaled Poisons

When a person has inhaled a poisonous substance, emergency help is necessary. Do not attempt to rescue a person without notifying someone of your location. If it is safe to do so, the person can be removed from the danger of the gas, fumes, or smoke. Windows and doors should be opened to remove the fumes. The rescuer should take several deep breaths of fresh air, and then hold his breath when entering, holding a wet cloth over his nose and mouth. Lit matches or lighters should not be used as a light source, because some gases can catch fire.

After rescuing the person from danger, clothing around the neck and chest should be loosened. The person's pulse, airway, and breathing should be checked and monitored. If necessary, CPR or rescue breathing should be initiated (see American Heart Association recommendations for rescue breathing and CPR).

Symptoms that may indicate inhaled poison include excessive coughing; shortness of breath, wheezing, and a burning sensation of the nose and throat; pale or bluish color to skin; dizziness, headache, nausea, and vomiting; and chest pain or tightness. Carbon monoxide (CO) is the most commonly inhaled poison and results in a **cherry red color of the mucous membranes**. A carboxyhemoglobin level should be obtained and the patient should be treated with 100% oxygen.

until the carboxyhemoglobin level is less than 10%. In carbon monoxide poisoning, the readings of pulse oximetry and the values of arterial blood gases can appear normal despite significant toxic exposure. Hyperbaric oxygen (HBO) therapy eliminates CO from hemoglobin more rapidly than just oxygen administration. HBO is not available at many facilities, and studies have not shown a clear benefit in patient outcomes. Current CO poisoning treatment guidelines do not include HBO therapy; however, it is frequently implemented at facilities with HBO capability ([Shochat, 2015](#)).

Safety Alert

In addition to smoke alarms, carbon monoxide detectors are required in certain residential buildings in most states.

Bites and Stings

Human Bites

A human bite that breaks the skin is termed an *occlusive bite*. When a tooth meets the skin and muscle of a clenched fist, it is aptly named a *clenched-fist injury*. Infection occurs in 10% to 15% of human bite injuries and can be severe because of delay in seeking treatment. Occlusive bites are of concern because of the potential disruption of tissue, tendons, bones, and structures underlying the area of bite injury. Copious irrigation is required to clean the wound, which may or may not be closed. Prophylactic antibiotics are indicated ([Barrett, 2014](#)).

Animal Bites

Family pets, especially dogs and cats, are the most common source of animal bites. Dog bites are more common than cat bites and occur most frequently in adults. However, children tend to sustain bites to the head and neck, which warrant more intensive medical care ([Doud Galli, 2014](#)). When a wild animal, such as a squirrel or fox, attacks and bites a human being without provocation, rabies should always be suspected as the cause of the animal's unusual behavior.

Treatment

Bite wounds should be cleaned immediately with soap and rinsed with warm running water for 5 to 10 minutes. The affected area is then treated with antibiotic ointment, covered with a clean bandage, and immobilized. Medical attention includes copious irrigation; suturing may be done if the wound is on the face or hand. Puncture wounds on the arms or legs are typically left unsutured and allowed to drain. If the patient has not had a tetanus shot in the past 5 years, a booster will be given.

The possibility of rabies infection must always be considered in an animal bite. The local animal control agency should be contacted to catch the animal if necessary. If it has been killed, animal control will take the body for examination. If a diagnosis of rabies in the animal has been confirmed or if there is no proof that the animal has been immunized against rabies, the victim is given rabies immune globulin (20 units/kg infiltrated around the wound and the remainder given intramuscularly). A series of intramuscular injections of human diploid rabies vaccine is given at the time of injury and on postinjury days 3, 7, and 14. Antibiotics are given for deep puncture wounds, particularly cat bites ([Doud Galli, 2014](#)).

Snakebite

In the United States 4000 to 7000 snakebites occur annually; approximately 2000 are from poisonous snakes. Fatalities are rare. In a 20-year review of data 97 fatalities were identified ([Daley, 2014](#)). There are four kinds of poisonous snakes in the United States: copperheads, rattlesnakes, coral snakes, and cottonmouths (or water moccasins). Copperheads, rattlesnakes, and cottonmouths are all called pit vipers because they have pits or depressions behind their nostrils; coral snakes are small snakes with characteristic red, black, and yellow bands. Coral snakes have shorter fangs and smaller mouths than the pit vipers, and their venom injection resembles a chewing motion.

A venomous snakebite usually can be distinguished by two fang marks (though there may be only one on a small surface, such as a toe or finger), severe pain and swelling in the area, discoloration at the site of injection of venom, nausea and vomiting, respiratory distress, changes in vision, and increased sweating and saliva production. If prompt intervention is not taken, shock may occur. Nonpoisonous snakebites usually appear as either small scratches or lacerations.

Treatment

Nonpoisonous snakebites are treated as simple wounds and require only a cleansing of the wound with soap and water and the application of a mild antiseptic. First aid for a poisonous snakebite includes washing the wound, lowering the extremity or area and immobilizing it, keeping the victim calm so the venom does not circulate as quickly, and seeking medical attention as soon as possible. Getting a description of the snake can help with treatment. In the field, rescuers should

not apply suction, make incisions over the wound, apply ice, or give alcoholic beverages or stimulants. Prehospital care is centered on supporting the ABCs and prompt transport to a medical facility.

When a snakebite victim reaches a hospital or clinic, the victim is treated based on evaluation of the extent of the envenomation, whether it is localized or systemic, and whether coagulation abnormalities exist. Newer antivenins are recommended earlier in the treatment with more liberal dosing. Prevention of compartment syndrome has been noted with earlier administration. Most victims are admitted for observation for up to 24 hours and provided a tetanus immunization, antibiotic prophylaxis, and symptom management (Daley, 2014).

Bug Bites and Stings

Systemic reactions to the bites and stings of insects and bees account for more deaths each year in the United States than do snakebites. A systemic reaction is caused by hypersensitivity to the venom of bees, wasps, hornets, fire ants, harvester ants, puss caterpillars, scorpions, or spiders. Symptoms of a systemic reaction include hives, swelling, general weakness, tightness in the chest, abdominal cramps, constriction of the throat, loss of consciousness, and possibly death from severe **anaphylaxis**. When the interval between the sting or bite and the development of symptoms is short, the possibility of death increases. Most bug bites result in local reactions and are not reported. Symptom relief is provided, and medical help is sought only if there are complications to the bite or sting.

Safety Alert

A severe local reaction to a bug bite or sting puts the patient at risk for a systemic reaction with a subsequent exposure.

The black widow and the brown recluse spiders are the best known spiders that have a potentially serious bite. The symptoms of a black widow spider bite may not be obvious initially; the bite may feel like a pinprick with some slight redness and swelling. Within a few hours abdominal pain and muscle cramps occur. Other symptoms include nausea, vomiting, chest pain, and respiratory distress. A brown recluse spider bite usually goes unnoticed initially. Symptoms usually develop 2 to 8 hours after the bite and include severe pain and itching at the site, nausea, vomiting, fever, and muscle pain. The tissue may heal without problems, or blistering and development of necrotic tissue may occur, requiring surgical intervention.

Older Adult Care Points

Anyone older than 65 years should seek medical attention if bitten by a brown recluse or black widow spider. Older adults are more at risk for developing complications related to the bite.

Treatment

Treatment for a systemic reaction is to subcutaneously or intramuscularly inject aqueous epinephrine (1 : 1000 solution) in dosages of 0.3 to 0.4 mL for adults and 0.15 to 0.3 mL for children. An antihistamine, such as diphenhydramine (Benadryl), is given. An ice pack may be applied to reduce swelling and relieve pain. Patients who appear to be in shock should be kept warm and should remain lying down with the legs elevated and the head flat. If symptoms persist after 20 minutes and the patient has not yet reached a medical facility, a second injection of epinephrine should be given. Many patients who have a known allergy carry autoinjectable epinephrine in a prefilled syringe device that delivers a measured dose of medication when activated.

The female worker honeybee injects a venom sac that may remain embedded in the victim's skin. **The “stinger” should be removed as quickly as possible.** Do not use tweezers to remove an insect stinger; this may cause squeezing of the venom sac and increase the severity of the symptoms. Use a credit card or any rigid item with a smooth, flat edge to scrape out the stinger.

An emergency kit that contains drugs, syringe, tourniquet, towelette, and tweezers is available by prescription and is used for treatment of systemic reactions to stings and bites. Individuals with known hypersensitivity to insect and bee venom should carry medical identification and an

emergency kit and be thoroughly familiar with its use **before** the need arises. Persons who have systemic reactions or even severe local reactions with swelling beyond two joints should be referred for hyposensitization therapy.

Applying a paste of baking soda and water or household ammonia and a cold compress treats less serious stings of bees, wasps, yellow jackets, and hornets. Meat tenderizer also has been found effective in relieving the symptoms of minor insect sting reactions. Topical cortisone cream can relieve inflammation and itching.

Bites from venomous spiders, scorpions, and other poisonous insects are treated in the same manner as poisonous snakebites. Antivenin specific to the spider, scorpion, or other poisonous creature is available at hospital EDs and clinics that serve rural areas.

Ticks can carry Rocky Mountain spotted fever or Lyme disease. The tick is removed by grasping it as close to the skin as possible with tweezers and pulling it straight out without twisting. Applying turpentine, mineral oil, petroleum jelly, nail polish, or insecticide on the tick is not recommended, because the tick may regurgitate stomach contents into the skin ([CDC, 2014c](#)). After the tick is removed, the area should be washed with soap and water and a mild disinfectant applied. A provider can be consulted for possible infection or disease symptoms.

Electrical Injuries and Burns

When an electrical current passes through the body, it can cause severe damage to the entire body, including cessation of breathing, circulatory failure, and serious burns. The current travels along the path of least resistance, which is usually the fluid-filled blood vessels, and may be conducted through the heart. The amount of voltage and current involved, the length of time in contact with the electricity source, and the condition of the skin all play a role in how much damage may occur as a result of an electrical shock.

Emergency treatment of electrical shock involves CPR if breathing has ceased or the heart has stopped and treatment of burns or other concurrent injuries. The proper procedure for separating a victim from a live conductor of electricity is shown in [Figure 44-4](#). **Remember that water serves as a conductor of electricity, and wet objects can transmit a fatal electric current to a person trying to rescue the victim of electrical shock.** All electrical shock victims, including those struck by lightning, must be observed for cardiac dysrhythmias and evidence of internal injury.

Safety Alert

Lightning

There are no safe locations outside during a lightning storm. The National Weather Service slogan is "When thunder roars, go indoors." When camping or participating in other outdoor activities, plan ahead for shelter. If no safe shelter is available, avoid water, high ground, open spaces, and metal objects. Do not seek shelter under canopies, small picnic or rain shelters, or trees. If out in the open, do not lie down, but keep moving toward shelter. If inside, avoid plumbing fixtures and electrical appliances, including computers and cord phones. If in the car, do not touch surfaces that readily conduct electricity (National Oceanic and Atmospheric Administration, *National Weather Service Lightning Safety*, n.d.).

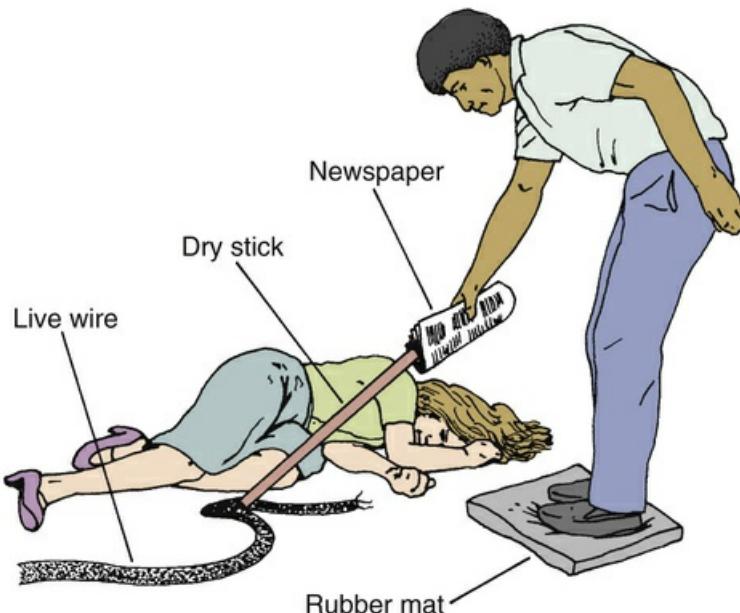

FIGURE 44-4 Separating a victim from a live electrical wire while avoiding similar shock.

Chemical Injury

Strong chemicals capable of burning the skin and mucous membranes will continue to destroy tissue unless they are diluted and removed immediately. For this reason, any area burned by chemicals must be quickly flushed with large amounts of water (with some exceptions) until all traces of the chemical have been removed; the burned area is then covered with a dressing.

Water is not used for burns caused by dry lime or phenol. Dry lime should be brushed from the skin and clothing unless there is enough water to remove *all* traces of the powder. Small amounts of water will react chemically with the lime to produce a highly **corrosive** (destroys gradually) substance. Phenol (carbolic acid) is not water soluble. The phenol is first removed by alcohol, and the burned area is then rinsed with water. **If a corrosive chemical has been ingested, the poison control center should be contacted for instructions and proper dosage of an antidote.** Vomiting should **not** be induced or encouraged. No attempt should be made to neutralize an ingested chemical substance, because this can cause further damage to the esophagus and stomach.

Patients with chemical burns should be transported to a hospital as soon as possible. If possible, the treating provider should be informed about (1) the offending agent, physical form, and concentration; (2) the route and volume of exposure; (3) the timing and extent of irrigation; and (4) any coexisting injuries.

Choking Emergencies

Obstructed airway is the sixth leading cause of accidental death. Adults as well as children can become choking victims and need immediate intervention to prevent death from asphyxiation. Both partial and complete airway obstruction should be treated promptly, even a partial obstruction can result in inadequate air flow. **If the person is conscious and able to cough or speak, he may not need assistance in expelling the object from his throat.** In this situation, he should be encouraged to cough vigorously and breathe as deeply as he can. His coughing efforts are more effective than outside intervention; others present should stay with him and call for help as needed. When the choking victim cannot speak, cough, or independently expel the foreign object, abdominal thrusts are used to force the object up and out (see [Chapter 13](#)).

Think Critically

You are dining in a restaurant and observe someone at another table apparently choking. What steps would you take to assist?

Cardiopulmonary Resuscitation

Many phenomena cause sudden cessation of breathing and circulation, from electrical shock to drowning to cardiac arrest. CPR is indicated when the person shows (1) absence of response to stimuli, (2) absence of respirations, and (3) absence of a carotid pulse. When a person stops breathing spontaneously and his heart stops beating, "clinical death" has occurred. Within 4 to 6 minutes, the cells of the brain, which are most sensitive to lack of oxygen, begin to deteriorate. If the oxygen supply is not restored immediately, the patient suffers irreversible brain damage and "biologic death" occurs.

The American Heart Association (AHA) Guidelines for CPR are revised every 5 years to reflect the most current research and consensus by international experts. The 2010 guidelines implemented the **C-A-B (chest compressions, airway, breathing)** sequence and the 2015 guidelines have not changed the recommendation. The guidelines emphasize the importance of high-quality CPR. The guidelines are based on research that indicates that the highest survival rates for cardiac arrest among adults occurs for witnessed ventricular fibrillation (VF) or pulseless ventricular tachycardia in which the critical interventions of chest compressions and defibrillation are implemented. There should be minimal delay or interruption to chest compressions for pulse checks or any other action. The AHA recommends **hands-only CPR** for the lay rescuer. The idea of hands-only CPR for lay rescuers is intended to encourage bystanders to intervene only with chest compressions and to **push hard, push fast** at a rate of at least 100 compressions per minute. Beyond the fear of contagion, it was determined that the positioning of the head and delivering the initial breaths was delaying the delivery of chest compressions. In the health care setting, high-quality CPR means that the chest compressions must be delivered with the correct depth and rate with adequate recoil and that any pauses for ventilation, pulse checks, or switching rescuer positions or procedures such as application of equipment or defibrillation must be kept to the absolute minimum.

Health care providers are held to a higher standard of care, and intervention must be based on assessment of the patient and tailored to address the most likely cause. For example, if a nurse witnesses a sudden collapse of a patient in the hospital, VF would be a likely assumption. The sequence would be to establish unresponsiveness and breathlessness, activate the response team, check the pulse in 10 seconds or less, start compressions, defibrillate with the **automated external defibrillator (AED)** as soon as it is available, and ventilate with an Ambu bag. Adapt and delegate as personnel and equipment arrive at the scene.

In the community, the use of the AED combined with activation of the EMS response system and CPR gives a victim of VF the best chance for survival. AEDs are now located in most public buildings, health clubs, airlines, malls, and sporting venues. As soon as the AED is brought to the scene, the device must be turned on; it will audibly give step-by-step instructions. When the AED indicates that it is analyzing the rhythm, all CPR and any direct contact with the victim must stop. If the AED identifies a shockable rhythm, it will either automatically charge or give instructions to charge the device. Once the AED is charged, the instructions will state to "stand clear" of the victim. To prevent being shocked, everyone must avoid touching the victim when the charge is delivered. If indicated, a single shock is delivered and CPR is immediately resumed.

Table 44-2 presents current techniques of CPR. For the most up-to-date science, refer to a current CPR handbook. Recertification is generally required every 2 years; however, studies show that skills are not retained for that length of time unless reviewed.

Table 44-2

Cardiopulmonary Resuscitation for Adults

COMPONENT	ACTION FOR LAY RESCUER	ACTION FOR HEALTH CARE PROVIDER
Recognize symptoms and need for assistance	If victim is unresponsive, or is not breathing or gasping only. Call for help.	The sudden collapse of an adult is likely to be cardiac in origin; call for help, start CPR, and defibrillate as soon as the AED is available. Any adult that is unresponsive or has breathing issues needs EMS care. The sooner the call is placed, the sooner help will arrive.
Pulse check	Lay rescuers are not taught this step.	≤10 sec, carotid.
CPR sequence	C-A-B.	C-A-B.
Compression rate	At least 100-120/min. Pushing hard, pushing fast, and allowing for the chest to recoil between compressions has been found to be the most effective.	At least 100-120/min. Pushing hard, pushing fast, and allowing for the chest to recoil between compressions has been found to be the most effective. Consider using an automated chest compression device for consistent high-quality chest compressions.
Compression depth	At least 2 inches (differs for children and infants).*	At least 2 inches (differs for children and infants).*
Compression interruption	Minimize interruptions in chest compressions.	Limit interruptions to less than 10 sec (i.e., rotating compressors, delivering shock, pulse check). Rescuers should change compressors q2min to prevent fatigue and decreased efficiency of compressions.
Airway	Untrained lay rescuers should not delay compressions to open the airway. Head tilt–chin lift; use jaw thrust if cervical injury is suspected.	

Compression ratio to rescue breathing (no advanced airway placed)	Compressions only for untrained lay rescuers.	30 : 2 for one or two health care rescuers. Use one-way valve for mouth to mask ventilations. Use bag-valve-mask as soon as available.
AED use	Use as soon as possible.	Use as soon as possible. For an out-of-hospital, unwitnessed cardiac arrest, EMS may initiate 1.5 to 3 min of CPR before attempting defibrillation.

*Consult a pediatrics text and the American Heart Association guidelines for additional data that are specific to children and infants.

AED, Automated external defibrillator; C-A-B, chest compressions, airway, breathing; *CPR*, cardiopulmonary resuscitation.

Shock

Shock is a condition that starts at the cellular level and gradually spreads to produce clinical signs and symptoms. The hallmark of shock is lack of adequate **perfusion** (blood supply) to tissues, which results in lack of oxygen and nutrients. This deficit causes anaerobic metabolism and the production of lactic acid and organ dysfunction. Conditions of low circulating volume (hypovolemic shock), decreased cardiac output (cardiogenic shock), impairment of circulation (obstructive shock), or maldistribution of volume (neurogenic, anaphylactic, or septic shock) cause decreased perfusion (Table 44-3). Perfusion requires adequate blood volume; the blood vessels must be intact, without obstruction to flow and the pump (the heart) must be working correctly.

Table 44-3
Comparison Chart of Shock

TYPE	CAUSE	CLINICAL SIGNS AND SYMPTOMS	MANAGEMENT
Hypovolemic	External blood loss Trauma GI losses Burns Internal bleeding	↓ BP ↑ HR Tachypnea Oliguria Cool, pale skin Altered mentation	Stop fluid loss Replace lost volume
Cardiogenic	Myocardial infarction Cardiomyopathy Valve dysfunction	↓ BP ↑ HR Dysrhythmias Oliguria Cool, pale skin Altered mentation Chest pain	Improve contractility with medications Mechanical support as needed Prevent/treat dysrhythmias
Obstructive	Cardiac tamponade Tension pneumothorax Pulmonary embolism Aortic stenosis	↓ BP ↑ HR dysrhythmias Oliguria Cool, pale skin Altered mentation Chest pain JVD	Eliminate the source of obstruction or compression
Distributive			
Neurogenic	Cervical spinal cord injury Spinal anesthesia	↓ BP ↓ HR Hypothermia Warm, dry, flushed skin Oliguria Altered mentation	Eliminate and treat the cause. Maintain BP with IV fluids
Anaphylactic	Chemicals (latex, perfume, soap) Drugs (antibiotics, contrast media, blood products) Food (peanuts, shellfish, eggs, wheat, nuts, milk) Bites or stings (wasps, bees, spiders, fire ants)	↓ BP ↑ HR dysrhythmias Tachypnea Chest pain Warm, dry, flushed skin Oliguria Dyspnea, cough stridor	Remove offending agent or slow absorption Maintain airway Modify or block effects of mediators: epinephrine, antihistamines, steroids
Septic	Bacteria Immunosuppression Malnutrition Invasive procedures and devices Traumatic wounds or burns Infection elsewhere in the body (urinary tract, peritoneum, respiratory tract)	↓ BP ↑ HR Oliguria Cool, pale skin Altered mentation Hyperthermia	Identify source of infection Antibiotic therapy Medical asepsis Support BP with fluids and pressors if needed Avoid NPO status; initiate and maintain nutrition Control hyperthermia

BP, Blood pressure; GI, gastrointestinal; HR, heart rate; IV, intravenous; JVD, jugular venous distention; NPO, nothing by mouth.

Adapted from Sole ML, Klein DG, Moseley MJ: *Introduction to critical care nursing*, ed. 6, Philadelphia, 2012, Saunders.

Signs and Symptoms

Early recognition and treatment of impending shock results in better outcomes. Compensated shock occurs when the body is able to maintain blood pressure and perfusion by increasing heart rate and vasoconstriction of peripheral vessels. The only clinical signs at this point may be increased heart rate and cool skin. The clinical symptoms associated with the second stage of shock reflect lack of oxygen to essential organs; this is decompensated shock. Signs and symptoms reflect decreased cardiac output, such as confusion, restlessness, diaphoresis, rapid thready pulse, increased respiratory rate, cold clammy skin, decreased blood pressure, and diminishing urinary output to less than 20 mL per hour (Figure 44-5). Decompensated shock can quickly move to the third stage, which is irreversible shock from which recovery is impossible.

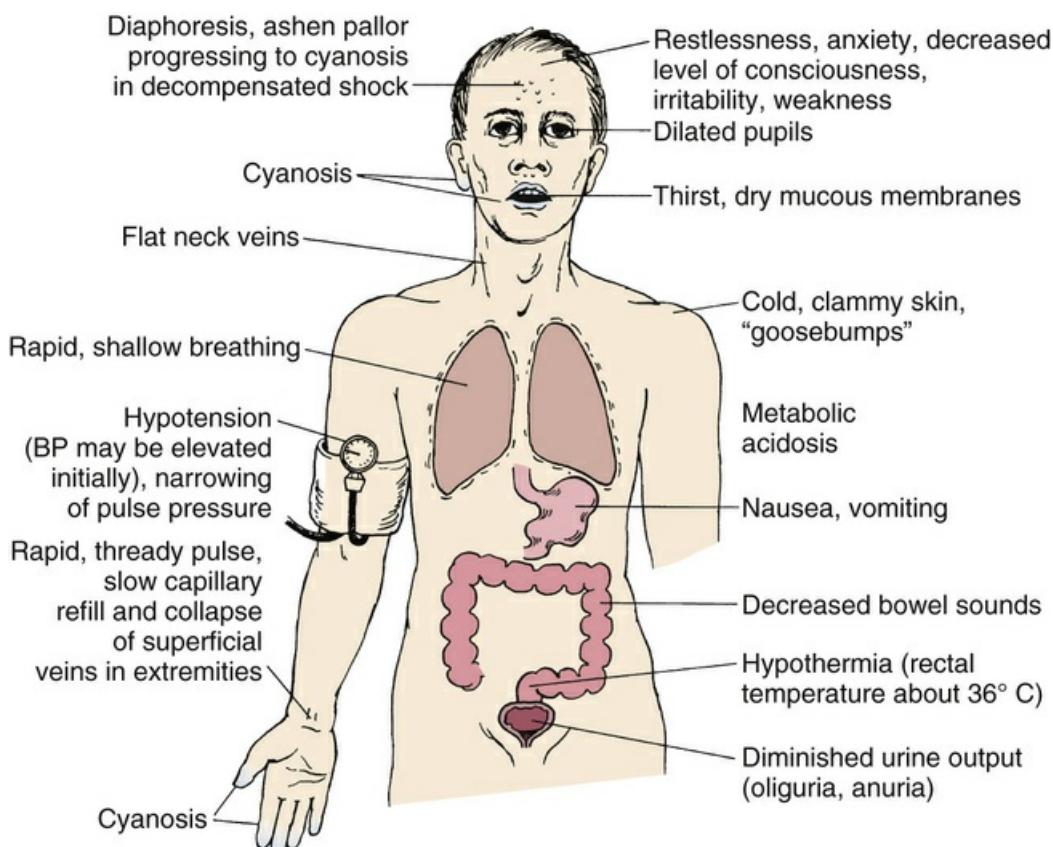

FIGURE 44-5 Clinical signs of shock. BP, Blood pressure.

Hypovolemic Shock

Hypovolemic shock is the most common form of shock. A blood loss of even 500 mL in a typical adult may cause hypovolemic shock. [Table 44-4](#) shows the amount of blood loss and consequent clinical manifestations. Any significant loss of fluid volume can result in hypovolemic shock ([Figure 44-6](#)). Blood loss from trauma or gastrointestinal (GI) bleeding, plasma leaking from a burn, severe vomiting and diarrhea, and internal bleeding from pancreatitis are examples of conditions that may lead to hypovolemia.

Older Adult Care Points

Older adults may develop shock with smaller blood loss because of decreased vascular tone and impaired cardiac function. Many are on antihypertensive medications that impair the vasoconstrictive ability of vessels.

Table 44-4
Clinical Manifestations of Blood Loss

VOLUME LOST	CLINICAL MANIFESTATIONS
10%	None
20%	At rest, no signs or symptoms; slight postural hypotension when standing; tachycardia with exercise
30%	Blood pressure and pulse normal when supine; postural hypotension and tachycardia with exercise
40%	Below-normal blood pressure, central venous pressure, and cardiac output at rest; rapid, thready pulse and cold, clammy skin
50%	Shock and potential death

Adapted from Lewis SL, Dirksen SR, Heitkemper MM, Bucher L: *Medical-surgical nursing: Assessment and management of clinical problems*, ed. 9, St. Louis, 2014, Mosby.

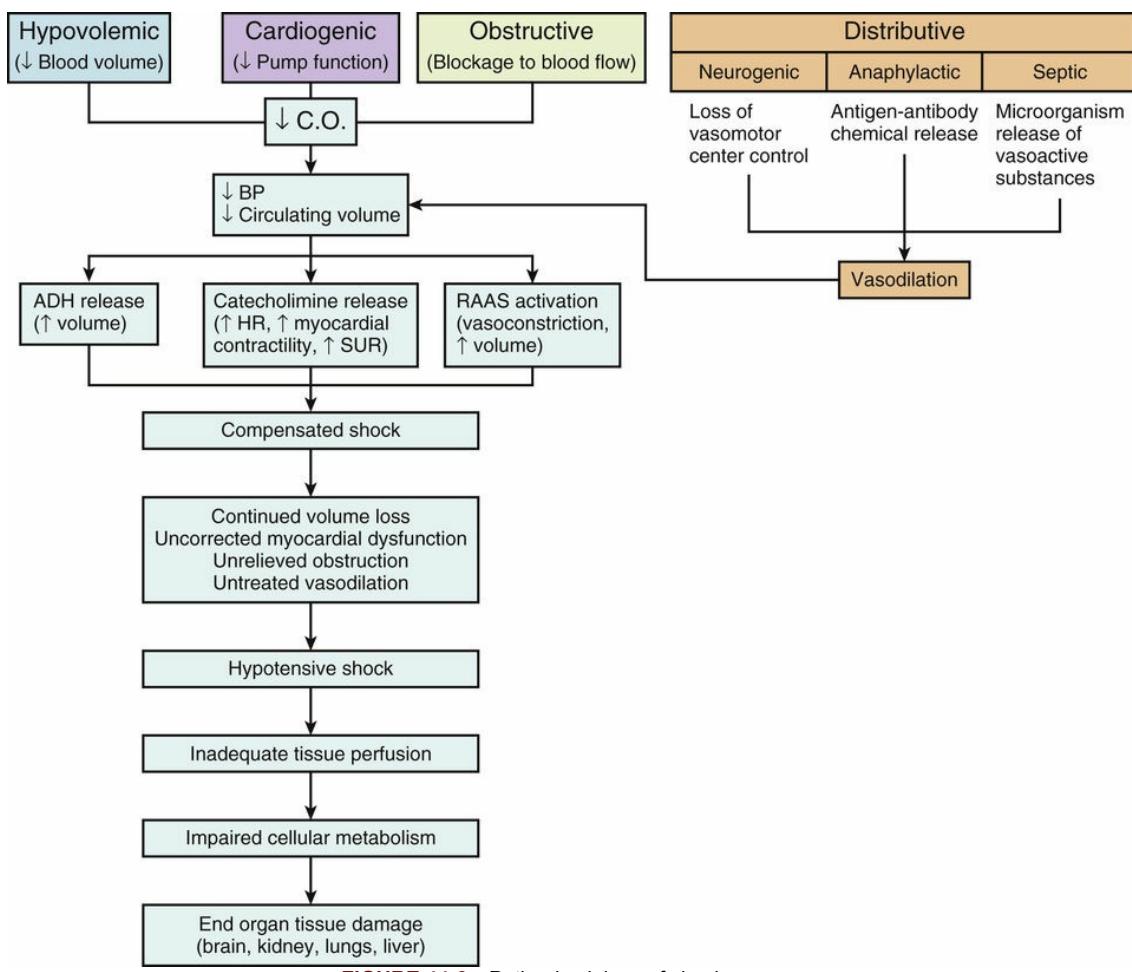

FIGURE 44-6 Pathophysiology of shock.

Treatment

The primary interventions for **hypovolemia** are to stop the fluid loss, if possible, and to replace fluids. In all situations of hypovolemic shock, **volume replacement is essential**. To infuse large volumes of fluid and/or blood products, adequate IV access is extremely important. Two large-bore peripheral IV sites or placement of a central line with multiple lumens are needed. If IV access cannot be obtained, intraosseous access may be implemented (Kolecki, 2014). If large volumes of fluid are required for fluid resuscitation, warming of the fluids can help prevent hypothermia. If hemorrhage is present, crystalloids (i.e., normal saline or lactated Ringer solution) or colloids (e.g., albumin or hetastarch) will be infused until blood products are available for transfusion. Packed red cells are given to replenish cell volume. Units of packed cells contain citrate as an anticoagulant. If multiple units of blood are rapidly infused, the citrate can bind with ionized calcium, decreasing the amount of circulating calcium. This can depress cardiac function and alter coagulation; therefore in massive transfusions, IV calcium is also given. If a large volume of blood is lost, clotting factors will also need to be replaced. Fresh frozen plasma is given for replacement of clotting factors. Platelets may also be given.

If fluid loss is from GI sources, isotonic solutions will be used to replenish the fluid and electrolytes. Burn patients require replacement of lost plasma, which is rich in protein. Crystalloids containing salt and colloids, such as albumin, will be administered to rehydrate burn victims (see Chapter 42). Monitoring of vital signs, level of consciousness, and urine output helps to assess response to therapy.

Clinical Cues

Oxygen should always be administered to patients in shock or suspected shock.

Think Critically

You are caring for a patient who has vomited large amounts of blood. You expect to see a compensatory increase in pulse, but in fact the pulse rate remains between 50 and 60 beats per minute. Why would you want to double-check this patient's medication history?

Cardiogenic Shock

Cardiogenic shock occurs when the heart is incapable of pumping enough blood to meet the needs of the body because of a primary cardiac injury or dysfunction. MI is the primary cause of coronary cardiogenic shock because of the direct damage of the heart muscle from a heart attack. The heart also can be rendered ineffective as a pump by noncoronary causes, such as cardiomyopathy or valvular dysfunction.

Treatment

In cardiogenic shock, the first-line treatment is to restore myocardial function if possible. Myocardial ischemia resulting from acute coronary syndromes is the primary cause of cardiogenic shock. Percutaneous coronary intervention or coronary artery bypass grafting can help restore oxygen to the myocardium, improving function. Chemical and mechanical treatments are used with the goal of supporting the impaired heart muscle without increasing the workload of the heart. Vasopressor agents (e.g., norepinephrine and dopamine), inotropic agents (e.g., dobutamine), or phosphodiesterase inhibitors (e.g., inamrinone) are used to increase the contractility of cardiac muscle (positive inotropy) (Ren, 2014). However, as the heart works harder, it requires more oxygen. If the heart is already damaged, pushing it to do more will only worsen the inadequate circulation.

In conjunction with the positive inotropes, vasodilators (e.g., nitroglycerin or nitroprusside) are judiciously used to decrease cardiac workload by decreasing afterload. When the heart ejects blood into the systemic circulation, it has to overcome the pressure of the closed aortic valve and the resistance of the peripheral blood vessels. The blood vessels constrict as part of the compensatory mechanisms, similar to an adjustable nozzle on a hose: as the nozzle opening is enlarged, less pressure is required than if the nozzle is turned to the smallest setting. Similarly, if the blood vessels are dilated, the heart does not have to work as hard to expel the blood. Diminished workload lessens the oxygen demand of the cardiac muscle. Vasodilators must be used cautiously to enhance cardiac performance without compromising blood pressure. The intra-aortic balloon pump (IABP) is a mechanical left ventricular assist device that supports cardiac function; IABP is used in critical care units^E (see [Figure 19-3](#)).

Obstructive Shock

Tissue perfusion can be impaired when there is a mechanical obstruction to blood flow. In conditions such as pericardial tamponade, tension pneumothorax, or constrictive pericarditis, there is a physical obstruction that prevents adequate filling or emptying of the heart. In conditions such as aortic dissection or massive pulmonary embolus, there is a problem in the blood vessels that prevents forward flow of blood.

Treatment

Pericardial tamponade is treated by inserting a needle into the pericardial sac and removing the fluid that is compressing the heart. Tension pneumothorax is also treated by needle decompression. A needle or thoracostomy tube is inserted to release the air trapped in the chest that is putting pressure on the heart. Constrictive pericarditis does not usually have a sudden onset. It is typically a chronic problem with acute episodes. Medical treatment with anti-inflammatory medications may help, but the only definitive treatment is surgery. Aortic dissection is one of many causes of chest pain and diagnosis can be difficult, but the patient must be taken immediately to the operating room for repair of the vessel. Massive pulmonary embolus (PE) is usually fatal. A less severe PE will be treated with heparin to prevent further clot formation. Thrombolytic therapy in PE is controversial.

Distributive Shock (Maldistribution of Fluids)

Distributive shock involves a maldistribution of the fluid within the vascular system. If the vessels dilate and the volume of fluid stays the same, the pressure decreases (vasogenic shock). All forms of distributive shock involve vasodilation of blood vessels, resulting in a "relative hypovolemia." There is no actual volume loss, but physiologically the patient appears to be hypovolemic.

Anaphylactic Shock

Acute allergic reactions can result in life-threatening anaphylactic shock. Classic anaphylaxis is a massive immune response set up by a previous exposure to the antigen. However, the body can respond to substances without prior exposure causing the same clinical signs and symptoms. In anaphylactic shock, the antigen-antibody reaction that occurs releases **vasoactive** substances that cause massive vasodilation as well as increased capillary permeability. This combination of factors results in hypotension. These mediators can also cause bronchoconstriction and **angioedema** of the laryngeal tissue, causing an acute airway emergency. Other signs and symptoms may include skin rash and generalized flushing, headache, or light-headedness.

Treatment

If possible, the antigen should be removed immediately. With a bee sting, prompt removal of the stinger may help. If the anaphylaxis results from an ingested or inhaled substance, removal may not be possible, so treatment begins immediately. Treatment of anaphylactic shock includes airway management, including intubation when necessary, and administration of epinephrine intramuscularly in the vastus lateralis (thigh). Epinephrine helps maintain blood pressure, counteracts the effects of the released mediators and inhibits further release of mediators from mast cells and basophils. Bronchodilators may also be administered.

Administration of fluid is also needed. Although the actual circulating volume reduction from leaking capillaries is not enough to cause hypotension, vasodilation is more than enough to cause a significant drop in blood pressure. An antihistamine such as diphenhydramine (Benadryl) is given; dexamethasone or methylprednisolone is given to reduce the inflammatory response. Patients should be monitored for several hours even if response to treatment is good, because antihistamines and epinephrine will wear off ([Mustafa, 2014](#)).

Neurogenic Shock

Neurogenic shock, the rarest form of shock, has a triad of symptoms: hypotension, bradycardia, and hypothermia. Spinal injury or anesthesia can cause a blockage in sympathetic outflow from the vasomotor center of the brainstem. Most blood vessels are never completely constricted or completely dilated. This in-between state is known as *vascular tone* and allows for constriction or dilation as necessary. The sympathetic nervous system maintains this state of readiness. When spinal cord injury happens or high levels of spinal anesthesia are administered, the sympathetic impulses regulating the state of the blood vessels are blocked, and passive vasodilation occurs. The volume of fluid circulating in the blood vessels is the same, but the space within the blood vessels enlarges. This results in a lower blood pressure leading to hypotension and a shock state. Proper stabilization of spinal injuries can prevent or minimize conditions that lead to neurogenic shock.

Treatment

Treatment includes administering crystalloids to maintain blood pressure. Dopamine is given for a combination of hypotension, bradycardia, and decreased cardiac output. Hypothermia is treated with warming blankets and environmental temperature control.

Systemic Inflammatory Response Syndrome, Sepsis, and Septic Shock

Systemic Inflammatory Response Syndrome

The inflammatory response is part of the cascade of events that is part of the body's immune response. Once the threat has been dealt with, feedback mechanisms inhibit the release of

chemicals, and the immune system goes back into a state of readiness. In some situations, this does not happen, and the substances that cause inflammation continue to be released. This clinical picture is known as **systemic inflammatory response syndrome (SIRS)**. SIRS can occur because of an infection or from noninfectious conditions.

SIRS is the first part of a continuum that leads to sepsis, then severe sepsis, and ultimately **multisystem organ dysfunction syndrome (MODS)**, defined as two or more organ systems showing signs of dysfunction. The usual clinical progression starts with symptoms indicating SIRS, moving into sepsis, then severe sepsis and MODS complicated by disseminated intravascular coagulation (DIC). If this sequence of events continues, mortality rates range from 28% to 80%. The wide range is affected by multiple variables such as age, preexisting illnesses, and access to treatment. Early recognition and effective treatment of this cascade of events are the most significant factors in reducing mortality risk.

A patient presenting with two or more of the following is diagnosed with SIRS:

1. Temperature greater than 102.2° F (39° C) or less than 96.8° F (36° C)
2. Heart rate greater than 90 beats per minute
3. Respiratory rate greater than 20 breaths per minute or Paco_2 less than 32 mm Hg
4. White blood cell count greater than 12,000 cells/mm³ or less than 4000 cells/mm³ or more than 10% bands

Many hospitalized patients meet these criteria. Nurses need to pay attention to vital signs and laboratory results so notification can happen quickly. Early recognition is the key to treatment (Kaplan, 2014).

Meeting the SIRS criteria in the presence of an infection is diagnosed as *sepsis*. *Severe sepsis* is defined as sepsis with organ dysfunction. Septic shock is severe sepsis with hypotension despite adequate fluid resuscitation. These terms reflect deterioration in the patient's status and a more profound risk to life.

Symptoms of septic shock that reflect the hypotensive state include altered mental status, hypoxemia, oliguria, ileus, and decreased capillary refill.

During septic shock, the inflammatory process, in addition to causing clotting and activation of the immune system, releases chemicals that cause vasodilation and increased capillary permeability. The vasodilation, as with the other forms of distributive shock, causes blood pressure to fall. The leaking capillaries cause fluid loss, which increases the severity of the hypotension. The infecting organism secretes toxins from the cell wall that also react with the blood vessels and cell membranes, causing further increased capillary permeability and further loss of fluid from the vascular space, cellular injury, and greatly increased cellular metabolic rate.

Bacteria are the organisms most commonly associated with infections leading to sepsis and septic shock. Gram-negative bacteria such as *Pseudomonas aeruginosa*, *Escherichia coli*, and *Klebsiella pneumoniae* and gram-positive bacteria such as *Staphylococcus* and *Streptococcus* are normally present in the environment. Health care-associated infections can lead to sepsis with deadly outcomes. Meticulous care must be taken with IV sites, Foley catheters, and other devices that disrupt the body's protective mechanisms.

Treatment and nursing management.

In 2003, 11 international organizations launched the "Surviving Sepsis Campaign." Since then the recommendations have been revised several times to reflect current research. Recommendations include initiation of a sepsis resuscitation bundle as soon as hypoperfusion is recognized. Early detection of sepsis is a cornerstone to successful outcomes; thus the importance of good nursing assessment and prompt reporting of findings is underscored. When a patient is at risk for sepsis, nurses should monitor for slight changes in condition: warm, dry, flushed skin; full, bounding pulse; normal to high blood pressure; and elevated urine output. The temperature may be normal or slightly elevated. Some patients do experience a high temperature with sepsis; however, older adults or others may experience hypothermia when septic.

When sepsis is identified, be vigilant for signs of septic shock. **If hourly urine output begins to decrease, the provider should be notified.** Monitor breath sounds for crackles; check for an

increasing heart rate; and assess for increased fatigue, feelings of anxiety, and changes in mental status. Dependent edema may develop. If shock occurs, the skin will become cool and clammy and the peripheral pulses will be weak and thready. Blood pressure will fall as hypovolemia becomes more pronounced.

Once sepsis is suspected, appropriate treatment begins immediately. This includes fluid resuscitation with crystalloids or colloids to maintain blood pressure and oxygenation; intubation and mechanical ventilation may be required. Blood cultures are obtained, and broad-spectrum antibiotic therapy is started within 1 hour of diagnosis of septic shock. Norepinephrine or epinephrine may be ordered to maintain blood pressure. Dobutamine may be used if the blood pressure and cardiac output do not respond to fluid challenge or vasopressors ([Society of Critical Care Medicine, 2015](#)).

When the immune system initiates the inflammatory response, it also initiates the clotting cascade. The body is responding to an unknown threat and prepares to fight off foreign organisms and/or to stop bleeding, so both systems are activated. In sepsis, the heightened coagulant state of the body leads to multiple small clots forming in the microcirculation, which is known as *disseminated intravascular coagulation (DIC)*. These small clots clog up the circulation to organs. This clotting leads to organ damage throughout the body.

The extensive clotting that occurs throughout the body in DIC uses up most of the clotting factors in the blood. As a result, bleeding occurs easily. Patients may ooze blood from previously dry wounds, from their gums, and around IV catheters and may bruise very easily. The clinical sign most noticeable is bleeding from any break in the skin.

If an event occurs that triggers clotting, normally the process to dissolve the clot is also activated. This allows the clot to stop the bleeding and then be reabsorbed when no longer needed, conserving the clotting factors for reuse. In DIC this process is altered. To restore the normal sequence, anticoagulants are given to stop the clotting factors from being used up. Although it may seem contradictory to give a medication that will prevent clots when the patient is bleeding, the clots that have formed in the small blood vessels are harming the patient by blocking blood flow to vital organs. The clotting factors are being used for clots that are harmful while not being available in the areas they are needed.

❖ Nursing Management

You must be vigilant in identifying patients who are at risk for developing shock. For example, postsurgical patients are always at risk for hemorrhage, which could lead to hypovolemic shock or infection, potentially causing sepsis and septic shock. Maintaining adequate fluid volume and blood pressure are key components in adequately managing shock.

■ Assessment (Data Collection)

Ongoing evaluation of the patient's level of consciousness, vital signs (including temperature), skin signs, and urine output is essential to the recognition and management of shock. Serial assessment data are compared with the previous data and with the baseline assessment. **Watching for changes and trends in physical and laboratory findings is extremely important.** This information must be reported to the provider so she can make treatment decisions. In accordance with National Patient Safety Goals, recognition and response to changes in a patient's condition is particularly applicable to the prognosis of shock. The Joint Commission requires the availability of rapid response teams to help with the assessment and management of patients who are unstable. Early activation of appropriate help can save lives.

■ Nursing Diagnosis, Planning, and Implementation

The primary problem for a patient in shock is altered tissue perfusion. The planning of care for a patient in shock should include measures to monitor and maintain a patent airway, tissue perfusion, body temperature, and skin integrity ([Nursing Care Plan 44-1](#)).

Nursing Care Plan 44-1

Care of a Patient Exhibiting Symptoms of Shock

Scenario

Bob Jones, a 22-year-old, was involved in a motor vehicle accident and sustained an abdominal injury and multiple fractures.

Problem Statement/Nursing Diagnosis

Fluid volume deficit/*Deficient fluid volume related to blood loss.*

Supporting Assessment Data

Objective: BP 90/40, P 150, skin pale and clammy. Patient alert and oriented with complaints of 10/10 pain.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will have adequate BP to maintain vital organ perfusion.	Monitor vital signs, central venous pressure (when used), urine output q 5 min to 1 hr as indicated by patient condition.	Maintain a high index of suspicion for hypovolemia and shock. Early detection and treatment of shock prevents complications.	BP is maintained at greater than 90 mm Hg systolic and urine output is ≥ 30 mL/hr.
	Maintain patent IV sites. Administer fluids as ordered.	Volume replacement is essential and requires adequate access.	IV fluid bolus of 500 mL given. IV fluids infusing at 150 mL/hr via peripheral IV sites in both forearms (total of 300 mL/hr).
	Note quality/strength of peripheral pulses with vital signs.	Weak, thready pulses indicate decreased cardiac output.	Pulses are weak and thready.
	Monitor laboratory and radiography results.	Evaluate patient's response to therapy.	Laboratory and radiograph results are pending.

Problem Statement/Nursing Diagnosis

Potential for altered gas exchange/*Risk for impaired gas exchange related to altered blood flow.*

Supporting Assessment Data

Objective: BP 80/40, blood loss secondary to trauma, respiratory rate 32/min.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
ABGs, pulse oximetry, and respiratory rate will be within patient's normal range.	Maintain patent airway. Elevate head of bed if tolerated by BP and spinal fracture is ruled out.	Enhances lung expansion.	Patient breathing is rapid, but not labored at 32/min. Supine position maintained for BP 90/40.
	Administer oxygen to keep $SaO_2 \geq 95\%$. Monitor pulse oximetry.	Maximizes the oxygen-carrying capacity of the available hemoglobin.	SaO_2 is $\geq 95\%$. Pulse oximetry reading is 99% with patient on nonrebreather mask.
	Auscultate breath sounds q2-4h.	The patient is at risk for ARDS.	Lung sounds clear or changes are identified and reported promptly.
	Investigate alterations in level of consciousness.	Decreased levels of oxygen can cause alterations in sensorium.	No change in level of consciousness. Is alert, talkative, and seems anxious.

Problem Statement/Nursing Diagnosis

Fear of possible death/*Patient/family fear related to presence of a life-threatening situation.*

Supporting Assessment Data

Subjective: Patient states that he is scared and wants to know if he will live.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient/family will express concerns and fears.	Maintain a calm and reassuring presence.	This will reduce anxiety and the patient's oxygen need.	Patient/family is reassured when the nurse is present.
	Explain activities, medications, treatments, and equipment simply and honestly.	Information facilitates cooperation and increases feelings of control.	The patient/family states that all of their questions were answered.
	Demonstrate concern and respect for patient and family.	Extending an attitude of concern makes it easier for patients/families to discuss concerns.	The patient/family discussed concerns with the health care team.

Critical Thinking Questions

- What complications is this patient at risk for developing?
- If this patient were 72 instead of 22 years old, how would that change your care?

ABGs, Arterial blood gases; *ARDS*, acute respiratory distress syndrome; *BP*, blood pressure; *IV*, intravenous; *P*, pulse; SaO_2 , percentage of hemoglobin saturated with oxygen.

The treatment goals for shock are to restore circulating volume and to treat the underlying cause, if possible. In most types of shock, blood pressure responds to administration of IV fluids. The exception to this is cardiogenic shock, in which the pump cannot manage the fluids that are already present and pump support is needed. If an IV is not in place, volume can be redistributed to the

central circulation by laying the patient flat and elevating the legs 10 to 12 inches.

Evaluation

If interventions are effective, there should be improvement in tissue perfusion. This can be evaluated by evaluating blood pressure, urine output, and level of consciousness. These are key indicators of adequacy of blood flow to vital organs. Other indicators to monitor include capillary refill, color and temperature of the skin, and the amplitude of pulses in the extremities. With adequate fluid and medication administration, blood pressure should be maintained above 90 mm Hg systolic. This should provide enough blood flow to the kidneys to generate 20 to 30 mL of urine output per hour. If there are no preexisting neurologic problems, the patient should return to previous level of consciousness.

Get Ready for the NCLEX® Examination!

Key Points

- Good Samaritan laws protect medical personnel from liability when offering emergency medical care for victims of accidental injury.
- Signs and symptoms that usually precede aggression or attack include increasing agitation or resistance, aggressive behavior, pacing, frowning, hyperalertness, increasing demands, or glaring.
- Victims of domestic abuse and violence may be reluctant to voluntarily reveal abuse or identify the abuser.
- Three elements that emergency nurses use for clinical decisions are (1) events or incidents that preceded the emergency visit, (2) mechanism of injury, and (3) index of suspicion.
- **Triage** is the process of setting priorities for treatment.
- Neck or spinal injury is suspected in multiple injuries, falls, or blunt force impact.
- Flail chest occurs when three or more ribs are broken in two or more places; flail chest compromises respirations, because the chest wall is unstable. Treatment includes intubation and mechanical ventilation.
- Symptoms of pneumothorax or hemothorax include labored, shallow respirations; lack of movement on one side of the chest when the person inhales and exhales; and chest pain.
- Penetrating abdominal trauma is frequently associated with gun or knife wounds. Patients with blunt trauma to the abdomen should have serial assessments to identify slow hemorrhage or occult injury.
- Poison control centers need the following information to assist in diagnosis and treatment: patient's age; weight; medical and medication history; allergies; what, when, and why the substance was taken; current signs and symptoms, with vital signs and laboratory results; and any treatment rendered.
- Bite wounds should be cleaned immediately with soap and warm running water for 5 to 10 minutes.
- Chemical burns should be flushed with large amounts of water (with some exceptions) until all traces of the chemical have been removed.
- The American Heart Association guidelines emphasize C-A-B (chest compressions, airway, breathing) and the importance of high-quality CPR and recommend hands-only CPR for the lay rescuer.
- Treatment of shock generally includes infusion of large volumes of IV fluid.
- Blood pressure support in cardiogenic shock involves support for the pump (the heart) rather than adding volume.

Review Questions for the NCLEX® Examination

1. To control a gushing bleed of the lower leg, what should the nurse do initially?

1. Apply direct pressure to the wound.
2. Compress the artery above the wound.
3. Check the circulation to the foot.
4. Snugly secure a bulky dressing.

NCLEX Client Need: Physiological Adaptation

2. In the event of any type of poisoning that occurs in the home setting, what is the initial course of action?
1. Save the poison container and contents.
 2. Save a sample of vomitus for analysis.
 3. Call poison control.
 4. Induce vomiting.

NCLEX Client Need: Safety and Infection Control

3. A teenager—alert, oriented, and in no apparent distress—is brought to the ED by EMS on a backboard with spine immobilization in place. He reports diving into a lake and bumping his head. Based on the mechanism of injury, which assessment is the nurse most likely to initiate?
1. Assessment of water safety behavior
 2. Serial abdominal assessments with hematocrit
 3. Frequent vital signs to monitor for shock
 4. Peripheral motion and sensation with mental status checks

NCLEX Client Need: Reduction of Risk Potential

4. A nurse makes a home visit to a 70-year-old patient on a cold winter day. On her arrival, the patient demonstrates excessive coughing, shortness of breath, drowsiness, and confusion. Mucous membranes are cherry red. What is the nurse's first action?
1. Question the patient about recent food or fluid consumption.
 2. Call for emergency help and open the windows.
 3. Search the house for evidence of poisons and then call poison

control.

4. Locate the source of odors or try to get the patient to walk out of the house.

NCLEX Client Need: Physiological Adaptation

5. The nurse is talking to a community group about strategies to prevent heat-related illness. What advice is appropriate to give to the group? (*Select all that apply.*)

1. Drink fluids that are nonalcoholic, noncaffeinated, and low in sugar content.
2. When you are thirsty, drink fluids and avoid eating salty foods.
3. Stay indoors with cooling systems.
4. In the heat, wear lightweight, light-colored, loose-fitting clothing.
5. Limit outdoor activities to spring or fall when the weather is cooler.
6. Use sun protection such as wide-brimmed hats, sunglasses, and sunscreen.

NCLEX Client Need: Reduction of Risk Potential

6. A 24-year-old man is brought to the ED with respiratory distress after being stung by a bee. Which order from the provider should the nurse anticipate as a priority intervention?

1. Administer racemic epinephrine by inhalation.
2. Establish peripheral IV access.
3. Give 0.03 mg of epinephrine intramuscularly in the lateral thigh.
4. Draw blood for laboratory tests.

NCLEX Client Need: Physiological Adaptation

7. A patient is brought to the ED with severe gastrointestinal bleeding and hypovolemic shock. What is the priority intervention for this patient?

1. Insert a nasogastric tube and attach to low wall suction.

2. Draw a blood sample for a type and crossmatch.
3. Measure the amount of emesis and check for blood.
4. Establish two large-bore peripheral IV sites.

NCLEX Client Need: Coordinated Care

8. When taking care of a patient with sepsis, what is the first sign that would signal impending septic shock?

1. Increasing urine output
2. Decreasing heart rate
3. Decreasing blood pressure
4. Change in mental status

NCLEX Client Need: Physiological Adaptation

9. A patient is 6 hours postoperative with signs of deficient fluid volume. The provider orders a fluid challenge of 200 mL lactated Ringer solution stat over 20 minutes. What would be considered a desirable response to the treatment?

1. Decrease in blood pressure
2. Increase in urinary output
3. Increase in body weight
4. Increase in pulse rate

NCLEX Client Need: Pharmacological Therapies

10. A patient was bitten by a stray dog and rushed to the ED. Which measure must be done first?

1. Apply antibiotic ointment on affected sites.
2. Cover with a clean bandage and immobilize.
3. Rinse wound with soap and warm running water for 5 to 10 minutes.
4. Give tetanus booster shot if patient has not had one in the past 5

years.

NCLEX Client Need: Coordinated Care

Critical Thinking Questions

Scenario A

While watching a sporting event from the stands, you notice the person sitting in front of you has slumped over. You touch her shoulder and ask if she is all right. There is no response and you see no signs of breathing.

1. What is the most likely explanation for this witnessed event of sudden unconsciousness?
2. What should you do first?
3. An AED is on scene. What is your role in use of this equipment?
4. How do "Good Samaritan Laws" affect you and any interventions that you may perform on this woman?

Scenario B

You are on your way home from work and you see a car hit a teenage boy on a bicycle. You stop to help the bicyclist. He is unconscious, has a large scalp laceration that is bleeding profusely, and has an obviously fractured left leg.

1. If you need to open his airway, what method should you use?
2. What should you do about the scalp laceration and broken leg?
3. What is your legal obligation in this setting?

Scenario C

While working as a student nurse in the hospital's emergency unit, you notice that patients who have been injured or are very ill sometimes become hostile and combative. Some try to assault members of the emergency team and others use abusive and threatening language.

1. Discuss with your classmates some reasons why patients may behave in these ways when they are injured or very ill.
2. What are some ways in which violent patients who are not mentally ill can be handled to prevent assault and encourage cooperation with the emergency staff?
3. What resources are available to help manage combative patients?
4. What patient history or information might help to clarify aggressive behavior?

Scenario D

Your 80-year-old male patient, admitted yesterday for pneumonia, has become confused, hypotensive, oliguric, clammy, and pale.

1. What are the possible explanations for his clinical signs and symptoms?
2. What are your priorities for his care?
3. Discuss what treatment is indicated.
4. How will you know if your treatment has been effective?

UNIT XVI

Mental Health Nursing of the Adult

OUTLINE

Chapter 45 Care of Patients With Anxiety, Mood, and Eating Disorders

Chapter 46 Care of Patients With Substance Abuse Disorders

Chapter 47 Care of Patients With Cognitive Disorders

Chapter 48 Care of Patients With Thought and Personality Disorders

CHAPTER 45

Care of Patients With Anxiety, Mood, and Eating Disorders

Objectives

Theory

1. Analyze the significance of anxiety in the general adult population.
2. Compare and contrast normal anxiety with anxiety disorders.
3. Describe the signs and symptoms and treatment for anxiety disorders.
4. Present assessment factors, nursing diagnosis, and nursing interventions for patients with anxiety disorders.
5. Determine the variances of normal mood and discuss mood alterations that become debilitating.
6. Discuss assessment, nursing diagnosis, and nursing interventions for patients with bipolar disorder and major depressive disorder.
7. Summarize factors that are essential when assessing a suicidal patient.
8. Correlate the effects of family, peer, and media pressure on patients with eating disorders.
9. Describe assessment, nursing diagnosis, and nursing interventions for patients with eating disorders.

Clinical Practice

10. Watch the movie *As Good as It Gets* and discuss behaviors that are debilitating for the main character.
11. Implement a teaching plan for a patient with a mood disorder to increase medication compliance.
12. Write at least six interventions for the problem of potential for self-directed violence due to suicidal ideations.

KEY TERMS

affect (ăf-ĕkt, p. 1058)

anorexia nervosa (ăn-ō-RĒK-sē-ă nĕr-VŌ-să, p. 1066)

pressured speech (p. 1057)

psychomotor retardation (sǐ-kō-MŌ-těr rē-tär-DĀ-shǔn, p. 1061)

Anxiety and Anxiety Disorders

Anxiety is considered normal and healthy unless it becomes debilitating and prevents a person from functioning in everyday life. Abnormal or debilitating anxiety is intense and feels life threatening to the individual. One in four people will experience symptoms of an anxiety disorder during his or her lifetime. A genetic association has been concluded after studying families with individuals prone to anxiety. Older adults are at high risk for anxiety disorders because of physical illness; psychosocial stress; depression; cognitive impairment; and personal factors related to female gender, lower education, or substance abuse.

Anxiety is often self-limiting and alleviated without specific medical or nursing intervention. However, intervention may be necessary to prevent potential harm toward self or aggression toward others. Nurses can be instrumental in helping a patient recover from a panic level of anxiety. **Table 45-1** describes the various levels of anxiety and their nursing management, and **Figure 45-1** depicts the relationship among stress, anxiety, and related behaviors. By remaining calm and supportive, the nurse provides a safety net for the patient. Panic-level anxiety is challenging and commonly requires medication. Patients with increased anxiety need teaching about how to prevent further attacks. They need to be taught how to relax and should attempt to determine the underlying cause of their anxiety. Anxiety can recur at a greater level of severity; therefore early intervention is important. Patients with anxiety disorders may have another mental health issue such as major depressive disorder or substance abuse.

Think Critically

Recall a time when you felt very anxious. What were your feelings and behaviors? What strategies did you use to manage your own anxiety?

Table 45-1
Nursing Management for Levels of Anxiety

LEVEL OF ANXIETY	ASSESSMENT	NURSING GOAL	NURSING MANAGEMENT
Mild	Increased alertness, motivation, and attentiveness.	To assist patient to tolerate some anxiety	Help patient identify and describe feelings. Help patient develop the capacity to tolerate mild anxiety, and use it conscientiously and constructively.
Moderate	Perception narrowed, selective inattention, physical discomforts.	To reduce anxiety; long-term goal directed toward helping patient understand cause of anxiety and new ways of controlling it	Provide outlet for tension such as walking, crying, working at simple, concrete tasks. Encourage patient to discuss feelings.
Severe	Behavior becomes automatic; connections between details are not seen; senses are drastically reduced.	To assist in channeling anxiety	Recognize own level of anxiety. Link patient's behavior with feelings. Protect defenses and coping mechanisms. Identify and modify anxiety-provoking situations.
Panic	Overwhelmed; inability to function or communicate; possible bodily harm to self and others; loss of rational thought.	To be supportive and protective	Provide nonstimulating, structured environment. Avoid touching. Stay with patient. Medicate patient with tranquilizers if necessary.

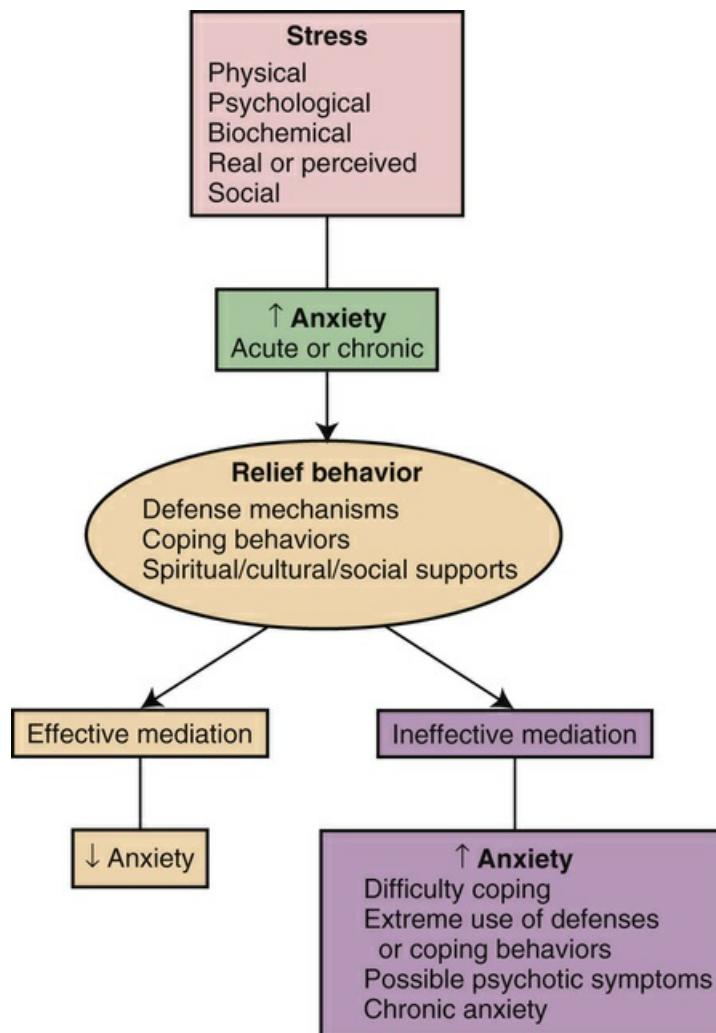

FIGURE 45-1 Stress, anxiety, and behavioral effects.

Generalized Anxiety Disorder

A person who experiences persistent, unrealistic, or excessive worry about two or more life circumstances for 6 months or longer is exhibiting symptoms associated with **generalized anxiety disorder (GAD)**. GAD usually develops slowly and is chronic in nature. As a case study, consider John Evans. John has GAD. He worries about his work performance, despite good evaluations. John worries that his children are not happy, smart, popular, or excelling, and he worries constantly about their future. John worries about paying the bills, and he worries about the well-being of his older adult parents. There are currently no actual problems, yet despite his wife's support and reassurance, John cannot stop worrying. He experiences the signs and symptoms of excessive physiologic response such as tachycardia, restlessness, sweating, fatigue, muscular tension, and shortness of breath. His cognitive symptoms include difficulty with problem solving and poor concentration. John also demonstrates limited coping skills.

Phobic Disorder

A person with a **phobic disorder** experiences excessive fear of a situation or object. This fear can lead to avoidance or extreme anxiety that interferes with normal responsibilities and routines. As another case study, consider Max Payne. Max has a specific type of phobia known as social anxiety disorder. Max is chronically unable to hold a job; he fears scrutiny of his abilities and is afraid of being embarrassed by coworkers or supervisors. Work settings cause him to feel pressured, overwhelmed, and distressed, and he experiences physical symptoms such as trembling, blushing, and nausea. He avoids opportunities by creating a variety of excuses not to pursue them, and this

further lowers his self-esteem. He acknowledges that his fears are unreasonable, but he continues to make excuses to avoid professional challenges or situations of occupational risk-taking.

Obsessive-Compulsive Disorder

When a person has an **obsessive-compulsive disorder (OCD)**, she experiences an **obsession**, recurrent or intrusive thoughts that she cannot stop thinking about, and these thoughts create anxiety. A **compulsive act** is an act that the person feels compelled to perform. For example, a person may experience anxiety and so performs repetitive handwashing in an attempt to reduce that anxiety. Time spent in these thoughts and rituals can become overwhelming to the point of interfering with normal life. Consider the case study of Jane Forman, who is constantly thinking about the boyfriend who left her. Jane does not want to think about him; however, she **ruminates** (repeatedly talks or thinks about the same topic) on their relationship. She scrubs and cleans everything that he might have touched. Jane begins to miss work and stops socializing with friends because she cannot stop cleaning. Her compulsive thoughts have led to obsessive behavior, and Jane has an obsessive-compulsive disorder.

Post-Traumatic Stress Disorder

Post-traumatic stress disorder (PTSD) is characterized by a previous event that involved threatened death or serious injury to self or others during which the individual experienced intense fear, helplessness, or horror. The remembrance of such events produces feelings of intense distress along with anxiety, nightmares, and/or flashbacks that are recurrent. PTSD can occur after any traumatic event that was outside of usual experience. Military combat, detention as a prisoner of war, natural disasters, plane or train accidents, assault, and rape are examples of traumatic experiences that may cause PTSD. Symptoms typically begin within 3 months of the trauma, but a delay of months or years before its onset is not uncommon. Flashbacks are dissociative experiences in which the event is relived. The person acts as if the traumatic event is happening now. There is continued avoidance of any stimuli associated with the trauma, including talking about it or participating in activities that are reminders of the event. People who remind the individual of the trauma are avoided. The person with PTSD may have difficulty sleeping, be very irritable, have difficulty concentrating, and be hypervigilant. Difficulty with relationships of all kinds usually accompanies PTSD, and trust is difficult to establish. The person usually feels detached from others. Chemical abuse may occur in an effort to relieve anxiety.

Cultural Considerations

Post-Traumatic Stress Disorder and Military Personnel

Many veterans who served in combat zones develop PTSD, particularly those who were injured, were present when comrades were killed or seriously injured, or were involved in fighting where many civilians were killed. In studies of war veterans, there was a greater risk for PTSD among those who were young, female, Hispanic, or African American, and for those who had more combat exposure or were injured ([National Center for PTSD, 2014](#)).

Consider Holly Harris, who was a rape victim 2 months ago. Holly frequently relives the traumatic experience in her mind, although she tries to avoid thinking or talking about what happened. She feels detached from others and disinterested in her normal activities. She fears she may not ever be able to have loving feelings toward a man and feels bleak about the future in general. She is irritable and has difficulty sleeping and concentrating. She is hypervigilant, yet she startles very easily.

Cultural Considerations

Post-Traumatic Stress Disorder and Immigrant Patients

Patients who have emigrated from war-torn countries such as Vietnam, Iraq, or Afghanistan are at

risk for PTSD. Language differences and a reluctance to seek professional help for psychiatric problems are barriers to care.

The following websites provide screening tools for PTSD and other resources to help veterans with PTSD:

- www.ptsd.va.gov/professional/assessment/overview/index.asp
- www.maketheconnection.net
- www.ptsd.va.gov/public/treatment/therapy-med/va-ptsd-treatment-programs.asp
- www.realwarriors.net/veterans/treatment/ptsdtreatment.php

Desensitization; support groups; exercise regimens; and medications such as sleep aids, antidepressants, and anxiolytics can be very helpful. There are several websites for civilians to find help, such as Bridge to Recovery and the National Center for PTSD.

A relatively new short-term therapy for PTSD is eye movement desensitization and reprocessing (EMDR). While the patient thinks about the distressing event, she shifts her gaze from one side to the other. As unpleasant feelings are uncovered, the therapist redirects the eye movements using EMDR, and this helps the patient to release the emotions. In another new therapy for PTSD, the patient wears a headset and is exposed to a virtual reality environment. The clinician controls what the patient hears, sees, and smells, and the patient learns to tolerate anxiety (National Center for PTSD, 2014).

Diagnosis of Anxiety Disorders

To help clinicians define and diagnose behavioral disorders more consistently, the American Psychiatric Association publishes a regularly updated manual that establishes guidelines for how diagnoses are made. The *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition, text revision (DSM-5) provides a set of diagnostic criteria (specific behaviors) and a specific time frame for each mental health disorder. For example, a patient might feel mildly anxious for 1 or 2 days before surgery, but mild anxiety for a short period before such an event would be considered normal; therefore that patient would not meet the criteria for any of the anxiety disorders. In contrast, a person such as John Evans (described previously) is **dysfunctional** because of **continuous worry for at least 6 months** and his behavior would meet the criteria for GAD. PTSD was moved into the chapter on Trauma- and Stressor-Related Disorders in the DSM-5.

Treatment of Anxiety Disorders

People with anxiety disorders can be treated with supportive therapy and **anxiolytic** (antianxiety) medications. Supportive therapies include individual therapy, education about relaxation techniques, and stress management. Patients who are anxious need much reassurance, and a nurse who is nonjudgmental will be a good listener. Evidence-based practice indicates that for older adults with GAD, cognitive-behavioral therapy (CBT) is the first-line psychotherapy (Box 45-1).

Clinical Cues

Your patient may need referral to a stress management class; however, there are a few basic suggestions that you can make to help your patient cope with stress. These suggestions include talking to a friend, listening to music, taking a warm bath or shower, doing a large-muscle activity such as walking or throwing ice cubes against the back fence.

Box 45-1

Advanced Practice Psychotherapeutic Interventions

- *Psychodynamic therapy*: Therapist helps the patient to link a past event to current feelings. This insight is believed to help patients modify feelings and behavior.
- *Cognitive-behavioral therapy*: Therapist helps the patient to identify unhealthy thoughts or undesirable responses that occur because of a situation or event, and then the patient is assisted to change ways of thinking about an event and therefore to change emotional response and

behavior.

- *Motivational interviewing:* Therapist enhances motivation for change by matching the patient's ability to problem solve with specific strategies. Principles include expressing empathy, developing discrepancy, supporting self-efficacy, and working with resistance.
- *Interpersonal therapy:* Therapist helps the patient to identify the problem, then selects a strategy to address the problem. The goal is to eliminate symptoms by improving social relationships.
- *Group therapy:* Therapist leads group sessions of 5 to 10 patients who have similar needs or problems. Patients share feelings, thoughts, ideas, and experiences; they realize, "I am not alone in my experience."
- *Behavioral therapy:* Therapist assists the patient to change behavior by using rewards, punishment, repetition, imitation, or exposure to stimuli—but understanding of the underlying cause is not essential. There are four types of behavioral therapy: modeling, operant conditioning, systematic desensitization, and aversion therapy.

Benzodiazepines are commonly prescribed for anxiety disorders. Drugs from this category are alprazolam (Xanax), chlordiazepoxide (Librium), oxazepam (Serax), lorazepam (Ativan), and diazepam (Valium). Patients taking these drugs must be advised to use medications with caution because **tolerance** (the need for an increased dosage to achieve the desired effect) and physical and psychological dependency can occur.

Safety Alert

Sensitivity to Benzodiazepines

Older adults are very sensitive to benzodiazepines, and use is generally restricted during alcohol or sedative withdrawal. Ativan and Xanax can cause confusion, oversedation, or disinhibition (Lyons et al, 2009).

Buspirone (BuSpar), in a class by itself, takes 3 to 4 weeks to reach therapeutic efficacy. The advantage of BuSpar is less sedation with a decreased risk of dependency. Another class of drugs, the selective serotonin reuptake inhibitors (SSRIs), are becoming first-line drugs for anxiety because they have fewer adverse effects. Examples from the SSRI category include citalopram (Celexa) and sertraline (Zoloft). **Table 45-2** presents a list of common medications used to treat anxiety.

Safety Alert

Even short-term use of SSRIs tends to pose a significant risk for upper gastrointestinal (GI) bleeding. Observe for signs of such bleeding and check other medications the patient is receiving for similar risk.

 **Table 45-2**

Drugs Commonly Used to Treat Anxiety

CLASSIFICATION	ACTION	NURSING IMPLICATIONS	PATIENT EDUCATION
Benzodiazepines			
Alprazolam (Xanax)	Has depressant action on the CNS and inhibits stimulation of the brain	Watch for signs of orthostatic hypotension.	Warn to not take any other CNS depressants, including alcohol.
Chlordiazepoxide (Librium)	Used for anxiety disorders and insomnia	Watch for side effects: drowsiness, confusion, palpitations, dry mouth, nausea and vomiting, and occasional nightmares. Older adults have significantly increased risk for falls.	Potentially addictive; use only as prescribed. Can cause drowsiness and lethargy. Advise not to stop taking these medications abruptly.
Diazepam (Valium)	Depresses the CNS		
Lorazepam (Ativan)			
Oxazepam (Serax)			
Clorazepate (Tranxene)			
Nonbenzodiazepines			
Buspirone (BuSpar)	Interacts with serotonin receptors Used for anxiety and sleep disorders	Always a scheduled medication, never PRN. May cause headaches, dizziness, or drowsiness, but much less so compared with the benzodiazepines.	Takes 7-10 days for symptoms to subside and several weeks for optimal results. No evidence of tolerance or physical dependence. Advise not to stop taking this medication abruptly.
Dual-Action Reuptake Inhibitors (Serotonin and Norepinephrine) (SNRIs)			
Duloxetine	Increases activity of	Most common side effects are nausea, dry mouth, sleepiness, and	Advise that driving or operating machinery could be

(Cymbalta) approved for GAD	serotonin and norepinephrine	constipation.	dangerous initially.
Venlafaxine (Effexor)	Inhibits reuptake of serotonin and norepinephrine	Side effects include nausea, drowsiness, headache, dry mouth, constipation, anorexia.	Teach to take with food and not to stop drug abruptly. Advise to avoid tasks requiring motor skills and alertness until response to drug is known.
SSRIs (see Table 45-4)			

CNS, Central nervous system; GAD, generalized anxiety disorder; PRN, as needed; SSRIs, selective serotonin reuptake inhibitors.

❖ Nursing Management

■ Assessment (Data Collection)

Anxiety-prone patients should be assessed for subjective feelings of fear, apprehension, isolation, or the need for increased space. The patient's ability to concentrate and make rational judgments should be assessed and the sources of preoccupation and worries explored. Physical symptoms may include trembling, feeling shaky, increased muscle tension, muscle soreness, easy fatigability, and restlessness. Patients may be hypervigilant, have difficulty sleeping, and be very irritable. In addition, an autonomic nervous system response can cause an increase in blood pressure, dyspnea, palpitations, dry mouth, dizziness, and nausea.

▣ Cultural Considerations

Hispanic and Latino Patients

A Hispanic or Latino patient may have a cultural belief that an emotional trauma will result in a fright sickness called *susto*. Symptoms of *susto* include crying, insomnia, restlessness, nightmares, diarrhea, and fever. Treatment is brushing the body with a rough object. The patient might also believe in *brujeria*, which is a magical or supernatural illness. Symptoms include paranoia, delusions, hallucinations, and being controlled by others. The patient may reject the provider in favor of a *brujo* (witch) for reversal of the spell or hex.

Evidence-based guidelines suggest that screening tools can be used by **any** health care worker if an older adult is showing signs of an anxiety disorder. These assessment tools include the Mini-Mental State Examination, Geriatric Anxiety Inventory, Short Anxiety Screening Test, Hospital Anxiety and Depression Scale, and Rating Anxiety in Dementia Scale ([Smith and Brighton, 2009](#)). After initial screening, the provider is notified to determine the diagnosis. 

▣ Clinical Cues

When a short-acting anxiolytic is prescribed, observe the patient for signs of anxiety, such as pacing, restlessness, and facial expressions of fear or concern. Assess for feelings of apprehension and the patient's ability to concentrate. For example, "Mrs. Smith, you seem a little restless. Let's sit for a while and you can tell me what is going on." If therapeutic communication is not successful, and the patient shows progressively escalating signs of hostility, trembling, agitation, irritability, or inability to relax and converse, it would be appropriate to offer the medication.

▣ Older Adult Care Points

Older adults often have strong spiritual beliefs that assist in coping with stress and illness. Friendships, social contacts, and activities associated with religious organizations also play a large part in positive mental health. Evidence suggests that older adults will benefit from tactful assessment and individualized interventions that incorporate personal spiritual beliefs ([Ehrlich, 2011](#)). 

■ Nursing Diagnosis

Problem statements for anxiety include:

- Anxiety due to threat to self-concept
- Fear due to environmental threat
- Potential social isolation due to extreme anxiety in social situations

- Altered ability to cope due to panic attack
 - Altered role performance due to inability to carry out work responsibilities
 - Powerlessness due to inability to cope when facing a specific phobic object (e.g., a spider)
 - Grief due to multiple loss of colleagues (i.e., war trauma)
 - Post-trauma distress due to an overwhelming life-threatening event (e.g., rape)
- Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

■ Planning

Expected outcomes are written for each problem. For the problems mentioned, expected outcomes might include:

- Patient will demonstrate decreased symptoms of anxiety (e.g., pacing, crying) within 3 days.
- Patient will verbalize feelings of safety before discharge.
- Patient will attend group meeting today accompanied by primary nurse.
- Patient will practice three coping strategies to use during a panic attack before discharge.
- Patient will identify three tasks at which she excels at work, during this shift.
- Patient will verbalize increased feelings of control when encountering phobic object within 1 month.
- Patient will express grief and loss related to multiple losses before discharge.
- Patient will experience fewer nightmares related to traumatic event within 3 months.

Planning care for a patient with an anxiety disorder involves promoting a physically and psychologically safe environment⁸. For example, a quiet, clean, and noncluttered environment and verbal reassurance should be provided ("Mrs. Smith, you are safe here. The staff is here to help you."). Methods to reduce the symptoms of anxiety include therapeutic communication, such as active listening, being physically present, offering emotional reassurance, giving clear and concise instructions, and using pharmacologic methods.

■ Complementary and Alternative Therapies

Essential Oils

Essential oils that have a calming and soothing effect include basil, bergamot, chamomile, jasmine, rose, and lavender. These oils can be used in an aromatic bath or as massage oil.

■ Complementary and Alternative Therapies

Reduce Stress to Decrease Anxiety

Research has demonstrated that massage reduces cortisol levels with "stress alleviating" effects and increases serotonin and dopamine with "activating" effects. Yoga, exercise, and amino acid therapy also can potentially reduce stress, anxiety, and depression (Smith and Segal, 2014).

■ Nutrition Considerations

Promoting Relaxation

Advise your patient that stimulants such as coffee and colas should be avoided to help decrease anxiety and nervousness. Consumption of raw nuts and seeds, whole grains, and fresh fruits and vegetables helps to build the body's reserve and strength. Bananas, rice, milk, turkey, and pasta contain tryptophan, which helps to induce relaxation.

As the acute anxiety passes, the focus of care is to help the patient recognize that certain behaviors (such as avoidance) are being overused. The patient is then assisted to develop new methods of coping and to resume participation in family, social, and occupational roles.

Older Adult Care Points

Older adults often express somatic complaints rather than openly verbalizing emotional distress. You may observe an anxious older adult complaining of an upset stomach, inability to sleep, fatigue, or increased need to urinate. Medications (e.g., levothyroxine [Synthroid], theophylline [Slo-Phyllin]) that the older adult is taking may increase feelings of anxiety. Certain medical conditions, such as problems with the thyroid gland, problems with the cardiac system, and altered blood sugar, can also mimic anxiety disorders.

Implementation

When intervening with a patient who is experiencing extreme levels of anxiety, you must maintain a calm and reassuring attitude. You should stay with the patient and attend to physical needs as necessary. The stimulation in the immediate surrounding environment should be decreased, such as dimming the lights, turning off the television or radio, and limiting the number of people in the area. Be sure to use clear, simple statements and repeat them as necessary. When extreme levels of anxiety resolve, additional interventions are used to help the patient learn to control her anxiety (see [Table 45-1](#)).

Clinical Cues

Anxiety is contagious and can spread rapidly from person to person until the entire group is affected; likewise, nurses are not immune to these feelings. Fortunately, you can use therapeutic communication skills to help the patient de-escalate. Use a calm voice and a relaxed body position, and convey confidence in your own ability to maintain control of your own anxiety. Self-control by the nurse helps the patient to mimic calm behavior and control her anxiety.

When the anxiety is under control, you can assist in helping the patient to use problem-solving strategies. The long process of determining root causes of the anxiety can take years of therapy, but you can make referrals as needed and provide support.

Evaluation

Ongoing evaluation of patients with anxiety is necessary. Evaluation includes the status of the patient before discharge from the hospital, clinic, or emergency department. You must carefully document that outcome criteria were met and symptoms were relieved. **If symptoms are not totally resolved, you should clearly document that the patient's level of anxiety is not a threat to self or others at the time of discharge.** Also include a plan for follow-up care and a plan to obtain emergency care if needed.

Mood Disorders

The incidence of mood disorders is very high. Unfortunately, these disorders are often inaccurately diagnosed and treated. **Dysthymia** refers to a disturbance in mood that may manifest in either depression or elation (**mania**). An individual experiencing clinical depression is more than just sad. Depressed or dysthymic individuals feel a sense of hopelessness and despair that cannot be alleviated by usual means. This hopelessness can lead to thoughts of suicide.

Mania is an elevation in mood that includes increased grandiosity or irritability that is present for at least 1 week. A manic person may exhibit **pressured speech**, which is talking that is loud and rapid and difficult to interrupt; or **flight of ideas**, in which the speaker goes from topic to topic with little or no connection. There is an inability to concentrate; a decreased need for sleep or nutrients; and an increase in goal-directed activity, impulsive spending, and hypersexuality. Unstable and frequently changing, or **labile**, behavior is often seen in manic patients; a mood of frivolity and joking can rapidly change to agitation and extreme paranoia. **The agitation and irritability seen in manic patients can lead to aggressive behavior.** Manic individuals may require hospitalization for an inability to eat or sleep for days that leads to complete physical and mental exhaustion and aggressive behavior. Sometimes individuals will rapidly switch from being extremely depressed to being euphoric and manic. This condition is called *bipolar disorder* and occurs equally in men and women. It commonly is initially diagnosed in young adults, but it may be diagnosed at any time during the life span.

Bipolar Disorder

Bipolar disorder is suspected when a patient experiences episodes of extreme sadness, hopelessness, and helplessness interspersed with periods of extreme elation and hyperactivity. According to the DSM-5, four types of bipolar disorder are recognized. Bipolar I disorder is characterized by episodes of major depression with at least one episode of manic or hypomanic behavior. Bipolar II disorder is characterized by one or more depressive episodes with at least one episode of hypomania. Patients with cyclothymia exhibit hypomanic episodes alternating with minor depressive episodes. Bipolar disorder unspecified designates disorders with bipolar features that do not meet the criteria for the other specified disorders. **Hypomania** is a hyperinflated or irritable mood for at least 4 days. Patients may display loud, rapid speech and flight of ideas, decreased need for sleep, distractibility, and an increase in goal-directed activity, but hospitalization is not indicated because it does not involve psychotic behavior.

Treatment

Mood stabilizers are the mainstay of treatment. Lithium carbonate was the drug of choice used to stabilize manic behavior for decades. Lithium has a narrow therapeutic range, so serum lithium levels must be determined 8 to 12 hours after the first dose, then two or three times per week for the first month, and then weekly to monthly. See [Table 45-3](#) for nursing implications for patients taking lithium. Because it may take 2 to 3 weeks for lithium to become effective, currently, anticonvulsant drugs such as divalproex sodium (Depakote) and carbamazepine (Tegretol) are used in the treatment of mania along with quetiapine (Seroquel), an atypical antipsychotic, and BusPar or another antianxiety drug are also used. Lamotrigine (Lamictal) is effective for the depressive episodes. The Food and Drug Administration (FDA) has approved risperidone (Risperdal), aripiprazole (Abilify), and ziprasidone HCl (Geodon) for treatment of bipolar disorder. All of these can be used safely in combination with lithium. In addition to stabilizing the patient with medication, it is sometimes necessary to hospitalize patients with manic symptoms, particularly if they are a danger to themselves or others or are suffering from exhaustion caused by extreme hyperactivity. Two thirds of bipolar patients respond to the rapid antidepressive effects of a small dose of ketamine (Ketalar). A simple blood test can determine whether the drug will be effective ([Grohol, 2014](#)).

Table 45-3

Nursing Implications for Patients Taking Lithium

CLASSIFICATION	ACTION	NURSING IMPLICATIONS	PATIENT TEACHING
Antif manic	Alters the release, synthesis, and reuptake of neurotransmitters in the brain (i.e., dopamine, norepinephrine, serotonin) Does not cure bipolar disorder, but helps to decrease the manic behavior.	Takes 7-14 days to reach therapeutic level (1.0-1.5 mEq/L). Blood levels should be drawn 8-12 hr after the first dose, then two or three times per week for the first month and then weekly to monthly until a maintenance level is reached. Sodium depletion or dehydration could cause toxicity; therefore monitor fluid intake and dietary sodium. Diuretics should be avoided. Monitor renal and thyroid function periodically.	Encourage normal salt intake. Teach to drink 2500-3000 mL of fluids per day. Advise to take with meals to decrease gastric distress and to avoid caffeinated drinks because of diuretic effects. Instruct to immediately report diarrhea, vomiting, tremors, or lack of coordination.

❖Nursing Management

■ Assessment (Data Collection)

Assessing for mood disorders involves observing for mood, affect, and physical signs and symptoms. Mood is assessed by asking the patient questions about feelings and observing facial expressions and verbalizations. **Affect** is a term used to describe a person's external expression of emotion. A person with a flat or blunted affect may report feeling fine, but her facial expression and overall demeanor convey sadness. The sadness described by depressed individuals is intense and creates feelings of worthlessness and hopelessness. Conversely, the mood of a manic patient is one of grandiosity and general well-being. In the midst of a manic episode, the patient may feel invincible and recklessly engage in extremely dangerous behavior.

Many physical signs and symptoms are classic for mood disorders. An initial question concerns sleep. A depressed patient may report sleeping all of the time (**hypersomnia**) or falling asleep easily but then waking up after 2 to 3 hours and being unable to get back to sleep (**insomnia**). Manic patients are unable to sleep, and it is not unusual for them to report that they have not slept for days.

■ Nursing Diagnosis

Typical problem statements for mania may include:

- Altered nutrition due to shortened attention span while trying to eat and weight loss
- Potential for violence toward self or others due to labile emotional state
- Disrupted sleep pattern due to hyperactivity
- Altered communication ability due to flight of ideas and pressured speech
- Altered role performance due to inability to perform child care duties
- Absence of compliance due to refusal to take medications during manic phase

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

■ Planning

For these problems, expected outcomes include:

- Patient will consume at least 1500 calories during a 24-hour period.
- Patient will refrain from hurting self or others during this shift.
- Patient will sleep and rest at least 6 hours within a 24-hour period.
- Patient will demonstrate a decrease in pressured speech and flight of ideas before discharge.
- Patient and family will identify and use substitutes and resources for child care until the patient is able to resume family responsibilities.
- Patient will identify two methods of ensuring medication compliance before discharge.

Planning care for a patient with mania involves intervention to promote safety, adequate nutrition, and sleep. Patients in a manic state can be a source of danger to others on the unit. Manic patients can quickly escalate in behavior from good-natured humor into active aggression. It is often necessary to assign a nurse or nursing assistant to stay with the patient until the medications have reduced agitation and hyperactivity.

■ Assignment Considerations

Hygienic Care of Manic Patients

On a medical-surgical unit, the nursing assistants (NAs) are likely to assist patients with hygienic needs in the morning. When caring for a manic patient, inform the NA that the patient may have a

shortened attention span and a tendency to be argumentative; therefore the hygienic care may have to be accomplished in small steps over the course of the day, for example, washing hands and face on waking, brushing teeth after breakfast, combing hair midmorning, and taking a shower in the afternoon.

■ Implementation

Nursing interventions for a manic patient include keeping the patient safe, providing a high calorie intake, administering mood stabilizer medications, and providing for a restful sleep. Manic patients may come into the hospital malnourished. Small, frequent, high-calorie meals and finger foods are typically necessary, because the manic patient will not sit down long enough to eat. Close observation and documentation of mood, verbalizations, and behavior are very important. It may be necessary to place a manic patient in a quiet area away from others to decrease environmental stimulation.

When communicating with a manic patient, it is essential to maintain a calm demeanor. **Until the medications are effective, therapeutic communication consists of setting limits.** When setting limits, it is necessary to clearly state the initial expectations of the patient's behavior. For example, you might say, "Mr. Smith, I am talking to Ms. Jones right now, so please stop interrupting us and wait for me in the dayroom. I will be with you as soon as we are finished." The consequences for noncompliance should be stated with the request; consistent follow-through on consequences is essential. "If you interrupt us one more time, I will not help you with your project today and you will have to wait until tomorrow." To avoid being manipulated by the patient, it is important that all staff members be consistent. Sometimes, because of the severity of the mania, the manic patient is unable to comply with simple requests. In these instances, it is necessary to distract or redirect the patient rather than attempt to use reason.

When the patient is stabilized, providing her with information about medications and the rationale for their long-term use is important to increase medication compliance. Compliance is important because it is not unusual for the patient to stop taking medications once the manic symptoms subside ([Nursing Care Plan 45-1](#)).

✳ Nursing Care Plan 45-1

Care of a Patient With Bipolar Disorder (Manic Phase)

Scenario

Bobby Holmes, 25 years old, is diagnosed with bipolar disorder. He is currently euphoric, grandiose, loud, and very talkative. Although he can be charming, he is currently argumentative and intrusive and is verbally aggressive toward other patients. He states, "I'm going to get in your face whenever I feel like it!" He is continuously walking around the unit and has trouble sitting still for meals or conversation. He states, "I haven't slept well or eaten much for the past 3 days."

Problem Statement/Nursing Diagnosis

Potential for violence/*Risk for other-directed violence related to manic state.*

Supporting Assessment Data

Subjective: "I'm going to get in your face whenever I feel like it!"

Objective: Argumentative, intrusive, and verbally aggressive toward others.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient and others on unit will remain free from harm during this shift.	Observe patient's behavior frequently (q15min).	Changes in behavior can signal impending violence toward self or others.	Patient pacing and talking loudly; checked q15min × 3.
	Redirect or distract patient (e.g., walk outside, make bed, talk to nurse).	Helps control impulses and channel excess energy.	Patient easily redirected with verbal suggestions; likes to talk to nursing staff and mental health assistant.
	Move patient away from others as necessary.	Agitated and aggressive behavior is contagious and will escalate in proximity to others.	Patient was verbally directed to go to room. Patient was observed for 1 hr on a 1:1 basis by mental health assistant.
	Administer tranquilizing medications as prescribed and monitor effectiveness.	Chemical restraints may be necessary if patient cannot control his behavior.	Administered PO lorazepam. Patient continues to be hypervigilant and loud, but able to sit for 5-6 min without pacing, 45 min after given lorazepam. Patient and others remain free from harm. Outcome met. Continue plan.

Problem Statement/Nursing Diagnosis

Altered nutrition/*Imbalanced nutrition: less than body requirements, related to inability to sit long enough to eat.*

Supporting Assessment Data

Subjective: "I haven't ... eaten much for the past 3 days."

Objective: Patient observed continuously moving and not eating meals.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will assume regular eating habits within 1 wk.	Weigh daily. Record food intake and calculate calorie counts.	To monitor nutritional status. To determine whether nutritional intake is adequate.	Patient's current weight is 160 lb (normal weight is 170 lb). Patient ate sandwich (300 calories) and glass of milk (120 calories).
Determine food likes and dislikes.	Increases likelihood that he will eat if given favorite food. Offer small, frequent, high-calorie meals and finger foods.	Patient will eat any type of food, but needs constant reminders to finish food.	Patient will eat any type of food, but needs constant reminders to finish food.
	Stay with patient during meals.	Patient will eat any type of food, but needs constant reminders to finish food.	Patient was offered eggs, toast, bacon, and orange juice for breakfast. Patient was able to eat bacon, orange juice, and toast "on the run" but refused eggs.
	Administer vitamin and mineral supplements.	Provides support and encouragement to eat as much as possible. To replace any dietary deficiencies.	Patient able to eat meals, but requires less coaching if given PRN lorazepam 30 min before meals. Patient agrees to take supplements for duration of hospitalization. Patient eating three meals per day, but requires monitoring and lorazepam. Outcome partially met. Continue plan.

Problem Statement/Nursing Diagnosis

Disrupted sleep pattern/*Sleep deprivation related to manic activity.*

Supporting Assessment Data

Subjective: "I haven't slept well ... for the past 3 days."

Objective: Observed continuously walking.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will return to his normal patterns of rest and sleep within 3 days.	Provide a quiet environment with low stimuli.	Quiet environment is conducive to rest and sleep.	Patient placed in private room; however, quiet environment was not helpful last night.
	Monitor and record sleeping patterns.	To determine whether rest is adequate and normal pattern is resuming.	Patient slept 2 hr last night and 6 hr after lunch.
	Before bedtime provide comfort measures such as back rub, warm bath, and relaxing music.	Teaches habits that signal bedtime and helps with relaxation.	Patient having difficulty with sleeping; warm milk offered. Suggested resting in bed even if not sleepy, but patient continued to be restless, rising frequently to come to nurses' station last night.
	Prohibit intake of caffeine-containing foods in the evening hours.	CNS stimulants can cause restlessness.	Patient agrees to stop drinking coffee for duration of hospitalization, "but it won't make any difference."
	Administer sedative medications as prescribed.	Potentiates sedation at the biochemical level.	Temazepam (Restoril) offered for sleep, but refused. Patient is sleeping 2-3 hr at night, but has not been able to reestablish normal cycle. Outcome partially met. Continue plan.

CNS, Central nervous system; PO, oral.

Critical Thinking Questions

- How will you respond to Bobby's intrusiveness and constant need for attention?
- Why is Bobby at risk for injury to himself if he is not hospitalized during the manic phase?

See Evolve for Nursing Care Plans for patients with anxiety, depression, and anorexia nervosa.

■ Evaluation

Ongoing evaluation of patients with bipolar disorder is necessary. You must determine whether the outcome criteria for the patient's physical needs—such as safety, nutrition, and rest—were met. In addition, are the symptoms resolving? Is the patient able to communicate effectively and resume social and occupational roles? Do both the patient and the family have a plan to maintain medication and follow-up appointments?

Major Depressive Disorder

Major depressive disorder is diagnosed when at least five symptoms characteristic of depression have been present for at least 2 weeks. These symptoms include an overwhelming feeling of sadness, inability to feel pleasure or experience interest in daily activities, weight gain or loss not attributed to dieting, sleep disturbances, fatigue or loss of energy, feelings of worthlessness, difficulty in making decisions or concentrating, and suicidal thoughts. Depressed patients may have **psychomotor retardation** in which speech, movements, and thought processes are slowed. However, it is not uncommon to see agitation and irritability in a depressed person. These symptoms may be **subjective** (described by the patient) or **objective** (observable by others).

Clinical Cue

The Centers for Disease Control and Prevention (CDC) reported that there were 41,149 suicides in 2013. That is more than the number of deaths from motor vehicle accidents. The suicide rate for those aged 35 to 64 years increased 28.4% since 1999 ([Centers for Disease Control, 2013](#)).

Before making a diagnosis of depression, the provider must be certain that there are no medical conditions present that could mimic depression, such as hypothyroidism or chronic fatigue syndrome. In addition, a patient who has suffered a stroke or myocardial infarction, has cancer, or is newly diagnosed with a chronic disease such as diabetes needs to be screened for depression, because major illness can lead to depression. Moreover, a pharmacologic type of depression may be induced by many medications, including antihypertensives, sedatives, anxiolytics, antipsychotics, steroids, and hormones. In addition, substance abuse—especially of alcohol—often produces symptoms that mimic those of depression. In other cases, consuming large amounts of alcohol will actually cause a person to feel depressed because alcohol is a central nervous system depressant. A diagnosis of alcohol dependence needs to be considered. When a person has an emotional problem such as depression and abuses a substance such as alcohol, she has a **dual diagnosis**. See [Chapter 46](#) for more on substance abuse.

Think Critically

How would you differentiate symptoms of depression and hypersomnia from the medication side effects of drowsiness or sedation?

There is increasing evidence that major depressive disorder is caused by a biochemical imbalance. However, most scientists agree that the majority of chronic illnesses result from a combination of heredity and environment. What is not understood is how these elements interact to precipitate an episode of major mental illness. Whereas the signs and symptoms of mild depression usually subside, research findings indicate that an attack of major depression is very likely to recur with even greater severity; therefore, regardless of the cause, symptoms of depression need to be addressed and not ignored.

Older Adult Care Points

Although older adults have many risk factors for depression (such as loss of friends and body changes) that increase with age, symptoms of major depression are not a normal part of the aging process. Research shows that most older adults are not depressed most of the time. Older adults want to enjoy good mental health, but cost and access to mental health services are barriers.

Treatment

Patients who are depressed respond best to a combination of antidepressant medication and psychotherapy.

Complementary and Alternative Therapies

St. John's Wort

Herbal remedies such as St. John's wort have been used for mild to moderate depression and anxiety; however, patients should be advised that taking monoamine oxidase inhibitors (MAOIs) or SSRIs with St. John's wort can cause adverse drug-herb interactions. Many medications can interact with St. John's wort.

Complementary and Alternative Therapies

Music Therapy for Depression

Evidence-based practice suggests that people with major depression are receptive to music therapy and show improvement in mood ([Maratos et al, 2008](#)). 

Hospitalization may be necessary if the patient has a high potential for suicide. Since the 1960s, medications have made a great difference in the lives of people who are depressed. The first-line medications used to treat depression are tricyclic antidepressants (TCAs), SSRIs, and selective norepinephrine reuptake inhibitors (SNRIs), as well as atypical antidepressants. Second-line drugs are MAOIs. Drugs are very effective in treating depressive symptoms; however, they can cause some serious side effects ([Table 45-4](#)). There is a risk of GI bleeding when taking an SSRI for even a brief period.

 **Table 45-4**

Drugs Commonly Used to Treat Depression

CLASSIFICATION	ACTION	NURSING IMPLICATIONS	PATIENT TEACHING
Tricyclics			
Amitriptyline (Elavil) Clomipramine (Anafranil) Imipramine (Tofranil) Maprotiline (Ludiomil) Nortriptyline (Pamelor) Desipramine (Norpramin) Doxepin (Sinequan) Protriptyline (Vivactil) Trimipramine (Surmontil) Amoxapine (Asendin)	Inhibit the reuptake of neurotransmitters (serotonin and norepinephrine). Used to treat depression.	Watch for side effects: dry mouth, blurred vision, tachycardia, cardiac dysrhythmias, postural hypotension, constipation, urinary retention, and esophageal reflux. Usually taken at bedtime. Monitor patient for suicidal ideation. An overdose of these medications could be fatal.	Mood elevation may take 7–28 days. Full recovery from major depression may take 6–8 wk. Instruct to avoid alcohol and working around machines and heavy equipment. Drowsiness, dizziness, and hypotension will subside after the first few weeks. Warn not to stop taking these medications abruptly.
MAO Inhibitors (MAOIs)			
Isocarboxazid (Marplan) Phenelzine (Nardil) Tranylcypromine (Parnate) Selegiline (Eldepryl)	Inhibits the MAO enzyme, thereby preventing the breakdown of dopamine, norepinephrine, and serotonin.	Common side effects: weight gain, postural hypotension, edema, change in cardiac rate and rhythm, urinary retention, constipation, insomnia, weakness, and fatigue. Monitor blood pressure very closely during the first few weeks of treatment. Take a medication history to identify use of medications that increase the heart rate, such as ephedrine, stimulants, alcohol, narcotics, TCAs, or antihypertensives; report findings to provider or RN.	Instruct to avoid foods high in tyramine, such as aged cheeses; red wine, sherry, and beer; pickled or smoked fish; fermented meats; and artificial sweeteners, because drug-food interactions can cause a life-threatening hypertensive crisis. If the medication is discontinued for any reason, dietary restrictions should continue for at least 14 days. Advise to go to the ED immediately for headaches.
Selective Serotonin Reuptake Inhibitors (SSRIs)			
Citalopram (Celexa) Escitalopram (Lexapro) Fluoxetine (Prozac) Paroxetine (Paxil) Sertraline (Zoloft) Fluvoxamine (Luvox)	Block the reuptake of serotonin. Used for depression, anxiety disorders, and bulimia.	These medications elevate mood faster than the TCAs or MAOIs. They are not as sedating and do not have the anticholinergic side effects of TCAs or MAOIs. Common side effects include nausea, nervousness, insomnia, anxiety, and sexual dysfunction.	Take with food if GI distress occurs. Take drug in the morning for optimal effects. Full therapeutic effects may take up to 4 wk. Decreased libido or impotence may occur; check with provider rather than stopping medications abruptly.
Atypical Antidepressants			
Trazodone (Desyrel, Oleptro) Bupropion (Wellbutrin) Nefazodone (Serzone) Mirtazapine (Remeron) Venlafaxine (Effexor) Duloxetine (Cymbalta) Desvenlafaxine (Pristiq)	Block the reuptake of norepinephrine, serotonin, and dopamine. — — — — — — —	Side effects are similar to the SSRIs. In doses >450 mg/day, can cause seizures; assess for history of head trauma or seizure disorder. Used to treat depression in patients who are not responding to other antidepressants. Can cause liver failure. Can cause agranulocytosis. In doses >300 mg/day, potentiates risk of sustained hypertension; assess for history of hypertension. Side effects are similar to the SSRIs. Common side effects: dizziness, fatigue, headaches, nausea, dry mouth, diarrhea, constipation, decreased appetite.	Instruct to immediately contact provider if priapism (a painful, prolonged erection of the penis) occurs. Instruct to immediately contact provider if seizures occur. Teach to report yellowing of the skin or sclera, anorexia, or malaise. Warn to immediately report sore throat, fever, or other infection signs. Instruct to continue taking BP medications as prescribed. Monitor for hypoglycemia. Instruct patient and family to report suicidal ideations.

BP, Blood pressure; GI, gastrointestinal; MAO, monoamine oxidase; MAOIs, monoamine oxidase inhibitors; TCAs, tricyclic antidepressants.

Evidence-based practice indicates that medications should be started at the lowest dose and increased gradually; however, it is also important that the patient receives a sufficient dose for an appropriate length of time. If the patient experiences medication failure, compliance is more difficult to achieve ([Substance Abuse & Mental Health Services Administration, 2011](#)).

Safety Alert

Serotonin Syndrome

SSRIs have the potential to cause serotonin syndrome. This is a potentially life-threatening condition that could start 30 minutes to 48 hours after taking the medication. Symptoms include change of mental status, increase in pulse and fluctuation in blood pressure, loss of muscular coordination, and hyperthermia. Treatment includes stopping the medication, administering intravenous (IV) fluids, and decreasing the patient's temperature.

Electroconvulsive therapy (ECT) is the oldest form of brain stimulation therapy used for severe depression. After several regimens of medication are unsuccessful, or if the patient is severely depressed or actively suicidal, ECT is considered. Evidence suggests that ECT is more effective in some patients than pharmacology ([Tokutsu et al, 2013](#)). Basically, ECT consists of an electrical shock delivered to the brain via electrodes applied to the temples. This shock artificially induces a grand mal seizure lasting 30 to 90 seconds. The patient typically receives 8 to 12 treatments spread over several weeks. ECT is typically done on an outpatient basis in the early morning.

The potential risks associated with the procedure include increased intracranial pressure, increased blood pressure (especially for those with essential hypertension), and cardiac dysrhythmias. Short-term memory loss, occasional headaches, and confusion are expected but will resolve in minutes to hours after the procedure, and this should be explained to the patient and family before treatment. The patient should take nothing by mouth for 6 to 8 hours before the procedure. Basic preoperative preparation includes obtaining a signed consent and removing dentures, jewelry, hairpins, contact lenses, and hearing aids. The patient will receive a preoperative medication such as atropine sulfate and a short-acting general anesthetic. After the procedure is completed, vital signs are monitored and the patient is reoriented. Before discharge, the patient is fed, and the family is reminded about the expected short-term memory loss.

Newer forms of brain stimulation therapy have shown promise. Repetitive transcranial magnetic stimulation (rTMS) and magnetic seizure therapy (MST) are noninvasive methods; a magnet is placed on the skull, then areas of the brain are stimulated by pulsations. Vagus nerve stimulation (VNS) and deep brain stimulation (DBS) use a surgically implanted pacemaker to stimulate nerve tissue. MST has been approved by the FDA, but DBS is still undergoing trials ([Pedersen, 2013](#)).

Programs are continuously being developed to improve outcomes for mental health patients. For example, IMPACT (Improving Mood–Promoting Access to Collaborative Treatment) is an evidence-based intervention for older patients who have major depression. A nurse, social worker, or psychologist and the primary care provider use a collaborative team approach that includes assessment, education about treatments, activities, and the patient's preference for depression treatment, such as antidepressant medications and psychotherapy ([SAMHSA's National Registry of Evidence-Based Programs, 2015](#)).

Nursing Management

Assessment (Data Collection)

You should collect information about feelings of sadness, hopelessness, and a loss of interest in usual activities. Nurses are responsible for identifying patients at risk for suicide. Assess the patient for changes in ability to fulfill family, social, or occupational obligations, as well as appetite, recent weight loss or gain, and changes in normal eating pattern. A person who is depressed may also have many somatic complaints, such as headache, stomachache, dizziness, nausea, indigestion, constipation, and change in sexual responsiveness. The inability to concentrate and indecisiveness are also hallmarks of mood disorders.

Nursing Diagnosis

Common problem statements for patients experiencing depression include:

- Altered activity tolerance due to psychomotor retardation
- Diminished hope due to inability to achieve career goals
- Spiritual disconnection due to questioning the meaning of life
- Grief due to loss (e.g., divorce)
- Decreased self-esteem due to past failures
- Altered self-care ability due to lack of motivation
- Potential for violence due to repressed anger and grief

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

■ Planning

For these problems, expected outcomes might include:

- Patient will participate in at least one unit activity today and gradually increase participation as activity tolerance improves.
- Patient will identify two short-term goals that would contribute to achieving overall long-term career goals by the end of shift.
- Patient will verbalize renewal of faith in a higher power after two or three visits from hospital clergy.
- Patient will express feelings of loss and sadness about divorce within 1 month.
- Patient will relate at least one “success story” about self every day for 1 week.
- Patient will participate with assistance (e.g., verbal coaching) in activities of daily living (ADLs) (e.g., brush own teeth) for 1 week and gradually increase independent completion of ADLs before discharge.
- Patient will refrain from harming self or others during this shift.

Planning care for a patient with depression involves promoting safety, adequate nutrition, and rest. Initially, the patient may require assistance in performing ADLs until the severe depression subsides. Mental energy and concentration to work on complex psychological issues are not available to a person who is still in the depths of depression. However, as the energy level improves, you need to help the patient begin to set some small goals such as meeting her own hygienic needs and gradually work toward the greater goal of reentry into the workforce.

■ Implementation

The priority nursing intervention for a depressed patient is to protect the patient from acting on impulses to harm herself. Medications to treat depression often are indicated, and you must help the patient understand that sometimes pharmacologic intervention is necessary to combat depression at the biochemical level; reversing depression is not merely a matter of thinking happy thoughts. Also, comparing the need for medication to that for a condition such as diabetes or a heart problem may help the patient to feel less stigmatized. **Once the antidepressant medications begin to take effect, the risk for self-harm actually increases, because the patient now has sufficient energy to complete the act.** Genuine caring and concern and close monitoring are very important.

Depressed patients can be difficult to be with because of their self-defeating thoughts and verbalizations. Set limits on the amount of time spent ruminating on negative thoughts and redirect the patient to discussions of the present reality, such as focusing on the small successes that the patient has achieved during the shift, such as combing her own hair or attending a group session.

Clinical Cues

When you spend a lot of time caring for a depressed patient, you may find that you feel very tired, subdued, or even mildly depressed. Share this experience with your clinical instructor or a classmate, and remember that to give excellent patient care, identifying your feelings and protecting your own mental health are essential.

Think Critically

What types of goals would be suitable for a 25-year-old female nursing student who is depressed? She is taking Zoloft, an SSRI, and is feeling better but continues to be overwhelmed.

Most depressed people complain of some type of sleep deprivation. Provide an environment that is conducive to sleep and educate the patient and family about the importance of regular sleep.

■ Evaluation

Daily evaluation of the patient's depression includes determining whether the outcome criteria for the patient's physical needs were met. These include safety and issues related to decreased energy levels, such as helping with ADLs. Also evaluate the patient's ability to participate in social activities and to express feelings. Part of this overall assessment will include determining the effectiveness of medications. Sometimes it takes several different trials of a combination of drugs to achieve the desired effect. In addition, many of the medications take 2 to 4 weeks to become effective, and the initial side effects of drowsiness and nausea may discourage long-term compliance.

Suicidal Patients

❖ Nursing Management

■ Assessment (Data Collection)

Risk factors for suicide include family history of suicide, history of a previous attempt, terminal illness, addiction to drugs or alcohol, diagnosis of major depressive disorder or bipolar disorder, and excessive stress. Suicide assessment includes determining the level of risk (low, moderate, or high) for accomplishing the act of suicide, the presence of a distinct plan, and means of acting on the plan. Be caring in your approach; however, do not be afraid to be direct. You cannot cause the patient to commit suicide with your questions. Moreover, the patient is likely to feel relieved that you are not afraid to hear about suicide and that you are capable of dealing with this painful disclosure.

▣ Clinical Cues

If you are working on a busy medical-surgical unit and you identify a patient with signs of suicidal thoughts or behaviors, first ensure patient safety, and then immediately report these behaviors to the provider or RN. The patient may need a psychiatric consultation, transfer to a medical-psychiatric unit, or initiation of intensive suicide precautions (i.e., one-on-one observation). These measures are beyond the routine care provided on a medical-surgical unit.

The probability of a completed suicide attempt increases with male gender, weapon availability (guns or knives), poor support system, social isolation, and the influence of mood-altering chemicals. However, all suicide threats and gestures should be taken seriously. Patients who are actively suicidal are considered unstable, and if you gather data that support this suspicion, the facts should be immediately reported to the provider or RN.

▣ Focused Assessment

Questions to Ask a Potentially Suicidal Patient

- Are you feeling suicidal?
- Do you have a plan? How do you plan to take your life?
- Can you think of any event that may have caused you to feel this way?
- Do you have a lethal weapon in your possession?
- Who is a part of your support system?
- Do you drink or use drugs on a regular basis?
- Has anyone in your family made a previous suicide attempt?
- Are you currently taking any antidepressants?
- Have you experienced a major loss within the last year?
- What is your history with past close relationships?
- Have you given away any of your possessions recently?
- Have you been having difficulty remembering things lately?

Think Critically

Women are two times more likely to attempt suicide, but men are four times more likely to complete the suicide act. Why might older white men have the highest rate for completed suicide?

■ Nursing Diagnosis

Common problem statements for patients at risk for suicide include:

- Potential for violence due to overwhelming feelings
- Potential for suicide due to history of previous suicide attempt
- Decreased power due to dependency in relationships
- Decreased hope due to viewing the future as bleak and grim
- Spiritual disconnection due to loss of belief in God
- Altered coping ability due to use of avoidance of problems
- Altered self-esteem due to unmet dependency needs

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see back cover).

■ Planning

For the problems mentioned, expected outcomes might include:

- Patient will refrain from injuring self during this shift.
- Patient will refrain from suicide attempts during this shift and will stop verbalizing suicidal thoughts before discharge.
- Patient will identify three examples of dependency in her relationships and describe how this dependency affects her life during group therapy sessions.
- Patient will verbalize one or two future events that she could look forward to and enjoy.
- Patient will demonstrate renewal of her usual spiritual activities (e.g., attending church, meditating) within 2 months.
- Patient will identify at least two additional coping mechanisms by the end of the week.
- Patient will list at least two ways to meet her own needs during this shift.

Planning care for a patient at risk for suicide involves ensuring a safe environment by determining the level of risk and initiating the appropriate suicide precautions.

Legal and Ethical Considerations

Safe Environment for a Suicidal Patient

Although patients have the right to bring and keep personal items, you have the legal responsibility for maintaining a safe environment for a suicidal patient. Belts, shoelaces, and even undergarments such as a bra could be used in a self-strangulation attempt and should be taken away as necessary.

As the risk for suicide decreases, the focus of nursing care shifts to assisting the patient to develop alternative methods to cope and solve problems.

■ Implementation

Protecting a suicidal patient from self-harm is a priority nursing intervention. Suicide precautions for a high level of risk consist of placing the patient in a seclusion room with one-to-one (1 : 1) observation, where one caregiver is assigned to be with the patient continuously. A provider's order is required for 1 : 1 seclusion; however, a 1 : 1 measure can be initiated temporarily by the nursing staff until the provider is notified. The observer may have to remain close enough (arm's length) to immediately intervene if the patient attempts self-harm. As the level of risk decreases, the patient is allowed to have more personal space; for example, 1 : 1 may continue in the dayroom, but visual contact must be maintained at all times. In addition, all items with a potential for self-harm must be removed, such as sharp or pointed objects, glass objects, or pills. Observe the patient for

“cheeking,” which is a ploy to avoid taking medication by holding the pill in the cheek pouch rather than swallowing it. Suicidal patients have been known to hoard medication and then use it in an attempt to overdose.

When assessment indicates that the suicide intent is less lethal, it is sufficient to maintain close observation and a contract with the patient to refrain from taking action. A no-suicide contract—preferably written—should be initiated and renewed as needed. Active listening and a caring attitude are necessary to build a trusting relationship with a severely depressed, suicidal patient. Even if the patient is unwilling to talk, you must indicate to the patient both verbally and nonverbally that you care and are available to listen. Your attention and presence convey respect and help the patient to build self-esteem and a sense of self-worth.

■ Evaluation

Unstable, suicidal patients need to be reassessed and evaluated frequently (i.e., every 15 to 30 minutes), and the plan of care should be adjusted accordingly to ensure safety and prevent self-harm. As the patient stabilizes and the level of risk decreases, evaluate patient outcomes related to gaining new coping skills, renewing hope and a sense of purpose, improving communication skills to get needs met, and preparing to resume life in a community setting. The status of the patient just before discharge should be carefully documented to reflect the absence of suicidal ideations and a follow-up plan with a specific method to access emergency care if suicidal feelings return should be included. According to The Joint Commission's National Quality Core Measures, when patients are discharged from a facility, the plan of care should be communicated to the provider who assumes the care of the patient. This is particularly important for patients who have attempted suicide or expressed suicidal thoughts.

Eating Disorders

Anorexia Nervosa

Anorexia nervosa is characterized by the patient's refusal to maintain minimal body weight or eat adequate quantities of food. There is a disturbance in the perception of body shape and size and an extreme fear of becoming fat. The patient strives for perfection and control by controlling caloric intake. These patients may act immaturely and are socially insecure and exhibit fluctuating moods. Intricate food rituals (e.g., shifting food around the plate, collecting recipes, and making elaborate meals for others) develop, and the patient may have superstitions about food (e.g., ice cream goes straight to your hips). Excessive exercise is commonly used as another means of staying thin. In many cultures, the emphasis on a slim body has influenced young women's body image. Anorexia nervosa occurs in about 1% of females in late adolescence or early adulthood. About 0.3% of males have the disorder. Anorexia nervosa is a dangerous disorder; 6% to 20% of patients with this diagnosis will die of starvation or suicide. Other psychiatric conditions accompany anorexia nervosa.

Diagnostic criteria include:

- Refusal to maintain body weight at or above a minimally normal weight for age and height (body weight less than 85% of that expected)
- Intense fear of gaining weight or becoming fat, even though underweight
- Disturbance in the way in which one's body weight or shape is experienced, or denial of this problem
- Absence of at least three consecutive menstrual cycles after onset of menstruation in women

Think Critically

How does your own culture influence your body image?

Bulimia Nervosa

Patients with **bulimia nervosa** induce vomiting after consuming large quantities of food. It occurs in about 1.5% of women and 0.5% of men. This binge eating occurs in a frenzied state and usually in secrecy; afterward, the patient experiences feelings of shame and self-criticism. Laxatives may be taken to purge the system after the binge. Many athletes suffer from an eating disorder. Bulimia and anorexia nervosa can occur simultaneously in some patients, and both conditions are difficult to cure.

Treatment of Eating Disorders

The goal of treatment in eating disorders is to restore nutritional health and a normal body weight. If there is a rapid weight loss of 30% and the patient is medically unstable, the first step is hospitalization to correct fluid and electrolyte imbalances and severe weight loss. After the medical condition is stabilized, behavior modification is the focus of treatment. Therapy is long term, requiring 1 to 6 years for reversal of the disorder. Both inpatient treatment and outpatient treatment are required with individual, group, and family therapy. Support groups can provide opportunities for growth and sharing of feelings and information. The long-term goal is for the patient to achieve a sense of self-worth and self-acceptance that is not exclusively based on appearance.

Nursing Management

Assessment (Data Collection)

Collect information about compulsive dieting, severe weight loss, excessive exercise, or an unrealistic body image. The patient and the family may be in denial. Amenorrhea and electrolyte imbalances occur, and as the disease progresses, a host of other symptoms appear. Problems related to vitamin and nutrient deficiencies occur, including dry skin, constipation, muscle wasting, and facial puffiness. **Lanugo** (downy hair covering the body) may occur. Cardiac dysrhythmias,

hypotension, and hypothermia can be life threatening.

Individuals with bulimia nervosa may maintain a normal weight. Assess for binge eating, tooth marks on the knuckles from repeated attempts to induce vomiting, and dental caries from exposure to stomach acid. Other signs and symptoms include fluid and electrolyte imbalances, complaints of heartburn, vomiting of blood, or constipation from dehydration.

■ Nursing Diagnosis

Common problem statements for patients with eating disorders include:

- Altered nutrition due to refusal to eat and fear of gaining weight
- Potential for electrolyte imbalance due to self-induced vomiting and limited intake
- Altered body image due to sociocultural and media influence
- Altered self-esteem due to repeated negative feedback from parents
- Altered coping ability due to using maladaptive dietary practices to cope with stress
- Altered family functioning due to the emotional growth and development of the adolescent family member

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

▣ Clinical Cues

A patient with an eating disorder is attempting to gain a sense of control by controlling dietary intake; therefore it is important to avoid power struggles over food. Use a matter-of-fact approach and help the patient to experience control in non-food-related areas. For example, "Jane, go ahead and finish your lunch and then you can show me what CDs you decided to take on your school trip."

■ Planning

For the above problems, expected outcomes might include:

- Patient will take in at least ____ calories per day for 1 week and gradually increase caloric consumption to regain 85% of ideal body weight within ____ months.
- Patient will refrain from self-induced vomiting during this shift.
- Patient will discuss four or five ways in which culture and media are influencing her self-image.
- Patient will identify examples of negative feedback from parents and discuss how that feedback is affecting her during today's group session.
- Patient will identify three alternative coping strategies to replace maladaptive dietary practices before discharge.
- Patient and family will identify three family activities (non-food related and non-exercise related) that provide support to the adolescent (e.g., discussing a homework assignment).

Planning care for a patient with an eating disorder involves ensuring a safe environment[®] and helping to restore weight and correct nutritional deficiencies. As the physical needs are met, the focus of nursing care shifts to assisting the patient to develop a more realistic body image, increase self-esteem, increase feelings of control, and practice new coping skills. *Healthy People 2020* goals include decreasing the proportion of adolescents who use eating behaviors to control weight.

■ Implementation

The initial interventions for eating disorders are targeted toward physical health and safety. Suicide precautions are initiated if necessary, and fluid and electrolyte imbalances are corrected. Nutritional status, weight gain, and behaviors such as excessive exercise or self-induced vomiting are monitored. Use a supportive, nonjudgmental approach to assist the patient in building self-esteem, assertiveness, a realistic body image, and age-appropriate peer relationships. Power struggles and discussions of food should be avoided.

▣ Clinical Cues

Evidence-based practice indicates that patients can learn to interrupt negative thoughts and

substitute positive affirmations (Peden et al, 2005). Teach your patients to use a personal positive affirmation statement that can be said out loud on a regular daily basis. You may even want to use a positive affirmation to build your own confidence while you are in nursing school. Wake up every morning and say to your mirror, "I am a good student and I am going to be a great nurse!"

■ Evaluation

In the acute phase, patients with eating disorders need evaluation of outcome criteria that ensure safety, nutritional, and electrolyte and fluid balance needs. Changing beliefs about food or body image, building self-esteem, learning new coping skills, and restructuring eating habits may take months or even years; therefore even small gains should be carefully documented. Evaluate the patient's readiness to resume life in a community setting with healthier eating habits and the family's ability to support the patient's efforts.

Community Care

As hospital stays become shorter, many patients with anxiety, mood, or eating disorders will be hospitalized only long enough to stabilize their life-threatening symptoms. They will then be seen in outpatient clinics, in long-term care, at home, or in day hospitals. Medication compliance is a major nursing responsibility. Once a patient feels better and the crisis is over, there may be a tendency to stop taking medications. Regular visits to the clinic or provider and a social support system are essential.

Get Ready for the NCLEX® Examination!

Key Points

- The four levels of anxiety are mild, moderate, severe, and panic.
- Examples of anxiety disorders include generalized anxiety disorder, phobic disorder, obsessive-compulsive disorder, and post-traumatic stress disorder.
- Assess for physical symptoms of anxiety: increased blood pressure, pulse, respirations, and urinary output; dry mouth; nausea; diarrhea; trembling; muscular tension; restlessness; hypervigilance; and insomnia.
- Assess for the psychological symptoms of anxiety: feelings of impending doom, fear, guilt, anger, helplessness, irritability, and low self-esteem.
- Interventions for patients with anxiety disorders include remaining calm, decreasing environmental stimuli, teaching relaxation techniques and stress management, medicating with anxiolytics as necessary, and determining root causes of anxiety as indicated.
- PTSD may occur after any extremely traumatic event and occurs both in combat veterans and civilians who have experienced such an event. It often appears within 3 months of the event but may not occur until months or years later.
- Bipolar disorder is characterized by episodes of extreme sadness, hopelessness, and helplessness alternating with periods of extreme elation and hyperactivity.
- Assess for physical indicators of bipolar disorder: hypersomnia or insomnia, change in appetite, and somatic complaints such as headache, stomachache, dizziness, nausea, indigestion, and change in sexual responsiveness.
- Assess for psychological indicators of bipolar disorder: irritability, grandiosity, delusions, labile emotions, flat affect, sadness, indecisiveness, and inability to concentrate.
- Interventions for patients in the acute manic phase include ensuring the safety of the patient and others, providing a high-calorie diet and finger foods, setting limits on behavior, administering and monitoring the effectiveness of antimanic medications, and encouraging rest and sleep.
- Assess for physical indicators of depression: weight loss or weight gain, sleep disturbances, fatigue or loss of energy, and psychomotor retardation.
- Assess for psychological indicators of depression: feelings of sadness, worthlessness, hopelessness, or excessive guilt; inability to feel pleasure or disinterest in daily activities; difficulty in making decisions or concentrating; and recurrent thoughts of death or suicide.
- Interventions for depressed patients include active listening, assessing for suicidal ideations, attending to physical needs, administering and monitoring the effectiveness of antidepressant medications, assisting in setting goals, and educating about medications and ECT.
- Assess for a suicide plan, including lethality level and means to act on the plan.
- Interventions for suicidal patients in the acute phase include developing a trusting relationship, one-on-one observation, removing dangerous objects, and initiating a no-suicide contract.
- Anorexia nervosa is the extreme fear of becoming fat, with a disturbance in perception of body size.
- Bulimia nervosa is characterized by the practice of inducing vomiting after binge eating.
- Assess for physical symptoms of an eating disorder: amenorrhea, electrolyte imbalances, dry skin, constipation, muscle wasting, facial puffiness, lanugo, dysrhythmias, hypotension, hypothermia, and dental caries (related to self-induced vomiting).
- Assess for psychological and behavioral symptoms of an eating disorder: denial of problem, compulsive dieting, preoccupation with food, unrealistic body image, low self-esteem, and shame (related to binge eating).
- Interventions for patients with eating disorders include monitoring nutritional intake and weight gain, monitoring behaviors such as excessive exercise and self-induced vomiting, and assisting to build self-esteem and assertiveness.

Review Questions for the NCLEX® Examination

1. A patient is irritable, pacing, crying, and becoming increasingly agitated. A nursing intervention that could be helpful is:

1. Initiate a contract stating suicide won't be attempted.
2. Administer ordered antidepressant medication.
3. Stay with the patient and make the surroundings less stimulating.
4. Offer small nourishing meals and finger foods to sustain nutrition.

NCLEX Client Need: Psychosocial Integrity: Implement Measures to Reduce Environmental Stressors

2. A 46-year-old woman is diagnosed with generalized anxiety disorder. Which behavior is more likely to be displayed with this diagnosis?

1. Runs out of the room when she notices a spider in the corner
2. Continuously checks to see if doors are shut and locked
3. Has difficulty concentrating and excessively worries about her family
4. Wakes at night screaming because of recurrent nightmares

NCLEX Client Need: Psychosocial Integrity: Identify Client Symptoms of Acute or Chronic Mental Illness

3. A nurse feels that there may be a need to administer ordered medication to an older adult for anxiety. Which strategy would help the nurse to make this clinical decision?

1. Listen to verbalization of apprehension.
2. Be sensitive to somatic complaints.

3. Initiate therapeutic communication.
4. Observe for escalation of agitation.

NCLEX Client Need: Psychosocial Integrity: Monitor Client Effective Use of Stress Management Techniques

4. A patient is taking lithium. Which are early signs of lithium toxicity?

1. Hypertension and headache
2. Diarrhea and slurred speech
3. Confusion and blurred vision
4. Convulsion and polyuria

NCLEX Client Need: Physiologic Integrity: Pharmacological Therapies

5. A patient demonstrates an overwhelming feeling of worthlessness, difficulty in making decisions or concentrating, and suicidal thoughts. The nurse determines the suicide risk by asking which question(s)? (*Select all that apply.*)

1. "Are you feeling suicidal?"
2. "Do you have a plan? How do you plan to take your life?"
3. "Why do you want to commit suicide?"
4. "What would you accomplish by killing yourself?"
5. "Do you drink or use drugs on a regular basis?"
6. "Have you considered how your family would feel?"
7. "Have you recently given away any of your belongings?"

NCLEX Client Need: Psychosocial Integrity: Therapeutic Communication

6. A patient is disheveled and disinterested in daily activities such as bathing or hygiene. She reports overwhelming feelings of sadness and loss of energy. A problem of altered self-care deficit regarding bathing and hygiene is identified. Which intervention(s) would be appropriate? (*Select all that apply.*)

1. Explain the importance of hygiene to health and appearance.

2. Encourage the patient to "look good and feel good."
3. Plan extra time to help the patient to complete ADLs related to hygiene.
4. Instruct the nursing assistant to do partial hygiene.
5. Encourage some participation and set limits.
6. Do everything for the patient until she feels better.
7. Have the same caregiver assist on a daily basis if possible.

NCLEX Client Need: Physiologic Integrity: Personal Hygiene

7. A patient who is taking an SSRI suddenly develops a rapid pulse, fluctuating blood pressure, fever, loss of muscle coordination, and mental status changes. The nurse anticipates that the provider is most likely to order which medical therapy?

1. Infuse IV fluids and administer an antipyretic.
2. Obtain an electrocardiogram and start oxygen through a nasal cannula.
3. Administer an antidote and encourage oral fluids.
4. Monitor the patient closely and continue the medication.

NCLEX Client Need: Physiologic Integrity: Pharmacologic Therapies/Adverse Effects

8. A nurse is admitting a young adult with a tentative diagnosis of bulimia. Which behavior is most likely to characterize this disorder?

1. Vomiting after eating large quantities of food
2. Being obsessed with exercising constantly
3. Stating suicidal thoughts to others
4. Cutting food on the plate into tiny bites

NCLEX Client Need: Psychosocial Integrity: Identify Client Symptoms of Acute or Chronic Mental Illness

9. A nurse is caring for an 18-year-old patient who is diagnosed with anorexia nervosa. The nurse

identifies altered nutrition as a priority problem. What is an appropriate expected outcome?

1. The patient will be able to eat 35% or more of her meals.
2. The patient will be able to develop improved eating behaviors.
3. The patient will be able to verbalize the importance of eating.
4. The patient will be able to identify barriers to eating.

NCLEX Client Need: Physiologic Care: Basic Care and Comfort—Nutrition and Oral Hydration

10. A patient is hospitalized for dehydration and weight loss. She is very restless and exhibits flight of ideas with easy distractibility. Which intervention is most appropriate for the problem of inadequate nutrition?

1. Give three high-calorie meals on a regular schedule.
2. Offer finger foods, such as a meat and cheese sandwich.
3. Provide a pleasant, odor-free environment.
4. Encourage family meals and socialization while eating.

NCLEX Client Need: Physiologic Integrity: Nutrition and Oral Hydration.

Critical Thinking Questions

Scenario A

You are working in a clinic, and the mother of an adolescent who was recently diagnosed with cancer becomes hysterical. You briefly assess her and find she is at a panic level of anxiety.

1. Explain why closed questions (questions that can be answered with a yes or no, or with very specific answers) and short simple sentences delivered in a firm, kind tone would be effective while she is at a panic level of anxiety.
2. What signs and behaviors would indicate that your interventions are successfully helping this mother to reduce her anxiety?

Scenario B

You are caring for an older adult couple in their home. The husband had a stroke 6 months ago. One day the wife takes you aside and tells you that she is concerned about her husband. She says that he is not sleeping well and that his appetite is poor. On further questioning, you find that he is verbalizing a desire to “end it all.”

1. What questions would you ask the husband? What questions would you ask the wife?
2. What type of community supports might be available for this couple?

Scenario C

Tony Garza, a 42-year-old, comes into the emergency department after a high-speed chase with the police. He is using vulgar, profane language and is unable to sit down even for a few minutes. Tony switches rapidly from being fun-loving and humorous to angry and aggressive. The psychiatrist tells you that Tony has bipolar disorder and orders a calming intramuscular injection.

1. How would the team approach Tony to give him the injection?
2. What are the major safety concerns for this patient while he is in the emergency department?
3. What other nursing interventions are necessary at this time?

Scenario D

You are assigned to care for Jacquie, a 19-year-old who has been admitted for treatment of anorexia nervosa. She tells you she would like to delay breakfast to take a walk around the unit. You kindly, but firmly, tell her that she cannot delay breakfast. Later you walk into her room and she is doing jumping jacks; the breakfast is untouched. She tells you she really cannot eat this morning because she feels so fat.

1. How will you respond to Jacquie?
2. What can you do to help her gain a more realistic body image?

Scenario E

You are caring for Mr. Moreno, an older adult who suffers major depression. Several regimens of medication were tried without success, and the psychiatrist has recommended ECT.

1. Give Mr. Moreno and his family a brief explanation of ECT.
2. What are the most common side effects?
3. What are the risks associated with the procedure?
4. Outline the preprocedural and postprocedural care for a patient undergoing ECT.

CHAPTER 46

Care of Patients With Substance Abuse Disorders

Objectives

Theory

1. Summarize the significance of substance use disorders in the general adult population.
2. Choose the diagnostic criteria included in the medical diagnosis of substance use disorder.
3. Determine the physical, behavioral, and psychological indicators of substance use disorder.
4. Examine the significance of denial and rationalization in substance use disorder.
5. Analyze the effects of substance use disorders on family and friends.
6. Discuss symptoms and complications of withdrawal from alcohol.
7. Construct at least six nursing interventions appropriate for a patient with a substance use disorder.

Clinical Practice

8. Visit a 12-step group and identify the advantages and disadvantages of the program for substance abuse patients.
9. Contribute to a teaching plan for a community presentation on smoking cessation.
10. Create a care plan with at least three problems and five nursing interventions per problem for a patient who is at risk for alcohol withdrawal.
11. Devise a care plan with at least three problems and five nursing interventions per problem for a patient who is taking a central nervous system stimulant (e.g., cocaine).

KEY TERMS

- abuse** (ăb-ūz, p. 1073)
- addiction** (ă-DĬK-shŭn, p. 1079)
- codependency** (KŌ-dĭ-PĚN-dĕn-sē, p. 1075)
- confabulation** (kōn-fāb-ū-LĀ-shŭn, p. 1078)
- denial** (dĕ-Nī-ăl, p. 1074)
- dependency** (dĭ-PĚN-dĕn-sē, p. 1073)
- detoxification** (dĕ-tōk-sĭ-fĭ-KĀ-shŭn, p. 1076)
- dual diagnosis** (p. 1073)
- enabling** (ĕn-Ā-blĭng, p. 1074)
- Korsakoff syndrome** (KŌR-să-kōf SĬN-drōm, p. 1078)
- “meth”** (p. 1080)

psychoactive substances (sī-kō-ĀK-tīv SŪBZ -tān-sěz, p. 1073)
rationalization (ră-shūn-ăl-ī-ZĀ-shūn, p. 1074)
substance abuse (SŪBZ-tānz āb-ŪZ, p. 1072)
substance use disorder (SŪBZ -tānz ūz dīs-ÖR-děr, p. 1073)
tolerance (TŌL-ür-üns, p. 1073)
Wernicke encephalopathy (VĚR-ně-kě ěn-sěf-ă-LÖP-ă-thě, p. 1078)
withdrawal (p. 1075)

Substance and Alcohol Abuse

Substance abuse (excessive use of drugs or alcohol that creates problems) has the potential for causing medical problems and death for the patient and also causes many emotional and physical problems for family, coworkers, and friends. There are many theories about the cause of substance and alcohol abuse. In 1956 alcoholism was recognized by the American Medical Association as a medical disease rather than a moral weakness. However, change in attitude takes time, and there are still many stigmas associated with alcoholism and the abuse of other substances. Research conducted in the mid-1980s identified a genetic predisposition to alcoholism. Neurobiologic theories suggest that some people are born deficient of endorphins (the brain's own morphine-like substances) or that other people have hormonal influences that make them more susceptible to peer pressure and so are more likely to abuse substances. Social and psychological theories suggest that users are trying to avoid adult responsibilities and use substances as a dysfunctional coping method. Ongoing research suggests that a variety of factors and circumstances increase the risk for substance abuse: aging ([Martin, 2012](#)); personality disorders ([Dual Diagnosis.org, 2014](#)); male gender; post-traumatic stress disorder ([Calhoun et al, 2010](#)); and those with lesbian, gay, or bisexual preference who experienced discrimination ([McCabe et al, 2010](#)).

Think Critically

What personal experiences have you or your family had with substance abuse, and how might such experiences affect your care of a patient who has a substance use disorder? Or care of the patient's family?

A **substance use disorder** is diagnosed when individuals have problems with alcoholism or substance abuse. This term implies that there is a recognizable set of signs and symptoms related to the ingestion of a psychoactive substance. **Psychoactive substances** are any mind-altering agents capable of changing a person's mood, behavior, cognition, level of consciousness, or perceptions. **Abuse** of substances is considered maladaptive and nontherapeutic, and manifestation of psychological or physical symptoms implies a **dependency** on substances. **Box 46-1** lists common terms associated with substance use. The *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition (DSM-5) outlines diagnostic criteria. The current definition suggests a substance use disorder if, within a 12-month period, the individual repeatedly demonstrates symptoms such as failure to meet usual obligations, creates danger to self or others, has legal problems, or has poor interpersonal relationships because of substance use ([American Psychiatric Association, 2013](#)). Mild substance use disorder requires two to three symptoms. Substance abuse and dependency have been combined into one disorder. **Dual diagnosis** indicates that a patient has been diagnosed with a substance abuse problem and with a mental health disorder.

Box 46-1

Common Terms Used to Describe Substance Use Disorders

- **Abuse:** Use of a psychoactive substance in a nontherapeutic manner or illicit use of prescription drugs.
- **Dependency:** Presence of physical and psychological symptoms of addiction.
- **Psychological dependence:** Craves or feels compelled to take a substance to feel good.
- **Addiction or physical dependence:** Needs the substance to prevent symptoms of withdrawal, not merely to sustain the feeling of euphoria that was present with early use of the drug.
- **Tolerance:** Need for increased amounts of substances to achieve the desired effect.

- **Withdrawal:** Stopping the drug results in a group of symptoms. Withdrawal symptoms are usually the opposite of the symptoms caused by use of the chemical.

This chapter addresses some of the more commonly abused substances: alcohol, narcotic analgesics, opiates (e.g., heroin), cocaine, amphetamines (includes methamphetamines), nicotine, cannabis (marijuana), hallucinogens (e.g., lysergic acid diethylamide [LSD]), and inhalants.

Think Critically

Treating patients with a **dual diagnosis** can be challenging and difficult. For example, your patient has schizophrenia and admits to drinking alcohol and using “lots of drugs all of the time.” What are the additional challenges to think about when this patient is discharged to a community setting?

Signs and Symptoms

Symptoms of substance abuse vary greatly, depending on the substance and on the duration of use and the **tolerance** that has developed. The patient should be observed for physical, behavioral, and psychological signs (Figure 46-1). Problems with fine motor control may be observed when the individual is trying to perform simple tasks such as walking or eating. Observe the skin for needle tracks, bruises, excessive perspiration, excoriation, or poor condition that suggests malnutrition. Behavioral symptoms should be compared with baseline; other conditions such as dementia, delirium, and metabolic or psychiatric disorders must be considered if behavioral changes are noted. For psychological symptoms, **denial** and **rationalization** are the most common defense mechanisms used by substance abusers. A typical example of denial would be: “I drink a few on the weekend.” A classic example of rationalization is, “I just have a few drinks to relax.” To be effective in treating these patients, you must remember that substance abusers usually do not seek help voluntarily. Denial and rationalization become entrenched behaviors and are difficult to eradicate. A review of defense mechanisms is presented in Table 46-1.

Legal and Ethical Considerations

Substance Abuse Among Health Care Workers

Those in the health care field are particularly vulnerable to substance abuse because of the availability of drugs and the tendency to care for others while ignoring personal problems. The American Nurses Association estimates that substance abuse among nurses reflects that of the general population at about 10%. In other words, if you work with 10 nurses, potentially one of them will have a substance abuse problem (Heacock, 2013). Approximately 40 states have established confidential programs to assist health care professionals to get help for the problem rather than immediately forfeiting their professional license. Signs and symptoms to be aware of among health care workers include frequently calling in sick or always working (to have access to drugs), sloppy patient care, frequently leaving for breaks, offering to give pain medications, and patients complaining of no relief after receiving  pain medications.

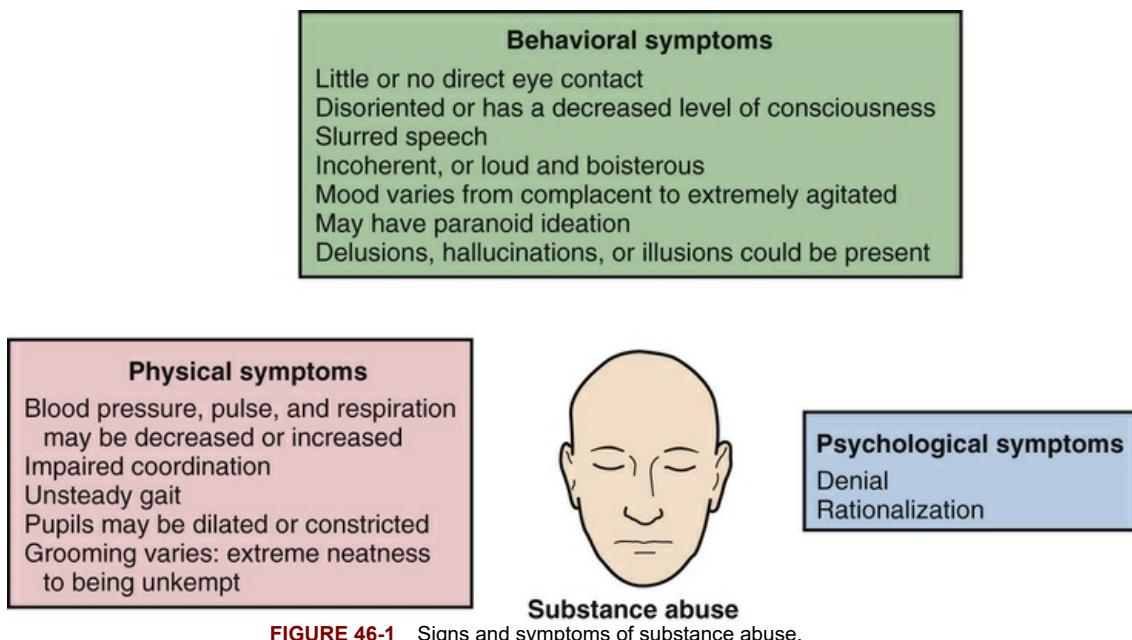

FIGURE 46-1 Signs and symptoms of substance abuse.

Table 46-1
Common Defense Mechanisms

DEFENSE MECHANISMS	CHARACTERISTICS	EXAMPLE
Denial	A simple and primitive defense mechanism. Person ignores reality and absolutely refuses to be swayed by evidence.	A person with alcoholism states, "I do not have a problem with alcohol. I never drink before 5 P.M."
Rationalization	Justifying a behavior or action by making an excuse or an explanation.	A student states, "I failed the class because the teacher didn't like me."
Displacement	Discharging intense feelings for one person onto another object or person who is less threatening.	A woman has an argument with her coworker and goes home and kicks the dog.
Identification	Modeling behavior after someone else.	A student starts dressing and talking like a popular schoolmate.
Intellectualization	Excessive reasoning and logic to counter emotional distress.	A nursing student is upset by the death of a patient, but talks at length about the equipment on the code cart.
Reaction-formation	An intense feeling that is unknowingly acted out in an opposite manner.	A person treats someone whom he unconsciously dislikes in an overly friendly manner.
Regression	Returning to an earlier level of behavior when severely threatened.	A 7-year-old resumes bed-wetting and thumb sucking during the first few days of hospitalization.
Repression	Unconsciously blocking an unwanted thought or memory from open expression.	A student truly does not remember cheating on an important test.
Splitting	Viewing people or situations as all good or all bad.	A patient praises a nurse one day and then hates and scorns her the next day.
Sublimation	Rechanneling an impulse into a more socially desirable acceptable activity.	A student has generalized angry feelings about school so she takes up kickboxing as an after-school sport.

Effects of Substance Abuse on Family and Friends

Anyone living in proximity to a substance-dependent person will be affected. People who are abusing substances are unavailable for emotional intimacy, because life becomes centered on the substance of choice rather than on relationships or responsibilities. **Family members experience a multitude of feelings, including anger, rage, embarrassment, guilt, shame, and hopelessness. The family also uses denial and rationalization to cope.**

Two terms commonly associated with the family and friends of a substance abuser are *enabling* and *codependency*. **Enabling** is “helping” a person so that consequences from unhealthy behavior are less severe; thus enabling “helps” the unhealthy behavior to continue.

In maintaining their own denial about the situation, **enablers** cover up for their troubled loved one and attempt to maintain a status quo. Calling in sick for the abuser is one common example of enabling behavior. Enabling keeps the substance-dependent person from facing consequences, and enabling ultimately supports continued denial. Enablers often have a difficult time understanding that their behavior is counterproductive to the health and well-being of the substance abuser and the abuser's family. Self-righteousness is a typical attitude observed in enablers, and it is difficult to confront.

Think Critically

How might a family enable their loved one? Is enabling ever helpful?

Codependency is another behavior that occurs in circumstances of substance abuse. The **codependent is any family member or friend who overcompensates and tries to “fix the situation” or to control the substance abuser.** For example, a teenage son may repeatedly go to the bar and retrieve his drunk mother when she binges and then assume all household and child care duties until she can function. Because overcompensating does not work, codependents feel powerless and attempt to control even more. A vicious, self-destructive cycle is established that is difficult to break. The overcompensating also keeps the substance abuser from facing reality objectively.

Disorders Associated with Substance Abuse

Alcohol Abuse

Alcohol is a central nervous system (CNS) depressant and is the most commonly abused substance. It is widely available, legally sanctioned, and relatively inexpensive, and abuse of this substance is found at all socioeconomic levels.

Alcoholism is a major health problem and is a factor in many other instances of death and morbidity. Some of the medical conditions include **cirrhosis** (liver damage), cardiomyopathy, **gastrointestinal bleeding**, pancreatitis, hypertension, stroke, sleep disturbances, malnutrition, peripheral neuropathies, cognitive impairment, **leukopenia** (decreased white blood cells), **thrombocytopenia** (decreased platelets), and chronic infection. Alcohol is also frequently associated with traffic accidents, murder, spousal abuse, child abuse, rape, and suicide. Concurrent abuse of other substances (**polysubstance abuse**) is common. Until alcoholism reaches advanced stages, it is often easy to conceal the problem from the general community. Beginning in early 2010, The Joint Commission conducted a pilot phase to develop and refine Core Measures for the assessment and treatment of alcohol abuse (see [Online Resources](#)).

Cultural Considerations

Religion and Alcohol

In a recent study of college students, students who were the least religious were 27 times more likely to be heavy drinkers and nine times more likely to be moderate drinkers compared with students who had strong religious affiliations and beliefs ([Wells, 2010](#)). How does your own cultural and religious background influence your attitudes toward alcohol consumption?

Symptoms of Intoxication and Withdrawal

A 12-oz bottle of beer, a 6-oz glass of wine, and a 1.5-oz single shot of whiskey contain the same amount of alcohol. It takes approximately 1 hour for the body to metabolize one standard drink. A person is intoxicated when the amount of alcohol ingested creates physical or mental impairment. A number of factors can affect intoxication, such as the quantity and speed of alcohol ingestion, food concurrently consumed, the history of alcohol use (e.g., heavy drinker, novice drinker, social drinker), general health status, and concurrent use of other drugs or substances that depress the central nervous system. Familiar early symptoms include drowsiness, slurred speech, loss of coordination, loss of inhibition, euphoria, and mild impairment of judgment. If drinking continues, motor function worsens, confusion progresses, and increasingly stronger stimuli are required to arouse the drinker. The late signs of excessive ingestion include urinary incontinence, coma, low blood pressure, respiratory depression, and possibly death ([Cohen, 2011](#)).

Withdrawal occurs when a person who has a physical dependence on alcohol stops drinking. Early symptoms of withdrawal may manifest within 6 to 12 hours after the last drink; these include anxiety, irritability, and agitation. Progressive symptoms include increased blood pressure and pulse, tremors, nausea and vomiting, diaphoresis, delirium tremens ("DTs"), hallucinations, and seizures. Major withdrawal symptoms can occur 2 to 3 days after the last drink and may last 3 to 5 days.

Older Adult Care Points

Older adults are at great risk for alcohol and substance abuse. Drinking can be an attempt to alleviate depression, pain, or loneliness. The function of vital organs (especially the liver and kidneys) diminishes with age; loss of body mass and decrease in body fluids result in a higher concentration of ingested substances. With decreased liver and kidney function, the by-products of alcohol are not cleared from the body as efficiently. Organ damage or failure and neuropsychiatric effects can occur ([Rehm, 2014](#)).

Diagnosis

To establish a diagnosis of alcohol dependence, the following criteria must be met: presence of withdrawal, significant impairment in family relationships and occupational productivity, **blackouts** (a temporary loss of recent memory that occurs while drinking), drinking despite serious consequences to health or occupation, and evidence of tolerance.

Making the diagnosis of alcohol dependence is not necessarily difficult. The difficulty lies in getting the patient to admit that there is a problem. Unless there is **self-diagnosis** ("I am an alcoholic"), treatment will be for the benefit of the treatment team and the family but will not foster long-term recovery for the patient.

Think Critically

You are caring for a patient with a history of alcohol abuse who has been admitted for surgery. After a visitor leaves, you notice the smell of alcohol on the patient's breath. How would you handle this situation?

Treatment

At one time it was believed that allowing alcoholics to experience a painful withdrawal would frighten them so much they would never drink again. Today we know that **withdrawal can be life threatening**, especially withdrawal from alcohol and certain anxiolytics, such as benzodiazepines. Withdrawal treatment consists of two phases. Initial priorities focus on detoxifying and stabilizing the patient. **Detoxification** refers to the process of ridding the body of the abused substance, without causing harmful ill effects. Treatment decisions may be based on assessment scales such as the Clinical Institute Withdrawal Scale for Alcohol & Revised (CIWA-Ar) ([Clin-eguide, 2009a](#)). CIWA-Ar indicates the severity of the withdrawal and suggests whether admission to the hospital is warranted or outpatient treatment is adequate. Chlordiazepoxide (Librium), diazepam (Valium), or oxazepam (Serax) is given in titrated doses. Phenytoin (Dilantin) and magnesium sulfate (if magnesium levels are low) may be given to prevent seizures. Promethazine (Phenergan), prochlorperazine (Compazine), ibuprofen (Motrin), or dicyclomine (Bentyl) may be given for the symptoms of nausea, vomiting, pain, or cramps. Intravenous (IV) fluids are used to correct dehydration, and a "banana bag," which includes normal saline, magnesium sulfate, folic acid, and multivitamins, may be ordered ([Hoffman and Weinhouse, 2014](#)). **Table 46-2** lists the medications used to treat substance abuse. The RN cares for patients undergoing detoxification.

Table 46-2

Drugs Commonly Used to Treat Substance Abuse

CLASSIFICATION	ACTION	NURSING IMPLICATIONS
Drugs Used to Discourage Relapse		
Naltrexone (ReVia, Vivitrol)	Competitively binds to opiate receptors to prevent narcotic's effects. Used for alcohol rehabilitation.	Advise patient about side effects of naltrexone: dizziness, fatigue, headache, nausea, nervousness, sleeplessness, and vomiting. Screen for history of liver problems. Vivitrol is a once-monthly injection. Caution that concurrent use of heroin can cause withdrawal symptoms or even death.
Acamprosate calcium (Campral)	Similar to naltrexone.	Advise patient about side effects: diarrhea, fatigue, nausea, and flatulence.
Nalmefene (Revex)	Similar to naltrexone.	Must be administered IM or IV. Side effects include nausea, vomiting, tachycardia, hypertension.
Drugs Used to Treat Heroin Abuse or Discourage Relapse		
Opioid Analgesic		
Methadone Buprenorphine (Suboxone, Subutex)	Produces mild euphoria; used as a heroin substitute in rehabilitation programs.	Extreme caution with use in older adults or debilitated patients, or patients with renal or hepatic impairment, hypothyroidism, Addison disease, head injury, urethral stricture, enlarged prostate, or respiratory conditions. Advise patient about side effects of dizziness or drowsiness. Monitor for constipation and encourage fluids and fiber. Methadone tablets should be dissolved in orange juice. Buprenorphine is taken sublingually.
Drug Used to Treat Heroin Overdose		
Narcotic Antagonist		
Naloxone (Narcan)	Competes with opioid receptors and blocks (or reverses) the action of narcotics. Used for patients who have narcotics overdose.	Abrupt reversal of CNS depression may cause nausea, vomiting, increased pulse and blood pressure. Short half-life; watch for recurrent respiratory depression. May have to give repeated doses q2-3min or an IV infusion.
Drugs Used to Treat Nicotine Addiction		
Nicotine polacrilex (Nicorette) Nicotine transdermal (Nicotrol)	Delivers lower doses of nicotine. Used in smoking or tobacco cessation programs.	Apply patch immediately after opening to prevent evaporation. Do not cut or fold patch. Instruct patient to chew gum slowly for about 30 min. Advise patient about gradual withdrawal from gum after 3 mo; not recommended for use longer than 6 mo. Advise patient to suck or lozenge until dissolved; no chewing, biting, or swallowing. Do not eat or drink for 15 min after finishing lozenge. Advise patient that patch should not be used longer than 3 mo. If no benefit within 4 wk, unlikely that continued use will produce desired effects; consult health care provider.
Bupropion (Zyban)	Weakly blocks reuptake of serotonin, epinephrine, and dopamine. At lower doses, used in smoking cessation programs; at higher doses is used as an antidepressant.	Advise patient that drug may cause insomnia; do not take at bedtime. Do not chew, divide, or crush tablets. Treatment usually lasts 7-12 wk. May not notice therapeutic effect for 1 wk. Instruct to avoid alcohol while taking this drug.

Varenicline (Chantix)	Blocks nicotine from binding at the receptor sites.	Teach patient to begin taking Chantix 1 wk before stop date. Side effects include nausea or decreased appetite, headaches, insomnia, or vivid dreams. Use cautiously in renal impairment. May cause suicidal tendency.
--------------------------	---	--

CNS, Central nervous system; IM, intramuscular; IV, intravenous.

See Evolve for drugs to treat alcohol withdrawal that are given by the RN.

Once the patient is stable and able to participate in a treatment program, therapy consists of confronting the patient's denial and encouraging self-diagnosis. Disulfiram (Antabuse) is a drug that causes unpleasant reactions if the patient decides to return to drinking any time after starting the drug and including 14 days after stopping it. Even small quantities of alcohol that might be inhaled from shaving lotion could trigger serious reactions such as chest pain, nausea and vomiting, hypotension, weakness, blurred vision, and confusion. Naltrexone (ReVia) can be used to block the craving for alcohol and to prevent relapse in the recovery phase; nalmefene (Revex) is similar to ReVia but lasts longer and is more potent. An oral form of Revex has been used in research studies, but it is currently only available in parenteral form. Acamprosate (Campral) has been used successfully in Europe and has been approved for use in the United States; patients show significantly higher rates of completing therapy programs on this drug. Vivitrol is a once-monthly injectable form of naltrexone.

Group therapy helps break through denial and gives the patient a new sense of belonging and identity. Behavioral therapy helps with self-discipline and discourages impulsive behavior. Limit setting is one of the hallmarks of behavioral therapy, and it is essential that all members of the behavioral team participate and completely agree about the limits. Brief intervention therapy at 1-year follow-up has been shown to significantly reduce weekly alcohol intake (McQueen et al., 2009). The acronym FRAMES defines the brief approach: Feedback about personal status, Responsibility to change, Advice for change, Menu for options, Empathy in counseling, and Self-efficacy for changes (Miller, 2013). In accordance with *Healthy People 2020* the use of evidence-based screening in level 1 and 2 trauma centers is essential, and brief intervention therapy should be initiated.

Think Critically

A woman brings her 85-year-old father into the clinic and insists that he be admitted to a detox (detoxification) program. The man tells you, "At my age, with my health problems, my fixed income and everything else I have to worry about, having a drink or two is the least of my problems." Discuss your personal reactions and your professional responsibilities in dealing with this family.

Referral to a 12-step program, such as Alcoholics Anonymous (A.A.), is also integral to most treatment plans. A.A. has been in existence for more than 50 years and is the dominant approach to alcoholism rehabilitation in the United States; although there is no "cure" for alcoholism, there is hope for ongoing recovery. Evidence-based practice shows that continued active participation in A.A. results in decreased alcohol consumption. Providers and nurses can assist by helping the patient to make the first call for A.A. information, locating local sites, and asking about the meetings. Box 46-2 lists the 12 steps of A.A.

Box 46-2

The Twelve Steps of Alcoholics Anonymous

1. We admitted we were powerless over alcohol—that our lives had become unmanageable.
2. Came to believe that a Power greater than ourselves could restore us to sanity.
3. Made a decision to turn our will and our lives over to the care of God *as we understood Him*.
4. Made a searching and fearless moral inventory of ourselves.
5. Admitted to God, to ourselves, and to another human being the exact nature of our wrongs.
6. Were entirely ready to have God remove all these defects of character.

7. Humbly asked Him to remove our shortcomings.
 8. Made a list of all persons we had harmed and became willing to make amends to them all.
 9. Made direct amends to such people wherever possible, except when to do so would injure them or others.
10. Continued to take personal inventory and when we were wrong, promptly admitted it.
11. Sought through prayer and meditation to improve our conscious contact with God, *as we understood Him*, praying only for knowledge of His will for us and the power to carry that out.
12. Having had a spiritual awakening as the result of these steps, we tried to carry this message to alcoholics, and to practice these principles in all our affairs.

From Alcoholics Anonymous: *The big book online*, ed. 4, New York, 2005, AA World Services, Inc. The Twelve Steps and Twelve Traditions are reprinted with permission of Alcoholics Anonymous World Services, Inc. ("AAWS") Permission to reprint the Twelve Steps and Twelve Traditions does not mean that AAWS has reviewed or approved the contents of this publication, or that A.A. necessarily agrees with the views expressed herein. A.A. is a program of recovery from alcoholism *only*—use of the Twelve Steps and Twelve Traditions in connection with programs and activities which are patterned after A.A., but which address other problems, or in any other non-A.A. context, does not imply otherwise.

Complications

A serious effect of chronic alcohol abuse is damage to brain cells. A condition that is reversible with treatment is **Wernicke encephalopathy**. This condition precedes **Korsakoff syndrome** (substance-induced persisting dementia), which is often irreversible. If the individual has a history of alcohol abuse and displays the symptoms of confusion, ataxia, and significant memory loss, Wernicke encephalopathy is suspected. Treatment involves large doses of thiamine (vitamin B₁) and abstaining from alcohol. Thiamine acts as a nerve insulator in the body and is absent in the diets of most chronic alcoholics.

Clinical Cues

Thiamine should always be given before glucose to prevent triggering Wernicke encephalopathy ([Schabelman and Kuo, 2012](#)).

An individual with Korsakoff syndrome has grossly impaired memory and gait disturbance. **Confabulation** (making up stories) commonly is seen as an attempt to communicate. A brain scan will show brain atrophy; currently there is no treatment to totally reverse this condition, but long-term administration of thiamine, other vitamins, and magnesium may improve symptoms.

Abuse of Other Central Nervous System Depressants

Other CNS depressants subject to abuse and dependence are barbiturates and anxiolytics, including benzodiazepines. It is not uncommon to see these drugs used in conjunction with alcohol, but this practice can be fatal because of the additive effects. Drugs in this category may be purchased illegally, or initially they may be prescribed by a provider for insomnia or anxiety. There has been an increase in nonmedical use of prescription drugs, and in 2011 emergency department visits for misused prescription or over-the-counter drugs totaled 1,428,145 (SAMHSA, 2013). The increase of abuse of prescription drugs suggests that policy and practice changes are required, such as health provider education, universal use of prescription monitoring programs, routine monitoring of insurance claims information, and increased vigilance for signs of abuse.

Benzodiazepines (e.g., lorazepam [Ativan], oxazepam [Serax], temazepam [Restoril]) have familiar side effects: drowsiness, hypotension, relaxation, and slurred speech. A chronic user may display lack of motivation, memory loss, poor concentration, irritability, aggression, anxiety, and an increased appetite with weight gain. When an individual who has been abusing drugs that depress the CNS goes through withdrawal, symptoms include an elevation in pulse and blood pressure, nervousness, and heightened anxiety. Flunitrazepam (Rohypnol) is classified as a benzodiazepine and may look like a packaged prescription medication because it is produced and used in Europe and Mexico for insomnia; however, it is illegal in the United States. Rohypnol gained notoriety in the 1990s as the date-rape drug. It produces **anterograde amnesia** (inability to remember events that happened while under the influence of a substance), along with muscle relaxation, drowsiness, and slowed motor performance.

Older Adult Care Points

Insomnia is not atypical in the older adult population. Great care must be taken when prescribing sedatives and hypnotics for this group. Decreased liver and renal function can quickly lead to toxicity and dependence. Benzodiazepines, in particular, have a long half-life and are not excreted readily by the body. Therefore patients with poor liver and renal function are subject to a cumulative effect and may experience toxic side effects. Patient education is very important.

Treatment

As with detoxification from alcohol, a person who is addicted to benzodiazepines may be given a drug from a similar category in titrated doses. The amount depends on the severity of the addiction. With the long half-life of benzodiazepines, the initial symptoms of withdrawal may not appear for 3 to 5 days. [Table 46-3](#) presents the symptoms of intoxication with and withdrawal from CNS depressants. Long-term treatment consists of referral to a 12-step program (i.e., Narcotics Anonymous) and perhaps individual and/or group psychotherapy. Patients need to be taught alternative ways to induce sleep and relieve anxiety.

Table 46-3
Characteristics of Commonly Abused Substances

SUBSTANCE	USUAL METHODS OF ADMINISTRATION	SYMPOMTS ASSOCIATED WITH USAGE	EFFECTS OF OVERDOSE	WITHDRAWAL SYNDROME
Alcohol	Oral	Drowsiness, ataxia, initial euphoria and aggressive or belligerent behavior, muscular incoordination. At higher alcohol levels, slurred speech, marked ataxia and muscular incoordination, marked cognitive impairment.	Amnesia, tremors, hypothermia, seizures, respiratory failure, coma, death.	Nausea, vomiting, anorexia, agitation, hallucinations, seizures, increased body temperature, increased blood pressure and heart and respiratory rate, possibly death.
Opiates (narcotic analgesics)	Oral, inhalation, IV	Euphoria, drowsiness, decreased respirations, constricted pupils.	Decreased respirations, shallow breathing, clammy skin, seizures, possibly death.	Watery eyes, runny nose, yawning, anorexia, irritability, tremors, panic, cramps, nausea, chills, sweating.
CNS stimulants (cocaine, amphetamines, "bath salts")	Inhalation, oral, IV, smoked	Increased alertness, excitation, euphoria, increased pulse and blood pressure, insomnia, anorexia.	Agitation, hyperthermia, hallucinations, convulsions, cardiac dysrhythmias, possibly death. Bath salts may cause paranoia, violence, and suicide.	Apathy, long periods of sleep, irritability, depression, disorientation.
CNS depressants (anxiolytics and barbiturates)	Oral	Slurred speech, disorientation, drunken behavior without odor of alcohol.	Shallow respiration, clammy skin, dilated pupils, weak and rapid pulse, coma, possibly death.	Anxiety, insomnia, tremors, delirium, convulsions, possibly death.
Cannabis (marijuana)	Inhaled, oral	Euphoria, relaxed inhibitions, increased appetite, disoriented behavior.	Fatigue, paranoia, psychosis.	None.
Hallucinogens (LSD, PCP)	Oral	Illusions, hallucinations, impaired perception.	Effects are increased and intensified; psychosis, flashbacks, possibly death.	None.

CNS, Central nervous system; IV, intravenous; LSD, lysergic acid diethylamide; PCP, phencyclidine.

Abuse of Opiates

Opiate analgesics can also be obtained both legally and illegally. The process of **addiction** may begin with a prescription drug for severe pain. If these individuals rely totally on narcotics to relieve chronic pain and have a tendency to abuse drugs, addiction may occur. Opiate addiction has become an increasing problem in the United States. Conversely, if narcotics and a variety of measures are used to alleviate the pain, there may be some increased tolerance and physical dependence. However, tolerance and physical dependence can be treated by slowly decreasing dosages of the opiates. For symptoms of use, withdrawal, and overdose see [Table 46-3](#).

Complementary and Alternative Therapies

Pain

Assist patients to explore adjunctive therapies to alleviate pain. These include meditation, visualization, biofeedback, hypnosis, and acupuncture. Aromatherapy with fragrant oils such as jasmine or patchouli can stimulate endorphins (natural pain killers produced by our bodies).

Treatment

The greatest danger with opiates is an overdose, which can result in respiratory depression and death. Treatment for an overdose usually consists of administration of a narcotic antagonist, such as naloxone (Narcan) or naltrexone (Vivitrol).

Clinical Cues

A dose of IV Narcan can produce dramatic and rapid results. A lethargic overdosed patient may arouse very suddenly with nausea, vomiting, tachycardia, and an increased blood pressure. **Do not assume that the danger is over.** The half-life of Narcan is short, and the opiate action will resume and cause respiratory depression; therefore anticipate that a continuous Narcan infusion may be ordered.

Clinical Cues

If activated charcoal is ordered as part of the treatment for an overdose of opiates, make sure that the patient is  fully alert and able to protect his own airway ([EB Medicine, 2013](#)).

Withdrawal from opiates is not life threatening, but patients can experience abdominal cramps, irritability, profuse sweating, yawning, muscle aches, fever and chills, and cravings. Treatment involves helping the individual withdraw from the drug. Methadone maintenance programs are successful in helping patients who have a heroin addiction. Buprenorphine (Suboxone or Subutex) has been approved in the United States for opiate substitute therapy; this drug can be given at a physician's office and comes in a sublingual form. There are restrictions on the number of patients a physician can have. This represents a significant barrier to treatment, considering that current estimates for the United States indicate 1.5 million people use heroin and 2.4 million use prescription drugs nonmedically, and there are far fewer slots for methadone clinics ([Pollack, 2013](#)). See [Table 46-2](#) for nursing implications related to medications to treat opiate overdose and recovery.

For street drugs such as heroin, rehabilitation is difficult unless the environmental and social factors (e.g., breaking off relationships with friends who abuse substances) are also changed. Heroin is less expensive than cocaine now. It is not unusual for an individual addicted to heroin to require up to 2 years in some type of supervised alternative living program. Group, individual, and behavioral therapy and a referral to a 12-step program (i.e., Narcotics Anonymous) are also essential to success. In a systematic review of psychosocial treatments, [Cleary and colleagues \(2009\)](#) found that motivational interviewing combined with cognitive-behavioral therapy reduced substance abuse for the short term and improved mental state (see [Box 46-1](#)). In a 5-year study of providers with substance abuse problems, a zero tolerance approach showed that 72% were successfully abstaining. The program included intensive monitoring and mandatory testing with severe consequences for even a single relapse ([McGovern and Carroll, 2013](#)). Network therapy is an evidence-based program that uses the patient's social network to support abstinence; biweekly meetings and aversive consequences are also part of the therapy ([NREPP, 2013](#)).

Support groups are useful to any individual who is trying to make a major life change or to someone who has experienced a major life-changing event. Substance abusers who are trying to change to a totally different lifestyle can also benefit from this extra support. The purpose of support groups is to help promote healthy relationships, learn and practice new coping skills, and reduce stress and anxiety. Support groups borrow from the principles of group therapy: universality (we have similar experiences), cohesiveness (we have a feeling of belonging), catharsis (expressing feelings makes us feel better), altruism (you help me, I'll help you), information giving (this worked for me, it might help you), improved social skills (you can say this in group, now say it

to your family), and intrapersonal learning (Yalom and Leszcz, 2005). Nurses should refer patients and encourage them to use this valuable resource.

Think Critically

Why might some people feel threatened by the idea of entering a support group? What are your personal feelings about disclosing information in a group?

Abuse of Stimulants

The two common categories of CNS stimulants are cocaine and amphetamines. Both categories of drugs have legitimate medical uses but are also abused. **Amphetamines can cause an increase in pulse rate and blood pressure, general excitation, anorexia, and hyperactive reflexes and can produce life-threatening conditions such as cardiac dysrhythmias, seizures, or hyperthermia.**

Misuse can range from small and infrequent amounts to ingestion of large amounts, which cause prolonged sleeplessness and anorexia. Sleep deprivation of this magnitude can lead to extreme agitation and hostility and a transient psychosis and can be fatal. People who are withdrawing from stimulants experience drowsiness, headache, lethargy, nausea, alterations in eating and sleeping patterns, and sometimes cravings.

Methamphetamine, known as "speed," "**meth**," "crank," or "crystal," is injected or smoked (Figure 46-2). White men ages 20 to 35 years have the highest abuse rate for methamphetamines. They are highly addictive, and users end up taking progressively larger doses. "Meth labs" are unfortunately easy to establish in any average household, garage, trailer, or similar structure; common household chemicals, brake fluid, antifreeze, batteries, matches, ammonia, or over-the-counter medications are "cooked," creating a harmful residue that lingers on the walls and in the air well after the cooking process is finished. Chronic users may develop toxic psychosis and experience paranoia, hallucinations, and delusions. "Meth" use functionally and structurally alters the brain. Weight loss, poor nutrition, skin sores, and serious tooth decay are common effects of methamphetamine addiction.

FIGURE 46-2 Methamphetamine. (Courtesy U.S. Drug Enforcement Administration.)

Cocaine use has become much more expensive, and its users have often switched to cheaper heroin. It is highly addictive and can cause death, even in small doses. Cocaine is a short-acting substance and is more commonly used for binges. It produces euphoria, increased energy, and a sense of well-being. The stimulating effects are very fast acting and energizing. However, the effects after the "high" are equally intense, and individuals are subject to severe emotional lows. The powder is either "snorted" (intranasal administration) or dissolved and taken intravenously. "Crack," a purified form of cocaine, is smoked by placing it in a pipe or smoking it with marijuana or tobacco (Figure 46-3). This "freebasing" of cocaine reduces it to its purest form. This is the most

dangerous type of administration; it produces an immediate rush and accounts for many overdoses and lethal reactions.

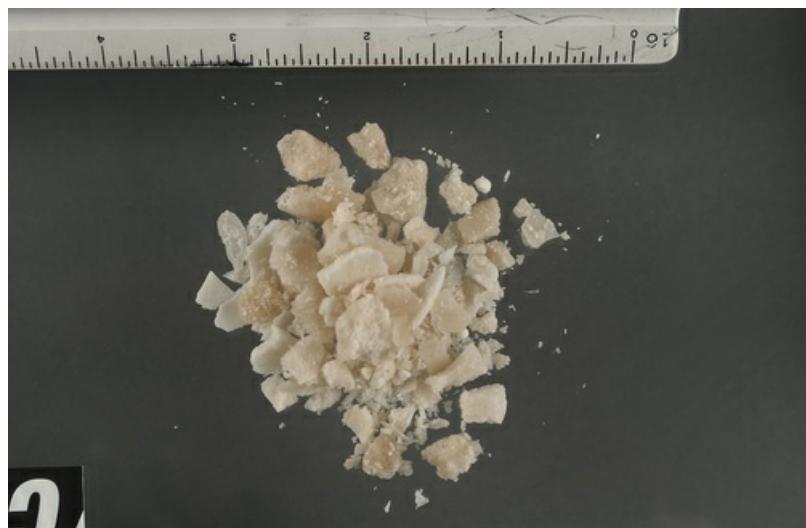

FIGURE 46-3 Crack cocaine. (Courtesy U.S. Drug Enforcement Administration.)

A stimulant newcomer is “bath salts” or “plant food,” a powder that is inhaled, injected, ingested, or smoked to produce an effect close to that of cocaine or amphetamine. It is available over the Internet and is popular among night-club patrons. It is not yet illegal in several states in the United States. These drugs are derived from cathinone, a Schedule I controlled substance. There are many varieties in varying chemical combinations. They are the most addictive drugs to date. High doses bring a risk of violence, paranoid psychoses, and suicide.

Treatment

Treatment for abuse of CNS stimulants is similar to treatment for alcohol abuse. Initially the treatment protocol is symptom specific and managed by medications. Anxiolytics or antipsychotics may be used for agitation or aggressive behavior, and antidepressants may be used for the depressive symptoms. A combination of behavioral and group therapy and referral to a 12-step program have been shown to reduce cocaine use (Carroll, 2014). Contingency or motivational incentives seem effective for initial abstinence from cocaine. Patients who abuse CNS stimulants must also be taught ways to cope with the psychological craving that often leads to relapse. Approaches currently being studied to address cognitive problems in addictive disorders are computer-assisted cognitive rehabilitation and pharmacologic manipulation of neurotransmitters (Pedrero-Perez et al, 2011). Therapeutic communities or residential programs are other options. The recovering addict stays 6 to 12 months while undergoing behavioral therapies.

Abuse of Nicotine

Nicotine is highly addictive and causes increased respiration, decreased pulmonary function, and a chronic cough. Use of tobacco is related to more than 400,000 deaths per year and contributes to development of lung cancer and other lung diseases, such as emphysema. Pipe smokers and people who chew tobacco are more prone to oral cancer. Smoking has been implicated in many other health conditions, including heart disease, stroke, many cancers, hypertension, premature wrinkling of the skin, bad breath, and discoloration of the fingernails. In addition, environmental tobacco smoking results in 440,000 deaths each year (Centers for Disease Control and Prevention, 2014). Withdrawal symptoms can begin as soon as 24 hours after the cessation of smoking and include irritability, tension, decreased heart rate, and insomnia. Cigarettes are legal and accessible, and the craving continues long after the patient quits smoking; therefore resumption of the habit is common, and many smokers stay in denial about the effects of nicotine. Electronic cigarettes have been touted as a safe alternative to cigarette smoking, but their health effects are not yet known. Although they do not contain the carcinogenic substances that cigarettes do, they do

contain nicotine. The U.S. Food and Drug Administration is studying their effect. They have been banned in Canada.

Cultural Considerations

New Consumer Markets

There has been a decrease in cigarette smoking in the United States in the past 25 years. In 1966 the U.S. Surgeon General's health warnings were placed on all cigarette packages. Since then, similar warnings have been put on other tobacco products. Television and radio advertising for cigarettes was banned in 1971. Education and an increase in cigarette taxes, along with restrictions on smoking in public places, have also contributed to the decrease. Nevertheless, new potential consumer markets are being targeted around the world. For example, cigarette manufacturers have now identified China as a good alternative consumer market, and as a result, many Chinese men and teenagers have developed this high-risk habit.

Treatment

Nicotine replacement therapy (NRT) is available in patches, lozenges, gum, sublingual tablets, inhalant, and nasal spray. Self-help groups, hypnosis, and acupuncture are among the treatments available for nicotine addiction. Bupropion (Zyban) and varenicline (Chantix) are approved as stop-smoking aids in the United States. Smoking cessation programs support the *Healthy People 2020* goals and emphasize the positive effects of quitting, such as better overall health for the individual and the family, an increased sense of smell and taste, and saving money. Evidence-based practice suggests that nursing intervention for smoking cessation increases the likelihood of quitting and helps patients succeed ([Centers for Disease Control and Prevention, 2014](#)). Multicomponent interventions for smoking cessation that include an on-site visit, follow-up phone calls, enhanced education about NRT, and motivational interviewing are effective. The most useful aspects of counseling are helping the patient develop a plan and identifying barriers to quitting. The plan can include setting a stop date, asking friends and family for help, anticipating how to combat cravings, and removing all tobacco products and accessories from the house, car, and workplace. The combination of counseling and medications is more successful than using one without the other ([AHRQ, 2012](#)).

Clinical Cues

The [AHRQ \(2012\)](#) recommends the “five As” approach for helping patients to quit using tobacco: (1) Ask about tobacco use, (2) Advise to quit, (3) Assess willingness to quit, (4) Assist to quit, and (5) Arrange follow-up.

Legal and Ethical Considerations

Do As I Say, Not As I Do

Studies suggest that nurses who use tobacco are less effective in helping patients with smoking cessation interventions; possibly they have the same misconceptions and difficulties in quitting that patients have. To be more effective in helping patients to quit, health care workers who are using tobacco should actively participate in their own smoking cessation efforts.

Abuse of Cannabis

The leaves and flowering tops of the *Cannabis sativa* (marijuana) plant are dried and loosely rolled in cigarette paper and smoked. It is commonly used as a “gateway substance” (substance that leads the way or opens the gate to more dangerous and serious substance abuse) by teenagers and as a recreational drug by adults. The active ingredient in marijuana is effective in controlling nausea in patients who are receiving chemotherapy and helping relieve some types of chronic pain. Medical marijuana is legally sold in 20 states and Washington, D.C. Two states have passed laws so that

recreational marijuana can be sold legally: Colorado, Washington, Oregon, and Alaska. However, recreational marijuana is still illegal under federal law.

Marijuana is typically smoked, but it can also be ingested. It acts quickly (15 minutes), and the effects last for up to 4 hours. **General effects are a mild euphoria, increased appetite, and increased sensitivity to sound, colors, and other environmental elements. Impaired coordination, decreased mental concentration, and altered judgment are also present.** In large doses, the person may experience psychotic symptoms. Marijuana is believed not to be physically addictive, but it may lead to psychological dependence and a lack of motivation and ambition. There is no particular withdrawal syndrome for cannabis, so treatment must focus on issues related to the general dangers of substance abuse.

❑ Think Critically

Substance abuse crosses all ethnic, gender, age, and socioeconomic backgrounds. You have three patients: a homeless older adult Asian American woman, a well-to-do African American teenager, and a middle-age white man who works as a carpenter. You must assess all three for marijuana (and other substances) use. First, identify your own biases and then describe your approach.

Abuse of Hallucinogens and Inhalants

Two common drugs that cause hallucinations are LSD and phencyclidine hydrochloride (PCP, or angel dust). These hallucinogens are believed to be somewhat less physiologically addictive compared with other psychoactive substances; however, there are extremely unpredictable effects. Hallucinogens cause distortion of the senses, an inability to separate fact from fantasy, impaired sense of time, and severely impaired judgment. Users never know whether they will have a good “trip” or a bad one. Uncontrolled **flashbacks** (feelings and sensations associated with use despite being drug-free) can occur. This group of drugs is very dangerous because use is known to cause panic, paranoia, and death from extremely impaired judgment.

Inhalants are psychologically and physiologically addictive. Commonly abused inhalants include glue, nail polish remover, aerosol-packaged products (e.g., deodorants), and paint thinner and other types of solvents. Symptoms of use are acute confusion, excitability, and sometimes hallucinations. Prolonged use of inhalants causes permanent damage to all body organs and a psychological dependence. Inhalants are most commonly used by teenagers and children because they are inexpensive and easily accessible.

❑ Think Critically

You are caring for a 14-year-old who admits to you that he has been experimenting with glue sniffing. He tells you that he has stopped and he asks you not to share this information with his parents. How will you handle this situation? Who can you consult to clarify your legal and ethical obligations?

Treatment

Medical treatment and intervention for both hallucinogens and inhalants include provision of safety for the individual who may be experiencing a bad “trip.” Emergency measures may be necessary to provide respiratory support for an individual who has impaired gas exchange as a result of inhalants.

❖Nursing Management

■ Assessment for Substance Abuse (Data Collection)

A general physical assessment, including vital signs, is necessary. Any life-threatening physical problems must be quickly identified and treated. For example, patients can and do die of cardiac dysrhythmias associated with stimulant abuse, whereas patients who have overdosed on heroin are at risk for respiratory arrest.

Any patient who enters the health care system should be screened for substance abuse, so that early intervention can prevent the immediate and long-term consequences of substance misuse.

Obtain a substance and alcohol history that includes the type of substance used, the amount taken, and the pattern of use. **For patients scheduled for surgery, a thorough preoperative history is absolutely essential, because a patient who normally drinks a lot of alcohol can return from surgery to a busy surgical unit and develop symptoms of alcohol withdrawal. An event of this type complicates postoperative recovery and can be fatal.**

Focused Assessment

Data Collection for Substance and Alcohol Use

Ask the following questions during history taking to determine past and present substance and/or alcohol use:

- Have you ever had a drinking or substance abuse problem?*
- When did you last drink or use drugs of any kind?*
- What substances (alcohol, tobacco, or illicit substances) are you currently using?
- What other types of drugs (prescription and nonprescription) do you routinely take?
- How much do you drink or how much do you use?
- How often do you drink or use substances?
- Have you ever tried to cut down or control your substance use or drinking?
- Have you noticed that now it takes more of the substance or drink to get the same effect you got several months ago?
- Have you noticed any withdrawal symptoms?
- Have you ever been treated for liver disease, hepatitis, heart disease, anemia, or overdose?
- Have you had any recent falls, accidents, or injuries?
- Have you ever stopped drinking or using drugs for a period of time?
- Have you ever been in treatment for substance abuse?
- Is there a family history of alcoholism or substance abuse?
- What is your marital status? If married, are you happily married?
- Have you ever been in trouble with the law?
- What is your occupation? Are you experiencing any difficulties at work?

*Direct questioning is found to yield highly sensitive responses, despite the common expectation that alcoholics deny or minimize alcohol usage (Tierney, 2009).

A quick and simple assessment tool for alcohol abuse is the CAGE questionnaire, which includes four questions regarding the patient's feelings about his or her drinking and specific habits. A "yes" answer to two or more of the four questions has a 90% correlation with alcohol abuse. Also, obtain information about past and current function in family, social, and occupational roles. Remember that denial is a primary defense mechanism used in these disorders. Therefore it often is necessary to ask the family to describe their perception of the user's problem and the extent of substance use. At the appropriate time, assess the effects of the user's behavior on the family and explore the

presence of codependent or enabling behaviors.

■ Nursing Diagnosis

Problem statements for substance use disorders include:

- Confusion due to excessive or chronic alcohol consumption
- Denial of physical and psychological dependence on a substance
- Altered family dynamics due to substance addiction
- Potential for injury due to impaired judgment
- Altered role performance due to inability to complete assigned work duties
- Absence of compliance with substance abstinence

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

▣ Clinical Cues

Patients enter the health care system with medical complaints or injuries who also have unidentified substance abuse problems. When taking a routine admission history, ask about the use of substances. This information is needed to evaluate drug-drug interactions and any potential toxic effects on the body organs (i.e., heart, kidneys, liver). Use a matter-of-fact tone of voice: "Do you smoke or drink alcohol? What kind of prescription, over-the-counter, or illicit (street) drugs do you use?" In accordance with National Patient Safety Goals, your findings contribute to a complete list of medications. This medication reconciliation list should be communicated to the health care team, sent to other facilities if the patient is transferred, and provided to the patient when discharged.

■ Planning

Expected outcomes are written for the specific individual problems chosen to resolve the patient's problems. For the problems mentioned, expected outcomes might include:

- Patient will demonstrate less confusion after receiving thiamine and abstaining from alcohol before discharge.
- Patient will discuss how reliance on substances is affecting his quality of life during today's group therapy session.
- During weekly sessions with social service counselor, the patient and family will communicate needs and identify sources of support to sustain the family.
- Patient will remain safe from harm or injury during this shift.
- Patient will resume job duties within ____ months.
- Patient will participate in a 12-step program at least three times per week.

▣ Older Adult Care Points

When working with older adults, be on the alert for substance use disorders; this group is at high risk because of loneliness, multiple losses, and limited resources. Health care providers commonly overlook substance abuse in older adults because behaviors may be attributed to aging, depression, or dementia. A predictor model for older women who had a high risk for alcohol abuse has been published (Blow et al, 2013). They found that regular use of over-the-counter drugs, ingestion of large amounts of coffee, and using alcohol to induce sleep were associated with alcohol abuse.

Collaborative goal setting is very important when working with an individual who is addicted to a substance. In addition to working with the patient, it is necessary that you collaborate with the family. Setting goals with the patient and excluding the family or friends often lead to failure or relapse. Planning care for a patient with a substance use disorder includes promoting physical and psychological safety, providing a safe withdrawal from the substance, and ensuring adequate nutrition and sleep. To prevent relapse, education regarding substance abuse becomes a priority goal. The education may be started in a treatment center but needs to be continued after discharge for at least 1 year. People who abuse substances need opportunities to learn and practice new

coping skills in a supportive environment.

Think Critically

Do you have any bad habits such as smoking, drinking a lot of alcohol, or drinking too much coffee? How does your personal behavior affect what you will say to your patients about making changes for a healthier lifestyle?

Implementation

Nursing intervention depends on the severity of the substance abuse disorder. Initial interventions for the patient focus on physical recovery. For example, cardiac monitoring, pulse oximetry, IV access, and other emergency measures may be indicated. Potentially fatal effects of drugs and/or alcohol, such as cardiac dysrhythmias, hypotension, and respiratory depression, must receive priority attention. If the patient is intoxicated, orienting to person, place, and time and providing for physical safety are essential. You may need to insist that the patient remains in a protected environment until judgment and coordination return. Ensuring adequate sleep and a balanced diet high in proteins and multivitamins are also part of early intervention.

If the patient is having symptoms of withdrawal, detoxification must be medically managed by giving antianxiety agents, such as chlordiazepoxide (Librium). Close monitoring of vital signs is important, because signs of alcohol withdrawal include an increase in blood pressure and heart rate. Preventing the patient from experiencing a seizure or delirium tremens is an essential part of the detoxification process.

Clinical Cues

When monitoring and reporting changes in blood pressure, keep several factors in mind: patient's baseline, trends (if available), and medications (last dose and type). Also assess for accompanying subjective symptoms such as dizziness or light-headedness (hypotension), headache, or blurred vision (hypertension).

Assignment Considerations

One-to-One Observation

A CNA or UAP is frequently assigned to sit with a patient who needs one-to-one (1 : 1) observation. Before assigning personnel to this task, clarify with the provider or RN the purpose of 1 : 1 observation and the stability of the patient. For example, recall that opioid withdrawal is not life threatening, but the restless patient may be temporarily placed on 1 : 1 observation to prevent **elopement** (leaving) to seek drugs to satisfy the intense craving. It would be appropriate to assign a CNA or UAP to prevent elopement. In contrast, an agitated patient who is withdrawing from alcohol is not physically stable, and his care should be managed by an RN.

Once the substance is cleared from the body, nursing intervention is directed toward helping the patient lead a drug-free life. This includes alleviating the symptoms and confronting denial. You must also observe for signs of suicide. Addicted patients often feel they cannot live without the euphoria and consolation of the substance experience.

Patients who are in the early recovery process from substance abuse benefit greatly from therapeutic conversations with the nurse, and a caring, concerned attitude is very important. Studies have shown that two 15-minute monthly meetings and two 5-minute follow-up nurse calls have beneficial effects ([Clin-eguide, 2009b](#)). Patients must grieve the loss of the substance, and they also feel guilt and shame for acts that were committed while under the influence. To help the patient "work through" these feelings, you need to be an active listener, offering support and validation as necessary. Mandating a patient to stop is usually not an effective intervention; however, you should support the patient's decision to stop and assist by reminding him that the physical symptoms of withdrawal will not last forever. The craving will last longer than the withdrawal symptoms but is manageable if the patient has a strong motivation to change toward a healthy lifestyle. You can assist these patients to identify ways to cope with the craving, such as

helping him to make a list of activities that he could use to distract his attention from the craving, such as calling a friend, taking a brisk walk, cleaning the house, or eating a nutritious snack. You can help him identify settings, circumstances, or relationships that were part of his substance abuse pattern, then identify alternative settings and relationships that are now part of his new lifestyle. For example, polysubstance use might routinely occur in a bar or lounge with friends after having a few beers, but is less likely to occur in a movie theater with friends who are having popcorn.

If the patient is addicted to heroin, the recovery process will be lengthy because of the lifestyle changes that are necessary. Typically, with heroin addiction, there have been some illegal actions and maladaptive coping. The patient needs to be educated about the disease process and needs to learn new coping methods ([Nursing Care Plan 46-1](#)).

Nursing Care Plan 46-1

Care of the Patient With a Substance Abuse Disorder

Scenario

Charles Hogan is a 46-year-old man brought in by his supervisor for admission to a “detox” unit. The supervisor last saw Mr. Hogan drinking about 10 hours ago. He states that Charles is a good worker but could lose his job. Mr. Hogan jokingly replies, “My boss is a worrier. I’m just a social drinker. My wife and kids know I’m okay.” The supervisor states that the wife frequently makes excuses but seems unaware of the problem. Mr. Hogan seems slightly anxious and irritable. He appears thin and malnourished.

Problem Statement/Nursing Diagnosis

Potential for injury/*Risk for injury related to effects of substance and complications of withdrawal.*

Supporting Assessment Data

Objective: Slightly anxious and irritable; last known drink 10 hours ago.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will remain free from any injury this shift. Patient will withdraw from drugs or alcohol without any dangerous effects.	Assess for early symptoms of withdrawal (e.g., agitation, irritability, anxiety) and notify provider or RN of first signs.	Early detection of withdrawal allows for prompt intervention to prevent life-threatening complications.	Is anxious and irritable.
	Administer medications (e.g., chlordiazepoxide [Librium]) as prescribed by provider.	Decreases neurologic irritability at the biochemical level.	30 min after administration of Librium, patient appears more relaxed.
	Remain with patient during times of confusion and disorientation.	Provides support and decreases agitation.	Currently alert and oriented.
	Restrain and/or place in seclusion as ordered if the patient becomes a danger to self or others.	May temporarily be unable to control aggressive or self-harm impulses. May attempt to leave.	Is verbally hostile and denies substance abuse problems, but shows no signs of physical aggression.
	Ensure safe environment (i.e., call bell within reach, bed in lowest position).	Safety is a priority, and patient judgment and coordination may be temporarily impaired.	Did not sustain any injury during the shift. Outcomes met. Continue plan.

Problem Statement/Nursing Diagnosis

Denial/Ineffective denial related to minimization of the symptoms of addiction.

Supporting Assessment Data

Subjective: States “My boss is a worrier. I’m just a social drinker.”

Objective: Supervisor’s report and Mr. Hogan’s perception of problem are mismatched.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will acknowledge the abuse of substances and the unhealthy effects on his life.	Approach the patient in a nonjudgmental manner.	Helps to build trust and rapport.	Is agreeable to talking but is unable to disclose feelings.
	Gently confront the denial as you gain the trust of the patient.	Breaking through denial is essential to recovery.	Denial continues.
Patient will openly acknowledge the need for substance abuse treatment.	Help the patient see the need for treatment and abstinence.	May be unaware of or is ignoring the long-term consequences.	Denies need for treatment.
	Inform the patient about the negative aspects of addictive processes.	Helps the patient to make an informed decision.	Verbally acknowledges that substances are harmful for others, “but I don’t drink that much.”
	Encourage patient to list the harmful effects that he has experienced.	Increases insight and facilitates self-diagnosis.	Denies that substances are harming him.
Patient will agree to attend 90 12-step meetings in 90 days.	Encourage attendance at a 12-step program to help break through the denial.	Provides support by others who have experienced the same difficulties.	Agrees to go to a 12-step program, but thinks it is unnecessary. Outcomes not met. Continue plan.

Problem Statement/Nursing Diagnosis

Altered family role performance/*Dysfunctional family process: alcoholism related to altered family roles, unexpressed feelings, family history of alcoholism.*

Supporting Assessment Data

Subjective: Per supervisor, wife frequently makes excuses but seems unaware of the problem.

Objective: Wife is absent; supervisor is advocating for treatment.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Family will be able to identify and share feelings.	Invite family to participate.	Family may be unaware, or need assistance to break through their denial.	Wife and children did come in to talk with provider and social worker about Mr. Hogan's condition.
	Assess for presence of denial, shame, or guilt.	Feelings of denial, shame, and guilt are expected, but may be repressed.	Family members expressed support for Mr. Hogan, but are unable to disclose personal feelings.
	Encourage expression of genuine feelings.	Opportunity for expression of feelings helps to build trust and rapport.	Trust and rapport are being established, but communication between family members continues to be ineffective.
	Teach how to recognize feelings and safe ways to express them (e.g., "I love you, but I am not going to stay here while you drink").	New communication methods are needed to help the family break old patterns.	Currently family is not openly acknowledging how Mr. Hogan's behavior affects each member, but they agree to attend group therapy.
	Educate the family about the altered roles present in addictive families (e.g., wife overcompensating for husband).	Family members may be unaware of how the illness is affecting role function.	Family is not identifying dysfunctional roles, but appear open to exploring the family situation.
	Define the term <i>enabling</i> for family members. Encourage family members to state at least one time when they engaged in enabling behavior.	Identifying and defining enabling help family to recognize this behavior. Increases insight into own behavior.	Entire family appears to be in denial at this time; denies enabling behaviors.
	Offer family members alternative choices to enabling behavior (e.g., telling him that he must call in sick for himself).	Family needs new ways to cope with old problems.	Family open to learning more about disease process and how to cope with Mr. Hogan's behavior.
	Have family members practice and role play alternative responses to enabling behavior.	Practice in a safe environment allows family to test new skills.	Family having difficulty with role play.
Family will agree to attend at least six 12-step meetings.	Encourage family members to attend a 12-step support meeting.	Provides support by sharing with others who are experiencing the same problem.	Family agrees to go to a 12-step group this weekend. Outcomes not met. Continue plan.

Problem Statement/Nursing Diagnosis

Altered nutrition/*Imbalanced nutrition: less than body requirements related to poor food intake, inadequate absorption of nutrients, poor appetite.*

Supporting Assessment Data

Objective: Appears thin and malnourished.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will self-select a nutritious diet.	Assess ability to feed self.	May have impairment in fine motor coordination.	Is able to independently feed self; shows some fine tremors in hands.
Patient will gain 5 lb within 1 mo; signs of peripheral neuropathy (numbness and tingling) will disappear.	Watch for nausea, vomiting, diarrhea. Administer antacids, antiemetics, and IV fluids as ordered.	Alcohol can cause gastritis and alterations in absorption.	Currently no nausea or vomiting.
	Document intake and output and food intake. Weigh patient.	To monitor nutritional status and progress toward goal.	Weighs 140 lb (ideal body weight 165 lb). Finishes food trays.
	Collaborate with patient to determine food preferences.	Increases likelihood of consumption.	Eats all types of food.
	Encourage small, frequent meals, high in proteins with 50% carbohydrates.	Small meals are easier to tolerate, and foods rich in nutrition will replace loss due to poor dietary practices.	States that he sometimes forgets to eat but knows he should gain some weight ("Will try harder").
	Administer multivitamins, especially thiamine (vitamin B ₁) and niacin, as ordered.	Patient is at risk for Wernicke encephalopathy.	Agrees that supplements are a good idea and will continue to take them after discharge.
	Consult nutritionist.	Collaboration with specialist ensures best plan.	Consultation with nutritionist deferred because patient agrees to eat everything on food trays. Outcomes partially met. Continue plan.

IV, Intravenous.

Critical Thinking Questions

- What are some questions that would be appropriate to ask Mrs. Hogan (if she is willing to come in and meet with the health care team)?
- Mr. Hogan is currently far from being ready for self-diagnosis. What are some things that might signal that he is breaking through the denial?

Intervening With the Family

A trusting relationship needs to be developed with the family, or they may continue to focus on the

patient rather than focus on their own recovery. Families need to learn in what manner they might have been enabling their loved one, and they need time to practice new behaviors that will require the substance abuser to be responsible for himself. Family members should be encouraged to express how the crisis is affecting them. There may be a need to refer families to legal or social services if the person is abusing illegal drugs or if there was an arrest for driving while intoxicated. The family feels shame and guilt and shares the stigma associated with substance abuse. Encourage them to seek support from groups such as Al-Anon or Alateen. Family members may consider substance abuse a moral weakness, rather than a disease. Educating them about the neurobiologic theories may help them to reconsider their attitudes and relieve some guilt. **To be effective in working with substance abusers, nurses must examine their own attitudes and make certain the patients and families are treated with respect.**

Think Critically

A patient tells you that he drinks socially, but his wife and children tell you that he drinks to the point of intoxication at least three times a week. What would you say to the family? What would you say to the patient?

■ Evaluation

Recovery from a substance use disorder is a lengthy process. Ridding the body of substances can take weeks, particularly if there is coexisting liver damage. Often the patient is malnourished, physically exhausted, and in poor general health. Return to an optimum healthy state may take 6 months to 1 year. Recovery of psychological or emotional health takes even longer. If the patient started abusing drugs at a very young age, emotional development may have been arrested. Coping mechanisms to deal with anxiety or emotional pain were never properly developed; the individual used the drugs instead.

Consequently, nurses working in the hospital may only see early physical recovery. Evaluating overall effectiveness of substance abuse treatment is measured in years rather than weeks. Admitting a patient to a hospital and guiding him safely through detoxification are very necessary, but small, beginning steps in the overall process.

Community Care

Nurses who work in emergency departments and busy outpatient clinics often see individuals who have medical problems related to substance abuse. Often these patients are treated only for their presenting medical problem. In these instances, the medical treatment team is reinforcing the patient's denial system. *Healthy People 2020* goals include a proactive approach to use these incidental contacts to screen for substance abuse and appropriately refer these patients to prevent costly long-term complications.

Inpatient hospital stays for individuals who are addicted are usually short. If the patient has some type of insurance, it is not unusual for the insurance company to pay only for medical detoxification. Any further treatment that is necessary would be performed on an outpatient basis.

Making a decision to become sober and/or substance free typically requires lifestyle changes. Changes of this magnitude are not made overnight. Addicted individuals may need ongoing medical support, as well as support from the recovery community. You should encourage patients who are attempting recovery to seek out help and make the recovery process a number one priority. You can be instrumental in facilitating public awareness and in educating patients about the responsible use, and ultimate hazards, of mood-altering substances. Nurses should also be politically attuned to and advocate for legislation that regulates product availability and marketing of substances such as tobacco and alcohol.

Older Adult Care Points

In dealing with substance abuse issues, older adults are likely to prefer home and community settings. Frame questions and substance problems with a linkage to a medical condition, to decrease feelings of stigma. Older patients are likely to have better adherence to treatment plans and less relapse ([Matthews, 2009](#)).

Get Ready for the NCLEX® Examination!

Key Points

- Substance use disorder is diagnosed when ingestion of psychoactive substances such as alcohol, drugs, or other psychoactive substances results in recognizable signs and symptoms.
- Psychoactive substances are mind-altering agents capable of changing or altering a person's mood, behavior, cognition, arousal level, level of consciousness, and perceptions.
- Abuse implies use of a psychoactive substance in a nontherapeutic manner or the illicit use of prescription drugs.
- Dependence implies the presence of physical or psychological symptoms of addiction; when the substance use is stopped, withdrawal symptoms appear.
- Withdrawal symptoms occur when there is an attempt to stop using a substance. Symptoms of withdrawal from CNS depressants include increased blood pressure and pulse, nervousness, and heightened anxiety.
- Symptoms of withdrawal from CNS stimulants include drowsiness, headache, lethargy, nausea, alterations in eating and sleeping patterns, and cravings.
- Medical conditions related to alcohol abuse include liver damage, cardiomyopathy, hypertension, gastrointestinal bleeding, stroke, sleep disturbances, malnutrition, peripheral neuropathies, chronic infection, cognitive impairment, Wernicke encephalopathy, and Korsakoff syndrome.
- Assess for physical, psychological, and behavioral symptoms of abuse or withdrawal.
- Take a history from the patient and the family to determine type, amount, and pattern of use.
- General nursing interventions include observing for life-threatening conditions, safely managing detoxification, orienting the patient to reality, providing a balanced diet high in protein and multivitamins, setting limits, confronting denial, identifying enabling behaviors and teaching new coping mechanisms, and referring the patient to a 12-step program.
- Denial and rationalization are primary defense mechanisms used by the substance abuser and the family.
- Enabling behaviors ("helping" a person so that the consequences of his unhealthy behavior are less severe) or codependency (family member or friend attempts to control the behaviors of the substance abuser) further inhibit recovery.
- Older adults may drink to alleviate depression and loneliness. Decreased liver and renal function can quickly lead to toxicity and dependence.

Review Questions for the NCLEX® Examination

1. A nurse is taking a history on an adult male who needs emergency surgery. He freely admits to using marijuana, alcohol, cocaine, and hallucinogens. What is the most important question that the nurse should ask this patient?

1. "Does your wife know that you are using all these drugs?"
2. "When was the last time you drank or took a substance?"
3. "How frequently are you using these drugs and alcohol?"
4. "Have you ever tried to control your substance use?"

NCLEX Client Need: Physiologic Integrity: Reduction of Risk Potential

2. A patient comes to the clinic with a history of alcohol abuse. The provider makes the medical diagnosis of Wernicke encephalopathy and orders large doses of vitamin B₁. Which response indicates that the treatment is working?

1. No seizure activity
2. Less confusion and improvement of memory
3. Decreased urge to drink alcohol
4. No tremors, nausea, or vomiting

NCLEX Client Need: Physiologic Integrity: Physiological Adaptation

3. Which statement by a patient to the nurse indicates a positive step in the recovery from alcohol dependence?

1. "I do think my job is at the root of my alcohol consumption."
2. "I don't have any power over the effects alcohol has on me."
3. "I don't ever want to use alcohol again."
4. "To stay sober I will increase my exercise and eat healthy foods."

NCLEX Client Need: Psychosocial Integrity: Recognize Change in Client Mental Status

4. The wife of an alcoholic keeps making excuses to their children when he fails to do things with them that he promised he would do. What is the priority problem?

1. Limited coping ability
2. Altered family functioning
3. Absence of compliance

4. Decreased self-esteem

NCLEX Client Need: Psychosocial Integrity: Recognize Client Use of Defense Mechanisms

5. The increased usage of “bath salts” is a societal problem because it: (*Select all that apply.*)

1. is illegal in all states under federal law.
2. is the most addictive of all abused substances.
3. is easily obtained over the Internet and in many stores.
4. potentially causes violence, paranoia, and suicide.
5. causes lung cancer if smoked excessively.

NCLEX Client Need: Health Promotion and Maintenance: Provide Information for Prevention of High Risk Behaviors

6. A postoperative patient who is a self-confessed drinker is given Librium for increased blood pressure, increased pulse, tremors, nausea and vomiting, and diaphoresis. Why did the provider prescribe this medication for the patient?

1. To prevent postoperative clot formation
2. To reduce the symptoms of alcohol withdrawal
3. To control the blood pressure
4. To relieve postoperative nausea and vomiting

NCLEX Client Need: Physiologic Integrity: Pharmacological Therapies

7. A self-confessed alcoholic asks, “What is the purpose of the Antabuse that has been prescribed by my doctor?” What is the best explanation to give to the patient?

1. “It blocks the craving for alcohol.”
2. “The medication causes unpleasant symptoms when you drink.”
3. “The medication keeps you from having seizures.”
4. “It controls symptoms of nausea, vomiting, pain, or cramps.”

NCLEX Client Need: Physiologic Integrity: Pharmacological Therapies

8. A patient's wife indirectly suggests that her husband has a substance abuse problem. Which initial assessment question(s) should the nurse ask the husband? (*Select all that apply.*)

1. "What substances (alcohol, tobacco, or illicit substances) are you currently using?"
2. "How often do you drink or use illicit substances?"
3. "When did you last drink or use drugs of any kind?"
4. "How do you feel about people who abuse substances?"
5. "Why does your wife think you have a substance abuse problem?"
6. "Is there a family history of alcoholism or substance abuse?"

NCLEX Client Need: Psychosocial Integrity: Identify Client Symptoms of Substance Abuse

9. The nurse would consider a dual diagnosis for a patient who states:

1. "I'm so very busy that I rarely get much sleep."
2. "I find it difficult to get up in the morning and face the day."
3. "I need a drink first thing in the morning to calm me down."
4. "Alcohol helps me to function better on a daily basis."

NCLEX Client Need: Psychosocial Integrity: Identify Client Symptoms of Substance Abuse

10. A patient is in the early recovery process and is attempting to lead a drug-free life. Which intervention is the most appropriate to assist the patient?

1. Remind the patient of the discomfort and pain that occurred during detoxification.
2. Tell the patient that there is no need to feel guilty or ashamed.
3. Help the patient to identify relationships that were part of the substance use pattern.
4. Advise the patient that stopping forever is the only choice for a drug-free life.

Critical Thinking Questions

Scenario A

Mr. Jackson, a 74-year-old white man, is recently widowed and misses his wife very much. He comes to the provider's office and he is stumbling. His speech is slurred, and his breath has an alcohol-like odor. He begins to cry and states he has changed his mind. He does not want to see the provider but is going to drive home.

1. How will you ensure his safety?
2. What type of assessment will you perform on this patient?

Scenario B

Ms. Pulido, age 26 years, is an ambulatory postoperative patient. She admits to a past history of illicit substance abuse, but claims to be drug free for several months. You notice that she leaves the unit and when she returns her coordination is slightly impaired and she seems inappropriately euphoric and giddy. Shortly thereafter, you observe her hiding a plastic bag; you suspect that she may be taking an illicit substance.

1. How would you handle this situation?
2. What types of documentation should you perform?

Scenario C

Mr. Hernandez, a 38-year-old construction worker, was admitted for emergency orthopedic surgery yesterday evening after an on-the-job accident. He begins yelling profanity and is irritable and argumentative. He seems to be having trouble concentrating on your questions. His wife says he forgot to tell the provider that he drinks 12 beers every night.

1. What do you suspect is wrong with Mr. Hernandez?
2. What other signs and symptoms would you watch for if you suspect alcohol withdrawal?
3. List the nursing interventions to care for Mr. Hernandez during the initial phase of withdrawal.

Scenario D

Ms. Genavarian's father confides that his daughter has a substance abuse problem. He reports that the family has frequent arguments about the issue. Further assessment reveals that Mr. Genavarian believes that the behavior is "just weakness," whereas the daughter and wife maintain that "it's not that big of a deal."

1. Discuss some of the emotional and psychological responses that are common among patients and families when there is a substance abuse problem.
2. What could you say to Mr. Genavarian to help him understand that substance abuse is a medical problem?
3. How could you help Mrs. Genavarian to understand that she may be enabling her daughter's behavior?

1833

CHAPTER 47

Care of Patients With Cognitive Disorders

Objectives

Theory

1. Examine the incidence and significance of cognitive disorders in the older adult population.
2. Compare and contrast the etiology and symptoms of **delirium** (acute cognitive disorder) and **dementia** (chronic cognitive disorder).
3. Describe the signs and symptoms of Alzheimer disease (AD) in relation to the three stages: (1) preclinical, (2) mild cognitive impairment (MCI), and (3) dementia.
4. Determine the assessment skills that are necessary to accurately monitor a cognitive disorder.
5. Choose appropriate nursing interventions for the care of patients with Alzheimer disease.
6. Develop nursing interventions that can be used to assist the family and friends of patients who have cognitive disorders.

Clinical Practice

7. Devise a care plan with at least six interventions for a patient who is confused and disoriented.
8. Implement a teaching plan for a family member who is caring for an older adult parent with Alzheimer disease in the family home.

KEY TERMS

Alzheimer disease (ĂWLTZ-hī-mĕr dī-ZĒZ, p. 1092)

biomarker (p. 1095)

cognition (kōg-NĬ-shūn, p. 1092)

vascular dementia (VĀS-kū-lär dĕ-MĒN-shē-ă, p. 1092)

Overview of Cognitive Disorders

Cognition refers to mental processes of perception, memory, judgment, and reasoning. It includes the ability to perceive and process information. A **cognitive disorder** is diagnosed when there is a significant change in cognition from a previous level of functioning. Cognitive disorders greatly affect the quality of life for affected individuals, families, and friends. Although cognitive disorders do occur across the life span, they are often linked to the neurobiologic changes that accompany aging. Cognitive disorders have become increasingly common with the aging of the population. Disorders of cognition include delirium and dementia.

Delirium (acute confusion) is characterized by a change in overall cognition and level of consciousness over a short time. **Dementia**, on the other hand, is characterized by several cognitive deficits, memory in particular, and tends to be more chronic. Both conditions are classified according to cause or origin of disease. One example of a cause for dementia is multiple small blood clots that cause brain tissue damage (known as **vascular dementia**). **Alzheimer disease** (AD; a degenerative disease of the brain) is another form of dementia, although the exact cause is unknown. The difference between the two conditions is that delirium is an acute condition that requires immediate treatment, and dementia is a chronic condition. Reversing the symptoms of delirium depends on timely diagnosis and treatment. It also is important to note that delirium can coexist with dementia. If delirium is recognized and promptly treated, a patient with preexisting dementia should be restored to a previous level of functioning.

Delirium

Many conditions or physiologic alterations can cause delirium. Some examples are cerebrovascular accident; drug overdose, toxicity, or withdrawal; tumors; systemic infections; anesthesia; fluid and electrolyte imbalances; and malnutrition. The onset of acute delirium is sudden. The patient may be alert or lethargic, depending on the cause of the delirium, or may appear very confused. The attention span changes, and overall awareness of the environment is decreased. Orientation is impaired, as are recent and immediate memory. Speech may be incoherent, and overall thinking can be disorganized and distorted. The patient will not be able to communicate her thoughts in a meaningful way. With delirium, a patient may experience **illusions** (misinterpretations of reality). For example, a pen appears to be a knife, or a shadow on the floor appears to be a menacing monster. If a patient appears to be talking to someone who is not there, it is likely that she is experiencing **hallucinations** (seeing or hearing things that are not there). If she insists that a nurse is an angel of death and destruction, this is an example of a **delusion** (belief in a false idea).

Clinical Cues

Assessment for and treatment of the underlying cause of delirium is essential. Physical restraints should be avoided. Reorientation, a calm environment and reduction of sound, explanations of proceedings, and calm reassurance are first-line interventions. An antipsychotic medication may be used to prevent harm to the patient or others if needed.

Problem-solving ability and judgment may be diminished but not completely absent. Consequently, the patient may not make good decisions, or may become combative or hostile if a nurse or family member attempts to intervene. The general features of delirium are the same for all the causes, and nursing care is basically the same; the main difference is in diagnosis and treatment of the underlying cause.

Older Adult Care Points

In hospitalized older adults with preexisting dementia, it is not unusual to see a patient who has been previously conscious and oriented become drowsy, disoriented, combative, and unable to recognize family and friends. An astute nurse should suspect delirium or acute confusion. An important evaluation is to note the type and response to medications. Anticholinergic medications have potent central nervous system effects and can cause a sudden episode of confusion. Is the

dose too high for age and physiologic functioning? Is there a cumulative effect? Are the medications interacting? Delirium and dementia can coexist, and the acute condition needs to be recognized and treated, not merely dismissed as part of the overall dementia.

Clinical Cues

Does your patient have depression, dementia, or delirium? A patient with depression can have poor personal hygiene, can have difficulty with concentration, and may be very quiet and withdrawn or very agitated (see [Chapter 45](#)). Subtle differences indicate depression, dementia, or delirium. For example, a depressed patient may speak very little, but the speech is generally logical and will contain sad and negative thoughts and feelings of hopelessness. A patient with dementia may confabulate or will have difficulty finding words. A patient with delirium is more likely to be incoherent or loud.

Substance-Induced Delirium

Substance-induced delirium can be caused by withdrawal from a substance, intoxication with a substance, or side effects from a medication (see [Chapter 46](#)). Many classes of medications can produce symptoms of delirium. Some common examples are anesthetics, analgesics, sedative-hypnotics, any products with anticholinergic activity (tricyclic antidepressants, antihistamines, theophylline derivatives, and antipsychotics), and histamine (H_2)-receptor blockers (e.g., famotidine, cimetidine, and ranitidine). Commonly prescribed beta blockers and nonsteroidal anti-inflammatory drugs (NSAIDs) can also cause symptoms of delirium.

Diagnosis and treatment depend on taking a thorough history. If the patient is unable to give a history, the family may be able to help. It is not unusual for a person to be taking large amounts of over-the-counter medications and forget to mention them because the medications were not prescribed by a provider. You should pay attention to drug interactions and incompatibilities, and consult with the pharmacist as needed. Early recognition can facilitate a faster recovery. If the medication accumulates over several days, elimination of the substance from the body takes much longer and places the patient in even greater danger.

Older Adult Care Points

Older adults have a high risk for substance-induced delirium because of overall decreased metabolism and reduction in liver and kidney function. A general principle that providers should use in prescribing medications to older adults is to give the smallest amount possible and increase the amount only as symptoms indicate. Therefore you must carefully observe and report subtle changes in behavior, vital signs, and laboratory results.

Dementia

There are several different types of dementia, and these conditions are also classified according to the underlying cause. Examples include AD, frontotemporal lobe dementia, Huntington disease, Korsakoff syndrome, vascular dementia, AIDS dementia complex, and Parkinson disease. The onset for dementia is slow, and the condition may progress over months to years. The patient is generally alert. Orientation to person, place, and time and recent memory may be impaired. In later stages of dementia, patients lose remote memory as well. Patients with dementia have difficulty with abstracting thoughts and have a poverty of thoughts. **Confabulation** (making up words or experiences to fill conversational gaps) and impaired judgment are common. Often, there is a noticeable change in personality. Hallucinations, delusions, and illusions usually are not present. These patients experience fragmented sleep rather than a reversed cycle.

Complementary and Alternative Therapies

Herbs With Sedative Effects

Herbs that have a sedative effect include chamomile, hops, and valerian. These can be used in a tea

or taken in capsules. A popular method of promoting sleep is to place a few drops of lavender onto the pillowcase. If your patients are using herbs or alternative therapies, advise them to inform their provider because of potential drug-herb interactions or contraindications because of medical conditions.

Alzheimer Disease

Etiology and Pathophysiology

AD is the most common degenerative disease of the brain. More than 5 million Americans have AD ([Alzheimer's Association, 2013](#)), and there is no known cause or cure. It has been determined that there is some link between exposure to pesticides, particularly DDT, a genetic variant, and AD. AD typically affects people older than 65 years but can also strike younger people. The age group of 85 years and older is currently the fastest growing age group in the United States. It is estimated that 50% of this age group have AD.

In AD, there is a loss of neurons in the frontal and temporal lobes. The atrophy in these areas accounts for the patient's inability to process and integrate new information and to retrieve memories. Brain biopsies of patients with AD have revealed nerve cells that are tangled and twisted and an abnormal buildup of proteins. Production of neurotransmitters (e.g., acetylcholine, serotonin) is relatively decreased for these patients. Risk factors for developing AD include advanced age, family history of AD, head trauma, cardiovascular disease, diabetes, high cholesterol, lack of exercise, exposure to toxins such as DDT, and poor diet ([Alzheimer's Association, 2014](#)).

Health Promotion

Diet and Memory

Studies show that fish and omega-3 polyunsaturated fats, fruits and vegetables, curcumin (curry spice), and a traditional Mediterranean diet may lower the risk for loss of cognitive function and/or AD. Moderate consumption (1 to 2 drinks a day) of alcohol, especially wine, is also associated with a reduced risk, but it is not recommended that a nondrinker take up wine  consumption ([Neafsey and Collins, 2011](#)).

Health Promotion

Exercise for the Brain

Longitudinal studies have shown that challenging intellectual activity is associated with a decreased risk for dementia. Reading, writing, debating, learning something new, using the nondominant hand, playing an instrument, and playing memory or puzzle games exercise the brain ( [Polidori et al, 2010](#)). Regular exercise and social interaction also can help maintain a healthy brain.

Signs and Symptoms

AD has a slow onset and variable rate of progression. Eventually, it is fatal. Although the Alzheimer's Association divides behavioral patterns and symptoms into seven stages, other sources prefer a division into three stages: mild cognitive decline, moderate cognitive decline, and severe or late cognitive decline. The early signs and symptoms of beginning mental deterioration include forgetfulness; recent memory loss; difficulty learning and remembering; inability to concentrate; and a decline in personal hygiene, appearance, and inhibitions. Later the patient becomes quite confused and unable to make judgments, has difficulty communicating, suffers losses in motor function, and becomes dependent on others. Behavioral manifestations can also be categorized into three stages ([Box 47-1](#)).

Box 47-1

Behavioral Patterns in Mild, Moderate, and Severe Alzheimer Disease

Mild

- Progressive short-term memory loss
- Slow, progressive loss of intellectual ability
- Difficulty in learning new things
- Small but noticeable changes in ability to perform at work or socially
- Decline in ability to plan ahead
- Decreased ability to perform usual ADLs
- Variable mood; depression is common and worsens symptoms
- Noticeable personality change
- Social withdrawal

Moderate Toward Severe

- Aware of deficits and confabulates to cover memory lapses
- Needs repeated instructions for simple tasks
- Needs day care or constant home care—can be very burdensome for the family
- Wanders away
- May have beginning incontinence
- Outbursts of anger, hostility, paranoia

Severe

- Unable to speak or ambulate
- Profound memory loss; no recognition of family
- Difficulty swallowing
- Weight loss
- Bedridden
- Fetal position
- End-stage consequences of poor nutritional state and bedridden status: pressure sores, respiratory failure, contractures, pneumonia

ADLs, Activities of daily living.

Patients have a progressive loss of common cognitive functions. You observe that an 85-year-old retired attorney has trouble remembering words (**anomia**) or verbally expressing himself (**aphasia**), and he is unable to write down his thoughts (**agraphia**) or understand written language (**alexia**). If he holds a common object such as a spoon, he does not seem to recognize it (**agnosia**), and he

cannot put on his shirt, although he has the strength and motor movement to dress himself (**apraxia**: inability to perform an activity despite motor function). He has difficulty planning ahead and he attends fewer social functions. He also displays some problems with balance and gait. He displays the criteria for dementia according to the *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition (DSM-5).

Complementary and Alternative Therapies

Pet Therapy

Pet therapy may help patients to improve memory (e.g., calling the therapy dog's name), coordination (e.g., throwing a ball for the dog), object identification (e.g., directing the dog to get the ball), language (e.g., talking to the dog), and attention (e.g., caring for the dog). Research conducted about pet therapy programs demonstrates consistent positive outcomes for both physical responses, such as improvement in vital signs, and psychological parameters, such as a decrease in anxiety, fatigue, depression, and confusion (Vann, 2010).

Think Critically

It is not uncommon for patients with dementia to act in a sexually inappropriate way because of loss of social reserve. Your older adult male is reaching to fondle your breasts when you turn him to do hygienic care and linen changes. How will you handle this?

Diagnosis

In 2011, new criteria and guidelines for the diagnosis of AD were presented as the result of an international collaboration to incorporate research findings to improve the diagnostic process. The new guidelines propose three stages: (1) preclinical AD, (2) very mild cognitive impairment (MCI) caused by AD, and (3) dementia caused by AD.

Currently there are no criteria for providers to use in making the diagnosis of preclinical AD. Future research on preclinical AD is based on the assumption that there are biologic processes that are occurring before the onset of actual symptoms. Research is under way to predict which cognitively normal older adults will develop AD as early as 7.5 years before symptoms appear. Biomarkers involved are positron emission tomography (PET) scans to detect deposits of beta-amyloid plaque in the brain and cerebrospinal fluid tests for a specific protein, tau, that predict who will develop dementia. (A **biomarker** is an objective measure that indicates the presence of disease.) The drug flutemetamol F 18 (Vizamyl) has been approved by the U.S. Food and Drug Administration for use with PET imaging in adults suspected of having AD. The drug attaches to beta-amyloid, helping to reveal areas of the plaque (Nursing2014, 2014).

In making a diagnosis of AD, the provider uses a detailed medical and family history and conducts a thorough physical, neurologic, and functional assessment. The benefits of early diagnosis include being able to include the patient in the planning for the future, to ensure safety, and to provide the family with understanding of the disease process (Alzheimer's Association, 2014). The patient may undergo magnetic resonance imaging (MRI) to rule out pathologic lesions. Research for new diagnostic tests for AD will continue. The DSM-5 provides behavioral criteria for AD.

Treatment

There are clinical trials under way for a vaccine to prevent AD. Currently medications are used that do not cure AD but may improve intellectual functioning and slow the progression of the disease (Anderson, 2013). The evidence indicates that the benefit of these drugs is modest. Research is being done on immunotherapies that target the protein that contributes to the formation of the neurofiber tangles (FightAging.org, 2013). Table 47-1 describes medications used to treat cognitive disorders and their nursing implications. Behavioral interventions include (1) identifying the behavior, (2) understanding its cause (pain, delirium, thirst, constipation, full bladder, etc.), and (3) adapting the environment to decrease distraction and stimulation and remedy the situation (Alzheimer's Association, 2014). A recent study has found a link between sleep apnea and AD.

(American Thoracic Society, 2013). Treating cognitively normal patients with AD biomarkers with continuous positive airway pressure (CPAP) over an extended period of time will enhance the research.

Table 47-1
Drugs Commonly Used to Treat Cognitive Disorders

MEDICATION	ACTION	PATIENT EDUCATION	NURSING IMPLICATIONS
Donepezil (Aricept) Galantamine (Razadyne) Memantine (Namenda) Rivastigmine (Exelon) Transdermal patch has been recently approved.	Causes elevated acetylcholine levels in the brain and slows progression of Alzheimer disease symptoms.	Take with food to decrease GI distress. Slows progression of symptoms but is not a cure. Take frequent drinks of cool liquids or use sugarless gum or candy for dry mouth. Increase fiber and fluids to prevent constipation. Common side effects (nausea, vomiting, headaches and dizziness, GI bleeding, urinary frequency, anorexia) should be reported to provider.	Be alert for abdominal pain, fatigue, hypotension, and agitation. Monitor CBC, liver, and renal function tests. Signs of overdose include severe nausea and vomiting, bradycardia, hypotension, convulsions, or severe muscle weakness. Rivastigmine patch: first patch should be applied on the day after the last oral dose, then rotate sites; replace every 24 hr.

CBC, Complete blood count; GI, gastrointestinal.

❖ Nursing Management

■ Assessment (Data Collection)

You may be the first health care professional who encounters a patient who is in the early stages of AD. Know and be vigilant for the 10 warning signs of AD (Alzheimer's Association, 2010) (Box 47-2). For example, the family may tell you, "We think Dad is having problems with his memory and in completing daily tasks, and we also think he is attempting to hide his forgetfulness because he keeps misplacing things and can't seem to solve ordinary problems. He insists on driving, but we are beginning to question his judgment. He often acts like he is searching for the right word and often makes up stories [confabulates] to make up for memory loss. We can't seem to teach him how to position a can to use a can opener. He is even confused about times when we have recently visited him, and he is moody and withdrawn during our regular visits." Ask the patient and the family questions about memory, ability to perform activities of daily living (ADLs), and any subtle changes in personality by giving specific common examples (e.g., "Does he forget to turn off the stove or to lock the doors?"). These patients should be referred to the RN or provider, because they need an in-depth assessment and an extensive physical examination. Assessment should include the necessary data to plan measures to protect the patient.

▣ Clinical Cues

Before you begin to assess an older adult patient, consider the changes that normal healthy older adults might be experiencing because of aging. For example, it is normal to have some decline in memory; however, a healthy older adult should be able to create new memories, act purposefully, and accomplish ADLs independently.

Box 47-2

Ten Warning Signs of Alzheimer Disease

1. Memory loss that disrupts daily life
2. Challenges in planning or solving problems
3. Difficulty completing familiar tasks at home, at work, or at leisure
4. Confusion with time or place
5. Trouble understanding visual images and spatial relationships
6. New problems with words in speaking or writing
7. Misplacing things with inability to retrace steps

8. Decreased or poor judgment
9. Withdrawal from work or social activities

10. Changes in mood or personality

From Alzheimer's Association. (2014). *10 warning signs of Alzheimer's*. Retrieved from www.alz.org/alzheimers_disease_10_signs_of_alzheimers.asp?type=more_information.

■ Nursing Diagnosis and Planning

Nursing problems are identified to maximize safety and to minimize complications resulting from loss of cognitive function. For example, Potential for injury, Wandering, Chronic confusion, Altered self-care ability, and Caregiver burden are some of the problem statements used for patients with AD. Planning care for a patient with AD is based on the stage of the disease, and the family should be encouraged from the beginning to participate in developing the long-term goals ([Nursing Care Plan 47-1](#)). As the disease progresses, the patient will sustain losses in every area of function.

▣ Clinical Cues

When caring for confused patients, evidence-based practice supports the need for careful observation and documentation of patterns of behavior. This process, **dementia care mapping**, can be used to improve care ([Downs, 2014](#)). For example, you observe that your confused patient consistently tries to get out of bed on the right side, despite the fact that the safety devices are on the left and that there is more room on the left side. This suggests that the patient has an automatic habit of getting out on the right side; these data can now be used to adapt the room and increase patient safety.

▣ Nursing Care Plan 47-1

Care of a Patient With Alzheimer Disease

Scenario

Mrs. Sarah Hughes, an 83-year-old with Alzheimer disease, has been living with her daughter. The daughter works full time and must take a business trip for 2 weeks. She has had to find respite living arrangements for her mother. "Mom is confused and withdrawn most of the time and needs reminders to eat and coaching to go to the bathroom. I really try my best, but Mom can be difficult." The daughter appears tired but is very patient with her mother. You observe Mrs. Hughes wandering alone and trying to go outside. You have to redirect her several times, and she mistakes you for her daughter.

Problem Statement/Nursing Diagnosis

Confusion/Chronic confusion related to cognitive impairment.

Supporting Assessment Data

Subjective: Per daughter, patient is "confused most of the time."

Objective: Mistakes you for her daughter.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will function at an optimal level for the degree of cognitive losses at this time.	Identify self.	Patient may not recognize people previously introduced.	Patient repeatedly mistakes nurses for her daughter. Does recognize provider.
Patient will follow concrete instructions.	Speak clearly and calmly and use short phrases and repeat as needed. Face the patient directly when talking.	Facilitates communication. Stimulation of two senses (visual and auditory) facilitates understanding.	Speaking slowly and clearly and repeating helps patient to understand.
	Do not approach patient from behind.	Surprises and scares the patient. Pictures are more easily understood than oral words.	Letting the patient see you prevents a fright reaction.
	Use pictures to communicate.		Use of arrows to bathroom also appears helpful.
	Be consistent in approach and assign the same staff and maintain daily structure and routine.	Familiar faces and repetitive patterns decrease confusion.	Patient functions best when A.M. routine is followed and primary nurse helps her.
	Break down all tasks into simple steps and encourage completion of one step at a time.	Single steps are less complex and easier to achieve.	This A.M. patient was able to brush own teeth if instructed, step by step.
	Encourage reminiscing about the past.	Remote memory is more likely to be intact than recent memory.	Appears to enjoy talking about "Maggie's cat."

			Outcomes met. Continue plan.
--	--	--	---------------------------------

Problem Statement/Nursing Diagnosis

Altered self-care ability/*Self-care deficit: Toileting/feeding related to cognitive and perceptual impairment.*

Supporting Assessment Data

Subjective: Per daughter, "needs reminders to eat and coaching to go to the bathroom."

Objective: Needs repetitive verbal prompting.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will perform ADLs independently or with minimal assistance from caregivers.	Assess the patient's ability to perform ADLs independently or with minimal assistance.	Provides baseline for daily planning (abilities may wax and wane).	Is able to physically perform most ADLs, but needs verbal coaching for each step.
	Encourage patient to maintain independence in performing ADLs.	Maintain maximal independence for as long as possible to increase self-esteem and stimulate mental processes.	Daughter reports that "it is really faster just to do everything for her" but acknowledges the benefit of allowing her independence.
	Allow patient to wear own clothes. Use clothing with zippers and Velcro.	Familiar objects decrease confusion. Ease of equipment decreases frustration	Usually recognizes own clothing, but needs coaching for dressing; can manipulate Velcro fasteners.
	Praise for any and all accomplishments.	Reinforces desired behavior.	Appears to enjoy interaction and feedback.
	Use simple, direct explanations when demonstrating the specific behavior patient is to complete.	Verbal and visual cues help to decrease confusion.	Follows instructions, but rarely asks for help.
	Maintain toileting schedule.	Bowel and bladder routine decreases incontinence.	Toileting schedule q4h; patient usually continent.
	Encourage the use of finger foods.	Simplifies eating while maintaining intake.	Eats all food if encouraged. Has difficulty cutting meat with knife and fork. Outcomes met. Continue plan.

Problem Statement/Nursing Diagnosis

Altered socialization/*Social isolation related to anxiety and depression, apathy, and confused state.*

Supporting Assessment Data

Subjective: Per daughter, confused or withdrawn most of the time.

Objective: Walking alone.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will participate in group activities.	Assess preferred patterns of social activity from earlier years.	Ideally, current socialization should mimic past patterns.	Social contact usually limited to family. Occasionally went to church.
Patient will demonstrate socially acceptable behavior.	Provide group activities that are simple, such as singing or simple crafts.	Simple activities decrease frustration and are a vehicle to interaction.	Appears to enjoy movies and musical groups.
	Stay with the patient during social activities as needed.	Provides support and reassurance.	Does not initiate conversation with others, but will respond if spoken to.
	If she becomes agitated do not force her to participate in any social activity.	Socialization can be stressful, and forcing is counterproductive.	Readily agreed to go to all activities today.
	Gradually increase social interaction with other staff and patients.	Gradual exposure increases comfort level and familiarity.	Will sit with others, but does not initiate any interaction. Will speak to other patients if they speak to her. Outcomes met. Continue plan.

Problem Statement/Nursing Diagnosis

Potential for caregiver burden/*Risk for caregiver role strain, related to high emotional and physical demands, safety concerns for the relative, and caregiver isolation.*

Supporting Assessment Data

Subjective: "I really try my best, but Mom can be difficult."

Objective: Daughter works full time and appears tired, but is very patient with her mother.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Caregiver will verbalize ways to perform the caregiver role without becoming exhausted. Caregiver will openly express feelings.	Assess caregiver's ability to meet the needs of the patient.	Baseline for planning.	Daughter expresses willingness to care for her mother, but does work full time.
	Actively listen to caregiver's fears and concerns.	Allowing expression helps to build trust and rapport; also helps speaker and listener to clarify issues.	Fears for mother's safety; is concerned about wandering.
	Educate the caregiver about cognitive disorders and the patient's specific cognitive deficits.	Accurate information allows daughter to have realistic expectations.	Written information given, and discussion of cognitive disorders provided for daughter.
	Help caregivers be realistic about the prognosis for their loved one.	Being realistic about prognosis helps the family to begin the process of anticipatory grieving.	Daughter appears unsure about the future, knows that her mother is going to get worse.
	Make caregiver aware of community	Community supports are available to provide care,	Referred to support group for caregivers

	resources such as respite care.	education, support, and advice.	of patients with Alzheimer disease.
	Encourage participation in support groups.	Sharing with people who are experiencing similar problems decreases feelings of alienation and allows sharing of information.	
	Will try to find an on-line support group. Support caregiver in taking steps to maintain own health.	Daughter must be healthy to continue supporting her mother.	Daughter discussed respite care and plans to take occasional breaks. Continue plan.

Problem Statement/Nursing Diagnosis

Wandering/Wandering related to cognitive impairment and loss of judgment.

Supporting Assessment Data

Subjective: Per daughter, "Mom is confused."

Objective: Wandering by herself and trying to get outside despite repetitive redirection.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will remain within the boundaries of the center (or the family property) unless accompanied by others.	Place in a limited-access unit. Put complex locks on the doors. Allow access to fenced yard.	Securing the environment allows the patient to roam safely, but without restraints.	Patient remained safe in secure unit. Went out to grounds with nursing student in the A.M.
	Use identification bracelets or sew ID labels on clothes.	ID methods facilitate location and return if she does get lost.	Discussed sewing labels into clothes with daughter.
	Label all rooms and doors.	Patient may be wandering because she cannot find the bathroom, cafeteria, etc.	Arrows to bathroom appear especially useful.
	Remove visual cues that trigger wandering (e.g., car keys, coat). Check on patient at frequent designated intervals.	Visual cues such as car keys can trigger a past familiar behavior (e.g., driving to work). Assists to keep patient safe.	Asked for coat, was reassured that it was in the storage closet. Redirected into common area. Has not been wandering.
	Notify police and neighbors to be on the alert.	Police and neighbors can quickly contact caregiver.	Discussed with daughter about notifying neighbors and police. Outcomes met. Continue plan.

Critical Thinking Questions

- How would you react if Mrs. Hughes's daughter complains about the care that Mrs. Hughes is receiving at the respite center at the nursing home?
- What interventions could you initiate to protect patients like Mrs. Hughes from physical injury related to confusion?

ADLs, Activities of daily living; *ID*, identification; *NA*, nursing assistant.

Implementation and Evaluation

Patients with AD need interventions that enhance memory, such as holiday decorations that are appropriate to the season or photos of family and friends to help them reminisce. Reminiscence therapy could also include creating a life-story book that helps the patient to review accomplishments and increase self-esteem. An Irish company is testing an interactive reminiscence software that holds promise in working with patients. Although safety is a primary concern, restraints are rarely appropriate for these patients; creative interventions that are specific to the individual and family can ensure safety while preserving dignity. For example, one family placed a pleasant musical bell on the front door to prevent a confused older adult from leaving the house undetected. Supporting the family will be a priority, particularly if the patient is being cared for at home. Help the family to have realistic expectations and refer them to respite care and support groups. Placing written name tags on commonly used household objects, such as the bathroom door or the patient's room door, seems to help the patient function better within the home setting. Visual cues such as a picture of a toilet on the bathroom door are helpful as the disease progresses.

Clinical Cues

If a patient becomes resistant or agitated when asked to do something or when trying to accomplish a task, redirect the client to something else and return to the desired task later.

Patients with AD may seem to require very infrequent evaluation, because the disease can progress very slowly and obvious changes in behavior or success in meeting goals may seem very gradual. However, vigilant evaluation will help you detect subtle changes in behavior that may

signal delirium or progression of the disease. Also, any small successes can and should be shared with the family (see [Nursing Care Plan 47-1](#)).

Vascular Dementia

Vascular dementia was formerly known as *multi-infarct dementia*. It is the second most common type of chronic cognitive disorder. **Vascular dementia is a broad term used to describe any type of dementia caused by vessel disease.** People who are predisposed to this type of dementia have a history of hypertension, hyperlipidemia, diabetes mellitus, or abuse of nicotine and alcohol.

Any type of vessel disease in the brain will cause brain damage. Lack of oxygen to the brain tissue because of clots or hemorrhage can cause death of brain tissue in a short time. The parts of the brain originally affected by cell death will be permanently damaged. The onset can be gradual or abrupt, and the neurologic impairment is localized rather than global. The progression of symptoms is more rapid than in AD. Neurologic deficits are present in whatever part of the brain has been destroyed. **Prompt treatment of hypertension and vascular disease is necessary to prevent long-term complications.**

Cultural Considerations

Race Factors

African Americans have twice the risk for developing AD, and Hispanic Americans have 1.5 times the risk. African Americans are also at greater risk for developing vascular dementia compared with whites. Patients with risk factors for vascular dementia, such as hypertension and diabetes, should be identified and educated to optimize healthy lifestyle practices ([Alzheimer's Association, 2014](#)).

AIDS Dementia Complex

AIDS dementia complex (ADC) is caused by infection with HIV. The central nervous system can be affected, and the patient may also have **peripheral neuropathy** (disturbance in the function of peripheral nerves that results in numbness or muscle weakness). ADC affects cognition, behavior, mood, and motor ability. There is great variability in the manifestation of symptoms. In the beginning, symptoms can be easily mistaken for depression: apathy, loss of interest, difficulty concentrating and slowed thinking, and irritability. Early symptoms may also include unsteady gait and poor hand coordination for things such as writing. In the later stages, the patient can develop bowel and bladder incontinence, confinement to bed, and psychosis or mania. ADC is diagnosed by computed tomography or MRI, spinal tap, and a mental status examination. Treatment includes anti-HIV drugs, and symptoms are treated with antidepressants, antipsychotics, and anxiolytics.

❖ Nursing Management

■ Assessment (Data Collection)

On admission, an extensive mental status examination should be conducted by the provider and the RN to obtain a baseline for the patient's thought content, intellectual functioning, mood, affect, and judgment. After the baseline is established, the Mini-Mental State Examination (MMSE) can be used for ongoing assessment. The MMSE is a popular shortened version of the mental status examination that was developed by Folstein and colleagues in 1975. It can be used for patients who have cognitive disorders or thought disorders to assess orientation, memory, and ability to follow commands. It consists of 11 easily scored items and should take about 5 to 10 minutes to administer. Examples of items would include "What day is it? What city is this? What am I holding (common objects such as a pen or paper clip)?" Administration should be done without the patient feeling it is a "test."

Differentiating between delirium and dementia is often difficult for nurses, because the patient is not a reliable historian. A mood disorder, such as depression, can further complicate the picture (see [Chapter 45](#)). Accurate recognition of these three conditions requires excellent assessment skills. An effective way to assess whether a patient has delirium or dementia is to note function in the

following five areas: *judgment*, *affect*, *memory*, *cognition*, and *orientation* (JAMCO).

Focused Assessment

Quick Assessment Guide for Delirium and Dementia: JAMCO

Judgment: Does the patient have insight into her behavior? Is the patient aware of danger or safety issues?

Affect: Is affect blunt, flat, inappropriate, suddenly changed, or variable?

Memory: Is memory intact? Does the patient have remote memory, but not recent or immediate? Is memory better during the day?

Cognition: Is the patient able to process abstract thoughts? Are thoughts fragmented or disorganized? Does the patient make up answers to questions (confabulate) to hide deficits?

Orientation: Is the patient oriented to person, place, and time? Does the patient recognize family and friends?

First, what is the status of the patient's **judgment**. Your patient insists on driving, despite the fact that she has had several minor accidents within the past 2 weeks. This connotes poor judgment, and you must work with the patient and the family to seek alternative transportation.

Assessing and documenting **affect** (emotional or feeling tone) are also important. Has there been a sudden change in mood from the previous assessment? The family will often say that they note a difference in mood when they visit the patient. You should pay attention to what family members tell you and elicit their opinions about the changes that they are seeing in their loved one.

Clinical Cues

Mood and affect are typically assessed simultaneously. **Mood** is the current state of emotion that a person is experiencing. **Affect** is the demonstration of emotion, usually by facial expression and body position. Ordinarily, affect and mood match, so those in a "good mood" would display a cheerful affect. Likewise, depressed people often display a flat or sad affect. In a flat affect, the face is devoid of expression, and the patient may appear to have little or no energy for interaction. A sad affect is usually apparent, and the patient may cry, frown, or have a worried, preoccupied expression.

When assessing **memory**, it is important to note recent and remote memory. In some types of dementia, a patient may not be able to remember what was on the breakfast tray, but may be able to talk at great length about events in her younger years. With delirium, both recent memory (a few hours before) and immediate memory (a few minutes before) may be absent.

Think Critically

Think of one or two ways you can assess immediate, recent, and remote memory. How would you know whether the patient's memory is accurate?

Cognition is the ability to abstract and process information. Obviously, there are links and overlaps to memory and perception when assessing cognition. The family should also be consulted whenever possible for valuable baseline information about the patient's past performance. For example, a patient's son tells you, "My mother was a former math teacher; now she cannot seem to balance her checkbook, and that was something that she could easily do in the past."

Finally, is the patient **oriented** to person, place, and time? Are there times when the patient is disoriented? It is not unusual for a patient to be completely oriented during the daytime hours and become confused and disoriented at night. This phenomenon is known as **sundowning** and needs to be documented. A dose of trazodone (Desyrel) in the afternoon or evening may be ordered to

reduce the symptoms associated with sundowning, because it helps reduce anxiety and causes sleepiness.

Complementary and Alternative Therapies

Agitated Patient

Music, recordings of soft ocean sounds, light touch or hand massage (avoid touching if the patient is violent or angry), or aromatherapy may help to calm an agitated patient with sundown syndrome. Having your patient sit by a light box in the early morning may also help, particularly if the patient has depression. These adjunct therapies may decrease the need for drug therapy ([Khachiyants et al, 2011](#)).

Think Critically

What implications does sundowning have for planning care and activities for the patient?

An assessment of mental status needs to be completed at least once per shift so any change can be detected promptly and appropriate interventions taken. This assessment should include orientation to person, place, and time and the other elements of JAMCO. The MMSE can be used at the nurse's discretion to validate mental status changes or according to the agency's policy for long-term care patients. When abrupt changes are noted, the RN and the provider should be notified to perform more detailed assessments.

Clinical Cues

In cases of delirium or acute confusion, you must assess the patient's medication history, look for any signs of infection, and assess current fluid and electrolyte status. Also, if you have reason to suspect that the patient may have sustained a fall, assess for head trauma.

Think Critically

How would you approach a pain assessment for a patient with dementia?

Nursing Diagnosis

Nursing problem statements for patients with cognitive disorders include:

- Acute confusion due to delirium induced by infection
 - Chronic confusion due to slow, progressive memory loss
 - Social isolation due to inability to recognize friends and family
 - Altered self-care ability due to decreased psychomotor abilities
 - Potential for injury due to faulty judgment
 - Disrupted sleep pattern due to age-related changes
 - Altered sensory perception due to hallucinations
 - Wandering due to disorientation to time and place
 - Potential for caregiver burden due to prolonged 24-hour responsibility of caregiving
- Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

Planning

Expected outcomes are written for the problems identified from assessment data. For these problems, they might include:

- Patient will demonstrate orientation to person, place, and time within 24 to 48 hours after starting antibiotic therapy.
- Patient will recognize self and primary caregiver (e.g., daughter) during hospital stay.
- Patient will interact with family and friends during weekly visits.

- Patient will perform ADLs with assistance as needed during this shift.
- Patient will be safe and free from harm during this shift.
- Patient will rest and sleep for at least 6 hours every 24-hour period.
- Patient will decrease behaviors that suggest hallucinations (e.g., listening to voices) within 1 week.
- Patient will remain on unit or within fenced grounds during this shift.
- Family will identify signs and symptoms of caregiver burden during counseling session at the end of the week.

Clinical Cues

When assisting older adults and confused patients to eat, slowly give one bite of an item, allow adequate time for chewing and swallowing, and then give another bite of a different food item. This varies the taste and texture and enhances the enjoyment of eating. Limit distractions. Also remember to include some time for socialization during the meal. Sit with the patient during the meal.

In accordance with National Patient Safety Goals, nurses must identify patients who have safety risks; this includes patients with cognitive disorders. Planning care for a patient with delirium involves accurately assessing the acute condition, stabilizing the patient, reducing environmental stimuli, providing reality orientation, and assisting the provider in determining the cause. Planning care for a patient with dementia frequently involves the caregivers and should be done with long-term goals in mind. Patients in the early stages of AD may be experiencing difficulties with ADLs; however, they may attempt to hide their condition. Forgetting to turn off the stove or to lock the doors is not uncommon. Regardless of the cause, the loss of cognition is devastating, and it is important to maintain the patient's dignity, provide for safety and optimal level of functioning, and promote quality of life.

■ Implementation

Interventions to provide safety and minimize anxiety for patients with dementia and delirium are similar. **However, when caring for a patient whose sudden change in behavior may be caused by delirium, time is of the essence.** Assess the patient frequently, document your findings, and be certain the provider is notified. Because the level of consciousness may be clouded, reduce distractions in the environment; for example, having the television on can create background noise that increases confusion ([Alzheimer's Association, 2015](#)). It may be necessary to medicate patients with anxiolytics for severe anxiety, or with antipsychotics if the misinterpretation of the environment causes them to be aggressive.

Safety Alert

Antipsychotic Drugs

Nurses should be aware that atypical antipsychotics such as olanzapine (Zyprexa), quetiapine (Seroquel), and risperidone (Risperdal) are approved for use in schizophrenia but are not approved for use with older patients who display behavioral changes related to dementia. Clinical trials showed an increased risk of death in this population with use of these drugs ([PsychCentral.com, 2011](#)).

Patients may be able to remember their own name but be confused about place and time. A patient who is experiencing acute confusion or delirium will benefit from repeated orientation to person, place, and time. It is not adequate to repeat this information once or twice. It must be repeated frequently and in a calm, soothing manner. Your calm attitude is very important in reducing the anxiety that is inevitably present for the patient. [Box 47-3](#) lists guidelines to conduct reality orientation for confused patients.

Assignment Considerations

Reality Orientation

Nursing assistants (CNAs) can be instrumental in the ongoing orientation of confused patients. First, identify those patients who would benefit from reality orientation. Then give the CNA specific instructions about how to orient to person, place, and time (e.g., "Hi, Mrs. Collins. I am Judy, the nursing assistant at Sunshine Care Center. It is 8 A.M. on Tuesday, June 28, 2010. It's a nice, warm summer day today."). Teach the CNA how to use visual cues to orient patients (e.g., "Mrs. Collins, this calendar will help you remember the day, month, and year.").

Box 47-3

Guidelines for Reality Orientation

What is Reality Orientation?

- Reality orientation is a therapeutic program consistently implemented by all nursing staff to orient a patient to person, place, and time. This method includes the use of verbal communication techniques, as well as written signs indicating the current date, month, or room identification. Clocks with large numbers are included to help the patient know the correct time ([Manepalli et al, 2009](#)).
- Special group sessions are also used to orient patients. These sessions focus on person, place, and time as well as certain holiday events. These groups improve orientation and provide opportunities for social interaction.

When to Use Reality Orientation

- The use of reality orientation is appropriate when a patient is experiencing acute confusion or delirium. A sudden episode of confusion is very frightening, and orienting the patient is a way to allay fear and anxiety.
- Patients experiencing global amnesia do not benefit from repeated verbal reality orientation.
- For patients with dementia, gentle reminders of the day or time need to be repeated often and without the expectation that the patient will remember something that was said 5 minutes ago.
- All aspects of reality orientation are helpful for all patients with cognitive disorders. However, in patients experiencing acute confusion, the ultimate expectation is that the patient will become completely oriented and return to a previous level of functioning. With chronic confusion, the goal is to preserve dignity and maintain optimum function.

Examples of Ways to Implement Reality Orientation and Reduce Confusion

- Under no circumstances should nurses ever chastise or become frustrated when a patient cannot remember. This has no therapeutic value.
- Verbalize to patients in a consistent and caring manner who you are, where they are, and the date and time: "Hi, Mr. Jones. I am your nurse, Betty, at the Davis Nursing Care Center. It is 8 A.M. on Wednesday, October 25, and it is time for breakfast."
- Look directly at the patient when you are speaking.
- Ask only one simple question at a time.
- Ask questions that can be answered with a "yes" or "no": "Would you like to eat in the dining room?"
- Eliminate environmental distractions when talking to a patient.
- Break down tasks such as dressing into simple one-step tasks.

- Ask the patient to do only one task at a time.
- Gently touch the patient to convey acceptance.
- If possible, provide caregivers who are familiar to the patient.
- Provide general orientation to the calendar year by using holiday decorations.
- Decrease the noise level in the environment by not using paging systems or call lights that ring or buzz.
- Label photos of people familiar to the patient with the names of the people who are in the photos.
- Limit visitors to one or two at a time.
- Place the patient's name in large block letters in his room and on clothing.
- Use symbols rather than words on signs indicating the location of the dining room or bathroom.
- When misperceptions are present, clarify them for the patient: "No, Mr. Jones, I am not your daughter; I am your nurse, Betty. Your daughter will be here after you eat your lunch."
- When special low-stimulus units designed for patients with chronic confusion are not available, use yellow tape to mark specific boundaries for the patient.
- Give frequent reassurances.
- Keep the patient's room well lit.
- Encourage the use of hearing aids and prescription glasses.
- Have clocks, calendars, and personal items in clear view of the patient.
- Encourage reminiscing about happy times in life.

A patient experiencing acute confusion may become combative or may attempt to crawl out of bed or remove therapeutic equipment. If restraints are used as a last resort, the patient may be at risk for physical problems such as immobility, strangulation, or asphyxiation or for psychological issues such as anger, humiliation, loss of autonomy, and decreased functioning.

Legal and Ethical Considerations

Use of Restraints

Remember, having to restrain a patient for behavior problems is considered an unusual circumstance that requires clear documentation and adequate elaboration as to the events leading to the need for restraints, **all alternatives tried before restraint**, the type of restraint, strict accounting for time in and out of restraints, and the assessment and care given to the patient while in restraints (Nadler-Moodie, 2009). (Do **not** forget to offer and document bathroom breaks, fluid and food, and skin care with each 1- to 2-hour check.) The total number of hours in restraints or seclusion must be noted with supporting documentation. **Box 47-4** presents guidelines on the use of restraints and alternatives to restraints.

Box 47-4

Alternatives to and Guidelines for the Use of Restraints

Alternatives to Restraints

Acute Care Settings

- Encourage family members and friends to stay with the patient.
- Assign a nurse or nursing assistant for one-on-one observation.
- Encourage oral feedings instead of intravenous or nasogastric feedings. (Avoid inserting tubes that can be pulled out.)
- Remove catheters and drains as soon as possible.
- Decrease glaring lighting, reduce noise, and minimize stimulation.
- Keep the patient close to the nurse's station.
- Be certain the call button is within easy reach.
- Place the bed in the lowest setting, and use three side rails to keep the patient from rolling out.
- Check on the patient frequently to offer nutrition, fluids, pain relief, and toileting assistance as appropriate.

Long-Term Care Facilities

- Place the mattress on the floor to prevent the patient from falling out of bed.
- Talk to the patient, even when the patient is not responding to you or is responding in an inappropriate way.
- Incorporate relaxation techniques into the care plan, such as back massage and hydrotherapy.
- Use therapeutic communication techniques to encourage the patient to verbalize feelings.
- Encourage ambulation whenever feasible.
- Encourage participation in recreational, physical, and occupational therapy.
- Encourage participation in as many ADLs as possible.
- Initiate diversional activities, such as listening to radio, television, and music.
- Maintain a schedule for toileting.

Guidelines for the Safe Use of Restraints

- Document all efforts to assist the patient without physical restraints and the outcomes.
- Use the least restrictive type of restraint that will accomplish the objective.
- Obtain informed consent from the patient or the patient's relatives before using restraints.
- Have an institutional policy on restraints written and available for the patient and family.
- Make certain that all staff have adequate in-service training on the use of restraints.
- Use hand mitts for patients who are receiving IV therapy or have catheters or nasogastric tubes.
- If hand mitts do not work, consider wrist restraints.
- All restraints must have a provider's order.
- Restraints must not be used to punish or control the patient.
- Apply restraints snugly, but ensure that circulation is not impeded.

- Check the area distal to the restraint every 2 hours (or according to the agency policy) for circulation and function.
- Remove the restraints and change the patient's position at least every 2 hours.
- Apply active or passive ROM to the affected joints and muscles.
- Secure restraints to the bed frames, not the side rails.
- Tie restraints with knots that can be quickly released.
- Consider restraints as a temporary solution.
- Clearly document in the patient record the reason for the restraint, the type selected, and the time frame for use.
- Document care given to the patient while in restraints.

ADLs, Activities of daily living; *IV*, intravenous; *ROM*, range of motion.

An individual with chronic confusion in the late stages of dementia will not benefit from repetitive information. If **global amnesia** (generalized loss of memory) is present, the patient will not be able to remember family, friends, or events, regardless of how many times you repeat the information. Moreover, expecting the patient to remember leads to frustration for you and the patient. Use of pictures or symbols, such as arrows pointing to the bathroom, can facilitate daily tasks and clarify communication. In addition, creative therapies such as video histories, use of familiar songs, pet therapy, and aromatherapy may enrich the quality of life for these individuals.

Complementary and Alternative Therapies

Smell

The limbic or “old brain” is associated with the sense of smell. Use of familiar smells reinforces remote memories. For example, the smell of pine or fir can trigger past memories of happy Christmas times spent with family and friends. Rosemary and clary sage have been found to be helpful. Aromatherapy can be administered by inhalation, bathing, massage, or topically ([Keville, 2014](#)).

Complementary and Alternative Therapies

Massage

Massage has been used to reduce agitation in patients with AD ([Valleti, 2011](#)). Additional benefits include meeting the human need for nurturing touch, decreasing mild depression, reducing mental stress, improving circulation, and relieving muscle tension and stiffness.

Think Critically

Is it always necessary to encourage a patient to see and acknowledge reality? What about older adult patients who have severe dementia and believe they are living in their own homes, even though they are in a nursing home?

Nurses who care for patients with dementia need to be aware of the importance of maintaining the dignity of the patient and family. In the later stages of dementia, there are numerous deficits in self-care, such as grooming and toileting. It is very important to treat both patients and families with respect. **Call the patient by name, provide for privacy, and individualize your care for this patient based on culture and history.** It is well documented in the nursing literature that when

patients are seen as people or human beings, nurses are likely to be more compassionate and caring.

Clinical Cues

Pull the curtain or close the door and drape the patient appropriately to provide privacy and protect dignity for toileting or when performing procedures whether or not the patient is cognizant.

Older Adult Care Points

When working with older adults, do not confuse clear and supportive communication with "elderspeak." Elderspeak is a style of speech that includes baby talk, exaggerated tones and slow speed, elevated pitch and volume, and simplified vocabulary. Being overly nurturing ("Come on, sweetie, let's eat now.") or overly controlling ("Sit down and finish your food!") is perceived as patronizing and demeaning, without improving communication.

Assessment of and Interventions for the Family

The family should also be assessed for their knowledge and ability to relate to the illness and care of a family member with dementia. The goal of treatment is preservation of function, and this should be clarified when working with the family. For example, if the patient lives at home, the family will need to realize that **a person with dementia responds much better if there are daily routines and a structured environment**. Assist the family to develop a schedule that includes adequate time for hygiene care, meals, medications, and activities such as walking. Home care nurses are in an excellent position to make suggestions to help the family create a safe environment. For example, potentially hazardous areas can be evaluated and then suggestions made for gates across stairwells or better lighting in dark hallways.

Clinical Cues

"Simple Pleasures" benefit patients and families. In this intervention, patients handle fleece-covered items, are shown photos of familiar people or places, or handle other familiar "activity" items such as cooking implements for women, or safe tool items for men. Handling the item reduces agitation in a patient with dementia ([New York Department of Health, 2014](#)).

If a patient has a tendency to wander or get lost, the family will live in a constant state of hypervigilance to ensure the safety of their loved one. Help family members to recognize potential wandering behaviors: looking for keys, preparing to go to "work," restlessness and pacing, getting lost going to the bathroom or to the bedroom, or performing a task without actually accomplishing anything (e.g., moving dirty dishes from place to place without actually washing them). Nurses can make practical suggestions such as sewing identification labels into clothing, using a bell that signals when an exit door is opened, or wearing a bracelet with a GPS chip. [Box 47-5](#) presents additional tips for families.

Box 47-5

Suggestions for Families Caring for a Person With Alzheimer Disease

- Make and keep a copy of the daily schedule, and stick to the schedule as closely as possible.
- Establish bedtime rituals.
- Orient the person as necessary to maintain safety and promote maximum functioning.
- Minimize the number of caregivers.
- Simplify the environment to minimize illusions and confusion; keep decorative items to a

minimum.

- Keep the environment as quiet as possible.
- Schedule rest breaks throughout the day for yourself and your loved one.
- Change your expectations; forcing thought and interaction causes frustration.
- Offer the person help when needed, and distraction as necessary.
- Always supervise the use of medications.
- Use sense of touch; there is an increased need for touch.
- Always approach the person from the front before touching.
- Use distraction if agitated. Walking, gardening, rocking in a rocking chair, sanding wood, and folding laundry are good examples of distraction.
- Use many of the safeguards for young children, such as storing all cleaning solutions, pesticides, medications, and nonedible items in locked cabinets.
- Put protective caps on all unused electrical outlets.
- Remove all sharp objects.
- Remove all throw rugs, and keep hallways and stairs free of clutter.
- Keep the house well lit.
- Allow smoking only under very close supervision.
- Attach safety grab bars in the bathroom.
- Protect windows and doors with Plexiglas.
- Rather than restrict the person from wandering, provide a safe area in which to wander.

Families should also be assessed for signs of caregiver role strain. Observe and assist family members to recognize when they themselves experience denial, irritability, anxiety, sleeplessness, and anger—and note that these signs suggest the illness of the older adult is taking its toll on the caregivers. Family members often are exhausted from the daily requirements of round-the-clock care. Evidence suggests that families who receive intensive support and counseling are able to manage the care of a patient with AD in the home for longer periods of time ([Messecar, 2012](#)).

Encourage caregivers to consider day care or respite care. These options give the family members a much-needed psychological and physical rest. In addition, families should be encouraged to use support groups, such as the Alzheimer's Association (see [Online Resources](#)). One of the *Healthy People 2020* objectives is to help family caregivers to access caregiver support [@services](#).

Think Critically

How would you help a family member to recognize and acknowledge the need for respite care?

Families also need to be encouraged to talk openly and frankly about quality of life, and about end-of-life issues such as advance directives. Preferably these talks should be completed before the diagnosis of dementia, when the patient still has cognitive functioning. If not, the family caregiver becomes the spokesperson and needs to be encouraged to get a power of attorney and a living will for the patient. Families need considerable support in these matters. Refer to [Nursing Care Plan 47-1](#) for additional nursing management information.

■ Evaluation

Because confusion is present in all cognitive disorders, keeping the patient free of injury is of primary importance. Is the patient returning to or moving toward a previous level of cognitive and psychomotor functioning? Has the cause of acute delirium been determined or eliminated? An additional expected outcome, particularly with patients with dementia, is that the family will be able to verbalize the stages of illness and maintain realistic expectations for their loved one.

Community Care

If patients with dementia or delirium are hospitalized, the inpatient stay will typically be for a short time and not for dementia alone. Patients with AD are not placed in psychiatric hospitals, because antipsychotic medications or psychotherapy does not work for these patients. For a variety of reasons, financial and personal, many families are choosing to keep their older adults at home. Nurses who make home visits will often encounter families attempting to care for a relative who is experiencing one of these conditions. Teaching must be done about the causes and stages of these illnesses. In addition, families are eager for practical knowledge that will make the living arrangement more acceptable (see [Box 47-5](#)).

In the later stage of dementia, nursing home placement sometimes is necessary. Many nursing homes have special units set aside for patients with AD. In these units, safety precautions are a primary concern. Entrance and exit doors have special codes so that patients cannot wander off the unit. "Wandering pathways" are created using corridors, walkways, or outdoor spaces that allow for walking and roaming with security and safety. Nurses in these units spend considerable time educating families about the stages of AD and helping families with the inevitable grieving process.

In addition to observing patients with delirium in the acute hospital setting, nurses often interact with these patients in outpatient clinics, emergency departments, or providers' offices. Excellent assessment skills are necessary to prevent any further decline.

Get Ready for the NCLEX® Examination!

Key Points

- Cognition includes the mental processes of perception, memory, judgment, and reasoning.
- Delirium is acute confusion; signs and symptoms may include a shortened attention span; disorientation; impairment in recent and remote memory; incoherent speech; disorganized thinking; and possible presence of delusions, hallucinations, and illusions.
- Dementia is chronic confusion that has slow onset (months to years); signs and symptoms include impairments in memory, poverty of thoughts, difficulties with abstract thoughts and judgments, confabulation, and changes in personality.
- Assess judgment, affect, memory, cognition, and orientation (JAMCO).
- AD is the most common degenerative disease of the brain and usually affects people older than 65 years; it has three or more stages.
- Vascular dementia describes any type of dementia caused by vessel disease, which causes brain damage. Onset is usually more abrupt, and neurologic impairment is localized rather than global.
- Goals of treatment for cognitive disorders include achieving an optimal level of functioning, ensuring safety, educating caregivers, and preserving the dignity of the patient and family.
- Nursing interventions for AD depend on the stage of illness. General interventions include maintaining a calm and soothing manner, ensuring environmental safety, using appropriate reality orientation, and monitoring the effects of medications.
- Families commonly elect to care for older adults at home; teach the family about cognitive disorders and provide practical knowledge about living arrangements.
- Observation for caregiver strain of the family caring for a cognitively impaired patient at home is needed.

Review Questions for the NCLEX® Examination

1. Alzheimer disease has a greater impact on society than delirium because: (*Select all that apply.*)

1. memory deficits become progressive.
2. it often improves with correction of the underlying cause.
3. it continues to cause mental decline and the need for more and more care.
4. the expense of care for dementia patients is a drain on society and families.

5. a family member may have to leave the workforce to care for the patient.

NCLEX Client Need: Psychologic Integrity

2. The nurse should recognize the following signs and symptoms in a patient as those of delirium:
 1. fading short-term memory, withdrawn behavior, and depression.
 2. inattention to hygiene, sad countenance, little verbal expression.
 3. confusion, incoherent speech, and sudden onset of symptoms.
 4. inability to recognize familiar objects, angry outbursts, confusion.

NCLEX Client Need: Psychosocial Integrity: Sensory/Perceptual Alterations

3. The nurse recognizes that a patient is in the early stage (mild) of Alzheimer disease when noting that the patient:
 1. has difficulty swallowing during meals.
 2. needs repeated instructions for simple tasks.
 3. has difficulty learning new things.
 4. cannot recognize familiar people.

NCLEX Client Need: Psychosocial Integrity: Sensory/Perceptual Alterations

4. A confused older adult man is hospitalized for a recent fall. He is accompanied by a daughter, who cries and says, "I can't take care of him any longer!" Initial assessment confirms a problem of caregiver burden. Which nursing intervention(s) would be appropriate? (*Select all that apply.*)

1. Encourage verbalization of feelings.
2. Refer to respite care or day care programs.
3. Tell the daughter to calm down and maintain composure.
4. Reassure the daughter that everything will be okay.
5. Encourage admission to a nursing home.
6. Assess for alternative family support and resources.

7. Tell the daughter to focus on past happy times with the father.

NCLEX Client Need: Psychosocial Integrity: Stress Management

5. A nurse is caring for a patient who has confusion resulting from Alzheimer disease. Which action requires more instruction about Alzheimer disease and confusion?

1. Uses season-appropriate holiday decorations and a calendar with large numbers
2. Labels family photos with names of family members and discusses photos with patient
3. Encourages the patient to acknowledge that he is not living in his own home
4. Helps the patient to perform one task at a time, giving step-by-step instructions

NCLEX Client Need: Psychosocial Integrity: Behavioral Management

6. The nurse is working in a long-term care facility and notices that one of the residents with chronic dementia is uncharacteristically drowsy and lethargic. What is the most appropriate nursing intervention?

1. Monitor the patient, but allow her to sleep.
2. Stimulate her by inviting her to join a social group.
3. Call the provider to report a change of mental status.
4. Perform a mental status examination and obtain vital signs.

NCLEX Client Need: Physiologic Integrity: Physiological Adaptation

7. To assist a family in caring for a member with Alzheimer disease, the nurse can teach the family to: (*Select all that apply.*)

1. place door locks up high on the doors.
2. redirect to another place or activity when the patient becomes obstinate.
3. keep lights low in the evening to decrease stimulation.

4. present finger foods to increase caloric intake when restless.
5. provide lively activity in the late afternoon to prevent sundowning.
6. provide clothing with Velcro or other easy fasteners.

NCLEX Client Need: Psychosocial Integrity: Behavioral Management

8. A nurse in an acute medical-surgical unit is caring for a confused, older adult patient who is trying to get out of bed. Which alternative to restraints would be appropriate for the patient and the setting?

1. Put the patient's mattress on the floor.
2. Keep the patient in a wheelchair close to the nurses' station.
3. Put four side rails up instead of tying the patient down.
4. Use hand mitts and a soft vest with Velcro fasteners.

NCLEX Client Need: Safe and Effective Care Environment: Least Restrictive Restraints and Safety Devices

9. The caregiver of a male patient with Alzheimer disease is given instructions regarding donepezil (Aricept). Which caregiver statement indicates a need for further instructions?

1. "I should always give Aricept with food to minimize gastric distress."
2. "I thought Aricept was rarely used because of liver problems."
3. "I must increase fiber and fluid in his diet."
4. "I need to provide frequent sips of cool liquids."

NCLEX Client Need: Physiological Integrity: Pharmacological Therapies

10. The nurse observes that a patient with dementia cannot put on his shirt, although he has the strength and motor movement to dress himself. Which intervention would be appropriate to accomplish dressing while maximizing the patient's dignity?

1. Verbally coach the patient using simple directions.
2. Leave the patient alone and give extra time and privacy.

3. Have the wife help the patient get dressed.
4. Give the patient a shirt with Velcro fasteners.

NCLEX Client Need: Psychosocial Integrity: Behavioral Management

Critical Thinking Questions

Scenario A

Margarita Munoz, 81 years old, has AD. Her daughter tells you that Mrs. Munoz has “good days and bad days,” but seems to be more forgetful and more withdrawn. “Do you have any suggestions for me? I know Mom is going to get worse, but I’d like to care for her at home as long as possible.”

1. What are some questions you should ask the daughter?
2. What can you do to help the daughter with the practical issues of caring for Mrs. Munoz at home?

Scenario B

You are caring for Mr. Abdul, who is a 77-year-old patient residing in a nursing home for the past 6 months. Today he becomes uncharacteristically combative when the nurse’s aide attempts to give him a bath. You have never observed Mr. Abdul exhibit this type of behavior before.

1. What would your initial nursing interventions be?
2. How might you explain Mr. Abdul’s sudden change in behavior?

Scenario C

Jill Capelli, a 42-year-old schoolteacher, accompanies her father, Arturo Capezzi, to the provider’s office where you are working. Mr. Capezzi, currently 67 years old, was diagnosed with vascular dementia 2 years ago. His condition is progressively deteriorating, and Ms. Capelli tells you that she is fearful that this type of dementia could happen to her.

1. How would you respond to Ms. Capelli?
2. What type of preventive education might be helpful for Ms. Capelli?

Scenario D

The night shift nurse recommends that you call the provider and obtain an order to restrain Mr. Jackson, who is an older adult patient with dementia. The patient currently has a feeding tube and an intravenous line, which he keeps trying to pull out. He is easily agitated and strikes out at caregivers. In addition, he is physically strong enough to get out of bed and has a history of falls.

1. What assessments would you make before calling the provider for the restraint order?
2. What interventions could you try before using restraints?
3. If restraints are ordered, describe what you must document.

CHAPTER 48

Care of Patients With Thought and Personality Disorders

Objectives

Theory

1. Examine the incidence of thought disorders in the general population.
2. Determine the signs and symptoms of schizophrenia.
3. Establish at least four nursing problems and the major nursing interventions that would be appropriate for a patient with a thought disorder.
4. Compare and contrast behaviors for each of the various personality disorders.
5. Choose at least four nursing problems and the major nursing interventions that would be appropriate for a patient with borderline personality disorder.
6. Illustrate how a nurse can identify and modify personal feelings that can occur when caring for a patient with borderline personality disorder.
7. Analyze your personal feelings related to caring for patients with manipulative behaviors.

Clinical Practice

8. Watch the movie *A Beautiful Mind* and develop a teaching plan to help the wife understand the husband's bizarre and erratic behavior.
9. Develop a care plan with at least six nursing interventions for a patient who is paranoid and suspicious.
10. Write a care plan with at least six nursing interventions for a patient who is manipulative.

word salad (p. 1116)

Overview of Thought Disorders

The *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition (DSM-5) defines **thought disorders** by the presence of psychotic symptoms. **Schizophrenia** is the most common thought disorder. Examples of **psychotic features** are **hallucinations** (hearing, seeing, smelling, tasting, or feeling something that is not really there), **delusions** (false fixed ideas), and disorganized speech and/or behavior.

The incidence of thought disorders is not as high as that of mood disorders, but thought disorders tend to be more chronic and debilitating. It is estimated that 1.1% of the general population is affected with schizophrenia, and in the United States this represents 3,432,000 Americans (Schizlife, 2014).

Schizophrenia

Etiology and Pathophysiology

The exact cause of schizophrenia is unknown, but several types of theories are considered: genetic, neurobiologic, brain structure abnormalities, and influences from psychological and environmental factors. Genetically, it is believed that several genes on several different chromosomes play a role. Neurobiologically, abnormality of the amount of the neurotransmitter dopamine is believed to exist. Neurotransmitters are chemical messengers that are produced and stored in the nerve terminal (**axon**) (Figure 48-1). Low dopamine activity in the cortex of the cingulate gyrus leads to the negative symptoms of schizophrenia, and higher than usual dopamine activity in the limbic system leads to the positive symptoms. Other neurotransmitters such as serotonin, norepinephrine, and gamma-aminobutyric acid (GABA) also interact in the disease. Glutamate is being researched as another factor. Brain structure abnormalities in individuals with schizophrenia have been identified and include enlargement of the lateral cerebral ventricles; reduced cortical, frontal lobe, and hippocampus volume; and increased fissure size on the surface of the brain.

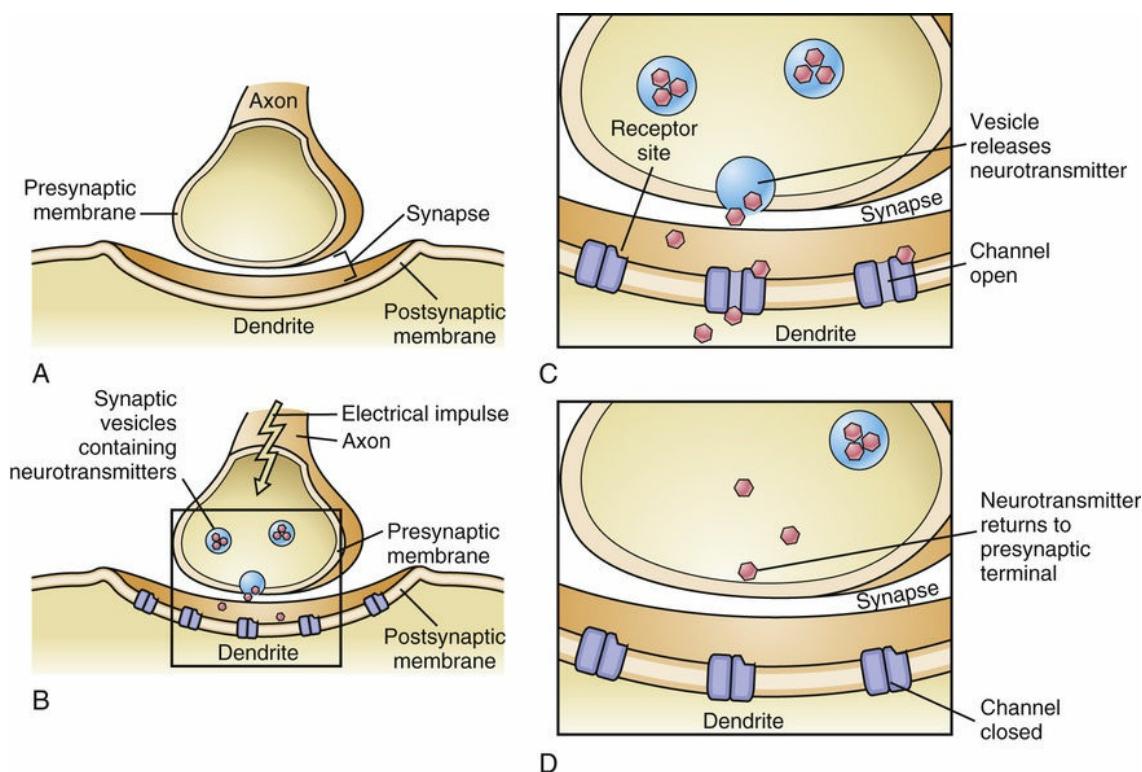

FIGURE 48-1 Neurotransmitters. **A**, Axon with stored neurotransmitters and dendrite with receptor sites.

B and **C**, Electrical impulse causes release of neurotransmitter. **D**, Receptor sites close and neurotransmitter returns to storage.

Prenatal stressors such as birth complications, prenatal viral infection, poor maternal nutrition, and exposure to toxins contribute to the potential for schizophrenia. Psychological stress appears to precipitate the disease when other factors are present in susceptible people. Environmental factors such as exposure to chronic poverty or a high-crime environment also have an effect on susceptible persons. Schizophrenia usually develops in late adolescence or the early 20s.

Complementary and Alternative Therapies

Omega-3 Fatty Acids

A study by Mossaheb and associates (2013) found that omega-3 fatty acids were effective at preventing progression to psychosis in young people and improved both negative and positive symptoms.

Signs and Symptoms

The signs and symptoms are divided into positive (present) and negative (absent) symptoms (Figure 48-2). **Positive symptoms** are those symptoms present in patients with schizophrenia that should **not** be there. These include the presence of hallucinations, delusions, and disordered thinking or loose associations between thoughts. Voices (**auditory hallucinations**) will tell the person what to do, and delusions develop as the disorder progresses.

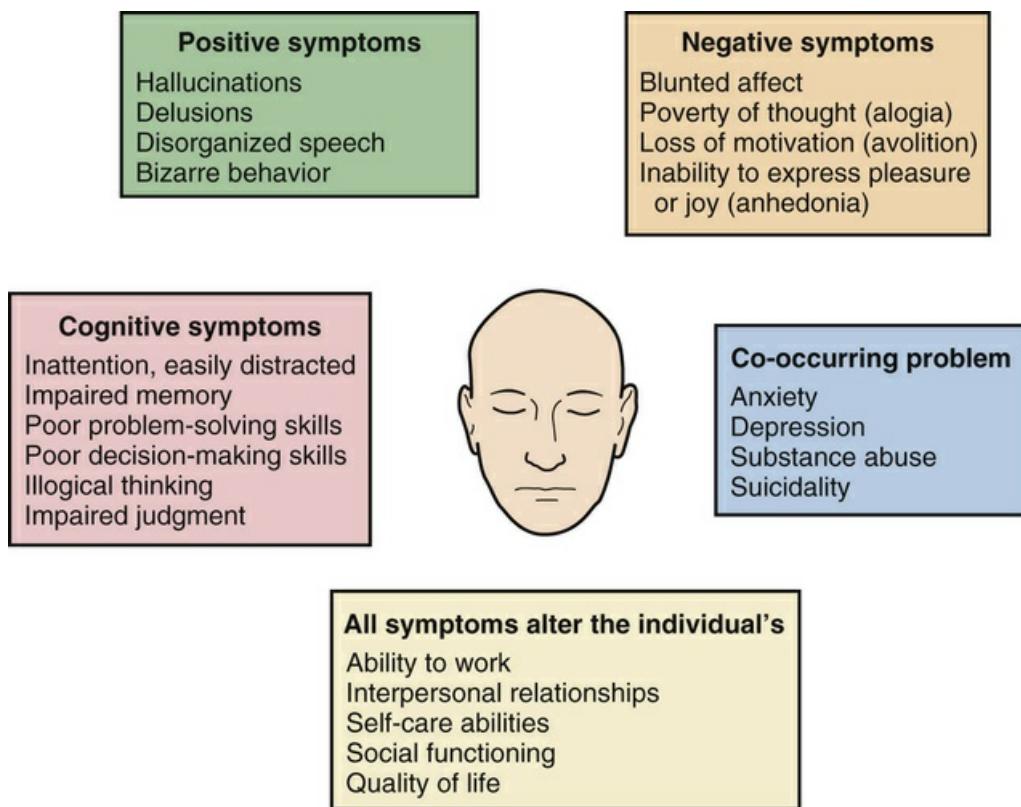

FIGURE 48-2 Signs and symptoms of schizophrenia.

Delusions can be either grandiose or persecutory. An individual who believes he is a king is having **delusions of grandeur**. Individuals with **delusions of persecution** believe that they are being persecuted by agencies, by other people, or by supernatural beings. An **illusion** is a misinterpretation of something that really exists. For example, an electrical cord appears to be a snake, or a pencil is misinterpreted to be a knife blade. When **ideas of reference** occur, the individual believes that events or situations are occurring because of—or specifically for—him. A common idea of reference is to believe that people on the television are sending special telepathic

messages. **Positive symptoms** are much more responsive to medication therapy compared with the **negative symptoms**; however, some patients will tell you that “the voices are always there, but if I take my medications the voices are less intrusive.”

Negative symptoms are abilities or personal characteristics that are **absent** or lost to the patient (negative symptoms are those that **should** be present).

For example, think of elements of personality that make people motivated, socially outgoing, happy, and active in daily life, and then take away those elements. The results are **negative symptoms**: apathy, social withdrawal, psychomotor retardation, flat affect (obvious absence of emotional expression), poverty of thoughts (**alogia**), lack of motivation (**avolition**), and inability to experience pleasure or joy (**anhedonia**). These symptoms are notoriously more difficult to treat because the symptoms, in and of themselves, inhibit the individual from seeking help. Negative symptoms are also linked to acquisition of important social skills and prognosis (Csernansky, 2013). For example, if a teenage patient withdraws because of feelings of persecution, he will miss the important socialization tasks that occur during adolescence, such as exploring identity and preparing to live independently away from his parents.

In addition, these patients have cognitive impairments that manifest as difficulty with memory, judgment, problem solving, and decision making. Concurrent mental health problems such as anxiety and depression can also occur. Overall the individual's quality of life is affected, and some will have great difficulty functioning in society.

Think Critically

Why might friends and family fail to recognize that there is a problem when schizophrenia first develops in a teenager or young adult? Describe how you might feel, and how it would change your life, if someone you loved developed schizophrenia in early adulthood.

Safety Alert

Be Cautious, Not Fearful

Nursing students are often afraid to enter a psychiatric unit because patients with schizophrenia can exhibit bizarre and unpredictable behavior; however, these patients are usually not overly prone to violence. Those with a dual diagnosis of substance abuse and schizophrenia are more likely to become violent (Volavka et al, 2010). To protect yourself and others, ask the charge nurse for advice about potentially violent patients.

Diagnosis

Diagnosis is not easy, and symptoms also resemble those of bipolar disease and brain tumor. Methamphetamine and phencyclidine (PCP) use can mimic the symptoms. Evaluating symptoms over the course of 6 months helps with diagnosis. An immunoassay blood test, VeriPsych, has been developed and is being refined before further testing. There are different types of schizophrenia (paranoid, catatonic, disorganized, undifferentiated, and residual), and diagnosis is based on guidelines in the DSM-5. Table 48-1 provides a description of the different types of schizophrenia. Note that many patients with schizophrenia have other mental illness problems and may have a dual diagnosis.

Table 48-1
Types of Schizophrenia and Associated Behaviors

TYPE	BEHAVIORS
Paranoid	Exhibits extreme suspiciousness, delusions of grandeur, and delusions of persecution. Can be hostile and aggressive. Auditory hallucinations are common.
Catatonic	Exhibits a stuporous condition associated with rigidity, unusual posturing, and waxy flexibility (maintains a limb in one position for a long time). Also demonstrates echopraxia (imitating the motions of others) and echolalia (involuntary repetition of words spoken by others). Exhibits unpredictable behavior because behavior is controlled by delusions and hallucinations.
Disorganized	Exhibits flat affect, silliness, and incoherence. Has gross thought disturbances, including word salad and neologisms. Delusions and hallucinations are common.
Undifferentiated	Exhibits symptoms found in more than one type, but does not meet adequate criteria for paranoid, catatonic, or disorganized types.
Residual	Exhibits negative symptoms (i.e., apathy, social isolation, psychomotor retardation, blunted affect, poverty of thoughts, and lack of motivation) of schizophrenia, with no evidence of hallucinations, delusions, or disorganized thoughts.

Treatment

There is evidence that early treatment for schizophrenia improves long-term prognosis. Patients who are treated for first episodes generally respond to the therapeutic effects and require lower doses of antipsychotic medications. After starting a medication, the patient should be monitored for 3 to 6 weeks for therapeutic response (Frankenburg, 2014). Antipsychotic medications (neuroleptics) **treat the positive symptoms of schizophrenia** (Box 48-1). The **conventional antipsychotics** are very effective in stopping the auditory hallucinations, enabling the patient to connect thoughts in a logical manner, and eliminating the delusional system. They do cause serious and unpleasant side effects and are becoming less commonly prescribed. However, some patients respond well to these drugs and, particularly for older patients who have taken them for a long time, it is likely that a successful drug regimen will continue.

Box 48-1

Drugs Used to Treat Schizophrenia

CONVENTIONAL DRUGS	ATYPICAL DRUGS*
Chlorpromazine (Thorazine)	Clozapine (Clozaril) [†]
Fluphenazine (Prolixin)	Aripiprazole (Abilify)
Haloperidol (Haldol)	Olanzapine (Zyprexa)
Loxapine (Loxitane)	Quetiapine (Seroquel)
Molindone (Molar)	Risperidone (Risperdal)
Perphenazine (Trilafon)	Ziprasidone (Geodon)
Thioridazine (Mellaril)	Paliperidone (Invega)
Thiothixene (Navane)	Iloperidone (Fanapt)
Trifluoperazine (Stelazine)	Asenapine (Saphris)

*These drugs have fewer side effects than the conventional medications.

[†]First atypical antipsychotic, now rarely prescribed because of potential agranulocytosis. Frequent monitoring of white blood cell count is necessary.

The side effects for these medications include the familiar anticholinergic effects (i.e., dry mouth, flushing, urinary retention, and constipation). In addition, these drugs have **extrapyramidal side effects** (EPSs): dystonia, pseudoparkinsonism, and akathisia (Figure 48-3). Dystonia or **dystonic reaction** is an acute muscle contraction, especially of the tongue, face, neck, and back. **Oculogyric crisis**, a fixed upward gaze or muscle spasm of the eye, can occur. **Pseudoparkinsonism**, or drug-induced parkinsonism, consists of poor balance, flat affect, slowed movements, tremors, and drooling. **Akathisia** manifests as motor restlessness (e.g., tapping a foot, rocking, pacing) or apprehension and irritability. Treatment for akathisia, dystonia, or pseudoparkinsonism is to lower the dosage or change the medication and to give benzotropine (Cogentin) or diphenhydramine (Benadryl).

FIGURE 48-3 Characteristics of pseudoparkinsonism, acute dystonia, akathisia, and tardive dyskinesia.

Tardive dyskinesia is a primary concern because **symptoms are irreversible once they have developed if not caught early**. Symptoms include tongue protrusion; lip smacking; sucking; chewing; blinking; lateral jaw movements; grimacing; shoulder shrugging; pelvic thrusting; wrist and ankle flexion or rotation; foot tapping and toe movements; and rapid, purposeless, and irregular movements. Movements are often described as writhing and wormlike. **Monitor for signs of tardive dyskinesia, particularly in patients who have been taking a conventional antipsychotic medication for longer than 6 to 12 months.**

Other adverse effects associated with the use of antipsychotic medications include blurred vision; bone marrow suppression; cardiac dysrhythmias; endocrine changes such as elevation of blood sugar, weight gain, and breast enlargement; and **hepatotoxicity** (liver injury and jaundice).

Neuroleptic malignant syndrome is a rare reaction; however, it is life threatening, and the patient typically will be transferred to the intensive care unit. Symptoms include high fever, increased pulse, muscle rigidity, stupor, incontinence, elevated white blood cell count, hyperkalemia, and renal failure.

Older Adult Care Points

Older adults who are taking antipsychotic medications are at a higher than usual risk for developing serious side effects. Baseline cardiac, renal, hepatic, and hematologic studies need to be done before initiating psychotropic drugs. The beginning dosages should be one half to one third of the normal adult dosage. Older adults need to be watched very closely for difficulty swallowing, constipation and fecal impaction, weight gain, memory impairment, and orthostatic hypotension.

Examples of newer medications—sometimes referred to as **atypical antipsychotics** (see Box 48-1)—have the advantages of fewer side effects, particularly tardive dyskinesia, and offer some success with treating the negative symptoms. Olanzapine comes in a quickly dissolving oral form that is a potential alternative to an injection. This form is more expensive; however, it eliminates the risk of needle-stick injury if the patient is combative, and it discourages “cheeking” (attempts to avoid swallowing by holding the pill in the cheek pouch). Aripiprazole (Abilify) is the first in a new class of antipsychotics, the dopamine system stabilizers. The most recently approved medications for schizophrenia include paliperidone (Invega), iloperidone (Fanapt), and asenapine (Saphris). Table 48-2 presents medication side effects and nursing implications for drugs used to treat thought disorders.

Table 48-2

Nursing Implications for Antipsychotic Drugs Used to Treat Thought Disorders

COMMON SIDE EFFECTS	NURSING IMPLICATIONS
Anticholinergic Side Effects	
Dry mouth	Provide adequate fluids. Suggest sugarless hard candy or gum and good oral care.
Urinary retention and hesitancy	Monitor voiding and elimination patterns.
Constipation	Administer stool softener. Encourage fluids and high fiber foods.
Blurred vision	Remind patient that blurred vision will cease once the body becomes accustomed to the drug.
Photophobia	Remind patient to wear sunglasses and a hat when in the sun.
Sexual dysfunction	Remind patient to alert treatment team for sexual difficulties.
Common Extrapyramidal Side Effects	
Pseudoparkinsonism: Masklike facies, stiff and stooped posture, shuffling gait, drooling, fine tremors, and pill-rolling movement.	May need to switch to a different antipsychotic. Administer anticholinergic medications such as trihexyphenidyl (Artane) or benztropine (Cogentin).
Akathisia: Characterized by pacing and motor restlessness.	Notify provider. Antipsychotic may need to be changed or an anticholinergic added to the drug regimen. Symptoms disappear when the drug is discontinued.
Other Adverse Neuromuscular Effects	
Tardive dyskinesia: Typically manifests after 6–12 mo or more of medication therapy. It is characterized by tongue protrusion, lip smacking, sucking, chewing, blinking, lateral jaw movements, grimacing, shoulder shrugging, pelvic thrusting, wrist and ankle flexion or rotation, foot tapping and toe movements, and rapid, purposeless, and irregular movements.	Prevention by assessment; encourage checkups every 3 mo. Discontinuing the drug does not always relieve the symptoms. No specific treatment other than discontinuing the drug. Give soft foods. Have patient wear soft shoes or slippers.
Neuroleptic malignant syndrome: A rare but potentially fatal reaction to antipsychotic medications. It is characterized by high fever, increased pulse,	Early detection increases survival rate.

muscle rigidity, stupor, diaphoresis, hyperkalemia, incontinence, elevated white blood cell count, and renal failure.		Stop all medications. Give supportive, symptomatic care. Decrease body temperature. Hydrate (oral and IV). Correct electrolyte imbalance. Medicate for dysrhythmias as ordered. Renal dialysis for renal failure.
Cardiovascular Side Effects		
Orthostatic hypotension Tachycardia Paliperidone (Invega) can cause cardiac dysrhythmias (i.e., QT prolongation)		Check blood pressure and pulse before giving medications. Inform patient to dangle feet before getting out of bed to prevent falls. Inform patient that tolerance will develop in several weeks. Report to provider or RN any history of cardiac disease before starting the medication. Increase fluid intake to expand vascular volume as ordered.
Miscellaneous Side Effects		
Sleepiness and fatigue		Inform patient that tolerance to the dosage will develop in 1-2 wk.
Photosensitivity		Administer medication at bedtime. Avoid direct sunlight. Wear protective clothing and sunscreen when outside.
Weight gain Hives and contact dermatitis		Monitor food intake. Notify provider if there is a rash; may need to discontinue or change the drug.

IV, Intravenous.

For patients with positive symptoms that do not respond to medication, repetitive transcranial magnetic stimulation (rTMS) may be an alternative (Frankenburg, 2014).

Clinical Cues

Clozapine (Clozaril) is significantly more effective than the other atypical antipsychotics but is less frequently prescribed because 1% of patients develop **agranulocytosis** (decreased white blood cells). Patients on this drug must have frequent blood tests (NAMI, 2014). The Joint Commission's National Quality Core Measures require that documentation reflects appropriate justification when patients are discharged with prescriptions of multiple antipsychotic medications.

Negative symptoms are treated with a therapeutic environment, including a therapeutic relationship with the nurse, and education regarding basic living skills. Historically, individuals with schizophrenia were shunned and stigmatized because of unusual and bizarre behavior. Evidence-based practice indicates that with early intervention these individuals can cope with symptoms and maintain independent and productive lives outside of an institution. Community mental health teams decrease likelihood of relapse (Frankenburg, 2014). Programs such as the Program for Assertive Community Treatment (PACT), Assertive Community Treatment (ACT), and Functional Adaptation Skills Training (FAST) include elements of patient and family support, education about disease management, and skills training (NAMI, 2014). If left untreated, individuals with schizophrenia are particularly vulnerable to poverty, homelessness, drug abuse, and suicide.

Cognitive-behavioral therapy (CBT), once believed to be helpful, has been shown by a team of international researchers to have little effect on schizophrenia symptoms (University of Hertfordshire, 2014).

Legal and Ethical Considerations

Rights of Psychiatric Patients

Psychiatric patients have the right to refuse medication and other therapies. Denial, paranoia, stigmatization, and lack of insight into illness contribute to the decision to refuse. In emergency situations, such as potential harm to self or others, the provider can order administration of involuntary medications. For routine ongoing treatment, the patient must be deemed incompetent and a court order must be obtained if the staff are to override the patient's right to refuse therapy.

Clinical Cues

Nursing students often have difficulty applying therapeutic communication skills with schizophrenic patients because these patients have trouble answering questions, conversing coherently, or expressing feelings. Remember to offer yourself ("Mr. Elliott, if you would like to

talk or walk around the unit, I can spend some time with you today.”) and attempt to understand (“Mr. Elliott, I am having a little difficulty understanding what you are saying, but I can tell you are trying to say something important.”). Spending even a few seconds with a paranoid schizophrenic patient is therapeutic because your attention builds trust and rapport and allows the patient to practice social skills. Also remember that the purpose of therapeutic communication is to meet the patient's needs, not to have your questions answered.

❖Nursing Management

■ Assessment (Data Collection)

When collecting information from patients who have thought disorders, the interview must be brief. Because there is a problem with logical thought processing, it is difficult for the individual to remain focused for very long. Mental status assessment tools, such as the Mini-Mental State Examination (MMSE) (see Chapter 47), are useful in evaluating thinking processes and the ability to abstract information. Assessment of a thought disorder involves observing the person's ability to think in a logical manner and the presence of psychotic features. Assessing the content and themes of hallucinations and delusions is important to ensure safety. For example, the patient may be receiving **command hallucinations** in which the voices are directing him to harm himself or others. Your patient may be experiencing delusions of persecution and be suspicious of staff and therefore refuse to eat. In addition, you should observe for stressors that seem to trigger or exacerbate disorganized behavior.

Patients with thought disorders may have difficulty verbalizing physical symptoms, and routine physical assessment should be performed to identify or monitor potential health problems. In addition, an initial and ongoing assessment of functionality, including activities of daily living (ADLs) and social skills, should be conducted. For example, the patient may have a disheveled appearance and dress in a bizarre fashion. Clothes may be worn in layers, backward, or inside out and be inappropriate to the season, or the patient may disrobe and stride about naked. One of the nursing goals would be to help the patient recognize and adopt socially appropriate attire.

■ Nursing Diagnosis

Typical problem statements for thought disorders may include:

- Confusion due to extreme anxiety and delusional thoughts
- Altered sensory perception (hallucinations) due to biochemical imbalance
- Limited coping ability in work or social situations
- Altered communication ability due to disorganized thoughts and loose associations
- Social isolation due to extreme distrust
- Altered self-care ability due to cognitive deficits
- Absence of compliance due to medication regimen
- Potential for violence due to command hallucinations

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

■ Planning

Sample outcomes for these problem statements might include:

- Patient will verbally acknowledge that delusional thinking and beliefs (e.g., accuses others of being FBI agents) increase during times of intense anxiety.
- Patient will spend decreased time attending to hallucinations (e.g., less time talking to self, less time listening for voices) before discharge.
- Patient will develop skills to adapt to a small social group within 6 months.
- Patient will communicate basic needs more clearly within 1 week.
- Patient will attend the community meeting for ____ minutes today.
- Patient will wash his face and hands with supervision this morning.
- Patient will identify three methods that will help him to continue medications (after discharge) at first follow-up appointment.
- Patient will refrain from hurting self or others during this shift.

Clinical Cues

Monitor your own appearance and clothing when you are working with patients who have thought disorders. First, be a role model for clear, matching, and appropriate clothing. Second, avoid flashy and dangling jewelry because patients are easily distracted by such objects. Third, watch what you put around your neck. An agitated patient can grab a long necklace, a scarf, a tie, or a stethoscope when out of control and in need of restraint.

Planning care for a patient with a thought disorder involves promoting safety, monitoring medications intended to relieve agitation or psychosis, observing for signs of medication side effects, promoting social skills, and ensuring adequate nutrition and sleep. **Care for these disorders will be long term, with intermittent treatment for acute episodes.** Patients need to be educated about the medications and coping skills necessary to function outside of a hospital setting. It is not unusual for a patient to stop taking medications because the voices returned and told him that all medications are unnecessary or harmful. For patients who are noncompliant with medications, a long-acting injectable form may be prescribed to prevent relapse ([American Psychiatric Association, 2004](#)). 

Think Critically

Can you think of some ways that nurses could devise to help individuals with thought disorders comply with the medication regimen?

Implementation

A priority intervention in working with schizophrenic patients is to administer antipsychotic medications. As with any medication, nursing responsibility includes not only giving the medication, but also monitoring the effectiveness and for any adverse effects. Antipsychotics have many serious side effects, some of which can be life threatening.

Patient Teaching

Antipsychotic Medications

Patients taking antipsychotic medications should be advised not to use alcohol. Combining alcohol and antipsychotic medications may impair judgment, thinking, and coordination because of the additional central nervous system depression.

Clinical Cues

In accordance with National Patient Safety Goals, there should be at least two identifiers before giving medication or blood products or taking blood samples. When patients are not able to state their correct legal name (because of confusion or psychosis), an alternative method would be to have two health care providers verify the patient's identity.

When dealing with an actively psychotic patient, use a calm and caring approach. Do not touch the patient without warning or permission, especially if he is agitated or paranoid. During active hallucinations, state reality and help the patient return to reality. "Mr. Elliott, you seem to be listening to something. I am not hearing any voices. Come and talk to me." Strategies for helping patients to manage persistent auditory hallucinations include monitoring what triggers the hallucinations, talking with someone, listening to music, watching TV, saying "stop," using earplugs, doing deep breathing or relaxation exercises, and doing a favorite activity.

You may have great difficulty understanding the patient because of **neologisms** (making up new words), **word salad** (disorganized mix of words, phrases, and fragments), or **loose associations** (expression of ideas that do not logically connect).

Cultural Considerations

Language

During times of stress, it is natural to revert to your first language. If your patient speaks English as a second language, obtain the assistance of a translator to determine whether the patient is having disturbances in communication (e.g., the patient's verbalizations might sound like word salad, but are actually a mixture of English and another language). Also, you can be charged with giving substandard care if you fail to call for a translator when the patient is unable to speak or understand English.

Use therapeutic communication and be attentive, respond to the underlying feelings, and gently verbalize concern. "Mr. Elliott, you seem really anxious to tell me something. I am trying to understand."

? Think Critically

You are caring for a patient who does not trust you. How does his distrust affect medication compliance? How will you establish trust and rapport with this patient?

General nursing interventions for the negative symptoms include establishing trust and teaching the patient and family how to manage the signs and symptoms. An attitude of acceptance is necessary to promote trust. Begin by offering yourself and being available to the patient even if he initially rejects your overtures to establish a therapeutic relationship: "I'm here if you want to spend some time talking today." You should model conventional social behaviors such as greeting the patient by name—"Good morning, Mr. Elliott"—and making friendly eye contact.

Cultural Considerations

Eye Contact

Lack of direct eye contact does not necessarily signal disinterest or an unwillingness to communicate. Direct eye contact may be considered a sign of disrespect by people from different cultural backgrounds (i.e., Asian, Hispanic/Latino).

Give patients positive feedback for making attempts to overcome negative symptoms: "You seemed very interested in the group discussion topic today." Do not make promises that you cannot keep, and if you make a promise, be sure to follow through.

Consistently invite the patient to join groups even if he rejects the initial invitations: "Mr. Elliott, we are going to play cards. Would you like to join us?" Acknowledge and thank the patient for his efforts to interact, even if he spends only a few seconds with you: "Thank you for talking to me today." Leave the door open for future interactions: "I understand if you don't want to talk today; maybe we can try tomorrow." Although these patients may have difficulty sustaining an interaction for even 1 or 2 minutes, persistent effort builds the **therapeutic alliance** (relationship between the patient and nurse) and increases the patient's self-esteem.

Complementary and Alternative Therapies

Music Therapy

Music therapy can be used with selected patients to treat positive and negative symptoms of schizophrenia. Participation in music groups increases socialization and stimulates interest. Encourage participants to express how the music makes them feel and to discuss their favorite kinds of music. Focused projects such as a performance event help patients to meet individual goals and experience success.

Administering medications and teaching the patient and family about antipsychotic medications are two additional nursing interventions. In addition, the side effects of the medications must be

monitored. **Nursing Care Plan 48-1** lists specific problem statements/nursing diagnoses, expected outcomes, and nursing interventions for individuals with thought disorders. **Box 48-2** lists additional interventions for patients who are angry, hostile, aggressive, manipulative, or paranoid.

*** Nursing Care Plan 48-1**

Care of the Patient With Schizophrenia

Scenario

George Coss is a 26-year-old man who was diagnosed with schizophrenia 7 years ago. He was taken to the emergency department yesterday after he destroyed his trailer home. George states, "There were demons in the walls." He is disheveled and unkempt and appears paranoid and reluctant to interact with the staff or other patients. He appears to be hearing voices and tells you, "I am Jesus, saving you, saving you; hear the demons. You, all of you are demons, yourselves are demons."

Problem Statement/Nursing Diagnosis

Confusion/Acute confusion related to delusional thinking, loosening of associations, or neurobiochemical imbalances.

Supporting Assessment Data

Subjective: States "You, all of you are demons, yourselves are demons."

Objective: Believes he is Jesus and believes others are demons.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will be able to talk for 5 min without discussion of delusions. Patient will be able to distinguish between reality and nonreality before discharge.	Assess the themes of delusions. Assess for situations that trigger anxiety and stress.	Delusional themes suggest fears and safety issues. Anxiety and stress are theorized to increase delusions and disorganized behavior.	Has a belief that he is being persecuted by demons. Currently very anxious and actively delusional; assessment for associated triggers continues. Patient is making continuous reference to demons.
	Reflect the underlying feelings ("It's frightening if you feel someone is trying to hurt you.")	Acknowledging feelings validates the patient's experience without agreeing with the delusional content.	Appears suspicious and fearful.
	State reality as you perceive it ("I believe that the hospital is a safe place.")	Corrects misperceptions without directly arguing against patient's perspective.	Reassured that the hospital is a safe place, but he continues to be fearful.
	Avoid arguing about the patient's delusional system.	Arguing causes patient to verbally defend own beliefs and potentially strengthens the delusional system.	Occasionally, patient appears to recognize certain staff members, but overall is highly delusional.
	Redirect discussions to real people and events.	Helps patient to stay focused on reality.	Continues unwavering in his beliefs in demons. Does respond when called by name (George); however, continues to verbalize the belief that he is Jesus.
	Administer antipsychotic medications as ordered and monitor for effectiveness and side effects.	Counteracts psychosis at the biochemical level.	Agrees to take risperidone (Risperdal) if administered by certain nurses. Outcomes not met. Continue plan.

Problem Statement/Nursing Diagnosis

Altered self-care ability/Self-care deficit related to cognitive impairment.

Supporting Assessment Data

Objective: Disheveled and unkempt.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will independently perform self-care within 1 wk.	Encourage the patient to independently perform ADLs according to current level of ability.	Performing ADLs helps the patient to focus on real tasks and decreases time spent in delusional thinking.	Is not initiating ADLs, but will perform brief tasks (e.g., washing face) with coaching.
Patient will dress appropriately and maintain appropriate hygiene before discharge.	Make available only the clothes the patient is to wear. Intervene as necessary if patient is unable to complete daily care.	Limiting choices decreases confusion and indirectly suggests appropriate attire. Initially the patient may not be able to complete ADLs because of impaired thought processes.	Is continuously changing clothes unless locked out of room. Mental health assistant verbally directed patient to shower. Patient became hostile; therefore shower deferred for today. Will try to have his brother assist him tomorrow.
	Offer positive reinforcement for any completed portion of ADLs.	Increase likelihood that desired behavior will be repeated.	Acknowledges feedback by looking up when spoken to.
	Assist the patient to make a structured plan if necessary.	Having a plan provides structure, goals, and ways to achieve goals, which helps the patient to complete tasks.	Verbally advised that shower is deferred for today, but that brother will help tomorrow. Agrees to wash hands and face today. Outcomes not met. Continue plan.

Problem Statement/Nursing Diagnosis

Altered sensory perception/Disturbed sensory perception related to neurobiochemical imbalance and anxiety.

Supporting Assessment Data

Subjective: States, "hear the demons."

Objective: Appears to be hearing voices.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will verbalize three ways to cope with hallucinations this week. Patient will verbalize a decrease in hallucinations before discharge.	Observe behavior that suggests that hallucination is occurring (e.g., talking to self, listening intently).	Staff can interrupt the hallucination in progress.	Observed in listening position and talking to self. Is actively hallucinating today (more than yesterday), appears upset; reason unclear.
	Assess for theme of hallucinations, especially command hallucinations (e.g., voices that say, "Kill others").	Knowing themes helps to anticipate violent or unexpected behavior.	Hearing command hallucinations ("I have the word, the word to save you").
	Redirect when hallucinations occur (e.g., "Talk with me.").	Interrupts hallucination in progress.	Patient does attend to nurse when spoken to; although he appears fearful, he will stay for 10-15 sec if he is given adequate space (e.g., 5 ft).
	Help patient recognize the feelings that are present before the hallucination.	Anxiety, fear, and stress are theorized to exacerbate hallucinations.	Unclear why patient is so agitated today; he is unable to verbalize specific feelings.
	State reality (e.g., "I understand that you hear voices. I do not hear those voices").	Helps patient to recognize and stay focused on reality.	Patient is actively hallucinating; only able to attend to nurse's voice for a few seconds.
	Teach patient to identify and use strategies to interrupt the hallucinations (e.g., seek out nursing staff, sing, listen to music).	Allows patient to cope with hallucinations. (For some patients, hallucinations never completely resolve.)	Unable to identify or teach alternative coping methods. Appears less agitated if not approached by other patients.
	Administer antipsychotic medications and monitor effectiveness and side effects.	Counteracts psychosis at the biochemical level.	Agrees to take risperidone (Risperdal) if administered by certain nurses. Outcomes not met. Continue plan.

Problem Statement/Nursing Diagnosis

Social isolation/Social isolation related to mistrust, bizarre behavior, or cognitive impairment.

Supporting Assessment Data

Subjective: "...all of you are demons."

Objective: Reluctant to interact with the staff or other patients.

Goals/Expected Outcomes	Nursing Interventions	Selected Rationale	Evaluation
Patient will engage in social interaction with others on the psychiatric unit (meals, outings, groups) within 2 wk.	Convey a warm, accepting attitude. Spend some structured time with the patient every day.	Builds therapeutic relationship. Encourages social interaction with a set time and purpose.	Has some trust toward selected nurses. Able to tolerate 10-15 sec of contact with nurses. Responds to his own name.
	Determine patient's interests.	Patient more likely to engage if interested in activities.	Family states that George is interested in baseball. Does show some interest in watching sports on television.
	Model social interaction and conversation. Create opportunities for socialization (e.g., card games).	Patient may be unaware of how to converse with others. Patient may not know how to independently engage others.	Is not initiating any conversations. Is able to attend group meeting for less than 1 min.
	Acknowledge and thank patient for any efforts to interact and participate in groups.	More likely to repeat behavior if encouraged and acknowledged.	Unable to participate in any group interaction today.
	Encourage the patient to interact with others, even if only briefly.	Brief contacts allow for gradual trust and familiarity to decrease suspiciousness.	Declined going to group music class this afternoon. Appears more restless and suspicious compared with yesterday. Patient unable to verbalize source of distress, no known event or trigger identified. Will continue to observe. Outcomes not met. Continue plan.

Critical Thinking Questions

1. Why is it important for a patient like George to have consistent social support after he is discharged from the hospital?
2. What can nurses do to help decrease the social stigma of chronic mental illnesses such as schizophrenia?

ADLs, Activities of daily living.

Box 48-2

Specific Nursing Interventions for Patients Who Are

Angry, Hostile, Aggressive, Manipulative, or Paranoid

Angry, Hostile, and Aggressive Behavior

- Continuously assess for nonverbal cues (pacing, fidgeting, and increase in verbalizations) and intervene early.
- Maintain a calm, self-assured attitude, even if you are frightened.
- Listen and acknowledge that you care and want to help.
- Be culturally aware of how your patient is interpreting eye contact.
- Allow the patient to have adequate personal space.
- Encourage the patient to find a quiet, safe place.
- Maintain your own safety—have adequate staff visually present in the background. However, only one person should attempt verbal de-escalation.
- Stand to the side or sideways to present yourself as a smaller target. Your hands should be relaxed at your sides or with the palms turned upward.
- Be aware of the exits and position yourself so that the patient is not blocking the exit.
- Ask for permission before touching. Defer therapeutic touching if the patient is highly agitated.
- Honestly verbalize the patient's options. For example, say, "You can stay in the dayroom if you can remain calm; otherwise it will be necessary for you to go to the quiet (seclusion) room."
- Set a time frame for verbal de-escalation. If progress is made within the time limit, continue. If not, remind the patient of the initial time limit.
- Offer appropriate PRN medications as ordered. If the patient continues to escalate and the behavior becomes aggressive, physical restraints may be necessary.
- Application of physical restraints requires a team approach by trained staff.
- Inform the patient of the staff's intentions and actions. Accurately document the entire episode, including all efforts to use the less restrictive measures before resorting to physical restraints.

Manipulative Behavior

- Set clear and realistic limits on specific behaviors.
- Establish realistic and enforceable consequences.
- Make certain that all staff are informed of the limits and are in agreement.
- Specific limits need to be documented in the plan of care/nurses' notes.
- The decision to discontinue limits should be made by the entire staff and should be made only when the patient has demonstrated consistent behavior.
- Be self-aware and establish clear boundaries.

Paranoid Behavior

- Assign only one or two staff members to the patient.
- Initially make brief contact with the patient, and do not make unnecessary demands.

- Increase credibility by being honest, adhering to a stated schedule, and following through on commitments.
- Do not touch a patient who is paranoid.
- Do not mix medications with food.
- Supply food in commercially wrapped packages if the patient is refusing to eat.

PRN, As needed.

■ Evaluation

To evaluate the effectiveness of nursing interventions, it is necessary to monitor the patient's progress toward expected outcomes. **Compliance with antipsychotic medications will decrease hallucinations and delusions (positive symptoms) and improve sleep.** It takes longer to achieve expected outcomes for the negative symptoms of schizophrenia than for the positive symptoms. Progress toward outcomes for the negative symptoms would include a decrease in psychomotor retardation, increase in self-care, improved affect, and an increase in motivation. In addition, the patient would exhibit a trusting attitude toward others and a decrease in social withdrawal.

Overview of Personality Disorders

Ordinarily, personality traits are flexible and adaptive. **Personality disorders** are enduring patterns of behavior in which there is no loss of contact with reality or impaired cognition. The patient with a personality disorder demonstrates an ongoing, inflexible pattern of behavior that is **very** different from others within the individual's culture.

Symptoms of personality disorders are usually first observed in late adolescence and early adulthood. Four characteristics of personality disorders are:

1. Inflexible and maladaptive response to life events
2. Serious difficulty in areas of personal and work relationships
3. Tendency to evoke interpersonal conflict
4. Tendency to evoke a negative empathic response from others

An actual diagnosis may not be made until the person reaches the late 20s or 30s; by then the entrenched behaviors are quite evident. It is not uncommon to note failed marriages, poor work histories, and considerable difficulty with interpersonal relationships.

The DSM-5 describes 10 different personality disorder types. Depending on the descriptive characteristics, these disorders are clustered into three separate categories. Cluster A includes behaviors that are considered **odd** or **eccentric** (schizotypal, schizoid, and paranoid). Cluster B describes behaviors that are considered **dramatic, emotional, and erratic** (antisocial, borderline, histrionic, and narcissistic). Individuals with Cluster C behaviors appear **anxious** and **fearful** (avoidant, dependent, and obsessive-compulsive). A final type of personality disorder is personality disorder NOS (not otherwise specified). **Box 48-3** provides a brief description of each of these personality disorders. Many psychiatrists feel a personality disorder cannot be diagnosed until a person is 18 years old. This chapter discusses borderline personality disorder because it is more commonly diagnosed and caring for patients with a borderline personality presents many challenges.

Box 48-3

Description of Personality Disorders

Cluster A (Odd and Eccentric)

- *Schizotypal*: Exhibits difficulty with close relationships, distortions in thinking and feeling, and odd or eccentric behavior.
- *Schizoid*: Exhibits withdrawal from social relationships and a restricted affect.
- *Paranoid*: Exhibits distrust and suspiciousness of others and feels that others wish him harm or evil.

Cluster B (Dramatic, Emotional, and Erratic)

- *Antisocial*: Exhibits disregard for, and violation of, the rights of others; lacks empathy.
- *Borderline*: Exhibits instability in interpersonal relationships and self-concept, labile emotions, and marked impulsivity.
- *Histrionic*: Exhibits pattern of extreme emotionality and attention-seeking behavior.
- *Narcissistic*: Exhibits grandiose behavior, intense need for admiration, and lack of empathy.

Cluster C (Anxious and Fearful)

- *Avoidant*: Exhibits social inhibition, feelings of inadequacy, and fear of rejection.
- *Dependent*: Exhibits behavior that is submissive and clinging; needy.
- *Obsessive-compulsive*: Exhibits behavior that is concerned with excessive orderliness, perfectionism, and need for control.

Borderline Personality Disorder

The main feature of **borderline personality disorder (BPD)** is “a pervasive pattern of instability in interpersonal relationships, self-image and emotions” (Grohol, 2014). Individuals with this disorder tend to be very impulsive, attach quickly and easily to others, and fear **real or imagined abandonment**. Emotions and relationships are very intense. In response to potential abandonment from caregivers or significant others, it is not unusual to see **self-mutilating behavior** (e.g., cutting on hands and wrists, cigarette burns) or **suicidal gestures**. Evidence-based practice suggests that the therapeutic goals for patients who self-mutilate include acquiring new coping methods, better impulse and emotional control, and increasing self-awareness (Warner and Spander, 2012).

Think Critically

You are assigned to escort a young patient to the smoking area. As she is finishing her cigarette, she touches the hot ash to her wrist and sustains a burn before you can stop her. She publicly announces to the staff and the other patients that you were negligent in watching her. How would you handle this?

Splitting, a primitive defense mechanism, involves the initial idealization of a caregiver or friend, followed by a hasty devaluing of that same person. A patient with BPD also may idealize one or two team members and devalue others. For example, the patient may say, “You are the best nurse I have ever had. No one else understands me like you do.” When the nurse returns after 2 days off, the patient would say, “I can't believe you didn't call me when you were off. I felt horrible and began cutting on my wrists, and it is your fault.” It is very important that the staff decide on an approach to use with a particular patient. To implement the plan properly, all team members must be consistent with the approach.

Impulsivity in at least two of the following areas also is characteristic of BPD: gambling, overeating, spending impulsively, abusing substances, engaging in unsafe sex, binge eating, or driving recklessly. Engaging in one or more of these impulsive behaviors is often the reason for admission to a hospital.

Treatment

Treatment for people with this disorder involves long-term psychotherapy, such as individual counseling and group or family therapy. The purpose of **psychotherapy** is to help the participants identify problem areas and work to change behavior and attitudes or modify feelings. The American Psychiatric Association recommends dialectical behavior therapy (DBT) for patients with BPD. This therapy includes individual counseling, telephone support, and skills training and has been shown to reduce self-destructive and impulsive episodes, anxiety, and hospitalization. In addition, DBT could be used to help the family members of patients. Patients with personality disorders can also benefit from milieu therapy. **Milieu therapy** uses the structured environment of a hospital or group home setting to help patients participate as active members of the milieu community and practice social behaviors. Medications are not indicated for personality disorders, although they are sometimes prescribed when there is a concurrent mood disorder.

Nursing Management

Assessment (Data Collection)

Collect information about how the individual views himself and others. Obtain a history of former relationships and identify how the individual typically expresses feelings. It is important not to make a hasty judgment and label a person with a personality disorder. For example, adolescents

may impulsively act out with substances and have identity problems, but these traits often disappear with maturity. In addition, when a patient is labeled as “borderline,” nurses may view the patient as “hopeless.” **Box 48-4** lists examples of behaviors nurses might observe when assessing a personality disorder.

Box 48-4

Guide for Assessing Patients With Personality Disorders

Observe and assess for the following:

- Acting without thinking; impulsivity
- Anger and possible rage when others do not share the same point of view
- Consistent poor judgment in making decisions
- Constant seeking of praise and admiration
- Evidence of self-destructive behavior
- Excessive use of manipulation to get needs met
- Expression of a need to control others
- Extreme envy of others
- Low self-esteem
- Self-centeredness
- Treatment of others as objects, not people
- Unreliability

Nursing Diagnosis

Typical problem statements for BPD may include:

- Social isolation due to immature and manipulative behavior
- Decreased self-esteem due to childhood abuse and neglect
- Limited coping ability due to emotional state outbursts
- Anxiety due to perceived threats of abandonment
- Potential for injury related to feelings of guilt and rejection

Specific NANDA-I diagnoses can be chosen from the NANDA-I list (see inside back cover).

Planning

Sample outcomes for the above problem statements include:

- Patient will discuss one example of how his behavior alienates others by the end of the week.
- Patient will share two things that he likes about himself in today's group meeting.
- Patient will identify three methods to cope with intense emotions (e.g., anger at staff or significant others) within 1 week.
- Patient will identify situations that provoke feelings of abandonment (e.g., favorite nurse is on vacation) and state two methods to reduce accompanying anxiety during this shift.
- Patient will substitute a safe behavior (e.g., talking to nurse, counting to 100) for self-mutilating behavior when experiencing feelings of guilt or rejection during hospitalization.

Planning for the care of a patient with BPD requires involvement of the entire team to define goals and to prevent the patient's inevitable attempts at staff manipulation. If possible, some staff debriefing time will help everyone to maintain a professional and optimistic focus when working

with patients who have this disorder.

Assignment Considerations

Interpersonal Skills

When planning care for your patients, incorporate the strengths and interpersonal skills of your team members and make assignments appropriately. For example, your patient is a 23-year-old woman who needs an escort to attend a group therapy class outside of the unit. She is known for her attempts to manipulate male staff members; therefore assign a mature female nursing assistant who is familiar with the patient's manipulative behavior.

Implementation

For individuals with BPD, setting limits is a priority intervention. Individuals must be taught healthy and nonmanipulative ways to have their needs met. To work with patients who have BPD, the staff needs to maintain good boundaries without being controlling, rigid, and inflexible. Patients with this disorder often ask you to “bend the rules” or grant special privileges. **The staff needs to consistently set limits with caring and empathy, offer a rationale, and decline negotiation.** If the patient views the limit setting as punitive, the behavior is certain to recur at a later time. This does not mean that the patient will always gladly accept the limit setting and be grateful for your concern. It does mean that you are assisting the patient in developing some internal sense of boundaries and subsequent changes in behavior.

It is also necessary to maintain a safe environment for patients with BPD, because they can be impulsive and do not have internal control. It may be necessary to initiate suicide precautions or help the patient who is self-mutilating to stop this behavior. See [Chapter 45](#) for information on suicide precautions.

Patients with personality disorders have an ability to “get under the skin” of caregivers. If you note a particularly intense reaction to a patient (excessive sympathy, empathy, anger, or frustration), it is important to talk about these feelings with a more experienced nurse or a trusted peer. Identify and express the feelings that the patient’s behavior evokes. Awareness of your own feelings will help you modify your reactions and focus on the therapeutic aspects of your relationship with the patient. Evidence suggests that the strength of the therapeutic alliance is related to overall outcomes of treatment ([Horvath et al, 2011](#)). In addition, the nurse’s skills and attitudes are just as important as any  prescribed medical intervention ([Fisher, 2011](#)). See the Evolve website for a Nursing Care Plan on personality disorders.

Evaluation

Achievement of long-term outcomes is demonstrated by new coping strategies for handling stressors, verbalizing anger without acting out, increasing independent decision making, and decreasing manipulative behaviors to have needs met. It is expected that in times of stress, the patient will revert to previously learned behaviors. When the stress has passed, you should encourage the patient to continue implementing new behaviors.

Community Care

At one time individuals with thought disorders were hospitalized indefinitely. With the introduction of antipsychotic medications, hospitalization is reserved for medication stabilization; then patients are released to a less restrictive type of care. In fact, community mental health teams are shown to increase patients' acceptance of treatment and reduce the need for hospitalization ([Malone et al, 2009](#)).

Older Adult Care Points

Because of the negative symptoms of social withdrawal, apathy, and sometimes paranoia, older adults with schizophrenia are not as likely to seek out nurses for help. They may ignore physical problems and often will not seek help for pain associated with physical disabilities.

Although there are fewer older adults with schizophrenia, they can present unique challenges for nurses who work in long-term care.

Safety Alert

Be Alert for Suicidal Ideations

Approximately 50% of patients who have schizophrenia think about suicide sometime during their lifetime. Community health nurses are in a position to make regular contact with these patients, assess for suicide even if the patient does not raise the issue, clearly communicate the intention to see the patient again, and help the patient to make a crisis response plan that includes hospitalization as needed ([Meerwijk et al, 2010](#)) (see [Chapter 45](#)).

Patients with personality disorders are not hospitalized unless they present an imminent danger to themselves via self-mutilation or suicidal gestures. Again, nurses come into contact with personality disorders in a variety of settings outside a psychiatric hospital. Setting limits and appropriate boundaries continues to be an effective intervention, regardless of the setting.

Patients with chronic mental illness are at high risk for social problems and may have limited encounters with health care professionals. For example, patients with schizophrenia are at a high risk for homelessness, and patients with personality disorders, particularly antisocial personality disorder, are more likely to be incarcerated. In accordance with *Healthy People 2020* goals, a greater percentage of people who are homeless and those who are in prison need mental health screening and access to treatment.

Get Ready for the NCLEX® Examination!

Key Points

- Thought disorders are characterized by disorganized thoughts and behavior and hallucinations. Mood and interpersonal relationships are altered.
- Schizophrenia is the most commonly diagnosed thought disorder and usually develops in late adolescence or the early 20s.
- The positive symptoms of schizophrenia (hallucinations, delusions, and disordered thinking) can be treated with antipsychotic medications.
- The negative symptoms of schizophrenia (apathy, social isolation, psychomotor retardation, blunted affect, poverty of thoughts, and lack of motivation) are responsive to some of the newer atypical medications but are more difficult to treat. Long-term social skills training and ongoing family and community support are essential.
- Older adults who are taking antipsychotics are at a greater risk for developing extrapyramidal symptoms, tardive dyskinesia, and neuroleptic malignant syndrome. Beginning doses should be one half to one third of the normal adult dose.
- General nursing management includes establishing trust and rapport, encouraging social skills, administering medications and monitoring effects, and educating the patient and family about the illness and the therapeutic regimen.
- Personality disorders are characterized by enduring traits.
- Borderline personality disorder is the most prevalent personality disorder. The hallmarks of personality disorders are inflexible and maladaptive response to life events, serious difficulty in personal and work relationships, a tendency to evoke interpersonal conflict, a tendency to evoke a negative empathic response from others, and impulsivity.
- For a patient with a personality disorder, assess the patient's view of self and others, expression of feelings, and behaviors that are interfering with life and relationships.
- General nursing management of patients with personality disorders includes building trust, setting limits, teaching coping skills, preventing self-harm, and encouraging insight into behavior.

Review Questions for the NCLEX® Examination

1. An older adult male patient on antipsychotic medications develops a flat affect with drooling and a shuffling gait. He has slowed movements, tremors, motor restlessness, apprehension, and irritability. The nurse would look for an order from the physician for which medication?

1. Benztropine (Cogentin)
2. Haloperidol (Haldol)

3. Chlorpromazine (Thorazine)
4. Perphenazine (Trilafon)

NCLEX Client Need: Physiological Integrity: Pharmacological Therapies

2. The nurse is administering medication to a familiar patient, who has been on the unit for several weeks. When asked to state his name, the patient replies, "I am Jesus Christ, the son of God." What is the best nursing action?

1. Give the medication, because the nurse knows he is confused.
2. Document that the patient cannot state his name and hold the medication.
3. Hold the medication until the family can bring in a picture identification.
4. Have a second nurse verify his identity and document accordingly.

NCLEX Client Need: Integrated Processes: Clinical Problem-Solving Process

3. The nurse discusses the effects of a patient's antipsychotic medication with him. Which patient statement indicates a need for further teaching?

1. "The medication helps me to think more logically."
2. "The medication makes my mouth dry."
3. "The medication improves my mood."
4. "The medication helps to stop the voices."

NCLEX Client Need: Integrated Processes: Teaching/Learning

4. A patient reports to the nurse that he has been taking chlorpromazine (Thorazine) for 4 months. Which symptom is the cause for greatest concern?

1. Muscle rigidity
2. Tongue protrusion
3. Photophobia

4. Dry eyes

NCLEX Client Need: Physiological Integrity: Pharmacological Therapies

5. When the nurse is talking with a patient who is having active hallucinations, what is the priority action?

1. Assess the content and themes of hallucinations.
2. Give an antipsychotic medication.
3. Take the patient to a secluded area.
4. Set boundaries and explain rationale.

NCLEX Client Need: Integrated Processes: Clinical Problem-Solving Process

6. A patient is suspicious and believes that he is surrounded by terrorists. He tells the nurse, "They put anthrax in the food and there is a bomb in the bathroom." What is the most therapeutic response?

1. "Who do you think is doing all these things?"
2. "Let's go together and check the bathroom."
3. "Tell me why you believe these things are happening."
4. "I believe that the hospital is a safe place."

NCLEX Client Need: Psychosocial Integrity: Therapeutic Communication

7. A patient demonstrates negative symptoms of apathy, social isolation, and lack of motivation. To establish trust, what should the nurse do? (*Select all that apply.*)

1. Offer self and be available.
2. Reorient to person, place, and time.
3. Keep all promises.
4. Invite the patient to join groups.
5. Leave the door open for future interactions.
6. Encourage independence in ADLs.

NCLEX Client Need: Integrated Processes: Clinical Problem-Solving Process

8. A patient is readmitted for an acute psychotic episode. He appears to be having command hallucinations. What is the priority problem on his care plan?

1. Altered sensory perception
2. Potential for violence
3. Anxiety
4. Altered coping ability

NCLEX Client Need: Integrated Processes: Clinical Problem-Solving Process

9. A nurse is caring for a patient with a personality disorder. Which statement by the nurse indicates a need for additional training and education on setting boundaries?

1. "I can spend 20 minutes talking with you and then I have to pass medications."
2. "I understand that you are bored, but you have to complete the task."
3. "If you promise not to cause trouble, I'll give you the magazine."
4. "When someone is speaking in group, it is polite to listen while they speak."

NCLEX Client Need: Integrated Processes: Teaching/Learning

10. A patient is becoming progressively louder and more aggressive about getting a personal item (belt) that was taken from him for safety precautions. What intervention(s) should the nurse use? (*Select all that apply.*)

1. Continuously assess for pacing, fidgeting, and increase in verbalizations.
2. Maintain a calm, self-assured attitude, even if frightened.
3. Listen and state, "I care and want to help."
4. Move in close to the patient to reassure him.
5. Give the patient the belt and set strict limits on his behavior.

6. Stand to the side or sideways to present yourself as a smaller target.
7. Explain the hospital policy and offer him a copy.

NCLEX Client Need: Integrated Processes: Clinical Problem-Solving Process

Critical Thinking Questions

Scenario A

You are caring for Mrs. Jackson, a 62-year-old who has a fixed delusional system with many religious overtones. You notice that she is pacing and becoming increasingly agitated. She begins to yell in a loud voice about God and salvation and not being saved.

1. How might you approach Mrs. Jackson and help her to de-escalate?
2. What behaviors would cause you to consider physically restraining Mrs. Jackson?

Scenario B

Mr. Philip Munoz, 38 years old, was recently discharged from a psychiatric facility after an extended stay. He comes to the clinic for a renewal of his antipsychotic medications, accompanied by his father, who reports that his son is noncompliant with medications and has limited social interaction.

1. What nursing interventions could increase Mr. Munoz's compliance with therapy?
2. What type of community referrals would be appropriate for this patient and his family?

Scenario C

Mr. Abdul is admitted to the psychiatric unit for chronic schizophrenia. It is very difficult to understand Mr. Abdul, because he has thought disorders and manifests word salad, neologisms, and loose associations. He has not demonstrated any aggressive behaviors toward anyone, but he is unable to sustain interaction for more than a few seconds at a time.

1. What interventions could be used for the problem of altered communication ability?
2. Write a communication goal that would be appropriate for Mr. Abdul.
3. Identify an activity that would be appropriate for this patient.

Scenario D

A 28-year-old patient, Cindy Stalling, arrives at the clinic with a superficial scratch on the wrist. She begins to cry, "You are the best nurse here. You're always so kind and understanding. Would you call my boyfriend and tell him that I am here? I cut myself because we just broke up." You know Ms. Stalling because she has been in the clinic many times with similar minor injuries. In the past, she has been manipulative and verbally abusive toward the staff.

1. What behaviors suggest that Ms. Stalling may have a personality disorder?
2. How would you respond to her request to call her boyfriend?

APPENDIX A

Most Common Laboratory Test Values

Table A-1
Reference Intervals for Hematology

TEST	CONVENTIONAL UNITS	SI UNITS
Acid hemolysis (Ham test)	No hemolysis	No hemolysis
Alkaline phosphatase, leukocyte	Total score, 14-100	Total score, 14-100
Cell Counts		
Erythrocytes		
Males	4.6-6.2 million/mm ³	4.6-6.2 × 10 ¹² /L
Females	4.2-5.4 million/mm ³	4.2-5.4 × 10 ¹² /L
Children (varies with age)	4.5-5.1 million/mm ³	4.5-5.1 × 10 ¹² /L
Leukocytes, total	4,500-11,000/mm ³	4.5-1.0 × 10 ⁹ /L
Leukocytes, differential counts*		
Myelocytes	0%	0/L
Band neutrophils	3%-5%	150-400 × 10 ⁶ /L
Segmented neutrophils	54%-62%	3000-5800 × 10 ⁶ /L
Lymphocytes	25%-33%	1500-3000 × 10 ⁶ /L
Monocytes	3%-7%	300-500 × 10 ⁶ /L
Eosinophils	1%-3%	50-250 × 10 ⁶ /L
Basophils	0%-1%	15-50 × 10 ⁶ /L
Platelets	150,000-400,000/mm ³	150-400 × 10 ⁹ /L
Reticulocytes	25,000-5,000/mm ³ (0.5%-1.5% of erythrocytes)	25-75 × 10 ⁹ /L
Coagulation Tests		
Bleeding time (template)	2.75-8.00 min	2.75-8.00 min
Coagulation time (glass tube)	5-15 min	5-15 min
D-Dimer	<0.5 mcg/mL	<0.5 mg/L
Factor VIII and other coagulation factors	50%-150% of normal	0.5-1.5 of normal
Fibrin split products (Thrombo-Welco test)	<10 mcg/mL	<10 mg/L
Fibrinogen	200-400 mg/dL	2.0-4.0 g/L
Partial thromboplastin time, activated (aPTT)	20-25 sec	20-35 sec
Prothrombin time (PT)	12.0-14.0 sec	12.0-14.0 sec
Coombs test		
Direct	Negative	Negative
Indirect	Negative	Negative
Corpuscular Values of Erythrocytes		
Mean corpuscular hemoglobin (MCH)	26.34 pg/cell	26.34 pg/cell
Mean corpuscular volume (MCV)	80.96 μm ³	80.96 fL
Mean corpuscular hemoglobin concentration (MCHC)	32.36 g/dL	320-360 g/L
Haptoglobin	20-165 mg/dL	0.20-1.65 g/L
Hematocrit		
Males	40-54 mL/dL	0.40-0.54 g/L
Females	37-47 mL/dL	0.37-0.47 g/L
Newborns	49-54 mL/dL	0.49-0.54 g/L
Children (varies with age)	35-49 mL/dL	0.35-0.49 g/L
Hemoglobin		
Males	13.0-18.0 g/dL	8.1-11.2 mmol/L
Females	12.0-16.0 g/dL	7.4-9.9 mmol/L
Newborns	16.5-19.5 g/dL	10.2-12.1 mmol/L
Children (varies with age)	11.2-16.5 g/dL	7.0-10.2 mmol/L
Hemoglobin, fetal	<1.0% of total	<0.01 of total
Hemoglobin A1C	3%-5% of total	0.03-0.05 of total
Hemoglobin A2	1.5%-3.0% of total	0.015-0.03 of total
Hemoglobin, plasma	0.0-5.0 mg/dL	0.0-3.2 μmol/L
Methemoglobin	30-130 mg/dL	19-80 μmol/L
Erythrocyte Sedimentation Rate (ESR)		
Wintrobe		
Males	0-5 mm/hr	0-5 mm/hr
Females	0-15 mm/hr	0-15 mm/hr
Westergren		
Males	0-15 mm/hr	0-15 mm/hr
Females	0-20 mm/hr	0-20 mm/hr

*Conventional units are percentages; SI units are absolute cell counts.

From McCloskey LJ: Reference intervals for interpretation of laboratory test values. In Bope ET, Rakel RE, Kellerman R (Eds), *Conn's current therapy 2010*, Philadelphia, 2010, Saunders.

Table A-2
Reference Intervals* for Clinical Chemistry (Blood, Serum, and Plasma)

ANALYTE	CONVENTIONAL UNITS	SI UNITS
Acetoacetate plus acetone		
Qualitative	Negative	Negative
Quantitative	0.3-2.0 mg/dL	30-200 μmol/L
Acid phosphatase, serum (thymolphthalein monophosphate substrate)	0.1-0.6 U/L	0.1-0.6 U/L
ACTH (see Corticotropin)		
Alanine aminotransferase (ALT), serum (SGPT)	1-45 U/L	1-45 U/L
Albumin, serum	3.3-5.2 g/dL	33-52 g/L
Aldolase, serum	0.0-7.0 U/L	0.0-7.0 U/L
Aldosterone, plasma		
Standing	5-30 ng/dL	140-830 pmol/L
Recumbent	3-10 ng/dL	80-275 pmol/L

Alkaline phosphatase (ALP), serum		
Adult	35-150 U/L	35-150 U/L
Adolescent	100-500 U/L	100-500 U/L
Child	100-350 U/L	100-350 U/L
Ammonia nitrogen, plasma	10-50 µmol/L	10-50 µmol/L
Amylase, serum	25-125 U/L	25-125 U/L
Anion gap, serum calculated	8-16 mEq/L	8-16 mmol/L
Ascorbic acid, blood	0.4-1.5 mg/dL	23-85 µmol/L
Aspartate aminotransferase (AST), serum (SGOT)	1-36 U/L	1-36 U/L
Base excess, arterial blood, calculated	0 ± 2 mEq/L	0 ± 2 mmol/L
Beta-carotene, serum	60-260 mcg/dL	1.1-8.6 µmol/L
Bicarbonate		
Venous plasma	23-29 mEq/L	23-29 mmol/L
Arterial blood	21-27 mEq/L	21-27 mmol/L
Bile acids, serum	0.3-3.0 mg/dL	0.8-7.6 mmol/L
Bilirubin, serum		
Conjugated	0.1-0.4 mg/dL	1.7-6.8 µmol/L
Total	0.3-1.1 mg/dL	5.1-19.0 µmol/L
Calcium, serum	8.4-10.6 mg/dL	2.10-2.65 mmol/L
Calcium, ionized, serum	4.25-5.25 mg/dL	1.05-1.30 mmol/L
Carbon dioxide, total, serum or plasma	24-31 mEq/L	24-31 mmol/L
Carbon dioxide tension (PCO ₂), blood	35-45 mm Hg	35-45 mm Hg
Ceruloplasmin, serum	23-44 mg/dL	230-440 mg/L
Chloride, serum or plasma	96-106 mEq/L	96-106 mmol/L
Cholesterol, serum or EDTA plasma		
Desirable range	<200 mg/dL	<52.0 mmol/L
Low-density lipoprotein (LDL) cholesterol	60-180 mg/dL	1.55-4.65 mmol/L
High-density lipoprotein (HDL) cholesterol	30-80 mg/dL	0.80-2.05 mmol/L
Copper	70-140 mcg/dL	11-22 µmol/L
Corticotropin (ACTH), plasma, 8 A.M.	10-80 pg/mL	2-18 pmol/L
Cortisol, plasma		
8 A.M.	6-23 mcg/dL	170-630 µmol/L
4 P.M.	3-15 mcg/dL	80-410 µmol/L
10 P.M.	<50% of 8 A.M. value	<50% of 8 A.M. value
Creatinine, serum		
Males	0.2-0.5 mg/dL	15-40 µmol/L
Females	0.3-0.9 mg/dL	25-70 µmol/L
Creatine kinase (CK), serum		
Males	55-170 U/L	55-170 U/L
Females	30-135 U/L	30-135 U/L
Creatinin kinase MB isoenzyme, serum	<5% of total CK activity <5% of ng/mL by immunoassay	<5% of total CK activity <5% of ng/mL by immunoassay
Creatinine, serum	0.6-1.2 mg/dL	50-110 µmol/L
Estradiol-17-beta, adult		
Males	10-65 pg/mL	35-240 pmol/L
Females		
Follicular	30-100 pg/mL	110-370 pmol/L
Ovulatory	200-400 pg/mL	730-1470 pmol/L
Luteal	50-140 pg/mL	180-510 pmol/L
Ferritin, serum	20-200 ng/mL	20-200 mcg/L
Fibrinogen, plasma	200-400 mg/dL	2.0-4.0 g/L
Folate, serum	3-18 ng/mL	6.8-41 nmol/L
Erythrocytes	145-540 ng/mL	330-1420 nmol/L
Follicle-stimulating hormone (FSH), plasma		
Males	4-25 mU/mL	4-25 U/L
Females, premenopausal	4-30 mU/mL	4-30 U/L
Females, postmenopausal	40-250 mU/mL	40-250 U/L
Gamma-glutamyltransferase (GGT), serum	5-40 U/L	5-40 U/L
Gastrin, fasting, serum	0-100 pg/mL	0-100 ng/L
Glucose, fasting, plasma or serum	70-100 mg/dL	3.9-5.55 nmol/L
Growth hormone (hGH), plasma, adult, fasting	0-6 ng/mL	0-6 mcg/L
Haptoglobin, serum	20-165 mg/dL	0.20-1.65 g/L
Beta-hydroxybutyrate	0.3-2.8 mg/dL	20-280 µmol/L
Immunoglobulins, serum (see Table A-8)		
Iron, serum	75-175 mcg/dL	13-31 µmol/L
Iron-binding capacity, serum		
Total	250-410 mcg/dL	45-73 µmol/L
Saturation	20%-55%	0.20-0.55
Lactate		
Venous whole blood	5.0-20.0 mg/dL	0.6-2.2 mmol/L
Arterial whole blood	5.0-15.0 mg/dL	0.6-1.7 mmol/L
Lactate dehydrogenase (LD), serum	110-220 U/L	110-220 U/L
Lipase, serum	10-140 U/L	10-140 U/L
Lutropin (LH), serum		
Males	1-9 U/L	1-9 U/L
Females		
Follicular phase	2-10 U/L	2-10 U/L
Midcycle peak	15-65 U/L	15-65 U/L
Luteal phase	1-12 U/L	1-12 U/L
Postmenopausal	12-65 U/L	12-65 U/L
Magnesium, serum	1.3-2.1 mg/dL	0.65-1.05 mmol/L
Osmolality	275-295 mOsm/kg water	275-295 mOsm/kg water
Oxygen, blood, arterial, room air		
Partial pressure (PaO ₂)	80-100 mm Hg	80-100 mm Hg
Saturation (SaO ₂)	95%-98%	95%-98%
pH, arterial blood	7.35-7.45	7.35-7.45
Phosphate, inorganic, serum		
Adult	3.0-4.5 mg/dL	1.0-1.5 mmol/L
Child	4.0-7.0 mg/dL	1.3-2.3 mmol/L
Potassium		
Serum	3.5-5.0 mEq/L	3.5-5.0 mmol/L
Plasma	3.5-4.5 mEq/L	3.5-4.5 mmol/L
Progesterone, serum, adult		
Males	0.0-0.4 ng/mL	0.0-1.3 mmol/L
Females		
Follicular phase	0.1-1.5 ng/mL	0.3-4.8 mmol/L
Luteal phase	2.5-28.0 ng/mL	8.0-89.0 mmol/L
Prolactin, serum		
Males	1.0-15.0 ng/mL	1.0-15.0 mcg/L
Females	1.0-20.0 ng/mL	1.0-20.0 mcg/L
Protein, serum, electrophoresis		
Total	6.0-8.0 g/dL	60-80 g/L
Albumin	3.5-5.5 g/dL	35-55 g/L
Globulins		
Alpha ₁	0.2-0.4 g/dL	2.0-4.0 g/L

Alpha ₂	0.5-0.9 g/dL	5.0-9.0 g/L
Beta	0.6-1.1 g/dL	6.0-11.0 g/L
Gamma	0.7-1.7 g/dL	7.0-17.0 g/L
Pyruvate, blood	0.3-0.9 mg/dL	0.03-0.10 mmol/L
Rheumatoid factor	0.0-30.0 U/mL	0.0-30.0 kU/L
Sodium, serum or plasma	135-145 mEq/L	135-145 mmol/L
Testosterone, plasma		
Males, adult	300-1200 ng/dL	10.4-41.6 nmol/L
Females, adult	20-75 ng/dL	0.7-2.6 nmol/L
Pregnant females	40-200 ng/dL	1.4-6.9 nmol/L
Thyroglobulin	3-42 ng/mL	3-42 mcg/L
Thyrotropin (hTSH), serum	0.4-4.8 mIU/mL	0.4-4.8 mU/L
Thyrotropin-releasing hormone (TRH)	5-60 pg/mL	5-60 ng/L
Thyroxine (FT ₄), free, serum	0.9-2.1 ng/dL	12-27 pmol/L
Thyroxine (T ₄), serum	4.5-12.0 mcg/mL	58-154 nmol/L
Thyroxine-binding globulin (TBG)	15.0-34.0 mcg/mL	15.0-34.0 mg/L
Transferrin	250-430 mg/dL	2.5-4.3 g/L
Triglycerides, serum, after 12-hr fast	40-150 mg/dL	0.4-1.5 g/L
Triiodothyronine (T ₃), serum	70-190 ng/dL	1.1-2.9 nmol/L
Triiodothyronine uptake, resin (T ₃ RU)	25%-38%	0.25-0.38
Tropponin I	0.05-0.50 ng/mL	0.05-0.50 ng/mL
Ururate		
Males	2.5-8.0 mg/dL	150-480 μmol/L
Females	2.2-7.0 mg/dL	130-420 μmol/L
Urea, serum or plasma	24-49 mg/dL	4.0-8.2 mmol/L
Urea, nitrogen, serum or plasma	11-23 mg/dL	8.0-16.4 nmol/L
Viscosity, serum	1.1-1.8 × water	1.1-1.8 × water
Vitamin A, serum	20-80 mcg/dL	0.70-2.80 μmol/L
Vitamin B ₁₂ , serum	180-900 pg/mL	133-664 pmol/L

*Reference values may vary, depending on the method and sample source used.

ACTH, Adrenocorticotrophic hormone; EDTA, ethylenediaminetetraacetic acid; mU, milliunit; mIU, microunit; kIU, killiunit; SGPT, serum glutamic pyruvic transaminase.

Table A-3

Reference Intervals* for Therapeutic Drug Monitoring (Serum or Plasma)

ANALYTE	THERAPEUTIC RANGE	TOXIC CONCENTRATIONS	PROPRIETARY NAME(s)
Analgesics			
Acetaminophen	10-40 mcg/mL	>150 mcg/mL	Tylenol, Datril
Salicylate	100-250 mcg/mL	>300 mcg/mL	Aspirin, Bufferin
Antibiotics			
Amikacin	20-30 mcg/mL	Peak >35 mcg/mL Trough <10 mcg/mL	Amkin
Gentamicin	5-10 mcg/mL	Peak >10 mcg/mL Trough >2 mcg/mL	Garamycin
Tobramycin	5-10 mcg/mL	Peak >10 mcg/mL Trough >2 mcg/mL	Nebcin
Vancomycin	5-35 mcg/mL	Peak >40 mcg/mL Trough >10 mcg/mL	Vancocin
Anticonvulsants			
Carbamazepine	5-12 mcg/mL	>15 mcg/mL	Tegretol
Ethosuximide	40-100 mcg/mL	>250 mcg/mL	Zarontin
Phenobarbital	15-40 mcg/mL	40-100 ng/mL (varies widely)	Luminal
Phenytoin	10-20 mcg/mL	>20 mcg/mL	Dilantin
Primidone	5-12 mcg/mL	>15 mcg/mL	Mysoline
Valproic acid	50-100 mcg/mL	>100 mcg/mL	Depakene
Antineoplastics and Immunosuppressives			
Cyclosporine	100-300 ng/mL	>400 ng/mL	Sandimmune
Methotrexate, high-dose, 48 hr	Variable	>1 μmol/L, 48 hr after dose	
Tacrolimus (FK-506), whole blood	3-20 mcg/L	>15 mcg/L	Prograf
Bronchodilators and Respiratory Stimulants			
Caffeine	3-15 ng/mL	>30 ng/mL	Elixophyllin
Theophylline (aminophylline)	10-20 mcg/mL	>30 mcg/mL	Quibron
Cardiovascular Drugs			
Amiodarone (obtain specimen more than 8 hr after last dose)	1.0-2.0 mcg/mL	>2.0 mcg/mL	Cordarone
Digoxin (obtain specimen more than 6 hr after last dose)	0.8-2.0 ng/mL	>2.4 ng/mL	Lanoxin
Disopyramide	2-5 mcg/mL	>7 mcg/mL	Norpace
Flecainide	0.2-1.0 mcg/mL	>1 mcg/mL	Tambocor
Lidocaine	1.5-5.0 mcg/mL	>6 mcg/mL	Xylocaine
Mexitilene	0.7-2.0 mcg/mL	>2 mcg/mL	Mexitil
Procainamide	4-10 mcg/mL	>12 mcg/mL	Pronestyl
Procainamide plus NAPA (N-acetyl procainamide)	8-30 mcg/mL	>30 mcg/mL	
Propranolol	50-100 ng/mL	Variable	Inderal
Quinidine	2-5 mcg/mL	>6 mcg/mL	Cardioquin, Quinaglute
Tocainide	4-10 ng/mL	>10 ng/mL	Tonocard
Psychopharmacologic Drugs			
Amitriptyline	120-150 ng/mL	>500 ng/mL	Elavil, Triavil
Bupropion	25-100 ng/mL	Not applicable	Wellbutrin
Desipramine	150-300 ng/mL	>500 ng/mL	Norpramin
Imipramine	125-250 ng/mL	>400 ng/mL	Tofranil
Lithium (obtain specimen 12 hr after last dose)	0.6-1.5 mEq/L	>1.5 mEq/L	Lithobid
Nortriptyline	50-150 ng/mL	>500 ng/mL	Aventyl, Pamelor

*Values may vary depending on the method and sample collection device used. Always consult the reference values provided by the laboratory performing the analysis.

Table A-4

Reference Intervals* for Clinical Chemistry (Urine)

ANALYTE	CONVENTIONAL UNITS	SI UNITS
Acetone and acetoacetate, qualitative	Negative	Negative

Albumin		
Qualitative	Negative	Negative
Quantitative	10-100 mg/24 hr	0.15-1.5 µmol/day
Aldosterone	3-20 mcg/24 hr	8.3-55 nmol/day
Delta-aminolevulinic acid (δ-ALA)	1.3-7.0 mg/24 hr	10-53 µmol/day
Amylase	<17 U/hr	<17 U/hr
Amylase/creatinine clearance ratio	0.01-0.04	0.01-0.04
Bilirubin, qualitative	Negative	Negative
Calcium (regular diet)	>250 mg/24 hr	<6.3 nmol/day
Catecholamines		
Epinephrine	<10 mcg/24 hr	<55 nmol/day
Norepinephrine	<100 mcg/24 hr	<590 nmol/day
Total free catecholamines	4-126 mcg/24 hr	24-745 nmol/day
Total metanephrines	0.1-1.6 mg/24 hr	0.5-8.1 µmol/day
Chloride (varies with intake)	110-250 mEq/24 hr	110-250 mmol/day
Copper	0-50 mcg/24 hr	0.0-0.80 µmol/day
Cortisol, free	10-100 mcg/24 hr	27.6-276 nmol/day
Creatine		
Males	0.40 mg/24 hr	0.0-0.30 mmol/day
Females	0.80 mg/24 hr	0.0-0.60 mmol/day
Creatinine	15-25 mg/kg/24 hr	0.13-0.22 mmol/kg/day
Creatinine clearance (endogenous)		
Males	110-150 mL/min/1.73 m ²	110-150 mL/min/1.73 m ²
Females	105-132 mL/min/1.73 m ²	105-132 mL/min/1.73 m ²
Cystine or cysteine	Negative	Negative
Dehydroepiandrosterone		
Males	0.2-2.0 mg/24 hr	0.7-6.9 µmol/day
Females	0.2-1.8 mg/24 hr	0.7-6.2 µmol/day
Estrogens, total		
Males	4-25 mcg/24 hr	14-90 nmol/day
Females	5-100 mcg/24 hr	18-360 nmol/day
Glucose (as reducing substance)	>250 mg/24 hr	>250 mg/day
Hemoglobin and myoglobin, qualitative	Negative	Negative
Homogentisic acid, qualitative	Negative	Negative
17-Hydroxycorticosteroids		
Males	3-9 mg/24 hr	8.3-25 µmol/day
Females	2-8 mg/24 hr	5.5-22 µmol/day
5-Hydroxyindoleacetic acid		
Qualitative	Negative	Negative
Quantitative	2-6 mg/24 hr	10-31 µmol/day
17-Ketogenic steroids		
Males	5-23 mg/24 hr	17-80 µmol/day
Females	3-15 mg/24 hr	10-52 µmol/day
17-Ketosteroids		
Males	8-22 mg/24 hr	28-76 µmol/day
Females	6-15 mg/24 hr	21-52 µmol/day
Magnesium	6-10 mEq/24 hr	3-5 mmol/day
Metanephrides	0.05-12.00 ng/mg creatinine	0.03-0.70 mmol/mmol creatinine
Osmolality	38-1400 mOsm/kg water	38-1400 mOsm/kg water
pH	4.6-8.0	4.6-8.0
Phenylpyruvic acid, qualitative	Negative	Negative
Phosphate	0.4-1.3 g/24 hr	13-42 mmol/day
Porphobilinogen		
Qualitative	Negative	Negative
Quantitative	<2 mg/24 hr	<9 µmol/day
Porphyryns		
Coproporphyrin	50-250 mcg/24 hr	77-380 nmol/day
Uroporphyrin	10-30 mcg/24 hr	12-36 nmol/day
Potassium	25-125 mEq/24 hr	25-125 mmol/day
Pregnanediol		
Males	0.0-1.9 mg/24 hr	0.0-6.0 µmol/day
Females		
Proliferative phase	0.0-2.6 mg/24 hr	0.0-8.0 µmol/day
Luteal phase	2.6-10.6 mg/24 hr	8-33 µmol/day
Postmenopausal	0.2-1.0 mg/24 hr	0.6-3.1 µmol/day
Pregnanetriol	0.0-2.5 mg/24 hr	0.0-7.4 µmol/day
Protein, total		
Qualitative	Negative	Negative
Quantitative	10-150 mg/24 hr	10-150 mg/day
Protein/creatinine ratio	<0.2	<0.2
Sodium (regular diet)	60-260 mEq/24 hr	60-260 mmol/day
Specific gravity		
Random specimen	1.003-1.030	1.003-1.030
24-hr collection	1.015-1.025	1.015-1.025
Urate (regular diet)	250-750 mg/24 hr	1.5-4.4 mmol/day
Urobilinogen	0.5-4.0 mg/24 hr	0.6-6.8 µmol/day
Vanillylmandelic acid (VMA)	1.0-8.0 mg/24 hr	5-40 µmol/day

*Values may vary, depending on the method used.

Table A-5
Reference Intervals for Toxic Substances

ANALYTE	CONVENTIONAL UNITS	SI UNITS
Arsenic, urine	<130 mcg/24 hr	<1.7 µmol/day
Bromides, serum, inorganic	<100 mg/dL	<10 mmol/L
Toxic symptoms	140-1000 mg/dL	14-100 mmol/L
Carboxyhemoglobin, blood	Saturation, percent	
Urban environment	<5%	<0.05
Smokers	<12%	<0.12
Symptoms		
Headache	>15%	>0.15
Nausea and vomiting	>25%	>0.25
Potentially lethal	>50%	>0.50
Ethanol, blood	<0.05 mg/dL <0.005%	<1.0 mmol/L
Intoxication	>100 mg/dL >0.1%	>22 mmol/L
Marked intoxication	300-400 mg/dL 0.3%-0.4%	65-87 mmol/L

Alcoholic stupor	400-500 mg/dL 0.4%-0.5% >500 mg/dL	87-109 mmol/L
Coma	0.5%	>109 mmol/L
Lead, blood		
Adults	<20 mcg/dL	<1.0 μmol/L
Children	<10 mcg/dL	<0.5 μmol/L
Lead, urine	<80 mcg/24 hr	<0.4 μmol/day
Mercury, urine	<10 mcg/24 hr	<150 nmol/day

Table A-6
Reference Intervals for Tests Performed on Cerebrospinal Fluid

TEST	CONVENTIONAL UNITS	SI UNITS
Cells	<5 mm ³ , all mononuclear	<5 × 10 ⁶ /L, all mononuclear
Protein electrophoresis	Albumin predominant	Albumin predominant
Glucose	50-75 mg/dL (20 mg/dL less than in serum)	2.8-4.2 mmol/L (1.1 mmol/L less than in serum)
Immunoglobulin G (IgG)		
Children <14 yr	<8% of total protein	<0.08 of total protein
Adults	<14% of total protein	<0.14 of total protein
IgG index	0.3-0.6	0.3-0.6
Oligoclonal banding on electrophoresis	Absent	Absent
Pressure, opening	70-180 mm H ₂ O	70-180 mm H ₂ O
Protein, total	15-45 mg/dL	150-450 mg/L

Table A-7
Reference Intervals for Tests of Gastrointestinal Function

TEST	CONVENTIONAL UNITS
Bentrimide	6-hr urinary arylamine excretion >57% excludes pancreatic insufficiency
Beta-carotene, serum	60-250 ng/dL
Fecal fat estimation	
Qualitative	No fat globules seen by high-power microscope
Quantitative	<6 g/24 hr (>95% coefficient of fat absorption)
Gastric acid output	
Basal	
Males	0.0-10.5 mmol/hr
Females	0.0-5.6 mmol/hr
Maximum (after histamine or pentagastrin)	
Males	9.0-48.0 mmol/hr
Females	6.0-31.0 mmol/hr
Ratio: basal/maximum	
Males	0.0-0.31
Females	0.0-0.29
Secretin test, pancreatic fluid	
Volume	>1.8 mL/kg/hr
Bicarbonate	>80 mEq/L
D-Xylose absorption test, urine	>20% of ingested dose excreted in 5 hr

Table A-8
Reference Intervals for Tests of Immunologic Function

TEST	CONVENTIONAL UNITS	SI UNITS
Complement, serum		
C3	85-175 mg/dL	0.85-1.75 g/L
C4	15-45 mg/dL	150-450 mg/L
Total hemolytic (CH ₅₀)	150-250 U/mL	150-250 U/mL
Immunoglobulins, serum, adult		
IgG	640-1350 mg/dL	6.4-13.5 g/L
IgA	70-310 mg/dL	0.70-3.1 g/L
IgM	90-350 mg/dL	0.90-3.5 g/L
IgD	0.0-6.0 mg/dL	0.0-60 mg/L
IgE	0.0-430 ng/dL	0.0-430 mg/L
Autoantibodies, serum, adult		
Antinuclear antibody	<1 : 40	—
Anti-dsDNA antibody	0-40 U	0-40 U/mL
Anti-CCP	0-19 units	—
Rheumatoid factor	0-30 mg/dL	—

Table A-9
Lymphocyte Subsets, Whole Blood, Heparinized

ANTIGEN(s) EXPRESSED	CELL TYPE	PERCENTAGE	ABSOLUTE CELL COUNT
CD3	Total T cells	56-77	860-1880
CD19	Total B cells	7-17	140-370
CD3 and CD4	Helper-inducer cells	32-54	550-1190
CD3 and CD8	Suppressor-cytotoxic cells	24-37	430-1060
CD3 and DR	Activated T cells	5-14	70-310
CD2	E rosette T cells	73-87	1040-2160
CD16 and CD56	Natural killer (NK) cells	8-22	130-500
Helper/suppressor ratio: 0.8-1.8	—	—	—

Table A-10
Reference Values for Semen Analysis

TEST	CONVENTIONAL UNITS	SI UNITS
Volume	2-5 mL	2-5 mL
Liquefaction	Complete in 15 min	Complete in 15 min
pH	7.2-8.0	7.2-8.0
Leukocytes	Occasional or absent	Occasional or absent
Spermatozoa		
Count	60-150 × 10 ⁶ mL	60-150 × 10 ⁶ mL
Motility	>80% motile	>0.80 motile
Morphology	80%-90% normal forms	>0.80-0.90 normal forms
Fructose	>150 mg/dL	>8.33 mmol/L

APPENDIX B

Standard Precautions*

Assume that every person is potentially infected or colonized with an organism that could be transmitted in the health care setting and apply the following infection control practices during the delivery of health care. *Category 1B/1C*

A. Hand Hygiene

1. During the delivery of health care, avoid unnecessary touching of surfaces in close proximity to the patient to prevent (1) contamination of clean hands from environmental surfaces and (2) transmission of pathogens from contaminated hands to surfaces.
2. When your hands are visibly dirty, contaminated with proteinaceous material, or visibly soiled with blood or body fluids, wash your hands with either a non-antimicrobial soap and water or an antimicrobial soap and water. *Category 1A*
3. If your hands are not visibly soiled, or after removing visible material with non-antimicrobial soap and water, decontaminate your hands. The preferred method of hand decontamination is with an alcohol-based hand rub. Alternatively, hands may be washed with an antimicrobial soap and water. Frequent use of alcohol-based hand rub immediately after handwashing with non-antimicrobial soap may increase the frequency of dermatitis. *Category 1B*

Perform hand hygiene:

- Before having direct contact with patients
 - After contact with blood, body fluids or excretions, mucous membranes, nonintact skin, or wound dressings
 - After contact with a patient's intact skin (e.g., when taking a pulse or blood pressure or lifting a patient)
 - If your hands will be moving from a contaminated body site to a clean body site during patient care
 - After contact with inanimate objects (including medical equipment) in the immediate vicinity of the patient
 - After removing gloves
4. Wash your hands with non-antimicrobial soap and water or with antimicrobial soap and water if contact with spores (e.g., *Clostridium difficile* or *Bacillus anthracis*) is likely to have occurred. The physical action of washing and rinsing your hands under such circumstances is recommended because alcohols, chlorhexidine, iodophors, and other antiseptic agents have poor activity against spores. *Category 2*
 5. Do not wear artificial fingernails or extenders if duties include direct contact with patients who are at high risk for infection and associated adverse outcomes (e.g., those in intensive care units [ICUs] or operating rooms). *Category 1A*
- Develop an organizational policy on the wearing of non-natural nails by health care personnel who have direct contact with patients outside of the groups specified above.

1899

B. Personal Protective Equipment (PPE)

Observe the following principles of use:

- Wear PPE when the nature of anticipated patient interaction indicates that contact with blood or body fluids may occur. *Category 1B/1C*
- Prevent contamination of clothing and skin during the process of removing PPE. *Category 2*
- Before leaving the patient's room or cubicle, remove and discard PPE. *Category 1B/1C*

Gloves

Wear gloves when it can be reasonably anticipated that contact with blood or other potentially infectious materials, mucous membranes, nonintact skin, or potentially contaminated intact skin (e.g., of a patient incontinent of stool or urine) could occur. Wear gloves with fit and durability appropriate to the task. Wear disposable medical examination gloves for providing direct patient care. Wear disposable medical examination gloves or reusable utility gloves for cleaning the environment or medical equipment. Remove gloves after contact with a patient and/or the surrounding environment (including medical equipment) using proper technique to prevent hand contamination. Do not wear the same pair of gloves for the care of more than one patient. Do not wash gloves for the purpose of reuse, because this practice has been associated with transmission of pathogens. Change gloves during patient care if your hands will move from a contaminated body site (e.g., perineal area) to a clean body site (e.g., face).

Gowns

Wear a gown that is appropriate to the task to protect skin and prevent soiling or contamination of clothing during procedures and patient care activities when contact with blood, body fluids, secretions, or excretions is anticipated. Wear a gown for direct patient contact if the patient has uncontained secretions or excretions. Remove gown and perform hand hygiene before leaving the patient's environment. Do not reuse gowns, even for repeated contacts with the same patient. Routine donning of gowns on entrance into a high-risk unit (e.g., ICU, neonatal ICU [NICU]) is not indicated.

Mouth, Nose, and Eye Protection

Use PPE to protect the mucous membranes of your eyes, nose, and mouth during procedures and patient care activities that are likely to generate splashes or sprays of blood, body fluids, secretions, and excretions. Select masks, goggles, face shields, and combinations of each according to the need anticipated by the task performed. During aerosol-generating procedures (e.g., bronchoscopy, suctioning of the respiratory tract [if not using in-line suction catheters], endotracheal intubation) in patients who are not suspected of being infected with an agent for which respiratory protection is otherwise recommended (e.g., *Mycobacterium tuberculosis*, SARS, or hemorrhagic fever viruses), wear one of the following: a face shield that fully covers the front and sides of the face, a mask with attached shield, or a mask and goggles (in addition to gloves and gown).

Patient Care Equipment and Instruments/Devices

Establish policies and procedures for containing, transporting, and handling patient care equipment and instruments/devices that may be contaminated with blood or body fluids. Remove organic material from critical and semicritical instruments/devices, using recommended cleaning agents before high-level disinfection and sterilization to enable effective disinfection and sterilization processes. Wear PPE (e.g., gloves, gown), according to the level of anticipated contamination when handling patient care equipment and instruments/devices that are visibly soiled or may have been in contact with blood or body fluids.

Care of the Environment

Establish policies and procedures for routine and targeted cleaning of environmental surfaces as indicated by the level of patient contact and degree of soiling. Clean and disinfect surfaces that are likely to be contaminated with pathogens, including those that are in close proximity to the patient (e.g., bed rails, overbed tables) and frequently touched surfaces in the patient care environment (i.e., door knobs, surfaces in and surrounding toilets in patients' rooms) on a more frequent schedule compared with that for other surfaces (e.g., horizontal surfaces in waiting rooms). Use Environmental Protection Agency (EPA)-registered disinfectants that have microbiocidal (i.e., killing) activity against the pathogens most likely to contaminate the patient care environment. Use in accordance with manufacturer's instructions. Review the efficacy of in-use disinfectants when evidence of continuing transmission of an infectious agent (e.g., rotavirus, *C. difficile*, norovirus) may indicate resistance to the in-use product and change to a more effective disinfectant as indicated.

Textiles and Laundry

Handle used textiles and fabrics with minimum agitation to prevent contamination of air, surfaces, and persons. If laundry chutes are used, ensure that they are properly designed, maintained, and used in a manner to minimize dispersion of aerosols from contaminated laundry.

Safe Injection Practices

The following recommendations apply to the use of needles, cannulas that replace needles, and, where applicable, intravenous delivery systems. Use aseptic technique to prevent contamination of sterile injection equipment. Do not administer medications from a syringe to multiple patients even if the needle or cannula of the syringe is changed. Needles, cannulas, and syringes are sterile, single-use items; they should not be reused for another patient nor to access a medication or solution that might be used for a subsequent patient. Use fluid infusion and administration sets (i.e., intravenous bags, tubing, and connectors) for one patient only and dispose of appropriately after use. Consider a syringe or needle/cannula contaminated once it has been used to enter or connect to a patient's intravenous infusion bag or administration set. Use single-dose vials for parenteral medications whenever possible. Do not administer medications from single-dose vials or ampules to multiple patients or combine leftover contents for later use. If multidose vials must be used, both the needle or cannula and syringe used to access the multidose vial must be sterile. Do not keep multidose vials in the immediate patient treatment area, and store them in accordance with the manufacturer's recommendations; discard if sterility is compromised or questionable. Do not use bags or bottles of intravenous solution as a common source of supply for multiple patients.

Infection control practices for special lumbar puncture procedures indicate wearing a surgical mask when placing a catheter or injecting material into the spinal canal or subdural space (i.e., during myelograms, lumbar puncture, and spinal or epidural anesthesia).

Worker Safety

Adhere to federal and state requirements for protection of health care personnel from exposure to blood-borne pathogens.

*Sections pertinent to adult health care nursing extracted from Siegel JD, Rhinehart E, Jackson M, et al: *Guideline for isolation precautions: Preventing transmission of infectious agents in healthcare settings 2007*, Atlanta, 2007, Centers for Disease Control and Prevention.

APPENDIX C

Standard Steps for All Nursing Procedures

At the Beginning of the Procedure

Step A: Perform Task According to Protocol

- Mentally review the steps of the task beforehand. If you are uncertain how to do a task, ask your team leader, resource nurse, instructor, or charge nurse.
- Plan for efficiency of time and effort while delivering safe care.

Step B: Check Orders, Collect Equipment and Supplies, and Perform Hand Hygiene

- Verify that the procedure is to be done for the patient.
- Check the agency's policies and procedures manual for the accepted method of performing the procedure.
- Process equipment and supply charges.
- Take all equipment and supplies to the patient's room.

Step C: Identify and Prepare Patient

- Greet the patient, introduce yourself, and check the patient's identification band. Use two identifiers during the identification process.
- Explain what you are going to do in terms the patient can understand.
- Elicit questions and answer clearly.
- Provide necessary teaching related to the procedure to be performed.

Step D: Provide Privacy, Institute Safety Precautions, Arrange Supplies and Equipment

- Close the door or curtains and drape the patient before beginning the procedure or discussing information the person might want kept confidential.
- Check equipment for breaks or wear and for safety.
- Set up the equipment and supplies in an orderly, methodical fashion.
- Raise the bed to an appropriate working height.
- Raise the side rail before turning the patient and be certain that the wheels are locked.
- Perform hand hygiene to prevent contaminating the patient with organisms from the chart, the nurses' station, and the supply room.

During the Procedure

Step E: Use Standard Precautions and Aseptic Technique as Appropriate

- Protect yourself from blood and body fluids by wearing gloves.
- If there is a danger of splashing blood or body fluids, wear protective glasses or goggles and an impermeable cover gown or apron.
- Be very careful with sharp instruments and needles so as not to nick your skin. (See Appendix B.)

At the End of the Procedure

Step X: Remove Gloves and Other Protective Equipment

- After making certain the patient is clean and dry, dispose of used supplies, remove goggles and other protective equipment, and discard or store appropriately.
- To remove gloves without contaminating yourself, begin by pulling one glove off without touching your skin; hold the removed glove in the palm of the remaining gloved hand and then reach to the inside of the other glove and roll it down the hand.
- Dispose of the gloves in the trash.
- Perform hand hygiene immediately.

Step Y: Restore Unit

- Collect the used equipment; dispose of, clean, or store items in the proper places.
- Make the person comfortable, tidy the bed and unit, place the call light and personal items within reach, and provide for safety by lowering the bed.
- Remove used equipment.
- Place soiled linens in a soiled-linen hamper.
- Clean reusable items and return them to the storage or processing area (central supply). Discontinue use of the equipment on the computer so no further charges will be made.
- Remove unsightly, odorous, or potentially infectious trash from the room.
- Inquire if anything else is needed.
- Perform hand hygiene before leaving the room.

Step Z: Record and Report Procedure

- Document assessment findings and the details of the procedure performed, or care given, in the chart. Include any problems encountered and the patient's response to the care or treatment. The recording should be accurate, specific, concise, and appropriate and should include the specific time the procedure was performed and how it was done.
- Report abnormalities encountered to the charge nurse or physician.

Glossary

A

abduction Movement away from the midline of the body.

ablation The removal of a part, as by incision; eradication.

ablation therapy A treatment for hyperthyroidism using radioactive iodine (¹³¹I).

abrasion A wound caused by rubbing or scraping the skin or mucous membrane.

absorption The passage of liquids or other substances through a body surface and into its tissues and fluids, as in absorption of the end products of digestion into the intestinal villi.

abuse Misuse; excessive or improper use.

acceptance Admission of reality, as in the reality of death; the final stage in the process of dealing with dying and death.

accommodation Adjustment, especially of the ocular lens for seeing objects at varying distances.

achlorhydria The absence of hydrochloric acid from maximally stimulated gastric secretions.

acid A substance that yields hydrogen ions in solution.

acid-base balance A normal condition in which the narrow range of normal pH and the normal ratio of carbonic acid to bicarbonate ions are maintained.

acidosis A condition in which the pH of body fluids is below normal range because of either a loss of base bicarbonate or an accumulation of acid.

acquired Occurring from factors outside the organism, as in response to the environment.

acquired immunity Immunity involving the functioning of the immune system acquired by natural infection or vaccination (active immunity), or transfer of antibody from an immune donor (passive immunity).

acquired immunodeficiency syndrome (AIDS) A group of symptoms believed to be caused by a virus (HIV) that infects and destroys T lymphocytes.

acromegaly A chronic disease of adults caused by hypersecretion of the pituitary growth hormone and characterized by enlargement of many parts of the skeleton.

active immunity Immunity acquired by producing one's own antibody.

active transport Movement of substances from an area of lower concentration to an area of higher concentration.

acuity The degree of seriousness of illness or injury.

acupressure The application of digital pressure on a part of the body to relieve pain or produce anesthesia.

acupuncture A technique for treating certain painful conditions and for producing regional anesthesia by passing long, thin needles through the skin to specific points.

acute myocardial infarction Ischemic necrosis of an area of the heart muscle resulting from sudden occlusion of blood flow through one or more branches of the coronary arteries.

acute pain Sharp, severe pain.

addiction A psychological craving for alcohol or drugs with the presence of withdrawal symptoms if the substance cannot be obtained.

Addisonian crisis Sudden insufficiencies of the mineralocorticoids and the glucocorticoids that can lead to shock.

adduction Movement toward the midline of the body.

adenohypophysis The anterior lobe of the pituitary gland.

adhesion A fibrous band that binds together two parts that are normally separated; often occurs after surgery in the abdomen.

adjvant That which assists, such as a drug added to a prescription that enhances the action of the principal ingredient.

adrenergic Having action that mimics that of the sympathetic nervous system.

adrenocortical Indicating the cortex of the adrenal gland.

adrenocorticotropic hormone (ACTH) A “tropic” hormone of the anterior pituitary gland that acts on the adrenal cortex.

adulthood A stage of life at which an individual has reached biologic maturity, usually at age 20 in humans.

advance directive A document prepared while an individual is alive and competent that contains instructions for future health care.

adventitious Acquired; arising sporadically.

aerobe A microorganism that requires oxygen for survival.

aerobic Requiring oxygen to live.

aerosol A suspension of a drug or other substance that is dispensed in a cloud or mist.

affect The external expression; mood.

ageism Prejudice against aging and elderly people.

agent A party authorized to act on behalf of another.

agglutination One type of antigen-antibody reaction in which a solid antigen clumps together with a soluble antibody.

agnosia The loss of the power to recognize the significance of sensory stimuli.

agranulocytosis A condition of deficiency, or absolute lack, of granulocytic white blood cells.

airway The passage by which air enters and leaves the lungs; also, a device used to secure unobstructed respiration.

akathisia A condition of motor restlessness; a common extrapyramidal side effect of neuroleptic drugs.

albumin, serum A plasma protein formed principally in the liver and constituting about 60% of the protein concentration in the plasma.

aldosterone A mineralocorticoid steroid hormone produced by the adrenal cortex. Works in the

renal tubules To retain sodium and conserve water by reabsorption; increases urinary potassium excretion.

alkalosis A condition in which the pH of body fluids is above normal because of either a loss of acid or an accumulation of base bicarbonate.

allergen(s) Any substance capable of triggering an exaggerated immune response.

allergy (allergies) An abnormal and individual hypersensitivity to a particular allergen; acquired by exposure to the allergen and manifested after reexposure.

alleviate To relieve; to make easier to bear.

alliance An agreement to cooperate made between a free-standing independent facility and a hospital.

allogeneic Having a different genetic constitution but belonging to the same species.

allograft Transplant tissue obtained from the same species.

alogia A psychiatric term meaning poverty of thoughts.

alopecia Baldness or loss of hair.

Alzheimer disease (AD) The most common degenerative disease of the brain, with no known cause or cure. The disease causes loss of neurons in the frontal and temporal lobes and primarily affects people older than 65 years but can also occur in younger people.

amenorrhea The absence of menstruation.

anabolic Constructive in nature; the opposite of catabolic.

anabolism The building up of the body substance; the constructive phase of metabolism.

anaerobe An organism that lives in an oxygen-free environment.

anaerobic Able to live in an oxygen-free environment.

analgesia The absence of normal sense of pain.

analgesic(s) A pain reliever.

anaphylaxis An unusual or exaggerated allergic reaction.

anasarca Generalized massive edema resulting from severe depletion of albumin.

anastomosis A communication between two tubular organs; also surgical, traumatic, or pathologic formation of a connection between two normally distinct structures.

androgen(s) Any steroid hormone that promotes male characteristics.

anemia(s) A condition in which there are too few functioning red blood cells to meet the oxygen needs of tissues.

anesthesia The loss of feeling or sensation.

aneurysm A sac formed by localized dilation of the wall of a blood vessel or the heart.

anger A feeling of hostility and bitterness against a situation or person; the second stage in acceptance of death.

angina pectoris Exertional chest pain caused by ischemia of the heart muscle and increased demand for oxygen.

angioedema A vascular reaction representing localized edema caused by dilation and characterized by development of giant wheals.

angiography Radiographic studies of the arteries, veins, or lymph vessels of the body.

animate Alive.

anion A negatively charged atomic particle.

ankylosis Abnormal immobility and consolidation and obliteration of a joint.

anorexia A lack or loss of appetite for food.

anorexia nervosa An eating disorder in which there is an aberration of eating patterns, severe weight loss, and malnutrition.

anosmia The absence of the sense of smell; also called *anospresia* and *olfactory anesthesia*.

anovulation Failure of the ovary to produce or release mature eggs.

antibiotic An agent that is capable of either killing or inhibiting the growth of microorganisms.

antibody (antibodies) An immune globulin molecule that is capable of adhering to and interacting only with the antigen that induced its synthesis.

anticoagulants Substances that suppress, delay, or nullify the coagulation of blood.

antidiuretic hormone A hormone that decreases the production of urine by increasing the reabsorption of water by the renal tubules. It is secreted by the hypothalamus and stored in the posterior lobe of the pituitary gland.

antidysrhythmic agents Substances that help return the heart rate and rhythm to more normal values and restore the origin of the heart's electrical activity to its natural pacemaker.

antiemetic An agent that prevents or relieves nausea and vomiting.

antifungal(s) An agent that is destructive to or inhibitive of the growth of fungi.

antigen(s) Any substance that can produce an antagonist.

antigen-antibody reaction An immune response that occurs when an antibody comes into contact with the specific antigen for which it was formed. In a transfusion reaction, the response is a clumping together, or agglutination, of the red blood cells carrying the antigens.

antihistamine An agent that counteracts the effects of histamine; used to relieve the symptoms of an allergic reaction.

antihypertensive A medication to prevent or control high blood pressure.

antimicrobial agent A substance capable of either killing or suppressing the multiplication and growth of microorganisms.

antineoplastic agent A substance that inhibits the maturation and proliferation of malignant cells.

antiseptic(s) Any substance that inhibits the growth of bacteria outside the body; in contrast, a germicide kills the bacteria outright.

antitoxin A specific kind of antibody produced in response to the presence of a toxin.

antitussive An agent that inhibits the cough reflex in the cough center in the brain.

antivenin A substance used to neutralize the venom of a poisonous animal.

anuria Diminished or absent production of urine by the kidney.

apathetic thyrotoxicosis Milder hyperthyroidism signs and symptoms seen in older adult patients compared with symptoms seen in the typical adult patient.

aphakic eye An eye without a lens, as after a cataract extraction.

aphasia A defect in or loss of the power of expression by speech, writing, or signs or in the comprehension of spoken or written language.

aphonia The loss of the voice.

apical Pertaining to the apex of a structure; particularly the heart.

aplastic Having deficient or arrested development.

aplastic anemia Deficient red cell production caused by a bone marrow disorder.

apnea Temporary cessation of breathing.

apraxia The loss or impairment of acquired motor skills.

arrhythmia (also dysrhythmia) Variation from the normal rhythm, especially of the heartbeat.

arteriosclerosis A group of diseases characterized by thickening and loss of elasticity of the arterial walls.

arthritis Inflammation of a joint.

arthrocentesis The surgical puncture of a joint cavity for aspiration of synovial fluid.

arthroplasty Surgery performed on a joint to increase mobility or decrease pain.

arthroscopy Endoscopic examination of the interior of a joint.

ascites The accumulation of edematous fluid within the peritoneal cavity.

asepsis, medical The destruction and containment of infectious agents after they leave the body of a patient with an infectious disease.

assessment, nursing Data-gathering activities for the purpose of collecting a complete, relevant database from which a nursing diagnosis can be made.

asterixos A motor disturbance marked by intermittent lapse of an assumed posture; a characteristic of hepatic coma. Also called "flapping tremor."

asthma A condition marked by recurrent attacks of paroxysmal dyspnea, with wheezing from spasmodic contraction of the bronchi.

astigmatism An error of refraction in which light rays are not sharply focused on the retina because of abnormal curvature of the cornea or lens.

ataxia Uncoordinated motor movements.

atelectasis The collapsed or airless state of the lung.

atherosclerosis A disease process in which fibrinous plaques are laid down on the inner walls of the arteries, thus narrowing the lumens of the vessels and predisposing them to the development of intravascular clots.

atopy The tendency to develop allergies.

atrial fibrillation Rapid, irregular, and ineffective contractions of the atria.

atrial natriuretic peptide A hormone involved in the regulation of renal and cardiovascular homeostasis. It is produced in the atrium and helps to normalize blood pressure and volume.

atrophy Wasting, or a decrease in size, from lack of use.

atypical antipsychotics Newer medications used for treating schizophrenia with fewer side effects.

audiometry The measurement of sound perception.

audit An official examination of the record of all aspects of patient care.

aura A peculiar sensation preceding the appearance of more definite symptoms, especially a sensation, that occurs immediately before an epileptic seizure.

aural Pertaining to the ear.

auscultation Listening for sounds produced within the body, usually with a stethoscope.

autograft A graft transferred from one part of a patient's body to another.

autoimmune A defective cellular immune response in which antibodies are produced against normal parts of the person's body.

autoimmune disease A disease caused by the body's failure to recognize its own cells, thus rejecting them as it would a foreign substance.

autoimmune thyroiditis (Hashimoto thyroiditis) A condition in which the body produces antibodies against the thyroid, which in turn destroy the gland.

autoinoculation Inoculation with microorganisms from one's own body.

autologous Indicating something that has its origin within an individual, as in transfusion with one's own blood.

automated external defibrillator (AED) A defibrillator found in many public places that is used to treat cardiac arrest.

automatisms Repetitive, automatic actions such as lip smacking.

autonomic dysreflexia Hyperreflexia, an uninhibited and exaggerated reflex response of the autonomic nervous system to some type of stimulation.

avolition A lack of motivation.

avulsion The tearing away of part or all of an organ or structure.

axon The projection, or process, of a neuron that transmits impulses away from the cell body.

azotemia Retention in the blood of urea, creatinine, and other nitrogenous protein metabolites that are normally eliminated in the urine.

B

Babinski reflex A reflex action elicited by stimulating the sole of the foot and characterized by dorsiflexion of the great toe and flaring of the smaller toes. A positive Babinski reflex indicates an abnormality in the motor control pathways of the nervous system.

bacteria Microscopically small organisms belonging to the plant kingdom, some of which are capable of producing disease in humans.

bacterial vaginosis A bacterial disease of the vagina.

bactericidal Able to kill bacteria.

bacteriophage A virus that destroys bacteria by lysis. The virus is usually of a type specific for the particular kind of bacteria it attacks.

bacteriostatic Able to slow duplication of bacteria.

bargaining An attempt to make an arrangement whereby one gives something to gain something in

return; the third stage in acceptance of death.

bariatrics The field of medicine that focuses on the treatment and control of obesity and diseases associated with obesity.

basal insulin Amount of insulin that would normally be produced by the pancreas.

base A substance that combines with acids to form salts.

basement membrane The noncellular layer that secures the overlying epithelium to the underlying tissue.

behavior The manner in which one conducts oneself in response to social stimuli, an inner need, or a combination of the two.

belief A currently held idea or value derived from culture and experience.

benign Not very harmful; nonmalignant.

benign pituitary adenoma A benign tumor of the pituitary gland that secretes growth hormone (GH), leading to continued growth. It can also antagonize the effect of the hormone insulin, resulting in increased blood glucose.

bereaved Experiencing the reaction of grief and sadness on learning of the loss of a loved one.

biliary Pertaining to bile, the bile ducts, or the gallbladder.

biliary colic Acute pain resulting from obstruction of a bile duct, usually caused by cholelithiasis.

binder A broad bandage most commonly used as an encircling support of the abdomen or chest.

biofeedback A training program designed to develop one's ability to control the autonomic (involuntary) nervous system.

biologic dressing Materials obtained from a patient's intact skin, cadavers, or animals that is used to treat burn victims.

biologic response modifier (BRM) An agent that manipulates the immune system in hopes of controlling or curing a malignancy.

biomedicine Biologic medicine; focuses on the biologic aspects of medicine.

biopsy Removal of living cells for the purpose of examining them microscopically.

biosynthetic A biologic substance created by chemical processes. A term used for artificial skin that can be used as a temporary measure for grafting in burn victims.

bioterrorism An attack that involves the deliberate release of microorganisms or toxins derived from living organisms that cause disease or death to humans, animals, or plants on which we depend for food.

bipolar disorder A mood disorder in which manic and depressive episodes occur.

bisexual An individual who is sexually attracted to others of either sex.

bivalve Split through all layers of the material.

bladder, cord A dysfunction of the urinary bladder caused by damage to the spinal cord.

bladder, neurogenic A dysfunction of the urinary bladder caused by a lesion of the central or peripheral nervous system and characterized by lack of awareness of the need to void.

blepharitis An infection of the glands and lash follicles along the margin of the eyelid.

blood gases, arterial (ABGs) The partial pressure exerted by oxygen and carbon dioxide in the

arterial blood. ABGs reflect the ability of the lungs to exchange these gases, the effectiveness of the kidneys to retain and eliminate bicarbonate, and the efficiency of the heart as a pump.

B-lymphocyte A sensitized lymphocyte that is responsible for antibody formation and the development of humoral immunity.

bolus dose A dose of short- or rapid-acting insulin that is used to manage elevations in blood glucose and bring the next blood glucose measurement into range.

borborygmi Gurgling, splashing sounds normally heard over the large intestine; rumbling in the bowels.

borderline personality disorder A mental disorder defined by the DSM-5 as “a pattern of instability in interpersonal relationships, self-image and affect, and marked impulsivity.”

botulism Food poisoning caused by a neurotoxin produced by *Clostridium botulinum*, sometimes found in improperly canned or preserved foods.

bradycardia An abnormally slow heart rate, usually fewer than 60 beats per minute.

bradykinesia Slow movement; a symptom seen with Parkinson disease.

bradypnea Abnormally slow breathing.

bronchiectasis Chronic dilation of the bronchi marked by fetid breath and paroxysmal coughing, with the expectoration of mucopurulent matter.

bronchodilator A drug that acts directly on the smooth muscles of the bronchi to relax them and relieve bronchospasm.

bronchogram A radiograph of the bronchial tree using a radiopaque substance that is introduced into the trachea.

bronchoscopy Insertion of an endoscope for diagnosis and treatment of disorders of the bronchi.

bruit An abnormal sound of venous or arterial origin heard on auscultation.

bulimia nervosa A mental disorder that occurs predominantly in females characterized by episodes of binge eating that continue until terminated by abdominal pain, sleep, or self-induced vomiting.

bulla (bullae) A blister; a round, fluid-filled lesion of the skin, usually more than 5 mm in diameter.

burns, full-thickness Burns in which all of the epithelializing elements of the skin and those tissues lining the sweat glands, hair follicles, and sebaceous glands are destroyed.

burns, partial-thickness Burns in which the epithelializing elements remain intact.

C

cachexia A profound state of general ill health and malnutrition.

calculus (calculi) An abnormal concretion, usually of mineral salts, occurring mainly in hollow organs or their passages (e.g., renal calculus, or kidney stone).

callus A thickened area of the epidermis caused by pressure or friction.

caloric testing Testing to check the oculovestibular reflex. A patient's eye movements are observed while the external ear canal is irrigated with cold water. Absence of eye movement indicates a brainstem lesion.

candidiasis An infection with a fungus of the genus *Candida*, especially *C. albicans*. It is usually a superficial infection of the moist cutaneous areas of the body, although it becomes more severe

in immunocompromised patients.

capitation A payment method wherein the health care provider is paid a monthly contracted rate for each member patient assigned regardless of the type or number of services provided.

capnography Measurement of inhaled and exhaled carbon dioxide as recorded on a capnogram.

caput medusa Dilated cutaneous veins around the umbilicus in patients who have cirrhosis of the liver.

carbuncles A collection of infected hair follicles. They most often occur on the back of the neck, the upper back, and the lateral thighs.

carcinogen Any substance or agent that produces or increases the risk of developing cancer in humans or lower animals.

carcinoma(s) A malignant growth made up of epithelial cells.

cardiac glycosides A group of compounds containing a carbohydrate molecule (e.g., digitalis) that affect the contractile force of the heart muscle.

cardiac tamponade Compression of the heart caused by collection of fluid in the pericardial sac.

cardiogenic shock A shock state caused by pump failure of the heart.

cardiomyopathy Disease of the myocardium, especially from primary disease of the heart muscle.

cardiomyoplasty A procedure in which the latissimus dorsi muscle is detached from its natural position, brought around to the front of the body, and wrapped around the heart. A pacemaker, connected to the heart and back muscle, helps boost the heart's pumping action.

cardiopulmonary resuscitation The reestablishment of heart and lung action after they have suddenly stopped.

cardiotonic(s) An agent that strengthens the contractions of the heart muscle.

cardioversion A mild electrical shock delivered to the heart at a specific time in the cardiac cycle to interrupt an abnormal rhythm and begin a new, normal rhythm of electrical impulse and contraction.

carpopedal spasm A spasm of the hand, thumbs, foot, or toes that accompanies tetany.

carriers People who harbor infectious organisms within their bodies without manifesting any outward symptoms of the infection.

cartilage A type of connective tissue in which fibers and cells are embedded in a semisolid gel material.

catabolic Destructive in nature; the opposite of anabolic.

catabolism The phase of metabolism in which larger molecules are broken down and energy is released; the destructive phase of metabolism.

cataract(s) An opacity of the lens of the eye.

catecholamines One of a group of biogenic amines that have a sympathomimetic action; examples are dopamine, norepinephrine, and epinephrine.

category-specific precautions A system of precautionary measures organized according to types of diseases (e.g., respiratory or enteric) and initiated to prevent the spread of disease.

cations Positively charged atomic particles.

cauterize To burn with a cautery, or to apply one.

CD lymphocyte A type of lymphocyte that is the master regulator of the human immune system. It is the primary site of replication for HIV.

cell(s) The basic structural unit of living organisms.

cell-mediated immunity Immunity resulting from activation of sensitized lymphocytes.

cellulitis Inflammation of cellular or connective tissue.

central hearing loss Impaired perception of sound caused by pathology above the junction of the eighth cranial nerve and the brainstem (in the brain).

cerumen Earwax.

chalazion An infection of the meibomian gland of the eye; an internal stye.

chancre A primary syphilis skin lesion that begins as a papule and develops into a red, bloodless, painless ulcer with a scooped-out appearance.

chemonucleolysis Treatment of a herniated intervertebral disk by dissolution of a portion of the nucleus pulposus by injection of a chemolytic agent.

chemotherapy Use of chemicals, especially drugs, in the treatment of such diseases as cancer, infection, and some mental illnesses.

cholecystectomy The removal of the gallbladder.

cholecystitis An inflammation of the gallbladder.

choledocholithiasis A condition in which gallstones lodge in the common bile duct.

cholelithiasis The presence of stones within the gallbladder or biliary tract.

cholinergic An agent that produces the effect of acetylcholine.

chorea Involuntary muscle twitching.

chronic pain Pain of long duration showing little change or slowly progressive pain.

chronologic Occurring in a natural time sequence.

Chvostek sign Low calcium level that manifests as muscle irritability when the facial nerve is gently tapped.

chyme The mixture of partly digested food and digestive secretions found in the stomach and small intestine during digestion of a meal.

cirrhosis A liver disease characterized by diffuse interlacing bands of fibrous tissue dividing the hepatic parenchyma into micronodular or macronodular areas.

cirrhosis of the liver A condition characterized by destruction of normal hepatic structures and their replacement with necrotic tissue and scarring.

claudication, intermittent A syndrome characterized by intensification of limb pain as exercise is increased; related to occlusion of arteries in the legs.

climacteric Endocrine, somatic, and psychic changes that occur at the end of the female reproductive period (menopause); also, normal diminution of testicular activity in the male.

clinical pathway A tool used to track patient progress along a set path in a managed care system.

clonic Alternating contraction and relaxation of muscles.

clonus Abnormal neuromuscular activity, characterized by rapidly alternating involuntary contraction and relaxation of skeletal muscle; occurs with epileptic seizure.

coarctation Narrowing (of the aorta).

code of ethics A set of rules governing one's conduct.

codependency A behavior pattern in which a family member or friend of a substance abuser attempts to control the behavior of the dependent person.

cognition The mental processes of perception, memory, judgment, and reasoning.

coinsurance Insurance in which both the insurer and the patient pay the medical bill.

coitus Sexual intercourse.

colectomy The removal of part of the colon.

colic A spasm causing pain; may be biliary, renal, intestinal, or uterine.

collaboration The act of working or cooperating with another.

collaborator One who works cooperatively with another.

collagen A fibrous protein found in skin, bone, cartilage, and ligaments.

colonization The process in which a group of organisms, especially bacteria, live together and multiply.

colostomy (colostomies) The surgical creation of an opening in the colon to allow fecal material to pass outside.

colporrhaphy The operation of suturing the vagina.

colposcopy The visual examination of the vagina and cervix with a specially designed endoscope that allows the detection of malignant growths in their early stages.

comedo (comedones) A plug of keratin and sebum in an enlarged pore; a blackhead.

communicable disease A disease that may be transmitted directly or indirectly from one individual to another.

compartment syndrome External or internal pressure that seriously restricts circulation to the area.

complementary and alternative medicine (CAM) Types of treatments for medical disorders that do not rely on traditional medicine, but frequently are combined with traditional medical treatment for a disorder.

complement system A complex series of enzymatic proteins that interact to combine with the antigen-antibody complex, producing lysis of intact antigen cells.

complement system of proteins A series of protective proteins that are activated in the inflammatory response.

complete blood count (CBC) The number of each kind of cell in a sample of blood.

compliance An expression of the ability of lung tissue to distend when filled with air.

computed tomography (CT) scan A computer-aided technique in which small sections of tissue within an organ can be visualized by radiograph.

concept(s) An idea, thought, or notion derived from experiences and information acquired from one's external environment.

concussion A closed head injury in which the brain is compressed by a portion of the skull at the time of the blow and temporary ischemia of the brain tissue results.

conductive hearing loss Impaired perception of sound caused by a dysfunction of either the

external or the middle ear.

confabulation A behavioral reaction to memory loss in which the patient fills in memory gaps with made-up facts and experiences.

confusion The state of not being aware of or oriented to time, place, or self.

congenital Present at birth.

congestive heart failure The exhaustion of the heart muscle and a resultant engorgement of the heart's chambers and the blood vessels. Eventually, sluggish blood flow leads to retention of fluid and edema in the lungs and elsewhere in the body.

conjugate Working in union; equally coupled.

conjunctivitis An inflammation of the membrane covering the eyeball and lining the eyelids.

consciousness Responsiveness of the mind to impressions made by the senses.

contactant A substance that produces an allergic or sensitivity response when in direct contact with the skin.

contamination The presence of a noxious agent, such as bacteria or radiation, in a place where it is not wanted.

contracture An adaptive shortening of skeletal muscle tissue that is not subjected to normal stretching and contraction.

contralateral On or affecting the opposite side of the body.

contusion A bruise; an injury of a part without a break in the skin.

conventional antipsychotics Neuroleptics used to treat the positive symptoms of schizophrenia. Cause serious and unpleasant side effects and are becoming less commonly prescribed.

convulsion A state of involuntary muscle contractions and relaxations.

copayment The amount a member of an HMO has to pay for each visit to the health care provider.

COPD Chronic obstructive pulmonary disease.

coronary artery bypass graft (CABG) Surgery in which a blood vessel is grafted onto the coronary artery to improve blood flow.

coronary insufficiency Decreased or insufficient blood flow in the coronary arteries.

coronary occlusion The closing off of a coronary artery and interruption of its blood flow.

cor pulmonale Heart disease characterized by hypertrophy of the right ventricle because of pulmonary hypertension.

corrosive Containing a destructive agent that produces disintegration or wearing away.

cost containment The need to hold costs to within fixed limits.

counter-regulatory hormones Growth hormone, glucagon, and epinephrine that are released during the night that cause an increase in blood glucose. They act "counter" to insulin.

coup-contrecoup injury An injury that occurs when the head is moving rapidly and hits a stationary object. The contents within the cranium hit the inside of the skull (coup) and then bounce back and hit the opposite side, causing a second injury (contrecoup).

crackles An abnormal respiratory sound heard on auscultation during inspiration; can be a bubbling noise or a popping sound. Crackles do not clear with coughing.

creatinine A nonprotein substance that is formed in muscle in relatively small and constant amounts, passes into the bloodstream, and is eliminated by the kidneys. Urine creatinine levels are diminished when glomerular filtration is impaired.

Credé technique Exerting downward pressure with the open hand over the suprapubic area to facilitate emptying of the urinary bladder.

cremasteric reflex The retraction of the testicles when the inner thigh is stroked. This reflex is absent with testicular torsion.

crepitition A sound like that of hair rubbed between the fingers; occurs when bone fragments rub together.

cretinism A congenital condition caused by lack of thyroid secretion characterized by arrested physical and mental development, dystrophy of the bones and soft parts, and lowered basal metabolism.

criterion A standard for judging a condition or establishing a diagnosis.

critical thinking Purposeful, considered, organized cognitive processing used to examine a problem or situation or evaluate the thinking of others.

crust An outer layer of solid matter formed by dried exudate or secretion.

cryoprecipitate Any precipitate that forms as a result of cooling.

cryosurgery The destruction of tissue by application of extreme cold, as in removal of cataracts.

cryotherapy The therapeutic use of cold or freezing.

cryptorchidism (cryptorchism) The failure of one or both of the testes to descend into the scrotum during fetal life.

culdoscopy The direct inspection of the female viscera through an endoscope introduced into the pelvic cavity through the posterior vaginal fornix.

culture The propagation of microorganisms or living tissue cells in media conducive to their growth.

curettage Cleansing of a surface of an organ with a spoon-shaped instrument (curet).

Curling ulcer A type of ulcer caused by decreased perfusion to other organs, which causes changes in the gastric mucosa.

cyanosis A bluish tinge to the skin caused by lack of oxygen and accumulation of carbon dioxide in the blood.

cystitis An inflammation of the urinary bladder.

cystocele A protrusion or herniation of the bladder through the wall of the vagina.

cystogram A radiograph of the urinary bladder using a contrast medium.

cystoscopy Endoscopic examination of the interior of the bladder.

cytokine A low-molecular-weight protein secreted by various cell types and involved in cell-to-cell communication. It coordinates antibody and T cell immune interactions and augments immune reactivity.

cytology The study of cells and their origin, structure, function, and pathology.

cytotoxic Destructive to cells.

D

dactylitis An inflammation of a finger or toe.

database A collection of facts and figures for analysis from which conclusions may be drawn.

data collection The systematic collection of physical and psychosocial data for a patient who is having a problem. Part of assessment within the nursing process.

dawn phenomenon A condition sometimes encountered in type 1 diabetes characterized by increased blood glucose in the morning caused by release of hormones during the night.

deaf Partially or completely lacking the sense of hearing.

death(s) The cessation of all physical and chemical processes that invariably occurs in all living organisms. *See also* Dying.

débride Peel away dead tissue.

débridement The removal of all foreign material and dead tissues from or adjacent to a traumatic or infected lesion until healthy tissue is exposed.

debriefing Questioning of personnel involved and obtaining knowledge about event and problems that occurred (during a disaster).

decerebrate posturing Extensor posturing; the arms are stiffly extended and held close to the body and the wrists are flexed outward. Indicates damage to the midbrain or brainstem.

decontamination The freeing of a person or an object of some contaminating substance such as radioactive material.

decorticate posturing Flexor posturing; extension of the legs and internal rotation and adduction of the arms with the elbows bent upward. Indicates damage to the cortex.

decubitus ulcer(s) A breakdown in the skin and underlying tissues caused by long-standing pressure, ischemia, and damage to the underlying tissue.

deductible The yearly amount an insured person must spend out-of-pocket before a medical insurance plan begins to pay its share.

defecate To evacuate the bowels; to have a bowel movement.

defibrillation Stopping fibrillation of the heart with electrical current.

dehiscence The separation of all layers of a surgical wound.

dehydration Excessive loss of water from tissues of the body.

delegate To authorize and send another as one's representative (to carry out a task).

delegation Allocation of patient care activities to team members.

delirium An altered state of consciousness that is usually acute and of short duration.

delusion A false, fixed belief that cannot be changed with rational explanation.

dementia A broad impairment of intellectual function that usually is progressive.

demyelination Destruction of the myelin sheath of nerve tissue.

demyelinization Demyelination.

dendrite Any of the thread-like extensions of the cytoplasm of a neuron.

denial A defense mechanism in which the existence of intolerable conditions is unconsciously

rejected; the first stage in the acceptance of death.

denuded When the protective layer or covering is removed through surgery, trauma, or pathologic change.

deoxyribonucleic acid (DNA) The primary genetic material of all cellular organisms.

dependency The state of reliance on a substance; implies that there are physical and psychological symptoms of addiction. Term used to describe substance use disorder.

dependent (nursing action) Requiring an order from a health care provider.

dependent rubor A dusky-red color dangling feet may take on after elevating the feet and legs above the heart for 1 to 2 minutes that indicates arterial insufficiency.

depression A morbid sadness, dejection, or melancholy; a stage in the acceptance of death.

depression (of immune function) The decreased ability of the immune system to function normally.

dermabrasion Planing of the skin done by mechanical means to smooth the skin and remove scars.

dermatitis An inflammation of the skin.

dermatology The medical specialty concerned with diagnosing and treating skin disorders.

dermatome A nerve tract.

dermatophytosis Any superficial fungal infection caused by a dermatophyte and involving the stratum corneum of the skin, hair, and nails.

detoxification The process of ridding the body of a drug without causing harmful ill effects.

developmental task(s) A task that should be completed during a specific life period to ensure continuing psychosocial growth and maturity.

deviation Departure from normal.

diabetes insipidus (DI) Occurs as a result of decreased production of the antidiuretic hormone (ADH) and is characterized by the production of copious amounts of dilute urine.

diabetic nephropathy Kidney disease secondary to chronic high blood glucose levels.

diabetic neuropathy A disorder of the peripheral nerves that is associated with diabetes mellitus and is characterized by sexual impotence in the male, neurogenic bladder, and pain or loss of feeling in the lower extremities.

diabetogenic Causing diabetes.

diagnosis, nursing A concise statement of a patient's actual or potential health problems that nurses, because of their education and experience, are able and licensed to treat.

diagnosis-related groups (DRGs) The classifications used to determine Medicare payments for patient care based on medical diagnoses.

dialysis The diffusion of solute molecules through a semipermeable membrane with the molecules passing from the more concentrated solution to the less concentrated one.

dialysis, peritoneal The use of the peritoneum as a dialyzing membrane to remove waste products that have accumulated in the body as a result of renal failure.

diaphoresis Excessive perspiration.

diastole The phase of the cardiac cycle in which the heart muscle relaxes between contractions; during this phase the two ventricles are dilated by blood flowing through them.

diastolic blood pressure Arterial pressure during diastole, recorded as the bottom number in the pressure measurement.

diffusion The spontaneous mixing of the molecules or ions of two or more substances; the result of random thermal motion.

digital Pertaining to or resembling a finger or toe.

digitalization The initial administration of digitalis to build up a therapeutic blood level of the drug.

diplopia Double vision; seeing two images.

disability Difficulty in performing certain tasks because of impairment.

disaster A natural or human-caused (bioterrorism or nuclear) event that overwhelms the community's existing emergency resources.

disease One possible outcome of an infection.

disease-specific precautions A system of precautionary measures organized according to the specific infectious disease presented by the patient.

disinfectant(s) An agent that destroys infection-producing organisms.

dislocation Stretching or tearing of ligaments around a joint with complete displacement of a bone.

disseminated Widespread.

disseminated intravascular coagulation (DIC) A disorder in which tissue damage causes widespread, excessive blood clotting in the microcirculation; subsequently, the body's clotting factors are depleted and hemorrhage occurs.

distal In a position farthest from the point of reference.

distraction Diversion of attention from present experience (e.g., pain).

diuresis The excretion of excess fluid in the urine.

diuretic(s) An agent that promotes secretion of urine.

diurnal Happening during daylight hours.

diverticulitis The inflammation of the diverticula.

diverticulosis The presence of diverticula, in the absence of diverticulitis.

diverticulum (diverticula) A small blind pouch resulting from a protrusion of the mucosa of a hollow organ through weakened areas in the organ's muscle wall.

documentation The recording of significant information on a patient's chart.

dowager's hump An abnormal backward curve of the cervical spine as a result of osteoporosis and/or Cushing syndrome.

Down syndrome A congenital disorder characterized by physical malformations and some degree of mental retardation; also called *trisomy 21 syndrome* because it involves an extra copy of chromosome 21.

DRGs See Diagnosis-related groups.

drusen Yellow exudates found beneath the retinal pigment epithelium, representing extracellular debris.

dual diagnosis The diagnosis of a patient with a substance abuse problem and a mental health

disorder.

dumping syndrome A group of symptoms caused by too-rapid passage of food through the upper gastrointestinal tract.

dying A stage of life; a process that, from a medical point of view, begins when a person has a disease that is untreatable and inevitably ends in death; or the final stages of a fatal disease. *See also* Death(s).

dynamic Having vital force or inherent power.

dysarthria Slurring or indistinct speech articulation; difficulty speaking.

dyscrasia An imbalance of formed elements, as in blood dyscrasia.

dysfunctional uterine bleeding Uterine bleeding at times other than during normal menstruation.

dysmenorrhea Painful or difficult menstruation.

dyspareunia Difficult or painful coitus in women.

dyspepsia Impairment of the power or function of digestion; usually referring to epigastric discomfort after meals.

dysphagia Difficulty in swallowing.

dysphasia Difficulty speaking; usually caused by a brain lesion.

dyspnea Labored or difficult breathing.

dysrhythmia A variation from the normal rhythm, especially of the heartbeat.

dysthymia A disturbance in mood that may manifest in either depression or elation.

dystonic reactions Acute contractures of the tongue, face, neck, and back.

dysuria Painful urination.

E

eccentric Departing from conventional custom or practice; differing conspicuously in behavior, appearance, or opinions.

echymosis (ecchymoses) An irregularly shaped, blue-black skin discoloration caused by bleeding beneath the skin.

ECG (also EKG) *See* Electrocardiogram.

ectopic Located away from normal position, as in ectopic pregnancy.

ectropion An outward turning of the eyelid.

edema An accumulation of fluid surrounding the cell.

edematous Pertaining to, or affected with, edema (abnormal fluid in the tissue).

EEG *See* Electroencephalogram.

effleurage A massage technique with long, light, or firm strokes over the spine and back. May be circular strokes done with the fingertips.

effluent A discharge or outflow (e.g., the contents flowing out of an ileostomy or colostomy).

effusion An escape of fluid into a part or tissue, as an exudation or transudation.

ejaculation Ejection of the seminal fluid from the male urethra.

elastance The extent to which the lungs are able to return to their original position after being barely distended.

electrocardiogram The record produced by amplification of the electrical impulses normally generated by the heart.

electroconvulsive therapy (ECT) The oldest form of brain stimulation therapy used for severe depression. Considered after several unsuccessful regimens of medication. Consists of electric shock to the brain via electrodes applied to the temples. This shock artificially induces a grand mal seizure lasting 30 to 90 seconds.

electroencephalogram A recording of changes in electric potentials in various areas of the brain.

electrolyte(s) A chemical substance that, when dissolved in water, dissociates into ions and thus is capable of conducting an electric current.

electromyography The recording and study of intrinsic electrical properties of skeletal muscle; useful in diagnosing neuromuscular disorders.

elimination Discharge from the body of indigestible materials and waste products of metabolism.

embolism A sudden obstruction of arterial blood flow by a blood clot or a mass that has been brought to the site in the bloodstream.

embolus A clot or plug of material (usually from a thrombus) carried by blood flow that lodges in a vessel and obstructs blood flow.

emesis Substance produced by vomiting.

empathy The ability to recognize and share the emotions and states of mind of another; understanding another's behavior.

emphysema A chronic pulmonary disease characterized by increase beyond normal in the size of air spaces distal to the terminal bronchiole with destructive changes in their walls.

empyema The presence of infected and purulent exudate within the pleural cavity.

enabling Doing something for a substance-dependent person that keeps the person from facing consequences. Term used with substance abuse.

encapsulated Surrounded by a fibrous capsule.

encephalopathy Any dysfunction of the brain.

endarterectomy The surgical removal of thickened atheromatous areas of the innermost layer of an artery.

endemic Present in a community at all times.

endocarditis An inflammation of the membrane lining the cavities of the heart and of the connective tissue bed on which it lies.

endocrine Secreting internally; refers to glandular function.

endogenous Coming from within.

endometriosis The presence of endometrial tissue in locations outside the uterus.

endorphin(s) Any of a group of opiate-like peptides naturally produced by the body.

endoscopy Examination with an endoscope that allows for direct visual inspection of the interior of hollow organs and body cavities.

endotoxin(s) A heat-stable toxin that is present in the intact bacterial cell wall, is pyrogenic, and is capable of increasing capillary permeability.

endotracheal intubation Airway management with a catheter or tube inserted through the mouth or nose into the trachea.

engraftment Successful establishment of the graft in bone marrow transplantation.

enteral feeding Feeding a patient by means of a tube passed into the stomach from the nasal passage.

enterocele A hernia containing intestines.

enterostomal Related to an abdominal stoma, or artificial opening of the intestine onto the surface of the body.

entropion Inversion of the eyelid margin.

enucleation Removal of an organ or other mass intact (e.g., the eyeball from the orbit).

environment All the physical and psychological factors that influence or affect the life or survival of an individual.

enzyme Any protein that acts as a catalyst, increasing the rate at which chemical reaction occurs.

epidemic(s) A disease that simultaneously attacks many people in a geographic area, is widely diffused, and spreads rapidly.

epidermophytosis A fungal infection that most often affects the feet, especially between the toes; also called *athlete's foot* or *dermophytosis*.

epididymis A small oblong body resting on and beside the posterior surface of the testes that constitutes the first part of the excretory duct of each testis.

epidural Situated on or outside the dura mater.

epidural hematoma A hematoma caused by rapid leakage of blood from the middle meningeal artery, which quickly elevates intracranial pressure.

epigastric Pertaining to the region over the pit of the stomach.

epilepsy A group of neurologic disorders characterized by recurrent episodes of convulsive seizures, sensory disturbances, abnormal behaviors, loss of consciousness, or all of these.

epistaxis Nosebleed.

equilibrium Balance.

erection The state of swelling, hardness, and stiffness observed in the penis of the male and to a lesser extent in the clitoris of the female.

erythema Redness of the skin.

erythrasma A chronic bacterial infection of the major skinfolds, marked by red or brownish patches on the skin.

erythrocyte sedimentation rate The rate at which red blood cells settle out of unclotted blood in 1 hour.

erythropoiesis Formation of red blood cells, or erythrocytes.

eschar A castoff of dead tissue, as from a burn, corrosive application, or gangrene.

escharotomy Surgical incision of a constricting eschar in a burn victim to permit the cut edges to separate and restore blood flow to unburned tissue.

esophageal varices Varicosities of branches of the azygous vein that connects with the portal vein in the lower esophagus; related to portal hypertension and cirrhosis of the liver.

estrogens The female sex hormones, including estradiol, estriol, and estrone.

etiology Study of the cause of disease; origin.

euthanasia An easy or painless death; active euthanasia, or mercy killing, is the deliberate ending of the life of a person who is incurably and terminally ill; passive euthanasia is the withholding of "heroic" measures and allowing the person to die.

euthymia A normal mood or feeling state.

evaluation, of outcome Appraisal of the patient's progress toward achievement of the goals and objectives stated in the nursing care plan.

evaluation, of process Appraisal of nursing activities and what has been done to assess, plan, and implement nursing care.

evaluation, of structure Appraisal of the physical facilities, equipment, staffing, and other characteristics of an agency that affect the quality of nursing care.

evagination (1) extrusion of internal organs; (2) removal of the contents of the eyeball, leaving the sclera intact.

excess An amount beyond what is usual or necessary.

excoriation Any superficial loss of substance, such as that produced by scratching the skin.

excursion Range of movement (of the lungs).

exercises, isometric Active exercises performed against stable resistance, without change in the length of the muscle.

exfoliate To separate or peel off in scales, layers, or flakes.

exocrine Secreting externally via a duct.

exogenous Coming from outside.

exophthalmos Abnormal protrusion of the eyeball.

exotoxin A potent toxin formed and excreted by the bacterial cell.

Expanded Precautions Use of Standard Precaution techniques with additional protective actions specific to the organism and location involved.

expected outcomes Results expected to be achieved by the patient from health care provided and personal contributions.

expectorate To spit out saliva or cough up materials from the air passageways leading to the lungs.

extension A movement that brings a limb into or toward a straight position by increasing the angle between the bones forming a joint; opposite of flexion.

extracellular Outside of the cell.

extracellular fluids Body fluids outside the cell walls that constitute the environment of each cell.

extracorporeal Outside the body.

exudate Fluid that contains dead cells, serum, phagocytes, bacteria, or pus.

F

fasciotomy Linear incisions in the fascia down the extremity.

fecal impaction The accumulation of putty-like or hardened feces in the rectum or sigmoid colon.

feedback The process of providing a system with information about its output.

feedback, negative A corrective action in which a system is informed that its output is not satisfactory and a change is needed.

feedback, positive Information that tells a system its output is satisfactory.

fee-for-service Fee paid for services provided; a type of medical practice.

fetor hepaticus Foul-smelling breath associated with severe liver disease.

fibroid A thickened vascular mass in the uterus.

fibroma A fibrous, encapsulated connective tissue tumor.

fibrosis Fibrous tissue formation.

filtration Passage of a gas or liquid through a filter to separate out unwanted matter.

fistula(s) Any abnormal, tubelike passage within the body between two internal organs or leading from an internal organ to the body surface.

flaccid Limp, weak, or relaxed.

flatulence Gas in the digestive tract.

flexion A movement that brings a limb into or toward a bent position by decreasing the angle between the bones forming a joint; opposite of extension.

flight of ideas Going from topic to topic in conversation with little or no connection.

flora Plant life, as distinguished from animal life.

fluid(s) The water and substances dissolved in it that form the internal environment.

fluid balance Equilibrium between the amount of fluid taken into the body and that lost through urine, feces, the lungs, skin, and possibly vomiting and fistulas.

fluid deficit(s) A fluid imbalance in which there is not enough fluid in one or more of the body's fluid compartments as a result of either inadequate intake or excessive loss.

fluid excess A fluid imbalance in which too much fluid accumulates in one or more of the body's fluid compartments as a result of either excessive intake or inadequate loss. *See also Edema.*

fluids, transcellular Body fluids that pass through cellular structures and eventually are eliminated from the body.

follicular pharyngitis An inflammation of the pharynx accompanied by purulent infection.

fracture(s) Interruption in the continuity of a bone.

friction rub A high-pitched, scratchy sound heard with the diaphragm of the stethoscope placed at the lower left sternal border of the chest; a symptom of pericarditis.

fructosamine assay A test that may be used to monitor control of glucose over a period of 2 to 3 weeks.

fulguration Destruction by electric cautery.

functional disorder A disorder that affects the function but not the structure of the body or body part.

fungus (fungi) A member of a group of organisms (mushrooms, yeasts, molds, etc.) that thrive in a warm, moist climate. Can cause infections that are difficult to eradicate because fungi tend to reproduce by means of spores that are resistant to ordinary disinfectants and antiseptics.

furuncles Inflammations of hair follicles. Also called *boils*.

G

galactosemia A genetic disorder in which there is a lack of the enzyme necessary for proper metabolism of galactose.

gangrene A necrosis, or death, of tissue, usually caused by deficient or absent blood supply.

gastritis An inflammation of the mucous membrane lining the stomach.

gastrojejunostomy The surgical creation of an anastomosis between the stomach and jejunum.

gastroparesis Delayed gastric emptying.

gastrostomy The surgical creation of an opening into the stomach to administer food and liquids.

gate control theory The proposal that synapses in the dorsal horn of the spinal cord act as gates and that pain signals compete with signals of other kinds of stimuli for passage through the gate and transmission to the brain.

gene One of the self-reproducing biologic units of heredity that make up segments of the DNA molecule that controls cellular reproduction and function.

generalized anxiety disorder A persistent, unrealistic, or excessive worry about two or more life circumstances.

genital Pertaining to the reproductive organs.

geriatrics The medical treatment of diseases commonly associated with aging and elderly persons.

gerontology The study of the problems of aging in all its aspects.

gigantism Excessive size. Seen in children with excessive secretion of growth hormone.

gingivitis An inflammation of the gingivae.

glaucoma A group of diseases of the eye characterized by increased intraocular pressure that can produce blindness if not managed successfully.

global amnesia Irretrievable total loss of memory.

globulin(s) A general term for proteins; separated into five fractions by serum protein electrophoresis and classified in order of decreasing electrophoretic mobility. The fractions are alpha₁, alpha₂, beta₁, beta₂, and gamma globulins.

glucagon(s) A polypeptide hormone secreted by the alpha cells of the islets of Langerhans.

glucocorticoid Any hormone released from the adrenal cortex that increases glucogenesis and thus raises the level of liver glycogen and blood glucose.

glucogenesis The formation of glucose from glycogen.

glucometer Blood glucose-monitoring machine.

glucose intolerance The inability to properly metabolize glucose.

glucose tolerance test A test to detect abnormal glucose metabolism; assists in diagnosis of diabetes mellitus.

glycemic Referring to the amount of glucose present in a substance.

glycemic control Control of glucose in the blood.

glycosuria Glucose in the urine.

glycosylated hemoglobin (Hb A_{1c}; A1C) Hemoglobin with glucose attached to it; periodic measurements of hemoglobin A1C can help determine a diabetic patient's average blood glucose level over a period of 3 to 4 months.

goal(s) A broad statement describing what is to be accomplished over a specified period.

goiter An enlargement of the thyroid gland.

gonads Gamete-producing glands; the ovaries and testicles.

goniometry The measurement of range of motion in a joint.

graft An implant or transplant of tissue or an organ.

gram negative Having the pink color of the counterstain used in the Gram method of staining microorganisms.

gram positive Retaining the violet color of the stain used in the Gram method of staining microorganisms.

granulocyte A leukocyte containing abundant granules in its cytoplasm; granulocytes include neutrophils, eosinophils, and basophils.

Graves disease An immune disorder that causes overproduction of thyroid hormones. Also called toxic goiter.

gynecomastia The development of abnormally large mammary glands in the male.

H

hallucination A sensory perception (touching, tasting, feeling, hearing, seeing) that occurs without external stimulation.

hand hygiene The primary intervention any health care provider can use to control the spread of infection; performed with soap and water, if the hands are visibly soiled, or with an alcohol-based hand-sanitizing solution.

handicap A social disadvantage that exists because of a disability.

"Hands-Only CPR" Intended only for lay rescuers and only chest compressions are delivered; rescue breathing or mouth-to-mouth resuscitation are not included.

Haversian system A canal system that runs through the bones and contains the blood and lymph vessels.

health The ability to function well physically and mentally and to express the full range of one's potential.

health care-associated infection Formerly known as a *nosocomial infection*. Can occur when a patient is cared for in any kind of health care setting.

health care-associated pneumonia (HCAP) Pneumonia that results from conditions related to being in a health care facility or receiving health care.

health maintenance organization (HMO) A type of group health care practice that provides basic and supplemental health maintenance and treatment services to enrollees who prepay a fixed periodic fee that is set without regard to the amount or kind of services received.

Healthy People 2020 A federal government mandate with goals for improving the health of the American people, with particular attention to health concerns of people in minority groups.

hearing loss Impaired perception of sound.

heat exhaustion A disorder resulting from overexposure to heat or to the sun; also called *heat prostration*. It is caused by excessive perspiration and loss of body water and salt.

heatstroke A life-threatening condition resulting from prolonged exposure to environmental heat; also called *sunstroke*.

Helicobacter pylori A species of gram-negative, microaerophilic bacteria of the family Spirillaceae that causes gastritis and pyloric ulcers in humans.

helping relationship A relationship in which at least one of the parties intends to promote growth, development, maturity, improved functioning, and improved coping in the life of the other.

hemarthrosis A collection of blood in the joint space.

hematemesis Vomiting of blood.

hematocrit The volume percentage of red blood cells in whole blood.

hematoma(s) A localized collection of blood, usually clotted, that has leaked from adjacent blood vessels into an organ, space, or tissue.

hematuria Blood in the urine.

hemianopsia Blindness for half the field of vision in one or both eyes.

hemicolecotomy Removal of part of the colon.

hemiparesis Weakness affecting only one side of the body.

hemiparesthesia Abnormal sensation on one side of the body.

hemiplegia Paralysis of one half, or one side, of the body.

hemodialysis The removal of nitrogenous wastes from the blood by circulating arterial blood through a dialysate and returning it to the venous circulation.

hemodynamics The study of the movements of blood and the pressures being exerted in the blood vessels and the chambers of the heart.

hemoglobin The protein found in red blood cells that transports molecular oxygen in the blood; oxygenated hemoglobin (oxyhemoglobin) is bright red; unoxygenated hemoglobin is darker.

hemoglobinuria The presence of free hemoglobin in the urine.

hemolysis The rupture of red blood cells with release of hemoglobin into the plasma.

hemolytic Pertaining to the breakdown of red blood cells.

hemophilia An inherited disorder in which there is deficiency of one or more specific clotting factors in the blood.

hemoptysis Coughing and spitting of blood that can originate in the lungs, larynx, or trachea.

hemorrhoid A varicosity of a vein of the rectum. It may be internal (inside the sphincter muscles of the anus) or external (outside the sphincter muscles).

hemorrhoidectomy The removal of hemorrhoids.

hemothorax A collection of blood in the pleural cavity.

hepatic encephalopathy Degenerative changes in the brain associated with liver failure.

hepatitis An inflammation of the liver.

hernia The protrusion or projection of an organ or a part of an organ through the wall of the cavity that normally contains it.

hernioplasty The repair of a hernia.

herniorrhaphy The surgical repair of a hernia.

herpesvirus Any of a large group of DNA viruses found in many animal species. Type 1 herpes simplex virus (HSV) produces lesions that are primarily nongenital. Type 2 HSV lesions most often are genital.

heterosexual A person who is sexually attracted to people of the opposite sex.

hiatal hernia Protrusion of a portion of the stomach through the opening in the diaphragm through which the esophagus passes.

hierarchy The arrangement of objects, elements, or values in a graduated series.

hirsutism The excessive growth of hair on the body.

HIV The causative agent for AIDS; *see* Human immunodeficiency virus.

HLA Human leukocyte antigen.

HMO *See* Health maintenance organization.

holism The belief that each person is a unified whole.

holistic health care Attention to the mental, social, spiritual, and physical aspects of health and illness.

Homans sign Pain on passive dorsiflexion of the foot; a sign of thrombosis of deep calf veins.

homeopathy A practice based on the theory that a substance that produces symptoms of a disease when given in large doses to a healthy individual will cure the same symptoms when administered in small amounts.

homeostasis A tendency of biologic systems to maintain stability in the internal environment while continually adjusting to changes necessary for survival.

homonymous hemianopia Blindness or defective vision in the right or left halves of the visual fields of both eyes.

homosexual A person who is sexually attracted to people of the same sex.

homozygous Having inherited a genetic trait from both parents.

hordeolum An external stye.

hormone A chemical produced by the cells of the body and transported by the bloodstream to target cells and organs on which it has a regulatory effect.

hospice A program that provides a continuum of home and inpatient care for terminally ill individuals and their families.

hospital-acquired pneumonia (HAP) Pneumonia symptoms that occur more than 48 hours after admission.

host An organism in which another, parasitic organism is nourished and harbored.

human immunodeficiency virus (HIV) A retrovirus that integrates itself into the genetic material

of the cell it infects, changing the DNA of the host cell.

human needs Basic needs for survival and personal growth shared by all humans.

human needs theory The proposal that basic human needs act as stimuli to human behavior; Maslow postulated five levels of human needs: physiologic, safety and security, love and belonging, esteem, and self-actualization.

humoral Pertaining to body fluids or substances contained in them.

humoral immunity Antibody-mediated immunity, the result of B-cell action and the production of antibodies.

hydrocephalus Increased cerebrospinal fluid in the ventricles of the brain.

hydronephrosis Distention of the renal pelvis and calices with urine that cannot flow through obstructed ureters.

hydrostatic pressure The pressure or force caused by the presence of a fluid.

hyperalimentation Total parenteral nutrition.

hypercalcemia An excessive amount of calcium in the blood (i.e., more than 5.5 mEq/L or 11 mg/dL).

hypercapnia An excessive amount of carbon dioxide in the blood.

hyperchloremia An excessive amount of chloride in the blood.

hyperesthesia Abnormal sensitivity to stimuli.

hyperglycemia An above-normal level of blood sugar, as in diabetes.

hyperkalemia An excessive amount of potassium in the blood.

hyperlipidemia An excessive amount of lipids in the blood.

hypermagnesemia An excessive amount of magnesium in blood plasma.

hypernatremia An excessive amount of sodium in the blood.

hyperopia A visual defect in which parallel light rays reaching the eye focus behind the retina; farsightedness.

hyperphosphatemia An excessive amount of phosphates in the blood.

hyperplasia An increase in the number of cells of an organ; extra cell growth.

hyperpyrexia An extremely elevated temperature.

hypersecretion Oversecretion.

hypersensitivity An exaggerated immune response to an agent perceived by the body to be foreign. *See also* Allergy (allergies).

hypersomnia Sleeping for long periods.

hypertension Persistently high blood pressure; in adults, a systolic pressure equal to or greater than 140 mm Hg and a diastolic pressure equal to or greater than 90 mm Hg.

hyperthermia Unusually high fever.

hypertonic Of greater concentration.

hypertonic solution A solution in which the osmotic pressure (concentration) is greater than that of body fluids.

hypertrophy An increase in size of a structure or organ.

hyperuricemia An excessive amount of uric acid in the urine.

hyperventilation An abnormal breathing pattern in which an above-normal amount of air is inhaled into the lungs.

hypervolemia An abnormal increase in the volume of circulating blood.

hypesthesia A dysesthesia consisting of abnormally decreased sensitivity, particularly to touch.
Also called *hypoesthesia*.

hypnosis A subconscious condition, usually artificially induced, in which there is a response to suggestions and commands made by the hypnotist.

hypoalbuminemia An abnormally low level of albumin in the blood.

hypocalcemia An abnormally low level of calcium in the blood (i.e., less than 4.5 mEq/L or 8.5 mg/dL).

hypocapnia An abnormally low level of carbon dioxide in the blood, resulting from hyperventilation.

hypochloremia An abnormally low level of chloride in the blood.

hypochromic Pertaining to a condition of the blood in which the red blood cells have a reduced hemoglobin content.

hypodermoclysis Injection of fluid into subcutaneous tissue via continuous infusion.

hypoesthesia See Hypesthesia.

hypogammaglobulinemia An immune deficiency characterized by abnormally low levels of generally all classes of serum gamma globulins with increased susceptibility to infectious diseases.

hypoglycemia An abnormally low level of blood sugar.

hypoglycemic agents Agents that lower the blood sugar level (i.e., oral medications that are used to treat some forms of diabetes mellitus).

hypokalemia An abnormally low level of potassium in the blood.

hypomagnesemia An abnormally low level of magnesium in the blood plasma.

hypomania Inflated or irritable mood for at least 4 days.

hyponatremia An abnormally low level of sodium in the blood.

hypophosphatemia An abnormally low level of phosphates in the blood.

hypophysectomy Excision of the hypophysis cerebri.

hyposecretion Undersecretion.

hyposensitization A treatment used in managing hypersensitivity to a known allergen; the program involves regular injections of minute quantities of selected antigens over an extended period.

hypothalamus That portion of the diencephalon that lies beneath the thalamus at the base of the cerebrum; it activates, controls, and integrates many of the body's vital functions (e.g., regulation of metabolism, volume of body fluids, electrolyte content, and release of hormones).

hypothermia A serious loss of body heat caused by prolonged exposure to cold.

hypothyroidism Deficient activity of the thyroid gland.

hypotonic Of lesser concentration.

hypotonic solution One in which the osmotic pressure (concentration) is less than that of body fluids.

hypotonic state Pertaining to abnormally decreased muscular tone or tension.

hypoventilation An abnormal breathing pattern in which insufficient amounts of air are inhaled into the lungs.

hypovolemia Diminished blood volume.

hypoxemia Insufficient oxygenation of the blood.

hypoxia Deficiency of oxygen.

hysterectomy Surgical removal of the uterus.

I

iatrogenic Caused by medical treatment or diagnostic procedure.

iatrogenic disorder An adverse condition induced by effects of treatment by a physician or surgeon.

icterus Bile pigmentation of the tissues, membranes, and secretions.

idiopathic Of unknown cause.

idiosyncrasy A special characteristic by which a person differs from others.

ileal conduit A surgically created passageway that uses a portion of the ileum to direct the flow of urine from the ureters to the outside of the body.

ileostomy (ileostomies) An artificial opening in the ileum, created surgically, to drain fecal material from the small intestine.

ileus Intestinal obstruction, especially failure of peristalsis.

illusion A misperception of an actual sensory perception; misinterpretation of reality.

imagery Imagination; the calling up of mental pictures or events.

immune deficiency A lack of immune bodies and resultant impairment of the immune response to foreign agents.

immunity Resistance to a specific disease.

immunity, active Immunity acquired by producing one's own antibody.

immunity, passive Immunity acquired from a source other than one's own body, such as by transfer of antibody or lymphocytes from an immune donor.

immunization The process of rendering an individual immune by passive immunity or of becoming immune by active immunity.

immunocompetence The capacity to develop an immune response after exposure to an antigen.

immunoglobulin(s) A protein of animal origin with known antibody activity and a major component of humoral immunity. *See also* Antibody (antibodies).

immunoscintigraphy A radioactive scan of the immune structures.

immunosuppression The deliberate inhibition of antibody formation; used in transplantation to prevent rejection of the donor organ.

immunotherapy Development of passive immunity in a person by administration of preformed antibody; also, the administration of immunopotentiators and immunocompetent lymphoid tissue for cancer treatment.

impairment Dysfunction of a specific organ or body system.

impetigo An infection of the skin, usually by streptococci or staphylococci.

implementation A deliberate action performed to achieve a goal; carrying out of nursing interventions.

impotence Inability of the male to achieve or maintain an erection.

impulsive Acting in response to an impulse because the action brings emotional release or pleasure even though the action may be harmful to oneself or socially unacceptable.

inanimate Not alive; dull, lifeless.

incidence The rate at which certain events occur.

incontinence An alteration in the control of bowel or urinary elimination, or both.

incubation The interval between exposure to infection and the appearance of the first symptom.

index of suspicion Keen observation to detect problems that are not initially obvious, but suspected because of history or circumstances that underlie the patient's decision to seek care.

induration An abnormally hard spot or place.

infarct A localized area of necrosis produced by ischemia caused by obstructed arterial supply or inadequate venous drainage.

infarction Occurrence of a localized area of dead tissue produced by inadequate blood flow.

infection The invasion and multiplication of pathogenic microorganisms in body tissue.

inference A deduction or conclusion.

infertility The condition of inability to produce offspring.

inflammation An immediate cellular response to any kind of injury to the cells and tissues.

ingestants Any substances taken orally, such as food or drink.

ingestion The taking of any substance, such as food, drugs, water, or chemicals, by mouth or through the digestive system.

inhalants Medication or compounds suitable for inhaling.

initial The beginning of a thing or process; the first.

injectables Fluids capable of being injected.

innate Belonging to the essential nature of something; existing in or belonging at birth.

innate immunity A person's natural (inborn) immunity to certain diseases.

inotropic Pertaining to the force or energy of muscular contractions, particularly of the heart.

insensible Unconscious; without feeling or consciousness.

inspection The process of visual examination.

insomnia A sleep disorder; an inability to sleep.

insufficiency The condition of being inadequate for a given purpose.

insulin A naturally occurring hormone secreted by the beta cells of the islets of Langerhans in the pancreas in response to increased levels of glucose in the blood.

insulin-dependent diabetes mellitus Type 1 diabetes; a form of the disease that requires replacement of endogenous insulin with regular injections of exogenous insulin.

insulin resistance A situation in which insulin interaction with glucose becomes less efficient and fat metabolism is abnormal.

intention tremor A tremor that occurs on attempt at voluntary movement.

interdisciplinary (collaborative) care plan A care plan composed through collaboration of all of the health care team members caring for a patient.

intermittent claudication Cramping pain in the muscles of the lower extremities brought on by exercise and relieved by rest. A common symptom of arterial insufficiency; pain usually occurs in the calves of the legs but can also affect the muscles of the thighs and buttocks.

interstitial Placed or lying between.

interstitial fluids Body fluids that are located in the tissue spaces around the cells. *See also* Edema.

intervention Nursing activities performed by the nurse to meet the specified goals of a nursing care plan.

intracellular Within cells.

intracellular fluids Body fluids that are within cell walls.

intractable pain Hard-to-manage pain; pain not relieved by ordinary methods.

intraocular Within the eye.

intrathecal Injected into the subarachnoid space of the spinal cord via lumbar puncture.

intrathoracic Within the thoracic cavity.

intravascular fluids Body fluids within the blood vessels composed of plasma and the substances it transports.

intravenous therapy The administration of fluids through a vein.

intussusception Telescoping of one part of the bowel into another.

inuria Abnormal presence of protein in the urine.

ions Atoms or groups of atoms that have an electrical charge through the gain or loss of an electron.

ipsilateral On or affecting the same side of the body.

iridectomy Excision of part of the iris.

ischemia A deficiency of blood supply to a part as a result of functional constriction of a blood vessel or of actual obstruction, as by a clot.

islets of Langerhans Pancreatic cells. Beta cells, which secrete insulin, are found in these cells.

isolation technique Special precautionary procedures used to set apart a patient with a communicable disease; the purpose is to prevent the spread of infectious agents from the patient to others.

isometric Having equal dimensions; maintaining the same length.

isometric exercises Exercises that involve generating tension between two opposing sets of muscles.

isotonic Of equal solute concentration.

isotonic contraction A contraction that occurs when tension is developed in a muscle.

isotonic solution A solution in which the osmotic pressure is the same as that of intracellular fluid (e.g., normal saline [0.9% concentration]).

isotope One of a series of chemical elements that have nearly identical chemical properties but differ in their atomic weight and electrical charge. Many isotopes are radioactive.

J

jaundice A yellowing of the skin and mucous membranes that reflects excessively high blood levels of bilirubin (bile pigment).

K

keloid Excessive, abnormal scar formation in the skin after trauma or surgical incision.

keratitis An inflammation of the cornea.

keratosis (keratoses) Any horny growth, such as a wart or callosity; usually either actinic keratosis or a seborrheic keratosis.

ketoacidosis The accumulation of ketone bodies in the blood because of incomplete metabolism of fats, resulting in metabolic acidosis.

ketonuria The presence of acetone bodies in the urine.

ketosis The accumulation in the body of the ketone bodies: acetone, beta-hydroxybutyric acid, and acetoacetic acid.

kinetic motion The motion of material bodies and the forces and energy associated with it.

Korsakoff syndrome Substance-induced persisting dementia.

Kupffer cells Large, highly phagocytic cells in the liver; they form part of the reticuloendothelial system.

kypnosis An abnormally increased curvature of the thoracic spine, which gives a "hunchback" appearance.

L

labile Unsteady, not fixed; easily disarranged.

labyrinthitis An inflammation of the internal ear, including the vestibule, cochlea, and semicircular canal.

laparoscopy The examination of the peritoneal cavity with a fiberoptic instrument inserted through a small abdominal incision.

laryngectomy The partial or total removal of the larynx by surgical excision; the person who has had a laryngectomy is called a *laryngectomee*.

laryngitis An inflammation of the larynx.

laryngoscopy Direct or indirect visual examination of the larynx.

laser Stands for *light amplification by stimulated emission of radiation*; converts light wavelengths into one small, intense, unified beam of single-wavelength radiation; used for diagnosis and surgery.

latent Not obvious; hidden.

latent TB infection (LTBI) An infection with *Mycobacterium tuberculosis* without current active disease.

lesions A circumscribed area of pathologically altered tissue.

leukapheresis A process by which blood is withdrawn from a vein, white blood cells are removed, and the remaining blood is reinfused in the patient.

leukemia A malignant disease of the blood-forming organs, marked by abnormal proliferation and development of leukocytes and their precursors in the blood and bone marrow.

leukocyte A colorless blood cell whose chief function is to protect the body against pathogenic

microorganisms.

leukocytosis An increase in the number of white blood cells, or leukocytes, in the blood.

leukopenia A reduction in the number of leukocytes in the blood to 5000 or less.

leukoplakia Patches of thickened, white tissue on mucous membrane; considered a precursor to cancer.

leukotrienes A class of biologically active compounds that occur naturally in leukocytes and produce allergic and inflammatory reactions similar to those of histamine.

level of consciousness (LOC) A standardized system to describe the state of consciousness (i.e., alert wakefulness, drowsiness, stupor, or coma).

Lhermitte sign An electrical shock-like sensation felt along the spine when the neck is flexed.

libido The conscious or unconscious sexual drive.

lifestyle habits Entrenched practices related to work, recreation, diet, exercise, and other activities of daily living.

ligament Connective tissue that joins the bones of a joint together.

ligate To tie or bind.

lipodystrophy A disturbance of or defect in fat metabolism.

lipoma A fatty tumor.

lipoprotein Any of the macromolecular complexes that are transported in the blood.

lithiasis The formation of stones.

lithotripsy The crushing of a calculus in the kidney, bladder, urethra, or gallbladder.

loose associations Disordered thinking with little connection between thoughts.

lordosis An abnormal forward curvature of the spine.

lozenge(s) A medicated tablet or disk.

lucid Clear, especially applied to clarity of the mind.

lymphadenitis An inflammation of the lymph nodes.

lymphadenopathy A disease of the lymph nodes, often producing enlargement.

lymphangiography Radiography of lymphatic vessels after injection of a contrast medium.

lymphangitis An inflammation of the lymph vessels.

lymphatic system An accessory system by which fluids can flow from tissue spaces into the blood.

lymphedema The swelling of tissues drained by the lymphatic system.

lymph nodes Small bundles of lymphatic tissue containing lymphocytes, the functions of which are filtration and phagocytosis.

lymphocyte A mononuclear, nongranular leukocyte that is chiefly a product of lymphoid tissue and is important in the development of immunity.

lymphocyte, sensitized A nongranular lymphocyte that has been processed either by the thymus (T lymphocyte) or an unknown processing area (B lymphocyte) and is responsible for either cellular or humoral immunity.

lymphocyte-transforming factor A protein mediator that causes transformation and clonal expansion of nonsensitized lymphocytes that produce a toxin destructive to antigen.

lymphoma Any neoplastic disorder of lymphoid tissue.

lyse To produce decomposition; to destroy.

lysis The gradual decline of a fever or disease; the opposite of crisis.

M

macrophage(s) A large, mononuclear phagocyte derived from monocytes; macrophages are components of the reticuloendothelial system.

macrophage-activating factor A mediator released by sensitized lymphocytes on contact with an antigen, the function of which is to induce in macrophages an increased content of lysosomal enzymes, more aggressive phagocytosis, and increased mitosis.

macrophage chemotaxis factor A protein mediator released by sensitized lymphocytes on contact with antigen, the function of which is to attract macrophages to the antigen site.

macule (macula) A discolored spot on the skin that is not raised above the surface.

major depressive disorder A mental disorder in which at least five symptoms characteristic of depression have been present for at least 2 weeks. Some of these symptoms include an overwhelming feeling of sadness, inability to feel pleasure or interest in daily activities, weight gain or loss not attributed to dieting, sleep disturbances, fatigue, difficulty concentrating, and suicidal thoughts.

malignancy *See* Carcinoma.

malignant Becoming progressively worse; resisting treatment and resulting in death; having the properties of anaplasia, invasiveness, and metastasis.

mammography The x-ray examination of the soft tissues of the breast.

mammoplasty Plastic surgery of the breast.

managed care Organization of health care delivery that coordinates care delivery by various health team members in a timely, cost-effective manner.

mania An elevation in mood characterized by feelings of elation, excitement, or extreme irritability.

mass casualties Casualties in such numbers that the normal health care system has difficulty providing adequate care.

mastication Chewing.

mean, mathematical An average (e.g., mean corpuscular hemoglobin concentration, which is the concentration of hemoglobin in the average erythrocyte).

measurable The ability to be expressed numerically, or to be described as to the extent or quantity (of a substance, energy, or time).

mechanism of injury Refers to how the injury occurred.

mediastinum The mass of tissues and organs separating the sternum in front and the vertebral column behind.

mediate To accomplish by indirect means; to act between two parties or sides.

Medicaid A federally funded state-operated program that provides medical assistance to eligible people with low incomes.

medical nutrition therapy A registered dietitian (RD) or a certified diabetes educator (CDE) performs an in-depth assessment of type of diabetes, height-to-weight ratio, usual dietary intake, food preferences, exercise level, and daily schedule. A range of interventions are considered when designing a plan that is individualized for the patient.

Medicare A federally funded national health insurance program in the United States for people older than 65 years.

meditation The act of contemplative thinking.

melanoma A malignant, darkly pigmented mole or tumor of the skin.

melena Black, tarry stools.

menarche The onset of menstruation.

Ménière disease A group of symptoms produced by an increase in fluid in the labyrinthine spaces with swelling and congestion of the mucosa of the cochlea.

menopause The span of time during which the menstrual cycle wanes and gradually stops; *see Climacteric.*

menorrhagia Excessive menstruation.

menses The onset of the menstrual cycle.

menstruation The shedding of the uterine lining.

mentate To think.

MET Acronym for "metabolic equivalent of task," a measure of heat production by the body. This term is used with cardiac rehabilitation patients.

metabolic acidosis A condition in which the pH of body fluids is below 7.4 because of either an excessive production of carbonic acid through the oxidation of fats or a loss of bicarbonate.

metabolic alkalosis A condition in which the pH of body fluids is above 7.4 because of either an excessive loss of acid, an above-normal intake or retention of base, or a low level of potassium in the blood.

metabolism The sum of the physical and chemical processes by which living tissue is formed and maintained and by which large molecules are disassembled to provide energy.

metastasis The movement of disease from one organ or body part to a distant location; for example, the migration of microorganisms and of malignant cells.

metrorrhagia Uterine bleeding occurring at irregular intervals and sometimes for prolonged periods.

microalbuminuria Presence of albumin in the urine, which is suggestive of **early** kidney disease.

microcytic Pertaining to a smaller-than-normal cell.

micron A unit of linear measure; equal to 0.001 mm.

micturition The voiding of urine.

milieu therapy Therapy in a structured environment of a hospital or group home setting to help patients participate as active members of the milieu community and practice social behaviors.

milliequivalent One-thousandth of a chemical equivalent, expressed as mEq; the concentration of electrolytes in a certain volume of solution is usually expressed as milliequivalents per liter (mEq/L).

mineralocorticoids A group of hormones produced by the adrenal cortex that have an effect on sodium, chloride, and potassium levels in extracellular fluid.

miotic A drug that constricts the pupil.

mitosis A type of cell division of somatic cells in which each daughter cell contains the same number of chromosomes as the parent cell. It is the process by which the body grows and by which somatic cells are replaced.

mittelschmerz A sharp pain in the right or left lower quadrant, sometimes felt at midcycle around the time of ovulation.

modulation The fourth of four phases associated with nociceptive pain in which the brain sends signals back down the spinal cord by release of neurotransmitters.

monocytes Mononuclear phagocytic leukocytes.

monoparesis Weakness in one limb.

monoplegia Paralysis of one limb.

morphologic Related to the science of structures and forms without regard to function.

mucolytic Dissolving or destroying mucus.

mucorrhea The free discharge of mucus.

mucositis An inflammation of a mucous membrane.

multidrug-resistant organism (MDRO) A pathogen that has mutated as a result of inadequate dosages or delays in administration of antimicrobial medication and is now resistant to many medications.

multisystem organ dysfunction syndrome (MODS) A syndrome in which there is concurrent dysfunction of several organs.

muscle tone The readiness of a muscle to contract and relax normally.

mutation An unusual change in a gene occurring spontaneously or by induction. Mutation can occur in pathogenic organisms.

mycosis (mycoses) Any disease caused by a fungus.

mydriatic Dilating the pupil.

myocardial infarction (MI) Necrosis of the myocardium as a result of interruption of the blood supply to the area.

myocarditis An inflammation of the heart muscle.

myomectomy Surgical removal of a tumor from the uterine wall, accomplished by use of an endoscope.

myopia The error of refraction in which parallel light rays focus in front of the retina; nearsightedness.

myringotomy An incision into the eardrum.

myxedema A condition in an adult in which there are low thyroid levels.

N

nebulizer An atomizer; a device for delivering drugs or water to the respiratory tract by forcing air

or oxygen through a solution.

necrosis The changes that occur as a result of death of cells; caused by enzymatic degradation.

necrotic Pertaining to death of a portion of tissue.

negative feedback In the endocrine system, if the hormonal need of a target tissue is being satisfied, production or secretion of the hormone will be inhibited.

negative symptoms One of the two divisions of signs and symptoms of schizophrenia; include apathy, social isolation, psychomotor retardation, and lack of motivation.

neologism(s) In psychiatry, an invented word whose meaning may be known only to the person using it and may be related to his or her conflicts.

neoplasm A tumor; any new and abnormal growth.

nephron The structural and functional unit of the kidney, which consists of the renal corpuscle, the proximal convoluted tubule, limbs of the loop of Henle, the distal convoluted tubule, and the collecting tubule; thus each nephron is able to form urine independently.

nephrosclerosis Atherosclerotic disease of the small renal arteries related to hypertension and eventual destruction of renal cells.

nephrostomy Formation of an artificial fistula into the renal pelvis of the kidney.

nephrostomy tubes Tubes inserted to drain the renal pelvis.

networking Meeting people, exchanging phone numbers, expressing interest in other people and what they are doing, and establishing a business relationship that might be mutually beneficial.

neuroglycopenia A shortage of glucose in the brain.

neuron Any of the conducting cells of the nervous system; consists of a cell body containing the nucleus and cytoplasm and the axon and dendrites.

neuropathic pain Pain associated with a dysfunction of the nervous system; specifically, an abnormality in the processing of sensations.

neuropathy Any disease of the nerves.

neutropenia An abnormal decrease in the number of neutrophils in the blood.

neutrophilia An increase in the number of neutrophils in the blood.

neutrophils Granular leukocytes; also called *polymorphonuclear leukocytes*.

nociceptive pain Pain associated with pain stimuli from either somatic or visceral structures.

nocturia Excessive urination during the night.

nodules Small masses of tissue that can be detected by touch.

noncommunicable Cannot be carried from one person to another.

non-insulin-dependent diabetes mellitus Type 2 diabetes; a form of diabetes in which levels of endogenous insulin are adequate and control can be managed by diet and exercise and perhaps by an oral hypoglycemic agent.

nonjudgmental Avoiding judgment based on one's personal standards.

normal flora Flora most often found on or in body systems that have some form of contact with the outside environment. This flora prevents most harmful microorganisms from colonizing the body.

normo- A combining form indicating normal or usual.

North American Nursing Diagnosis Association—International (NANDA-I) An organization that formulates and validates nursing diagnoses.

nosocomial Pertaining to or originating in a hospital.

nuchal rigidity Stiffness and pain in the neck from inflammation of the meninges.

nurse practice act A legal statute describing the parameters of nursing practice.

nursing The diagnosis and treatment of human responses to actual or potential health problems.
See also Nursing process.

nursing care plans Written plans of care that serve to communicate to the nursing staff and others the specific nursing diagnoses and prescribed nursing orders for directing and evaluating the effectiveness of the care given.

nursing diagnosis A statement of a health problem or of a potential problem in the patient's health status that a nurse is licensed and competent to treat.

nursing interventions Acts by nurses that implement the nursing care plan.

nursing process A goal-directed series of activities in which the practice of nursing accomplishes its goal of alleviating, minimizing, or preventing real or potential health problems.

nystagmus Involuntary, rapid rhythmic movement of the eyeball.

O

objective data Information obtained through the senses or measured by instruments.

objectives Well-defined steps toward the accomplishment of a goal; they should be realistic, be stated in measurable terms, and include the conditions under which they will be accomplished.

observation The act of watching carefully and attentively.

obsessive Having ideas, thoughts, or impulses that are persistent to an excessive degree.

obsessive-compulsive disorder A mental disorder characterized by recurrent or intrusive thoughts and rituals that can become overwhelming to the point of interfering with normal life.

obturator A device that is placed into a large-bore cannula during insertion to prevent potential blockage by tissues.

occult Obscure; concealed; hidden.

occult blood Hidden blood.

oculogyric crisis A side effect of antipsychotic medication characterized by uncontrolled rolling back of the eyes.

olfaction The act of smelling.

oligomenorrhea Decreased menstruation. Usually refers to menstrual periods that occur at an interval of 45 days or longer.

oliguria A diminished amount of urine formation.

oncogene A gene in a virus that has the ability to induce a cell to become malignant.

oncology The study of tumors.

onychomycosis A fungal infection of the fingernail or toenail.

oophoritis An inflammation of an ovary; ovaritis.

open access plan An insurance plan in which the patient can see any health care provider.

ophthalmologist A physician who specializes in treating eye disorders.

ophthalmoscope An instrument for examining the eye. The direct ophthalmoscope is used to inspect the back portion of the interior of the eyeball; the indirect ophthalmoscope permits stereoscopic inspection of the interior of the eye.

opportunistic infections (OIs) Infections that develop in an individual with a depressed immune system from organisms commonly found in the environment that are usually harmless.

opportunistic pathogen A fungus or bacterium, usually harmless, that causes infection in a person with a depressed immune system.

optic chiasm The part of the hypothalamus formed by the decussation, or crossing, of the fibers of the optic nerve from the medial half of each retina.

optician A specialist in the making of optical apparatus (e.g., eyeglasses).

optometrist A professional person trained to examine the eyes and prescribe eyeglasses or contact lenses to correct irregularities of vision.

orchectomy The excision of one or both testes.

orchitis An inflammation of the testes.

orthopedic Referring to the correction of deformities of the musculoskeletal system.

orthopnea The ability to breathe easily only in the upright position.

orthopneic position Sitting up in bed with two or three pillows behind the back.

orthostatic hypotension A fall in blood pressure that occurs when standing up from a sitting or lying position or when standing in a fixed position; it is characterized by dizziness, syncope, and blurred vision.

oscilloscope An instrument that makes visible on a screen the nature of an electrical current.

osmolality The osmotic pressure of a solution, expressed in osmoles or milliosmoles (mOsm) per kilogram of water.

osmosis The passage of solvent from a solution of lesser concentration to one of greater concentration through a selectively permeable membrane.

osmotic pressure Pressure that develops when two solutions of different concentrations are separated by a semipermeable membrane.

ossification Formation of or conversion into bone or a bony substance.

osteomyelitis A bacterial infection of the bone.

osteoporosis A porous condition of bone caused by demineralization associated with aging or steroid medication.

otalgia Pain in the ear.

OTC Over the counter; available without a prescription.

otitis media An inflammation of the middle ear.

otorrhea An inflammation of the ear with purulent discharge.

otoscope An instrument for examining the ear canal and eardrum.

outcome The result of an action.

ovulation The periodic ripening and rupture of the mature graafian follicle and the discharge of the ovum from the cortex of the ovary.

oxidation The process by which a substance combines with oxygen.

P

pacemaker A mechanical device that provides electrical stimulation when an anatomic pacemaker fails; a cardiac pacemaker provides electrical stimulation when there is heart block.

pain A feeling of distress or suffering caused by stimulation of specialized nerve cells; considered to occur whenever a person says it is present.

pain threshold The point at which pain is perceived.

pain tolerance The length of time or intensity at which a person will endure pain before outwardly responding to it.

palliative Designed to relieve symptoms when a disease cannot be cured.

palliative care Comfort care.

palliative surgery Surgery performed to make a patient more comfortable.

palmar erythema A persistent redness of the palms that may be seen in liver disease.

palpation A physical examination technique in which the texture, size, consistency, and location of body parts are felt with the hands.

palpitation A rapid, violent, or throbbing pulsation, as an abnormally rapid throbbing or fluttering of the heart.

pancreatitis An inflamed condition of the pancreas.

pandemic An international outbreak of disease.

panhysterectomy The surgical removal of the entire uterus.

papule A small, round, solid, elevated lesion of the skin.

paracentesis The surgical puncture of a cavity to aspirate fluid.

paradoxical respirations Respirations in which, on inhalation, the traumatized portion of the chest wall moves inward rather than outward.

paralytic ileus The absence of peristalsis; paralysis of the intestines.

paranoia A mental disorder in which a person exhibits delusions of persecution or of grandeur or a combination of both.

paraplegia Paralysis of the lower extremities.

parathormone A hormone produced and secreted by the parathyroid gland.

parenteral Administered by a route other than the digestive tract.

paresthesia A feeling of tingling or numbness.

passive immunity Immunity acquired by transfer of antibody or lymphocytes from an immune donor.

patent Wide open.

pathogen A microorganism or substance capable of producing a disease.

pathologic Caused by a disease.

patient advocate A person who will advocate on the patient's behalf with the hospital, insurance company, or health care personnel.

PCA Patient-controlled analgesia.

pediculosis An infestation with lice.

pelvic inflammatory disease Any inflammation in the pelvis that occurs outside the uterus, uterine tubes, and ovaries.

peptic ulcer The loss of tissue lining the esophagus, stomach, or duodenum.

perception The recognition and interpretation of sensory stimuli that serve as a basis for comprehending, learning, and knowing or for motivating a particular action or reaction. Also, the third of four phases associated with nociceptive pain, during which impulses reach the brain and pain is recognized.

percussion The physical examination technique of tapping the body surface with the fingertips or fist to evaluate the size, borders, and consistency of some of the internal organs or to detect the presence of fluid in a body cavity.

percutaneous Through the skin.

perforation A hole or break in the retaining walls or membranes of an organ, as in perforated ulcer and perforated eardrum.

perfusion Supplying tissues and organs with nutrients and oxygen by blood flow through the arteries.

pericardial effusion A collection of serous or purulent exudate in the pericardial cavity.

pericardiocentesis The surgical puncture of the pericardial cavity for aspiration of fluid.

pericardiotomy The surgical incision of the pericardium.

pericarditis An inflammation of the sac that encloses the heart and the roots of the great vessels.

periodontal Located around a tooth.

perioperative Pertaining to the period extending from the time of hospitalization for surgery to the time of discharge.

periorbital Surrounding the socket of the eye.

peripheral Pertaining to the area outside the central region or structure.

peristalsis Involuntary wavelike contraction of organs with both longitudinal and circular muscle fibers that passes along the organ and propels its contents, as in peristalsis of the digestive tract.

peristomal Pertaining to the area around a stoma.

peritonitis An inflammation of the serous sac that lines the abdominal cavity and encloses the abdominal organs.

permeable Permitting passage of a substance.

personality disorder A mental disorder characterized by inflexible and maladaptive responses to life events, serious difficulty in personal and work relationships, a tendency to evoke interpersonal conflict, and a tendency to evoke a negative empathic response from others.

personal protective equipment (PPE) Equipment that forms some type of barrier to protect a

person from exposure to blood-borne pathogens, body fluids, or other potentially infectious materials (e.g., gloves, covering gowns, and face masks).

pessary A hard rubber ring inserted in the vagina to help keep the abdominal organs in place.

petechiae Very small, nonraised, round, purplish spots, caused by intradermal or submucosal bleeding, that later turn blue or yellow.

pH The concentration of hydrogen (H) in a solution; the higher the concentration of hydrogen ions, the lower the pH of the solution.

phacoemulsification A technique of cataract extraction in which high-frequency vibrations are used to fragment the lens.

phagocytosis The engulfing of microorganisms and other foreign matter by phagocytes.

phantom pain A sensation of discomfort occurring where an extremity has been amputated.

pharyngitis An inflammation or infection of the pharynx that usually produces a sore throat.

phenylketonuria A genetic disorder in which there is a defect in the metabolism of phenylalanine resulting in the presence of this amino acid in the urine.

pheochromocytoma A rare tumor of the adrenal medulla that secretes catecholamines (epinephrine and norepinephrine).

phlebitis An inflammation of a vein.

phlebotomy The surgical opening of a vein to draw blood, often done with a needle.

phobic disorder Excessive fear of a situation or object.

photocoagulation The alteration of proteins in tissue by the use of light energy in the form of ordinary light rays or a laser beam.

photodynamic therapy A type of chemotherapy in which the action of the drug is enhanced by exposure to light.

photophobia Difficulty tolerating light.

pilonidal Pertaining to, characterized by, or having a tuft of hairs.

pilonidal sinus A lesion located at the cleft of the buttocks in the sacrococcygeal region; also called *pilonidal cyst*.

placebo(s) A supposedly inactive substance or procedure that can have either positive or negative effects on the relief of symptoms and that is usually given under the guise of effective treatment or in clinical trials of new drugs.

planning A phase of the nursing process in which a plan is developed with the patient, family, or significant other to provide a blueprint for nursing intervention to achieve specified goals. *See also* Nursing care plans.

plaque A patch or flat area.

plasma The liquid portion of blood in which formed elements are suspended; it contains plasma proteins, inorganic salts, nutrients, gases, wastes from the cells, and various hormones and enzymes.

plasma cell A spherical or ellipsoidal cell involved in the synthesis, storage, and release of antibody.

plasmapheresis The separation of the cells and components of the blood.

platelets The smallest formed elements in the blood; important in coagulation and blood clotting.

plethora A general term denoting a red, florid complexion or an excess of blood.

pleurisy An inflammation of the pleura.

Pneumocystis jiroveci An opportunistic pathogen that produces infection of the lung associated with acquired immunodeficiency syndrome (AIDS); formerly *Pneumocystis carinii*.

pneumonectomy The excision of lung tissue, especially of an entire lung.

pneumonia An inflammation of the lungs with consolidation.

pneumothorax The accumulation of air or gas in the pleural cavity, resulting in collapse of the lung on the affected side.

point-of-service (POS) option An option offered by some managed care plans in which a member pays an extra fee to see a desired physician outside of the care plan.

polyarteritis Multiple sites of inflammatory and destructive lesions in the arterial system.

polycystic ovarian syndrome An endocrine disturbance characterized by anovulation, amenorrhea, hirsutism, and infertility.

polycythemia An elevation in the total number of blood cells.

polydipsia Excessive thirst that results in drinking large quantities of water.

polymorphonuclear leukocytes The fully developed cells of the granulocyte series, especially neutrophils, the nuclei of which contain three or more lobes.

polyphagia Increased hunger.

polyuria The production of an excessive amount of urine.

positive symptoms One of the two divisions of signs and symptoms seen with schizophrenia; includes hallucinations, delusions, and disordered thinking.

postictal state The condition of a person right after a seizure.

post-traumatic stress disorder A mental disorder characterized by recurrent symptoms of anxiety that some individuals may experience after encountering an extreme, life-threatening event. Nightmares or flashbacks may be part of the symptoms.

PPO See Preferred provider organization.

precancerous Term used to refer to a growth that is not yet, but probably will become, cancerous.

precipitate A deposit separated from a suspension or solution by precipitation; the reaction of a reagent that causes the deposit to fall to the bottom or float near the top.

preferred provider organization (PPO) An organization of physicians, hospitals, and pharmacists whose members discount their services to subscriber patients.

premenstrual syndrome A group of symptoms experienced by some women for several days before the onset of the menstrual period.

prepuce The foreskin or fold of skin over the glans penis in the male.

presbycusis Impairment of hearing in old age.

presbyopia Farsightedness that occurs normally with aging.

pressor A substance that causes a rise in blood pressure. Norepinephrine is an example of a "pressor" hormone. Norepinephrine maintains blood pressure.

pressure ulcer A sore caused by pressure from a splint or other appliance or from the body itself

when it has remained immobile in bed for extended periods.

preventive Hindering the occurrence of something, especially disease.

priapism A prolonged penile erection resulting in a large, hard, and painful penis unrelated to sexual desire or activity.

primary union The joining of two edges of a wound that are close together, resulting in a thin scar after healing; also called *healing by first intention*.

priority Preference established on the basis of emergency or need.

priority setting Setting the sequence of actions according to importance or priority.

problem-oriented medical record (POMR) A system of documentation in which the information is arranged according to specific problems presented by the patient at the time of seeking health care. The four components are database, problem list, initial plan, and follow-up. *See also* Progress notes.

process A series of actions that move from one point to another on the way to completing a goal.

prodromal stage The early or very beginning stage of an illness.

prodrome An early sign of a developing condition or disease.

prognosis The predicted outcome of the course of a disease.

progress notes Entries in the medical record describing what has been done in the care of the patient and his or her response to the intervention.

prolapse The falling down or displacement of a part or all of an organ, as in prolapse of a stoma or prolapse of the uterus.

promoter(s) A type of epigenetic carcinogen that promotes neoplastic growth only after initiation by another substance; a cocarcinogen.

prophylactic Something done or used to prevent infection or disease.

prospective payment system A payment system for reimbursing hospitals for inpatient health care services in which a predetermined rate is set for treatment of specific illnesses.

prostaglandins A group of naturally occurring fatty acids that stimulate contraction of the uterine and other smooth-muscle tissue.

prostate-specific antigen (PSA) A protein produced by the prostate that is present in elevated levels in patients with cancer or other diseases of the prostate.

prosthesis An artificial substitute for a missing part, such as an eye, limb, or tooth, used for functional or cosmetic reasons, or both.

protease inhibitor A drug that works at the last stage of viral reproduction.

protective isolation Special precautionary procedures to minimize exposure to infectious agents in a patient who has an immune deficiency or who is otherwise susceptible to infection.

proteinuria An excess of serum proteins in the urine.

protocol The plan for a course of medical treatment.

protozoa A phylum comprising the unicellular organisms; most are free-living, but some lead commensalistic, mutualistic, or parasitic existences.

provider A person or an agency that provides health care services.

proximal Closest to a point of reference.

pruritus Itching.

pseudocyst An abnormal or dilated cavity resembling a true cyst but not lined with epithelium.
Also called *adventitious cyst* or *false cyst*.

psychoactive substances Mind-altering agents capable of changing or altering a person's mood, behavior, cognition, arousal level, level of consciousness, and perceptions.

psychomotor retardation A slowing of speech, movement, and thought process often seen in depressed patients.

psychotic features Hallucinations, delusions, and grossly disorganized behavior.

ptomaines Toxic substances produced by the action of putrefactive bacteria on proteins and amino acids.

ptosis The dropping of an organ below its usual position, for example, lowering of the eyelid so that it partially or completely covers the cornea.

pulmonary edema A diffuse accumulation of fluid in the tissues and air spaces of the lung.

pulmonary embolus A mass of clotted blood or other formed element in the lung.

pulse deficit The difference between the radial and apical pulse rates.

pulsus paradoxus A drop in systolic blood pressure of greater than 10 mm Hg on inspiration.

purpura Purplish areas caused by bleeding into the skin or mucous membranes.

purulence The condition of producing or discharging pus.

purulent Full of pus.

pus A liquid product of inflammation composed of albuminous substances, a thin fluid, and leukocytes; generally yellow.

pustule A small, round, pus-filled lesion of the skin.

pyelogram A radiograph of the kidney and ureters after injection of a contrast medium that may be administered intravenously (IV pyelogram) or by way of the ureters (retrograde pyelogram).

pyelonephritis An inflammation of the kidney and renal pelvis.

pyrogen Any agent that causes fever.

pyuria Pus in the urine.

Q

quadriplegia Paralysis of all four extremities.

quadriplegic A person with paralysis of all four limbs.

R

rad Radiation absorbed dose; the unit used for measuring doses of radiation.

radiation therapy The use of radiant energy from radioactive materials or high-voltage x-rays to treat disease.

radioimmunoassay A laboratory method for measuring minute quantities of specific antibodies or any antigen, such as a hormone or drug, against which antibodies have been produced.

radionuclide A radioactive substance given to the patient before radiography or scanning.

radiopaque Not penetrable by x-rays; appears white on radiograph.

rales Abnormal respiratory sounds heard on auscultation with a stethoscope indicating some pathologic condition.

range of motion The extent, measured in degrees of a circle, through which a joint can be extended and flexed.

rationalization A defense mechanism in which a patient finds logical reasons (justification) for his or her behavior while ignoring the real reasons.

realistic Attainable, based on the patient's condition and desire.

rectocele A protrusion of the rectum and posterior vaginal wall into the vagina.

recurrent Returning at intervals.

referred pain Pain felt in a part away from its point of origin.

reflex (reflexes) The sum of any particular autonomic (automatic) response mediated by the nervous system and not requiring conscious movement.

refraction The determination of refractive errors (inability to focus light rays on the retina) and their correction with eyeglasses.

regeneration The natural renewal of a structure.

regimen A prescribed scheme of diet, exercise, or activity to achieve certain ends.

rehabilitation The processes of treatment and education that help a disabled individual attain maximum function, a sense of well-being, and a personally satisfying level of independence.

remittent Having alternating periods of abating and returning, such as a fever that comes and goes.

replicate To duplicate, reproduce, or copy.

replication The process of duplicating or reproducing.

reservoir A passive host or carrier that harbors pathogenic organisms without harm to itself and is a source from which others can be infected.

residual urine Urine that remains in the bladder immediately after urination.

resorption Taking in or absorbing again.

respiration The taking in of oxygen, its utilization in the tissues, and the giving off of carbon dioxide.

respiratory acidosis A condition in which the pH of body fluids is below 7.4 because of failure of the lungs to remove sufficient amounts of carbon dioxide.

respiratory alkalosis A condition in which the pH of body fluids is above 7.4 because of excessive removal of carbon dioxide by the lungs, as in hyperventilation.

resuscitation Revival after apparent death.

reticuloendothelial system A network of cells and tissues found throughout the body, especially in the blood, connective tissue, spleen, liver, lungs, bone marrow, and lymph vessels; these cells play a role in blood cell formation and destruction and in inflammation and immunity.

retinopathy A pathologic condition of the retina associated with diabetes mellitus.

retrograde Moving backward; degenerating from a better to a worse state.

retrospective Dealing with the past.

retrospective payment system Medicare payment based on actual costs submitted to government; used before 1983.

retrovirus A type of virus that contains RNA.

reverse transcriptase An enzyme that is present in retroviruses.

rhinitis An inflammation of the mucous membrane of the nose.

rhinoplasty A plastic surgical operation on the nose, either reconstructive, restorative, or cosmetic.

rhonchi Coarse rattling sounds in the bronchial tubes caused by a partial obstruction.

rickettsia A genus of small, rod-shaped to round microorganisms found in tissue cells of lice, fleas, ticks, and mites and transmitted to humans by their bites.

rigor mortis The stiffness that occurs in dead bodies.

robotics The science of designing mechanical, computerized instruments for procedures.

Roux-en-Y Any Y-shaped anastomosis in which the small intestine is included.

rubor A dusky-red color seen in patients with arterial insufficiency.

rugae Ridges or folds on a mucous membrane.

S

safer sex Any sexual practice that is performed with the use of a barrier to prevent the exchange of body fluids.

salpingitis An inflammation of a uterine tube.

sarcoidosis A chronic, progressive, systemic granulomatous reticulosis of unknown etiology, involving almost any organ or tissue.

sarcoma A tumor, often highly malignant, composed of cells derived from connective tissue.

scabies An infestation with the mange mite.

scaling The shedding of small, thin, dry layers of skin.

scarring The replacement of damaged tissue with fibrous tissue.

schizophrenia A mental illness that causes unusual, bizarre behavior (hallucinations and delusions).

scleropathy The injection of a solution that causes the vessel to dry up and disintegrate.

scoliosis Lateral curvature of the spine.

scotoma An area of lost vision in the visual field.

sebaceous Containing or pertaining to sebum, an oily, fatty matter secreted by the sebaceous glands.

secondary union The healing of a wound in which the edges are far apart and cannot be brought together; the wound fills with granulation tissue and heals from the edges inward.

sedative(s) An agent that calms nervousness, irritability, and excitement.

seizure(s) An attack of uncontrollable muscular contractions; a convulsion.

self-care The process by which one initiates and carries out certain health practices to maintain life, health, and personal well-being.

semen A thick, opalescent, viscid secretion discharged from the urethra of the male at the climax of sexual excitement (orgasm).

seminal Concerning the semen or seed.

senile lentigines Areas where melanocytes increase in production, producing brown age spots.

senile purpura Dark purplish-red ecchymoses occurring on the forearms and backs of the hands in the elderly.

sensitivity reaction An exaggerated response to agents perceived by the body as foreign.

sensorineural hearing loss Impaired perception of sound caused by a dysfunction in the inner ear or the eighth cranial nerve.

sensory loss Impairment of acuity of sight, hearing, taste, touch, and smell.

sentinel infections Infections that may indicate an underlying immunosuppression.

sentinel node biopsy A biopsy of lymph nodes that receive drainage from the anatomic area of a breast cancer to determine spread of the disease.

sepsis Infection, contamination (refers to infection in the blood).

septicemia Invasion of the bloodstream by infective microorganisms.

sequelae An abnormal condition that follows and is the result of a disease.

seroconversion The point at which antibodies to specific antigens are detectable in the blood.

seroma A collection of serum forming a tumor-like mass.

serosanguineous Containing both serum and blood.

serum (sera) The clear, liquid portion of blood that does not contain fibrinogen or blood cells. Immune serum is blood serum from the bodies of people or animals that have produced antibody; inoculation with such serum produces passive immunity.

serum sickness A hypersensitivity reaction to a foreign serum or other antigen.

sexually transmitted infection An infection that is transmitted by sexual intercourse.

shearing action Superficial layers of tissue are pulled and stretched across deeper layers of tissue.

shedding Losing or casting off by a natural process.

Sheehan syndrome A rare but serious postpartum complication that involves infarction of the pituitary gland secondary to postpartum hemorrhage.

shock Acute peripheral circulatory failure caused by derangement of circulatory control or loss of circulating fluid.

shunting Physiologically bypassing, as when blood flows past the alveoli but the membrane is thickened and gases cannot cross into or out of the blood.

sickle cell disease All those genetic disorders in which sickle hemoglobin is found in the red cells.

slit lamp An instrument for examining the surface of the eye through a biomicroscopic lens.

smear A specimen for microscopic and cytologic study; the material is spread thinly and evenly across a slide with a swab or loop.

SOAP Acronym for Subjective and Objective data, Assessment, and Planning.

solute The substance that is dissolved in a solution.

Somogyi effect A rebound phenomenon caused by overtreatment with insulin.

source-oriented record keeping A system of documentation in which information is arranged according to the person, department, or other source of information.

specific gravity The weight of a substance compared with the weight of an equal amount of another substance taken as a standard; for liquids, the standard usually is water (specific gravity of 1).

spermatozoa The mature male sex or germ cells formed within the seminiferous tubules of the testes.

spider angioma A form of telangiectasis with a central elevated red dot the size of a pinhead from which small blood vessels radiate; often occurs with liver disease.

spirochete Any organism that is a member of the order Spirochaetales.

spirometer An instrument for measuring air taken into and expelled from the lungs.

splenomegaly Enlargement of the spleen.

splitting A personality trait that involves initial idealization of a caregiver or friend, followed by a devaluing of that same person.

spores Reproductive cells, usually unicellular, produced by plants and some protozoa.

sprain The wrenching or twisting of a joint with partial or complete tearing of the ligaments.

sputum A substance expelled by coughing or clearing the throat.

Standard Precautions Precautions designed to prevent the transmission of microorganisms from one patient to another as well as to protect health care workers from unnecessary exposure to infection.

stapedectomy The surgical removal of the stirrup of the middle ear and its replacement with a prosthetic device.

stasis Standing still; stagnation; usually refers to fluid.

status epilepticus A grave condition in which there is a rapid, unrelenting series of convulsive seizures without intervening periods of consciousness and with absence of respiration. Irreversible brain damage may occur if seizures are not controlled.

steatorrhea Stool that is bulky, frothy, and foul smelling and usually floats in the toilet.

stem cells Generalized mother cells, the descendants of which specialize, often in different functions; an example is an undifferentiated mesenchymal cell that is the progenitor of the blood and fixed-tissue cells of the bone marrow.

stenosis The narrowing or contraction of a passageway or opening.

stent A tubular device to give support to the interior of a vessel or tube, preventing its collapse.

stereotaxis A method of precisely locating areas in the brain.

stereotype(s) A simplification used to describe all members of a specific group without exception.

sterilization, microbe The process of rendering an article free of microorganisms and their pathogenic products.

Steri-Strips Small, reinforced, adhesive strips placed over a healing incision to hold it together after

sutures are removed.

STI Sexually transmitted infection.

stoma(s) A mouth-like opening, especially one that is created surgically for the elimination of urine or fecal material.

stomatitis A generalized inflammation of the oral mucosa.

strabismus A deviation of the eye that cannot be controlled voluntarily.

strain The pulling or tearing of either muscle or tendon, or both.

stress incontinence The loss of urine during a sneeze or cough.

stridor A harsh, high-pitched respiratory sound such as the inspiratory sound often heard in acute laryngeal obstruction.

stromal cells Connective tissue cells of the supporting tissue or matrix of an organ.

sty An infected swelling near the margin of the eyelid.

subcutaneous Beneath or to be introduced beneath the skin.

subcutaneous emphysema Interstitial emphysema characterized by the presence of air in the subcutaneous tissue, usually caused by intrathoracic injury.

subdural hematoma The accumulation of blood in the subdural space.

subjective data Data that the patient provides about a symptom that cannot be seen, felt, or heard by an examiner (e.g., pain).

subluxation A partial or incomplete dislocation of a bone from its place in a joint.

substance use disorder A problem with alcoholism or drug abuse.

subsystem A system within a larger system.

“sucking” chest wound A wound in which the pleural cavity has been penetrated, allowing air and gas to enter the cavity and produce pneumothorax.

suicidal gestures Things done or said that indicate a patient is contemplating committing suicide.

sundowning The phenomenon of becoming confused and disoriented at night, although oriented during the day.

suppression Inhibition, such as interfering with immune response.

suprasystem A highly complex system.

surge capacity The maximum services that a facility can offer when every resource is mobilized.

susceptible Being predisposed or sensitive to the effects of an infectious disease, allergen, or other pathogenic agent; lacking immunity or resistance.

sympathectomy A surgical excision or interruption in some portion of the sympathetic nerve pathways.

syncope Fainting.

syndrome A combination of signs and symptoms associated with a pathologic process or disease.

syndrome of inappropriate antidiuretic hormone (SIADH) Excessive amounts of ADH are produced, resulting in fluid retention.

synovial fluid The transparent viscid fluid found in joint cavities, bursae, and tendon sheaths.

synthesis The process or processes involved in the formation of a complex substance from simpler elements or compounds; opposite of decomposition.

synthesize To put together (data) into a logical whole.

system An organized whole composed of interacting parts.

systemic inflammatory response syndrome (SIRS) A condition in which the body's inflammatory response feedback mechanism fails, causing signs and symptoms (tachycardia, tachypnea, hypotension, oliguria, and fever) without a documented source of infection.

systole The phase of the cardiac cycle in which the ventricles contract and force blood into the aorta and pulmonary arteries; the systolic pressure is recorded as the top number in a blood pressure reading.

systolic blood pressure Arterial pressure during systole.

T

tachycardia An abnormally rapid heart rate, usually more than 100 beats per minute.

tachypnea Abnormal rapidity of respiration.

tamponade The stoppage of blood flow to an organ or part of the body by pressure.

tardive dyskinesia A common extrapyramidal side effect seen with antipsychotics; patients may exhibit lip-smacking, tongue protrusion, blinking, sucking, chewing, and lateral jaw movements.

target cells/tissues Cells and tissues that are affected by a specific hormone.

tendons Connective tissue that connects the muscles to the bones.

TENS Transcutaneous electrical nerve stimulation.

tertiary Third in order or stage.

testis The male gonad. One of two reproductive glands located in the scrotum that produce the male reproductive cells and the male hormone, testosterone.

tetany The continuous tonic spasm of a muscle; associated with calcium deficit, vitamin D deficiency, and alkalosis.

tetraplegia Another term for quadriplegia (paralysis of all four extremities).

thalamus Either of two large structures composed of gray matter and situated at the base of the cerebrum that act as a relay station for impulses traveling from the spinal cord and brainstem to the cerebral cortex.

thanatologist One who studies death.

thanatology The medicolegal study of the dying process and death.

theory (theories) A belief, policy, or principle proposed or followed as the basis of action.

therapeutic Having medicinal or healing properties.

therapeutic alliance Relationship between the patient and nurse established for the purpose of helping the patient to build trust and achieve therapeutic goals.

thermal Pertaining to heat.

thoracentesis The surgical puncture and drainage of the thoracic cavity.

thoracotomy The surgical incision of the wall of the chest.

thought disorder A mental disorder characterized by disorganized thought, behavior, and hallucinations. Mood and interpersonal relationships are altered.

thrombectomy The excision of a clot.

thrombocytopenia A decreased number of platelets.

thrombocytopenic purpura A bleeding disorder characterized by a marked decrease in the number of platelets, resulting in multiple bruises, petechiae, and hemorrhage into the tissues.

thrombolytic Dissolving or splitting up a thrombus.

thrombophlebitis An inflammation of a vein related to formation of a blood clot within the vessel.

thrombosis The formation, development, or presence of a blood clot within a blood vessel.

thrombus A blood clot that obstructs a blood vessel or a cavity of the heart.

thymus An endocrine gland that lies in the upper chest beneath the sternum and that, during fetal life, sensitizes certain stem cells that eventually become T lymphocytes.

thyrocalcitonin A hormone secreted by the thyroid gland.

thyroid crisis A sudden increase in the output of thyroxine and resultant extreme elevation of all body processes.

thyroid panel A group of tests performed to evaluate thyroid function.

thyroid storm *See* Thyroid crisis.

thyrotoxicosis A toxic condition that results from hyperactivity of the thyroid gland.

thyroxine (T₄) A hormone secreted by the thyroid gland.

time-referenced Measured by an educated guess as to how long it will take to attain the outcome.

tinea Ringworm; a name applied to many different kinds of fungal infections of the skin. The specific type usually is designated by a modifying term (e.g., tinea capitis, or ringworm of the scalp).

tinea pedis A fungal infection of the foot; also called *athlete's foot*.

tinnitus A ringing, buzzing, or other continuous noise in the ear.

T lymphocytes White cells destined to provide cellular immunity that have passed through the thymus and migrated to the lymph nodes.

tolerance Increased resistance to a drug or substance that occurs when there is a need for increased amounts of substances to achieve the desired effect. Term used with substance use disorder.

tonic A state of rigid contraction of the muscles.

tonometer An instrument for measuring tension or pressure, especially intraocular pressure.

tophus (tophi) A deposit of sodium biurate in tissues near a joint, in the ear, or in bone, as occurs in gout.

topical Pertaining to the surface of a part of the body, as in topical medications applied to an area of the skin.

torsion The act of twisting or condition of being twisted.

total parenteral nutrition Intravenous feeding to provide all nutritional needs over time.

tourniquet A device for compressing an artery or vein; its use as an emergency measure to relieve

hemorrhage is generally recommended only if the victim's life is threatened and other measures fail to stop massive blood loss.

toxin A poisonous substance.

tracheostomy A surgical incision into the trachea to insert a tube through which the patient can breathe.

traction The exertion of a pulling force, as that applied to a fractured bone or dislocated joint, to maintain proper positioning.

tranquilizers A group of agents that provide calm and relief from anxiety.

transcellular Between cells, but within an epithelial membrane.

transcellular fluid Secretions and excretions that move through cell membranes and eventually leave the body.

transduction The first of four phases associated with nociceptive pain. Tissue damage stimulates the nociceptors and initiates pain sensation.

transfer factor A factor occurring in sensitized lymphocytes that recruits additional lymphocytes and transfers to them the ability to confer cell-mediated immunity.

transformation A change to another form.

transfusion The administration of whole blood or blood components directly into the bloodstream.

transmission The second of four phases associated with nociceptive pain. Involves movement of sensation to the spinal cord.

triage The classification of casualties in an emergency room or location of a disaster by the gravity of the injury, urgency of treatment, and place for treatment.

triiodothyronine (T₃) A hormone secreted by the thyroid gland.

Trousseau sign Low calcium level manifested as a carpal spasm elicited by inflating a blood pressure cuff above the systolic blood pressure.

tuberculin test An evaluation of sensitivity to the tubercle bacillus; the most common method is intradermal injection of a purified protein derivative of tuberculin (the Mantoux test); a positive reaction indicates the need for further diagnostic procedures.

tuberculosis Any of the infectious diseases caused by species of *Mycobacterium* and characterized by the formation of tubercles and caseous necrosis in the tissues.

tumor marker A blood test to detect biochemical substances synthesized and released into the bloodstream by tumor cells; used mainly to confirm a diagnosis of cancer or response to cancer therapy.

tumor-node-metastasis (TNM) staging system A system for classifying cancers according to the extent to which the malignancy has spread.

turgor The normal tension of a cell; swelling, distention.

tympanoplasty An operative procedure on the eardrum or ossicles of the middle ear to restore or improve hearing in patients with a conductive hearing loss.

U

ultrasonography An imaging technique in which deep anatomic structures are recorded by depicting the echoes of ultrasonic waves that have been directed into the tissues; the echoes (reflections) returning from the structures are converted into electrical impulses that are

displayed on a screen, thus presenting a "picture" of the tissues being examined.

unlicensed assistive personnel (UAP) Nursing assistants, technicians, unit secretaries, and aides who do not hold a professional license to perform some aspects of health care delivery and are hired to perform specific repetitive tasks.

urea nitrogen A major protein metabolite that is not recycled by the body but is excreted in the urine; blood urea nitrogen levels indicate the ability of the kidney to filter and excrete waste products.

uremia Retention in the blood of urea, creatinine, and other nitrogenous wastes normally eliminated in the urine; more correctly called *azotemia*.

ureterostomy (ureterostomies) Surgical creation of a stoma to divert urine to the outside.

urinalysis Analysis of a sample of urine, most often done to detect protein, glucose, acetone, blood, pus, and casts.

uroflowmetry Pressure flow studies of the bladder.

urticaria Hives.

V

vaccination The injection of a vaccine into the body to produce immunity to a specific disease.

vaccines Suspensions of attenuated or killed microorganisms administered by injection to provide active immunity to infectious disease.

vagotomy The interruption of impulses carried by the vagus nerve or nerves; may be done to reduce the production of gastric secretions and to inhibit gastric motility, as part of the treatment for peptic ulcer.

Valsalva maneuver An increase of thoracic pressure by forcible exhalation against the closed glottis, as in straining at stool.

value A personal belief about the worth of something that is cherished or held dear.

valvuloplasty A procedure in which a balloon catheter is threaded via the circulatory system through the heart and into the valve. The balloon is inflated to break open a stenosed valve.

varices Twisted and swollen veins.

varicose veins Enlarged and tortuous veins in which the distorted shape is the result of accumulations of pooled blood.

vascular dementia A broad term used to describe any type of dementia caused by vessel disease.

vascular disorders An abnormal functioning of blood vessels, either arterial or venous. Peripheral arterial disorders are most commonly caused by atherosclerosis. Peripheral venous problems are caused by defective valvular function.

vasectomy Excision of the vas (ductus) deferens, or a portion of it; bilateral vasectomy results in sterility.

vasoactive Tending to cause vasodilation or vasoconstriction.

vector(s) A carrier, usually one that transmits disease.

venereal Pertaining to or resulting from sexual intercourse.

ventilation The movement of air from the external environment to the gas exchange units of the lung.

ventilator-associated pneumonia (VAP) Pneumonia that occurs 48 to 72 hours after endotracheal intubation.

vertigo A sensation of movement of one's self or of one's surroundings.

vesicant Blistering; causing or forming blisters.

vesicle A small sac containing a serous liquid; a small blister.

vesicostomy The formation of an opening into the urinary bladder.

viable Capable of living.

virulence The degree of ability of an organism to cause disease.

viscera The internal organs contained within a cavity.

viscous Sticky, gummy, gelatinous; thicker than usual.

vitrectomy The removal of the contents of the vitreous chamber and replacement with a sterile physiologic saline solution.

volvulus A twisting of the bowel upon itself, causing obstruction.

vulvectomy The excision of the vulva.

W

wart An epidermal growth of viral origin.

Wernicke encephalopathy Damage to brain cells caused by chronic alcohol abuse.

wheal A localized area of edema on the body surface.

wheeze A form of rhonchus characterized by a high-pitched or low-pitched musical quality caused by airflow through a narrowed airway.

withdrawal Symptoms that are the opposite of the symptoms caused by the ingestion of chemicals or drugs.

word salad A meaningless mixture of words and phrases characteristic of advanced schizophrenia.

X

xanthelasma A planar xanthoma involving the eyelid(s).

xanthoma A lipid deposit in the skin.

xenograft A surgical graft of tissue from an individual of one species to an individual of a different species.

xerostomia The lack of saliva; dry mouth.

Y

yeast A term for fungi that reproduce by budding.

Z

zygomatic Pertaining to the zygomatic bone.

1999

Incontinence, Risk for Urge Urinary
Incontinence, Stress Urinary
Incontinence, Urge Urinary
Incontinence, Bowel
Infection, Risk for
Injury, Risk for
Injury, Risk for Corneal
Injury, Risk for Perioperative-Positioning
Injury, Risk for Thermal
Injury, Risk for Urinary Tract
Insomnia

Jaundice, Neonatal
Jaundice, Risk for Neonatal
Knowledge, Deficient
Knowledge, Readiness for Enhanced
Latex Allergy Response
Latex Allergy Response, Risk for
Lifestyle, Sedentary
Liver Function, Risk for Impaired
Loneliness, Risk for
Maternal/Fetal Dyad, Risk for Disturbed
Memory, Impaired
Mobility, Impaired Bed
Mobility, Impaired Physical
Mobility, Impaired Wheelchair
Mood Regulation, Impaired
Moral Distress
Nausea
Noncompliance
Nutrition, Imbalanced: Less than Body Requirements
Nutrition, Readiness for Enhanced
Obesity
Oral Mucous Membrane, Impaired
Oral Mucous Membrane, Risk for Impaired
Other-Directed Violence, Risk for
Overweight
Overweight, Risk for
Pain, Acute
Pain, Chronic
Pain, Labor
Pain Syndrome, Chronic
Parenting, Impaired

Parenting, Readiness for Enhanced
Parenting, Risk for Impaired
Peripheral Neurovascular Dysfunction, Risk for
Personal Identity, Disturbed
Personal Identity, Risk for Disturbed
Poisoning, Risk for
Post-Trauma Syndrome
Post-Trauma Syndrome, Risk for
Power, Readiness for Enhanced
Powerlessness
Powerlessness, Risk for
Pressure Ulcer, Risk for
Protection, Ineffective
Rape-Trauma Syndrome
Reaction to Iodinated Contrast Media, Risk for
Relationship, Ineffective
Relationship, Risk for Ineffective
Relationship, Readiness for Enhanced
Religiosity, Impaired
Religiosity, Readiness for Enhanced
Religiosity, Risk for Impaired
Relocation Stress Syndrome
Relocation Stress Syndrome, Risk for
Renal Perfusion, Risk for Ineffective
Resilience, Impaired
Resilience, Readiness for Enhanced
Resilience, Risk for Impaired
Role Conflict, Parental
Role Performance, Ineffective
Role Strain, Caregiver
Role Strain, Risk for Caregiver

Self-Care, Readiness for Enhanced
Self-Care Deficit, Bathing
Self-Care Deficit, Dressing
Self-Care Deficit, Feeding
Self-Care Deficit, Toileting
Self-Concept, Readiness for Enhanced
Self-Directed Violence, Risk For
Self-Esteem, Chronic Low
Self-Esteem, Risk for Chronic Low
Self-Esteem, Situational Low
Self-Esteem, Risk for Situational Low
Self-Mutilation
Self-Mutilation, Risk for
Self-Neglect
Sexual Dysfunction
Sexuality Pattern, Ineffective
Shock, Risk for
Sitting, Impaired
Skin Integrity, Impaired
Skin Integrity, Risk for Impaired
Sleep, Readiness for Enhanced
Sleep Deprivation
Sleep Pattern, Disturbed
Social Interaction, Impaired
Social Isolation
Sorrow, Chronic
Spiritual Distress
Spiritual Distress, Risk for
Spiritual Well-Being, Readiness for Enhanced
Spontaneous Ventilation, Impaired
Standing, Impaired

Stress Overload
Sudden Infant Death Syndrome, Risk for
Suffocation, Risk for
Suicide, Risk for
Surgical Recovery, Delayed
Surgical Recovery, Risk for Delayed
Swallowing, Impaired
Thermoregulation, Ineffective
Tissue Integrity, Impaired
Tissue Integrity, Risk for Impaired
Tissue Perfusion, Ineffective Peripheral
Tissue Perfusion, Risk for Ineffective Peripheral
Tissue Perfusion, Risk for Decreased Cardiac
Tissue Perfusion, Risk for Ineffective Cerebral
Transfer Ability, Impaired
Trauma, Risk for
Vascular Trauma, Risk for
Unilateral Neglect
Urinary Retention
Ventilatory Weaning Response, Dysfunctional
Verbal Communication, Impaired
Walking, Impaired
Wandering
